PREFACE

The principal purpose of the Commentary is to provide a basic volume of knowledge and facts relating to building construction as it pertains to the regulations set forth in the 2015 *International Residential Code*[®]. The person who is serious about effectively designing, constructing and regulating buildings and structures will find the Commentary to be a reliable data source and reference to almost all components of the built environment.

As a follow-up to the *International Residential Code*, we offer a companion document, the *International Residential Code*[®] *Commentary—Volume I*. Volume I covers Chapters 1 through 11 of the 2015 *International Residential Code*. The basic appeal of the Commentary is thus: it provides, in a small package and at reasonable cost, thorough coverage of many issues likely to be dealt with when using the *International Residential Code* — and then supplements that coverage with historical and technical background. Reference lists, information sources and bibliographies are also included.

Throughout all of this, effort has been made to keep the vast quantity of material accessible and its method of presentation useful. With a comprehensive yet concise summary of each section, the Commentary provides a convenient reference for regulations applicable to the construction of buildings and structures. In the chapters that follow, discussions focus on the full meaning and implications of the code text. Guidelines suggest the most effective method of application, and the consequences of not adhering to the code text. Illustrations are provided to aid understanding; they do not necessarily illustrate the only methods of achieving code compliance.

The format of the Commentary includes the full text of each section, table and figure in the code, followed immediately by the commentary applicable to that text. At the time of printing, the Commentary reflects the most up-to-date text of the 2015 *International Residential Code*. Each section's narrative includes a statement of its objective and intent, and usually includes a discussion about why the requirement commands the conditions set forth. Code text and commentary text are easily distinguished from each other. All code text is shown as it appears in the *International Residential Code*, and all commentary is indented below the code text and begins with the symbol ❖. All code figures and tables are reproduced as they appear in the IRC. Commentary figures and tables are identified in the text by the word "Commentary" (as in "see Commentary Figure 704.3"), and each has a full border.

Readers should note that the Commentary is to be used in conjunction with the *International Residential Code* and not as a substitute for the code. **The Commentary is advisory only**; the code official alone possesses the authority and responsibility for interpreting the code.

Comments and recommendations are encouraged, for through your input, we can improve future editions. Please direct your comments to the Codes and Standards Development Department at the Central Regional Office.

Part I—Administrative

Chapter 1: Scope and Administration

General Comments

This chapter contains provisions for the application, enforcement and administration of requirements of the code. In addition to establishing the scope of the code, Chapter 1 identifies which buildings and structures come under its purview.

Chapter 1 is subdivided into two parts. Part 1 includes scope and application, Sections R101 and R102. Part 2 covers administration and enforcement, Sections R103 through R114.

- Section R101 addresses the scope of the IRC.
- Section R102 establishes the applicability of the code and addresses existing structures.
- Section R103 establishes the department of building safety and the appointment of department personnel.
- Section R104 outlines the duties and authority of the building official with regard to permits, inspections and right of entry. It also establishes the authority of the building official to approve alternative materials, used materials and modifications.
- Section R105 states when permits are required and establishes procedures for the review of applications and the issuance of permits.
- Section R106 describes the information that must be included on construction documents submitted with the application.
- Section R107 authorizes the building official to issue permits for temporary structures and uses.
- Section R108 establishes requirements for a fee schedule.
- Section R109 includes inspection duties of the building official or an inspection agency that has been approved by the building official.
- Section 110 details provisions for the issuance of certificates of occupancy.
- Section R111 gives the building official the authority to approve utility connections.
- Section R112 establishes the board of appeals and the criteria for making applications for appeal.
- Section R113 addresses administrative provisions for violations, including provisions for unlawful acts, violation notices, prosecution and penalties.

- Section R114 describes procedures for stop work orders.

Each state's building code enabling legislation, which is grounded within the police power of the state, is the source of all authority to enact building codes. Police power is the power of the state to legislate for the general welfare of its citizens. This power enables passage of such laws as building codes. If the state legislature has limited this power in any way, the municipality may not exceed these limitations. While the municipality may not further delegate its police power (e.g., by delegating the burden of determining code compliance to the building owner, contractor or architect), it may turn over the administration of the building code to a municipal official, such as a building official, provided that sufficient criteria are given to establish clearly the basis for decisions as to whether a proposed building conforms to the code.

Chapter 1 is largely concerned with maintaining "due process of law" in enforcing the building performance criteria contained in the body of the code. Only through careful observation of the administrative provisions can the building official reasonably hope to demonstrate that "equal protection under the law" has been provided. While it is generally assumed that the administration and enforcement section of a code is geared toward a building official, this is not entirely true. The provisions also establish the rights and privileges of the design professional, contractor and building owner. The position of the building official is merely to review the proposed and completed work and to determine if the construction conforms to the code requirements. The design professional is responsible for the design of a safe structure. The contractor is responsible for constructing the structure in compliance with the plans.

During the course of construction, the building official reviews the activity to ascertain that the spirit and intent of the law are being met and that the safety, health and welfare of the public will be protected. As a public servant, the building official enforces the code in an unbiased, proper manner. Every individual is guaranteed equal enforcement of the provisions of the code. Furthermore, design professionals, contractors and building owners have the right of due process for any requirement in the code.

Purpose

A building code, as with any other code, is intended to be adopted as a legally enforceable document to provide a reasonable level of safety and protection of public health, general welfare and property. A building code cannot be effective without adequate provisions for its administration and enforcement. The official charged with the administration and enforcement of building regulations has a great responsibility, and with this responsibility goes authority. No matter how detailed the building code may be, the building official must, to some extent, exercise his or her own judgment in determining code compliance. The building official has the responsibility to establish that the homes in which the citizens of

the community reside are designed and constructed to be structurally stable with adequate means of egress, light and ventilation, and to provide a minimum acceptable level of protection to life and property from fire.

Chapter 1 contains two parts. Part 1, Scope and Application, contains all issues related to the scope and intent of the code, as well as the applicability of this code relative to other standards and laws that might also be applicable on a given building project, such as federal or state. Part 2, Administration and Enforcement, contains all issues related to the duties and powers of the building official, the issuance of permits and certificates of occupancy, and other related operational items.

PART 1—SCOPE AND APPLICATION

SECTION R101 GENERAL

R101.1 Title. These provisions shall be known as the *Residential Code for One- and Two-family Dwellings* of [NAME OF JURISDICTION], and shall be cited as such and will be referred to herein as “this code.”

❖ The code is formally known as the *International Residential Code*® (IRC®) for *One- and Two-family Dwellings*, generally referred to as the *International Residential Code* or IRC for short. On adoption by the jurisdiction, it is known as the *Residential Code for One- and Two-family Dwellings* of the adopting jurisdiction, and in the document is often referred to as “the code.” It is offered for adoption as a model document of prescriptive provisions to jurisdictions as a stand-alone residential code that establishes minimum regulations for one- and two-family dwellings and townhouses. The forum under which the code is developed encourages consistency of application of its provisions, and it is offered ready for adoption by all communities, large and small, internationally.

The purpose of this section is to identify the adopted regulations by inserting the name of the adopting jurisdiction into the code.

R101.2 Scope. The provisions of the *International Residential Code for One- and Two-family Dwellings* shall apply to the construction, *alteration*, movement, enlargement, replacement, repair, *equipment*, use and occupancy, location, removal and demolition of detached one- and two-family dwellings and *townhouses* not more than three stories above *grade plane* in height with a separate means of egress and their *accessory structures* not more than three stories above *grade plane* in height.

Exceptions:

1. Live/work units located in *townhouses* and complying with the requirements of Section 419 of the *International Building Code* shall be permitted to be constructed in accordance with the *International*

Residential Code for One- and Two-Family Dwellings. Fire suppression required by Section 419.5 of the *International Building Code* where constructed under the *International Residential Code for One- and Two-family Dwellings* shall conform to Section P2904.

2. Owner-occupied lodging houses with five or fewer guestrooms shall be permitted to be constructed in accordance with the *International Residential Code for One- and Two-family Dwellings* where equipped with a fire sprinkler system in accordance with Section P2904.

❖ The provisions of the code apply to all aspects of construction for detached one- and two-family dwellings; multiple single-family dwellings, defined as townhouses; and all structures accessory to the dwellings and townhouses. This section sets a limitation in its scope of application to include only those townhouses, one- and two-family dwellings, as well as the accessory structures to such townhouses and dwellings, that are up to and including three stories above grade and where a separate means of egress system is provided for each of the dwelling units. The definition of townhouse covered in the code must meet four criteria: 1. It is not more than three stories in height; 2. It has a separate means of egress; 3. Each unit extends from foundation to roof; and 4. There is open space on at least two sides. Where a dwelling or townhouse exceeds the allowed height in stories, does not provide individual egress for each dwelling unit or does not conform to the prescriptive provisions of the code, the structures are then beyond the scope of the code and the provisions of the code cannot be applied. The building must then meet the provisions of the *International Building Code*® (IBC®) or other legally adopted building code of the jurisdiction. The actual height of the building, measured in feet and applied to the height of each story, is limited by the governing provisions for each specific material as found in Chapter 6 of the code. The user of the code will discover that, depending on which material is selected for the wall construction, the result may

be buildings of different permitted heights. For instance, where the wall system is of insulating concrete form construction as prescribed in Section R610, the building is limited to two stories above grade and each story is limited to 10 feet (3048 mm) in height. If wood stud wall framing is used pursuant to the requirements of Section R602, the allowable story height and overall building height will greatly exceed those permitted for the insulating concrete form wall construction method. The code does not limit the area of the building.

The provisions address all aspects of construction, alterations, repairs, maintenance, change of use, additions, relocation, or demolishing for any one-family dwelling, two-family dwelling, townhouse or accessory structure. The code regulates any and all activities that modify the buildings, as well as any structures that are of incidental use to the main buildings and that are also located on the same lot. The code regulates construction, plumbing, mechanical, electrical, equipment, fixture and gas piping installations that are done to the building and its operating systems, as well as to other structures incidental to the main building and on the same lot. Even work that is specifically exempted from permits must comply with the requirements of the code.

Exception 1 addresses live/work units that are designed to comply with Section 419 of the IBC and are equipped with an automatic sprinkler system complying with Section P2904. As stated in Section 419 of the IBC, a live/work unit is an option for a dwelling unit in which a significant portion (i.e., up to 50 percent) includes a nonresidential use such as an office, a hair styling shop or barbershop or small store. Section 419 of the IBC states that if the nonresidential portion of the building is an office that comprises less than 10 percent of the building area, the unit is not considered a live/work unit and does not need to be made to comply with the provisions of Section 419 of the IBC. Section 419 of the IBC places limitations on live/work units, including limitations on the nonresidential occupancies that can be included in a live/work unit, and addresses specific issues regarding means of egress, accessibility, ventilation, fire safety and structural requirements.

Exception 2 allows small bed and breakfasts to be constructed according to the code. A definition of "Lodging house" is included in Chapter 2 to generally encompass rental lodging within dwelling units, distinct from hotels and boarding houses that are "not occupied as a single-family unit."

R101.3 Intent. The purpose of this code is to establish minimum requirements to safeguard the public safety, health and general welfare through affordability, structural strength, means of egress facilities, stability, sanitation, light and ventilation, energy conservation and safety to life and property from fire and other hazards attributed to the built environment and to provide safety to fire fighters and emergency responders during emergency operations.

- ❖ The intent of the code is to establish regulations providing for safety, health and general welfare of building

occupants, as well as for fire fighters and emergency responders during building emergencies. The intent becomes important in the application of such sections as Sections R102, R104.11 and R113, as well as any enforcement-oriented interpretive action or judgment. Like any code, the written text is subject to interpretation. Interpretations should not be affected by economics or the potential impact on any party. The only considerations should be occupants' safety, protection of occupants' health and welfare and emergency responder safety.

SECTION R102 APPLICABILITY

R102.1 General. Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall be applicable. Where, in any specific case, different sections of this code specify different materials, methods of construction or other requirements, the most restrictive shall govern.

- ❖ In cases where the code establishes a specific requirement for a certain condition, that requirement is applicable even if it is less restrictive than a general requirement elsewhere in the code.

The following example illustrates the principle. Section R311.7 applies to all stairway types within the purview of the code. Section R311.7.5.1 limits the maximum height of risers to $7\frac{3}{4}$ inches (196 mm), thus providing a general requirement for stairway riser height. Section R311.7.10.1 limits risers within a spiral stairway to a maximum height of $9\frac{1}{2}$ inches (241 mm). This provision is specific to spiral stairways. In this case, the specific requirements of Section R311.7.10.1 take precedence over the general requirements of Section R311.7.5.1 in those applications specific to spiral stairways.

Where several code sections apply to the use of a material or a method of construction, the most restrictive requirements apply. An example would be in relating the requirements for foam plastics to the requirements for wall and ceiling finishes. The code might be interpreted to state that foam plastic boards meeting the requirements of Section R316.3, with a maximum flame-spread rating of 75, could be used as the final surface finish for walls and ceilings because Section R302.9 allows a flame spread classification for wall and ceiling finishes with a rating of up to 200. This, however, would be a mistake. The provisions of Section R316.4 require the foam plastic to be covered by a finish material equivalent to a thermal barrier that limits the average temperature rise of the unexposed surface to no less than 250°F (139°C) after 15 minutes of fire exposure in accordance with ASTM E119 standard time-temperature curve, or to be covered with minimum $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard. In this case, the uncovered foam plastic must be covered to meet the requirements of Section R316.4 and have the thermal barrier installed. Additionally, the final surface finish material that is chosen must comply with Section

SCOPE AND ADMINISTRATION

R316.4, and it must also meet the required flame spread rating of 200 or less, as specified in Section R302.9.

R102.2 Other laws. The provisions of this code shall not be deemed to nullify any provisions of local, state or federal law.

❖ Compliance with the requirements of the code does not entail authorization, approval or permission to violate the regulations of other local, state or federal laws. Other laws, ordinances and regulations not administered or enforced by the building official could be in existence and enforced by another authority having jurisdiction over those provisions. Although the requirements may have similar provisions to those of the code, the work must be in conformance to the other regulations.

R102.3 Application of references. References to chapter or section numbers, or to provisions not specifically identified by number, shall be construed to refer to such chapter, section or provision of this code.

❖ There are many instances in the code where a reference is merely a chapter number, section number or, in some cases, a provision not specified by number. In all such situations, these references are to the code and not some other code or publication.

R102.4 Referenced codes and standards. The codes and standards referenced in this code shall be considered part of the requirements of this code to the prescribed extent of each such reference and as further regulated in Sections R102.4.1 and R102.4.2.

Exception: Where enforcement of a code provision would violate the conditions of the *listing* of the *equipment* or *appliance*, the conditions of the *listing* and manufacturer's instructions shall apply.

❖ A referenced code, standard or portion thereof is an enforceable extension of the code as if the content of the standard were included in the body of the code. For example, Section R314.2 references NFPA 72 in its entirety for the installation of household fire alarms. In those cases when the code references only portions of a standard, the use and application of the referenced standard is limited to those portions that are specifically identified. If conflicts occur because of scope or purpose, the code text governs.

The intent of the exception is to allow for a tested product to be used effectively and safely in the manner it was approved. See the commentary to the definition of "Listed" in Chapter 2.

R102.4.1 Conflicts. Where conflicts occur between provisions of this code and referenced codes and standards, the provisions of this code shall apply.

❖ The use of referenced codes and standards to cover certain aspects of residential occupancy and operations, rather than write parallel or competing requirements into the code, is a long-standing code development principle. Questions and potential conflicts in the use of referenced codes and standards can arise, which can lead to inconsistent enforcement of

the code. Where such conflicts occur, the provisions of the code should be applied.

R102.4.2 Provisions in referenced codes and standards. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code, the provisions of this code, as applicable, shall take precedence over the provisions in the referenced code or standard.

❖ Section R102.4.2 expands on the provisions of Section R102.4.1 by making it clear that, even if a referenced standard contains requirements that parallel the code in the standard's own duly referenced section(s), the provisions of the code will always take precedence. This section does not intend to take the place of carefully scoped and referenced text for written standards for the code but, rather, provides the policy underpinnings on which sound code language should be based.

R102.5 Appendices. Provisions in the appendices shall not apply unless specifically referenced in the adopting ordinance.

❖ The provisions contained in Appendices A through U are not considered part of the code and are, therefore, not enforceable unless they are specifically included in the ordinance or other adopting law or regulation of the jurisdiction. See Section 1 of the sample legislation on page xvii of the code for where the appendices to be adopted are to be specified in the adoption ordinance.

R102.6 Partial invalidity. In the event any part or provision of this code is held to be illegal or void, this shall not have the effect of making void or illegal any of the other parts or provisions.

❖ There may be a situation where one or more specific provisions of the code are found to be void or illegal.

This may be because a local, state or federal ordinance, statute or law has precedence over the adopted construction provisions. Under such conditions, only those specific provisions found to be void or illegal are affected; the rest of the code remains in force.

R102.7 Existing structures. The legal occupancy of any structure existing on the date of adoption of this code shall be permitted to continue without change, except as is specifically covered in this code, the *International Property Maintenance Code* or the *International Fire Code*, or as is deemed necessary by the *building official* for the general safety and welfare of the occupants and the public.

❖ Buildings that exist legally at the time the code is adopted are allowed to have their existing use and occupancy continued if the use or occupancy of the structure was also legally in existence. This means that as long as a structure or building remains in a safe and sanitary condition it need not be upgraded to meet the more current standards. A specific level of safety in existing buildings is dictated by maintenance and hazard abatement provisions, as contained in this code, the IPMC and the IFC. However, any new construction, addition or remodeling will require such work to conform to the requirements of the new code. A change of

occupancy of the building also will force the building to conform to the new standards.

The existence of a building prior to the adoption of a new edition of the code does not grant it the status of a legal existence. A building is thought of as being “grandfathered” under prior rules and not needing to be brought up to current requirements when there are records to show that it was constructed to meet the regulations of the jurisdiction in force at the time it was built. The most common way to demonstrate legal compliance with the construction codes of a community is through the public records. Copies of past building permits can be researched at the jurisdictional archives. On discovery that a building does not have a legal existence, corrective actions will be needed to bring the structure into compliance with the regulations of the jurisdiction at the time the building was built.

R102.7.1 Additions, alterations or repairs. *Additions, alterations* or repairs to any structure shall conform to the requirements for a new structure without requiring the existing structure to comply with the requirements of this code, unless otherwise stated. *Additions, alterations, repairs* and relocations shall not cause an existing structure to become unsafe or adversely affect the performance of the building.

❖ An addition, alteration, repair or relocation is required to meet the provisions of this code for new materials, but the remainder of the building is not required to comply with the requirements of this code. However, another measure of the viability of the addition, alteration, repair or relocation is that it does not cause the existing structure to be adversely affected or made unsafe. The application of this provision can often be confusing regarding what code requirements apply to the addition, alteration, repair or relocation. For instance, removal and replacement of a fiberglass roof covering with the same type of roof covering would require that the new shingles, fasteners and underlayment meet the standards and methods specified in the code. However, this does not mean that the roof structure and decking would need to be designed to resist the snow loads in the code.

Another example is window replacement. Often, in very old homes, bedroom windows were not required to have the dimensions for emergency escape windows. If a window in a bedroom is being replaced by a new window, the new window would not need to meet the requirements for emergency escape. However, if the window installed was not as energy efficient, then the existing structure is adversely affected.

Where a building is located in a flood hazard area, a determination must be made regarding whether an addition, alteration or repairs constitute substantial improvement or repair of substantial damage (see commentary for Section R105.3.1.1). If the work is determined to be substantial improvement or repair of substantial damage, the existing building must be brought into compliance with the current requirements for flood-resistant construction. For guidance, see FEMA P-758.

PART 2—ADMINISTRATION AND ENFORCEMENT

SECTION R103 DEPARTMENT OF BUILDING SAFETY

R103.1 Creation of enforcement agency. The department of building safety is hereby created and the official in charge thereof shall be known as the *building official*.

❖ This section establishes a building department that provides plan review and inspections for buildings regulated by the code. It also establishes the position of the building official, who will be the administrator for the enforcement of the jurisdictional codes. The employees of the department may be given varying degrees of authority by the building official. The Department of Building Safety is charged with the responsibility for enforcing the provisions of the code.

The executive official in charge of the building department is named the “building official” by this section. In actuality, the person who is in charge of the department may hold a different title, such as building commissioner, building inspector or construction official. For the purpose of the code, that person is referred to as the “building official.”

R103.2 Appointment. The *building official* shall be appointed by the *jurisdiction*.

❖ The building official is an appointed officer of the jurisdiction, charged with the administrative responsibilities of the Department of Building Safety. Typically, the appointment is made by the mayor, council or commission and carried out through the city manager or other administrative authority.

R103.3 Deputies. In accordance with the prescribed procedures of this *jurisdiction* and with the concurrence of the appointing authority, the *building official* shall have the authority to appoint a deputy *building official*, the related technical officers, inspectors, plan examiners and other employees. Such employees shall have powers as delegated by the *building official*.

❖ The building official has the authority, acting in conjunction and in agreement with the appointing authority of the jurisdiction, to appoint officers and employees of the department. The building official can delegate certain powers of his or her authority to a deputy building official, as well as to all technical officers and employees of the Department of Building Safety. This group of deputies typically includes inspectors and plans examiners.

SECTION R104 DUTIES AND POWERS OF THE BUILDING OFFICIAL

R104.1 General. The *building official* is hereby authorized and directed to enforce the provisions of this code. The *building official* shall have the authority to render interpretations of this code and to adopt policies and procedures in order to clarify the application of its provisions. Such interpretations,

policies and procedures shall be in conformance with the intent and purpose of this code. Such policies and procedures shall not have the effect of waiving requirements specifically provided for in this code.

❖ The duty of the building official is to enforce the code. He or she is the “authority having jurisdiction” for all matters relating to the code and its enforcement. It is the duty of the building official to interpret the code and to determine compliance. Code compliance will not always be easy to determine and will require judgment and expertise, particularly when enforcing the provisions of Sections R104.10 and R104.11. In exercising this authority, however, the building official cannot set aside or ignore any provision of the code.

The building official establishes policies and procedures that will clarify the applications of the code. The development of those policies and procedures should not be simply for the convenience of the jurisdiction’s employees, but should be viewed as a way to effectively communicate to all interested parties involved in the construction process how the department will process applications, review construction documents, make inspections, approve projects, and determine and clarify the application of the code provisions. Properly developed, these policies and procedures can make the code enforcement department more predictable for those who are regulated and will also establish improved code compliance and public relations.

When interpretation of the code is needed, the building official is the one individual of the jurisdiction with the legal authority to interpret the code and determine how the provisions should be applied, in both general and specific cases. Some departments formalize the interpretation process and require the person with a question to submit their question in writing. Departments are encouraged to develop policies for both formal (written) and informal (verbal) requests for code interpretations. Any such interpretations must be in conformance with the intent and letter of the code and may not waive any requirements. It may be necessary in some cases for the building official to write these code interpretations into the permit.

R104.2 Applications and permits. The *building official* shall receive applications, review *construction documents* and issue *permits* for the erection and *alteration* of buildings and structures, inspect the premises for which such permits have been issued and enforce compliance with the provisions of this code.

❖ This section states that the building official must receive applications, review construction documents, issue permits, conduct inspections and enforce the provisions of the code. She or he is to provide the services required to carry the project from application for the permit to final approval. The building official is to accept all properly completed applications and not refuse the receipt of an application that meets the policy requirements. This same principle holds for the

review of the construction documents, issuance of permits, inspections and enforcement of the code’s provisions. The requirements of the code must be met, and approval will be granted only when compliance is verified.

R104.3 Notices and orders. The *building official* shall issue necessary notices or orders to ensure compliance with this code.

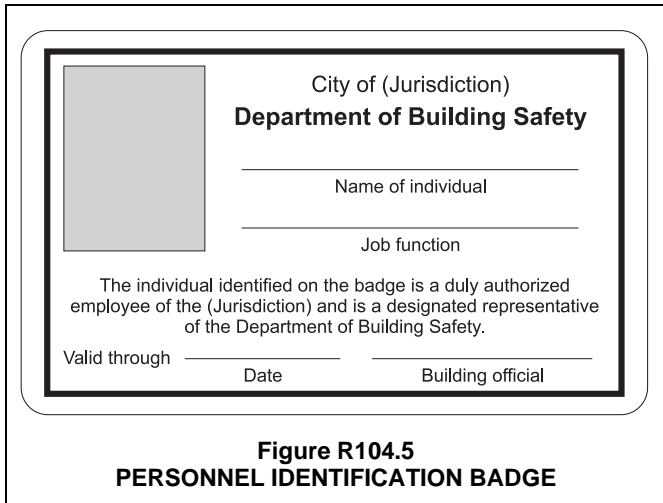

❖ Building officials are to communicate, in writing, the disposition of their findings regarding code compliance. If an inspection shows that the work fails to comply with the code provisions, the building official or technical officer who conducted the inspection must issue a written report noting the corrections that are needed. A copy of the report is to be provided to the permit holders or their agent.

R104.4 Inspections. The *building official* shall make the required inspections, or the *building official* shall have the authority to accept reports of inspection by *approved agencies* or individuals. Reports of such inspections shall be in writing and be certified by a responsible officer of such *approved agency* or by the responsible individual. The *building official* is authorized to engage such expert opinion as deemed necessary to report upon unusual technical issues that arise, subject to the approval of the appointing authority.

❖ The building official is required to make inspections as necessary to determine compliance with the code, or to accept written reports of inspections by an approved agency. Inspection of the work in progress or accomplished is another significant element in determining code compliance. The building official also has the authority to accept reports from other inspection agencies or private inspectors who have been granted prior approval by the building official to conduct inspections and provide reports. The reports submitted by the approved inspection agencies or individuals must be in writing and must be certified by only those individuals who have been approved by the building official as being qualified to submit the reports. When unusual technical issues arise during the course of construction, the building official has the authority to hire an expert to report on the conditions and technical issues germane to the subject at hand. Prior to hiring the expert for consultation services, the building official must seek approval from the appointing authority.

R104.5 Identification. The *building official* shall carry proper identification when inspecting structures or premises in the performance of duties under this code.

❖ When the building official and other employees of the jurisdiction are performing their duties and inspecting structures or premises of construction, they are required to carry and display identification that will identify them as employees of the jurisdiction. Commentary Figure R104.5 is an example of the proper identification.

R104.6 Right of entry. Where it is necessary to make an inspection to enforce the provisions of this code, or where the *building official* has reasonable cause to believe that there exists in a structure or upon a premises a condition that is contrary to or in violation of this code that makes the structure or premises unsafe, dangerous or hazardous, the *building official* or designee is authorized to enter the structure or premises at reasonable times to inspect or to perform the duties imposed by this code, provided that if such structure or premises be occupied that credentials be presented to the occupant and entry requested. If such structure or premises is unoccupied, the *building official* shall first make a reasonable effort to locate the owner, the owner's authorized agent, or other person having charge or control of the structure or premises and request entry. If entry is refused, the *building official* shall have recourse to the remedies provided by law to secure entry.

❖ The first part of this section establishes the right of the building official to enter the premises in order to make permit inspections required by Section R109. Section R109 identifies specific progress points (during intermediate phases and final approval) for inspections that must be conducted. Permit application forms typically include a statement in the certification signed by the applicant (who is the owner or owner's agent) granting the building official the authority to enter areas covered by the permit in order to enforce code provisions related to the permit. The right to enter other structures or premises is more limited. First, to protect the right of privacy, the owner or occupant must grant the building official permission before an interior inspection of the property can be conducted. Permission is not required for inspections that can be accomplished from within the public right-of-way. Second, such access may be denied by the owner or occupant. Unless the inspector has reasonable cause to believe that a violation of the code exists, access may be unattainable. Third, building officials must present proper identification (see Section 104.5) and request admittance during reasonable hours—usually the normal business hours of the establishment—to be admitted. Fourth, inspections must be aimed at securing or determining compliance with the provisions and intent of the regulations that

are specifically within the established scope of the building official's authority.

Searches to gather information for the purpose of enforcing other codes, ordinances or regulations are considered unreasonable and are prohibited by the Fourth Amendment to the U.S. Constitution. "Reasonable cause" in the context of this section must be distinguished from "probable cause," which is required to gain access to property in criminal cases. The burden of proof establishing reasonable cause may vary among jurisdictions. Usually, an inspector must show that the property is subject to inspection under the provisions of the code; that the interests of the public health, safety and welfare outweigh the individual's right to maintain privacy; and that such an inspection is required solely to determine compliance with the provisions of the code.

Many jurisdictions do not recognize the concept of an administrative warrant and may require the building official to prove probable cause in order to gain access on refusal. This burden of proof is usually more substantial, often requiring the building official to stipulate in advance why access is needed (usually access is restricted to gathering evidence for seeking an indictment or making an arrest); what specific items or information is sought; its relevance to the case against the individual subject; how knowledge of the relevance of the information or items sought was obtained, and how the evidence sought will be used. In all such cases, the right to privacy must always be weighed against the right of the building official to conduct an inspection to verify that public health, safety and welfare are not in jeopardy. Such important and complex constitutional issues should be discussed with the jurisdiction's legal counsel. Jurisdictions should establish procedures for securing the necessary court orders when an inspection is deemed necessary following a refusal.

R104.7 Department records. The *building official* shall keep official records of applications received, *permits* and certificates issued, fees collected, reports of inspections, and notices and orders issued. Such records shall be retained in the official records for the period required for the retention of public records.

❖ In keeping with the need for efficient business practices, the building official must keep official records pertaining to permit applications, permits, fees collected, inspections, notices and orders issued. Such documentation provides a valuable resource of information if questions arise regarding the department's actions with respect to a building. The code does not require that construction documents be kept after the project is complete. It requires that other documents be kept for the length of time mandated by a jurisdiction's or its state's laws, or administrative rules for retaining public records.

Certain records related to buildings in flood hazard areas must be retained permanently in accordance with the community's agreement with the National Flood Insurance Program (NFIP), including the lowest

floor elevation information collected (see Sections R109.1.3 and R109.1.6.1), determinations made when work on existing buildings is proposed to determine if the work constitutes substantial improvement or repair of substantial damage (see Section R105.3.1.1), and modifications granted (see Section R104.10.1). Communities agree to allow inspection of these records on request by the Federal Emergency Management Agency (FEMA) or the NFIP state coordinating agency.

R104.8 Liability. The *building official*, member of the board of appeals or employee charged with the enforcement of this code, while acting for the *jurisdiction* in good faith and without malice in the discharge of the duties required by this code or other pertinent law or ordinance, shall not thereby be rendered civilly or criminally liable personally and is hereby relieved from personal liability for any damage accruing to persons or property as a result of any act or by reason of an act or omission in the discharge of official duties.

❖ The building official, members of the appeals board and other employees charged with the duty to enforce the provisions of the code are relieved from personal liability, either civilly or criminally, by the jurisdiction when they are carrying out in good faith their official duties. This provision does not grant absolute immunity from all tort liability for employees of the jurisdiction in all cases; an employee acting maliciously is not relieved from his or her personal liability and will most likely not be defended by the jurisdiction. Building officials should not fear lawsuits even if their state does not guarantee them absolute immunity for their actions. Rather, the building official should understand those elements that a plaintiff must show in a lawsuit in order to prevail.

Public officials should familiarize themselves with the laws of their state regarding their exposure to tort liability. Only a few states grant absolute immunity from liability for any actions taken by public officials when those actions are within the scope of their employment.

R104.8.1 Legal defense. Any suit or criminal complaint instituted against an officer or employee because of an act performed by that officer or employee in the lawful discharge of duties and under the provisions of this code shall be defended by legal representatives of the *jurisdiction* until the final termination of the proceedings. The *building official* or any subordinate shall not be liable for cost in any action, suit or proceeding that is instituted in pursuance of the provisions of this code.

❖ This section establishes that building officials (or subordinates) must not be liable for costs in any legal action instituted in response to the performance of lawful duties. These costs are to be borne by the state, county or municipality. The best way to be certain that the building official's action is a "lawful duty" is always to cite the applicable code section on which the enforcement action is based.

R104.9 Approved materials and equipment. Materials, *equipment* and devices *approved* by the *building official* shall be constructed and installed in accordance with such approval.

❖ The code is a compilation of criteria with which materials, equipment, devices and systems must comply to be suitable for a particular application. Where the building official grants approval for the use of specific materials, equipment or devices as a part of the construction process, it is important that the approved items be constructed or installed in a manner consistent with the approval. For example, the manufacturer's instructions and recommendations are to be followed if the approval of the material was based, even in part, on those instructions and recommendations.

The approval authority given the building official is a significant responsibility and is a key to code compliance. The approval process is first technical and then administrative. For example, if data to determine code compliance are required, the data should be in the form of test reports or engineering analysis and not simply taken from a sales brochure.

R104.9.1 Used materials and equipment. Used materials, *equipment* and devices shall not be reused unless *approved* by the *building official*.

❖ Code criteria for materials and equipment have changed over the years. Evaluation of testing and materials technology has permitted the development of new criteria that old materials may not satisfy. As a result, used materials are required to be evaluated in the same manner as new materials. Used materials, equipment and devices must be equivalent to that required by the code if they are to be used again in a new installation.

R104.10 Modifications. Where there are practical difficulties involved in carrying out the provisions of this code, the *building official* shall have the authority to grant modifications for individual cases, provided the *building official* shall first find that special individual reason makes the strict letter of this code impractical and the modification is in compliance with the intent and purpose of this code and that such modification does not lessen health, life and fire safety or structural requirements. The details of action granting modifications shall be recorded and entered in the files of the department of building safety.

❖ The building official has the authority to accept modifications of code provisions in specific cases. For the building official to allow a modification, he or she must first determine that strict application of the code is impractical for a specific reason. When the building official grants a modification, it is not a waiver from the requirements. It should be thought of as fulfilling the requirements to the greatest extent possible, but deviating from the requirements slightly to satisfy the intent of the provisions. The modification must not lessen the health, fire safety, life safety or structural requirements of the code. All modification actions must be recorded in the files of the building department.

R104.10.1 Flood hazard areas. The *building official* shall not grant modifications to any provisions required in flood hazard areas as established by Table R301.2(1) unless a determination has been made that:

1. There is good and sufficient cause showing that the unique characteristics of the size, configuration or topography of the site render the elevation standards of Section R322 inappropriate.
2. Failure to grant the modification would result in exceptional hardship by rendering the lot undevelopable.
3. The granting of modification will not result in increased flood heights, additional threats to public safety, extraordinary public expense, cause fraud or victimization of the public, or conflict with existing laws or ordinances.
4. The modification is the minimum necessary to afford relief, considering the flood hazard.
5. Written notice specifying the difference between the design flood elevation and the elevation to which the building is to be built, stating that the cost of flood insurance will be commensurate with the increased risk resulting from the reduced floor elevation and stating that construction below the design flood elevation increases risks to life and property, has been submitted to the applicant.

❖ Section R322 contains provisions for determining flood hazard areas. A modification cannot be granted by the building official for structures located in flood hazard areas without making a determination regarding five listed factors. The regulations of the NFIP 44 CFR 60.3 require that proposals for structures meet or exceed the minimum provisions of the program. Requests for modifications to any provision related to flood hazard areas are to be handled according to the NFIP requirements for variances [see 44 CFR 60.6(a)]. A record of each determination should be retained as part of the community's permanent records.

Each of the listed determinations must be made in order for the building official to: 1. Consider granting a modification of any requirement applicable in flood hazard areas; and 2. Provide relief from selected provisions for flood-resistant construction. Granting of the modification must not cause additional public safety concerns beyond those already present. Therefore, building officials are cautioned to carefully evaluate the impacts of granting a modification, particularly modifications of the requirements for elevating buildings. The elements that are to be evaluated include impacts on the site, the applicant and other parties who may be affected, such as adjacent property owners and the community as a whole. Development in flood hazard areas that is not undertaken in accordance with the flood-resistance provisions of the code will be exposed to increased flood damage. As a consequence, federal flood insurance premium rates may be significantly higher. Decisions to grant modifications must be based solely on technical justifications

and not on the personal or financial circumstances of an owner or applicant.

Applicants sometimes request modification of the minimum elevation requirements to improve access for the disabled and elderly. Generally, modifications of this nature should not be granted because these are personal circumstances that will change as the property changes ownership. Not only would persons of limited mobility be at risk, but a building built below the base flood elevation (BFE) would continue to be exposed to flood damage long after the personal need for a variance ends. More appropriate alternatives are to be considered to serve the needs of disabled or elderly persons, such as varying setbacks to allow construction on higher portions of sites or the installation of personal elevators. Elevators may extend below the BFE; see FEMA TB #4.

All variances are to be the minimum necessary to afford relief. Thus, even if sufficient justification to warrant modification of one or more requirement is demonstrated, building officials should ensure that each modification is the minimum necessary rather than allow construction without any consideration of flood risk.

One determination to be made is whether failure to grant a modification would result in exceptional hardship by rendering the lot undevelopable. The determination of hardship is to be based on the unique characteristics of the site and not on the personal circumstances of the applicant. While small lots may have constraints if applicants propose to use fill to elevate buildings, other foundation types can be used even on small lots, thus lot size may be insufficient justification.

In guidance materials, FEMA cautions that financial hardship, inconvenience, aesthetic considerations, physical handicaps, personal preferences or the disapproval of one's neighbors do not qualify as exceptional hardships. Building officials are cautioned that granting a variance does not affect how the building will be rated for the purposes of federal flood insurance. Even if circumstances justify granting a variance to build a lowest floor that is below the required elevation, the rate used to calculate the cost of a flood insurance policy will be based on the risk to the building. Federal flood insurance, required by certain mortgage lenders, may be expensive. Although the permit applicant may not be required to purchase flood insurance, the requirement may be imposed on subsequent owners. The building official is to provide the applicant a written notice to this effect, along with the other cautions listed in this section.

R104.11 Alternative materials, design and methods of construction and equipment. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been *approved*. An alternative material, design or method of construction shall be *approved* where the *building official* finds that the proposed design is satisfactory and

complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, not less than the equivalent of that prescribed in this code. Compliance with the specific performance-based provisions of the International Codes shall be an alternative to the specific requirements of this code. Where the alternative material, design or method of construction is not *approved*, the *building official* shall respond in writing, stating the reasons why the alternative was not *approved*.

❖ Although the code reflects current technologies, it is impossible to foresee all potential applications of new materials, construction techniques or design methods. The fact that a material, product or method of construction is not addressed in the code is not an indication that such material, product or method is intended to be prohibited. The code encourages the use of new materials and technologies by allowing them to be presented to the building official for approval. The building official must approve a proposed alternative when it is found to be satisfactory and in compliance with the intent of the provisions of the code and is equivalent to that prescribed by the code. Approval may also be granted for the use of any alternative that is in compliance with the performance-based provisions of the *International Codes*[®]. The building official is responsible for determining if a requested alternative provides the equivalent level of protection of public health, safety and welfare, as required by the code. In order to ensure effective communication and due process of law, if an alternative is not approved, the building official should state in writing the reasons for the disapproval. This is similar to when a permit is rejected in Section R105.3.1.

R104.11.1 Tests. Where there is insufficient evidence of compliance with the provisions of this code, or evidence that a material or method does not conform to the requirements of this code, or in order to substantiate claims for alternative materials or methods, the *building official* shall have the authority to require tests as evidence of compliance to be made at no expense to the *jurisdiction*. Test methods shall be as specified in this code or by other recognized test standards. In the absence of recognized and accepted test methods, the *building official* shall approve the testing procedures. Tests shall be performed by an *approved* agency. Reports of such tests shall be retained by the *building official* for the period required for retention of public records.

❖ To provide the basis on which the building official can make a decision regarding an alternative material or method, sufficient technical data, test reports and documentation must be provided for evaluation. If evidence satisfactory to the building official indicates that the alternative material or construction method is equivalent to that required by the code, he or she may approve it. Any such approval cannot have the effect of waiving any requirements of the code. The burden of proof of equivalence lies with the applicant who proposes the use of alternative materials or methods.

The building official must require the submission of appropriate information and data to assist in the determination of equivalency. This information must be submitted before a permit can be issued. The type of information required includes test data in accordance with referenced standards, evidence of compliance with the referenced standard specifications and design calculations. A research report issued by an authoritative agency is particularly useful in providing the building official with the technical basis for evaluation and approval of new and innovative materials and methods of construction. The use of authoritative research reports can greatly assist the building official by reducing the time-consuming engineering analysis necessary to review these materials and methods. Failure to substantiate adequately a request for the use of an alternative is a valid reason for the building official to deny a request. Any tests submitted in support of an application must have been performed by an agency approved by the building official based on evidence that the agency has the technical expertise, test equipment and quality assurance to properly conduct and report the necessary testing. The test reports submitted to the building official must be retained in accordance with the requirements of Section R104.7.

SECTION R105 PERMITS

R105.1 Required. Any owner or owner's authorized agent who intends to construct, enlarge, alter, repair, move, demolish or change the occupancy of a building or structure, or to erect, install, enlarge, alter, repair, remove, convert or replace any electrical, gas, mechanical or plumbing system, the installation of which is regulated by this code, or to cause any such work to be performed, shall first make application to the *building official* and obtain the required *permit*.

❖ This section contains the administrative rules governing the issuance, suspension, revocation or modification of building permits. It also establishes how and by whom the application for a building permit is to be made, how it is to be processed, fees and what information it must contain or have attached to it.

In general, a permit is required for all activities that are regulated by the code and these activities cannot begin until the permit is issued, unless the activity is specifically exempted by Section R105.2. Only the owner or a person authorized by the owner can apply for the permit. Note that this section indicates a need for a permit for a change in occupancy, even if no work is contemplated. The purpose of the permit is to cause the work to be reviewed, approved and inspected to determine compliance with the code.

R105.2 Work exempt from permit. Exemption from *permit* requirements of this code shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other laws or ordinances of

this jurisdiction. Permits shall not be required for the following:

Building:

1. One-story detached accessory structures, provided that the floor area does not exceed 200 square feet (18.58 m²).
2. Fences not over 7 feet (2134 mm) high.
3. Retaining walls that are not over 4 feet (1219 mm) in height measured from the bottom of the footing to the top of the wall, unless supporting a surcharge.
4. Water tanks supported directly upon grade if the capacity does not exceed 5,000 gallons (18 927 L) and the ratio of height to diameter or width does not exceed 2 to 1.
5. Sidewalks and driveways.
6. Painting, papering, tiling, carpeting, cabinets, counter tops and similar finish work.
7. Prefabricated swimming pools that are less than 24 inches (610 mm) deep.
8. Swings and other playground equipment.
9. Window awnings supported by an exterior wall that do not project more than 54 inches (1372 mm) from the exterior wall and do not require additional support.
10. Decks not exceeding 200 square feet (18.58 m²) in area, that are not more than 30 inches (762 mm) above grade at any point, are not attached to a dwelling do not serve the exit door required by Section R311.4.

Electrical:

1. Listed cord-and-plug connected temporary decorative lighting.
2. Reinstallation of attachment plug receptacles but not the outlets therefor.
3. Replacement of branch circuit overcurrent devices of the required capacity in the same location.
4. Electrical wiring, devices, appliances, apparatus or equipment operating at less than 25 volts and not capable of supplying more than 50 watts of energy.
5. Minor repair work, including the replacement of lamps or the connection of approved portable electrical equipment to approved permanently installed receptacles.

Gas:

1. Portable heating, cooking or clothes drying appliances.
2. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.

3. Portable-fuel-cell appliances that are not connected to a fixed piping system and are not interconnected to a power grid.

Mechanical:

1. Portable heating appliances.
2. Portable ventilation appliances.
3. Portable cooling units.
4. Steam, hot- or chilled-water piping within any heating or cooling equipment regulated by this code.
5. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.
6. Portable evaporative coolers.
7. Self-contained refrigeration systems containing 10 pounds (4.54 kg) or less of refrigerant or that are actuated by motors of 1 horsepower (746 W) or less.
8. Portable-fuel-cell appliances that are not connected to a fixed piping system and are not interconnected to a power grid.

Plumbing:

1. The stopping of leaks in drains, water, soil, waste or vent pipe; provided, however, that if any concealed trap, drainpipe, water, soil, waste or vent pipe becomes defective and it becomes necessary to remove and replace the same with new material, such work shall be considered as new work and a permit shall be obtained and inspection made as provided in this code.
2. The clearing of stoppages or the repairing of leaks in pipes, valves or fixtures, and the removal and reinstallation of water closets, provided such repairs do not involve or require the replacement or rearrangement of valves, pipes or fixtures.

❖ This section of the code lists the types of work in five categories—building, electrical, gas, mechanical and plumbing—that do not require permits. However, all work, even work that does not require a permit, must be done in a manner that will comply with the code requirements.

Communities that participate in the NFIP are required to issue permits even for some of the work listed under the building category if that work takes place in flood hazard areas, including work on accessory structures, retaining walls, water tanks, and sidewalks and driveways if fill is involved. This responsibility may be handled under a separate floodplain management regulation or IBC Appendix G. For guidance, the requirements for these activities, including floodway encroachment impacts, are described in IBC Appendix G.

R105.2.1 Emergency repairs. Where equipment replacements and repairs must be performed in an emergency situa-

SCOPE AND ADMINISTRATION

tion, the *permit* application shall be submitted within the next working business day to the *building official*.

❖ This section recognizes that in some cases, emergency replacement and repair work must be done as quickly as possible, so it is not practical to take the necessary time to apply for and obtain approval. A permit for the work must be obtained the next day that the building department is open for business. Any work performed before the permit is issued must be done in accordance with the code and corrected if not approved by the building official. For example, if a concealed trap failed on a Sunday, the plumber could replace the trap at that time, but he would have to apply for a permit on Monday and have the repair pass an inspection.

R105.2.2 Repairs. Application or notice to the *building official* is not required for ordinary repairs to structures, replacement of lamps or the connection of *approved* portable electrical *equipment* to *approved* permanently installed receptacles. Such repairs shall not include the cutting away of any wall, partition or portion thereof, the removal or cutting of any structural beam or load-bearing support, or the removal or change of any required means of egress, or rearrangement of parts of a structure affecting the egress requirements; nor shall ordinary repairs include *addition to, alteration of, replacement or relocation of any water supply, sewer, drainage, drain leader, gas, soil, waste, vent or similar piping, electric wiring or mechanical or other work affecting public health or general safety.*

❖ There is a variety of ordinary repair, replacement or connection work that is exempt from the permit application process. This section identifies a number of general situations in which a permit is not required. The provisions then state the types of repairs for which a permit is required. Repair work done without a permit must still comply with the applicable provisions of the code.

R105.2.3 Public service agencies. A *permit* shall not be required for the installation, *alteration* or repair of generation, transmission, distribution, metering or other related *equipment* that is under the ownership and control of public service agencies by established right.

❖ When the ownership and control of equipment is held by a public service agency, such as a county water district, permits are not required for any work that might be done on that equipment. The scope of this provision includes not only repair activities, but also any installation or alteration work. It is clear from this section that public service agencies are self-regulating when it comes to work involving equipment used for generation, transmission, distribution and metering. Any equipment or appliances installed or serviced by such agencies that are not owned by them and under their full control are not exempt from a permit.

R105.3 Application for permit. To obtain a *permit*, the applicant shall first file an application therefor in writing on a

form furnished by the department of building safety for that purpose. Such application shall:

1. Identify and describe the work to be covered by the *permit* for which application is made.
2. Describe the land on which the proposed work is to be done by legal description, street address or similar description that will readily identify and definitely locate the proposed building or work.
3. Indicate the use and occupancy for which the proposed work is intended.
4. Be accompanied by *construction documents* and other information as required in Section R106.1.
5. State the valuation of the proposed work.
6. Be signed by the applicant or the applicant's authorized agent.
7. Give such other data and information as required by the *building official*.

❖ The code lists the minimum information required in an application for a permit. The owner or owner's agent is to fully describe the location of the site, the type and nature of the work to be done and all other pertinent information regarding the job. This provides the jurisdiction with a clear understanding of what will actually be done under the permit. The applicant must sign the application, and permit forms typically include a statement that if the applicant is not the owner, he or she has permission from the owner to make the application.

It is a common belief by some owners that all that is required of them is to complete an application form, and then the permit will be issued over the counter. Although issuance of over-the-counter permits may be practical when a water heater is to be installed or for other minor work, this is not the case for more complex work. The general public is often surprised when they discover a complete application includes the requirements to provide construction drawings as required by Section R106, detailed information about the property, engineering data and other information as required by the building department. The department should develop informational fliers and packets that will assist the applicant with understanding the requirements for obtaining a permit. Recognizing that incomplete applications do not serve the applicant's best interest (and create unnecessary delays with processing applications), many building departments have personnel who specialize in providing assistance to customers to ease them through the process.

R105.3.1 Action on application. The *building official* shall examine or cause to be examined applications for *permits* and amendments thereto within a reasonable time after filing. If the application or the *construction documents* do not conform to the requirements of pertinent laws, the *building official* shall reject such application in writing stating the reasons therefor. If the *building official* is satisfied that the proposed

work conforms to the requirements of this code and laws and ordinances applicable thereto, the *building official* shall issue a *permit* therefor as soon as practicable.

- ❖ This section requires the building official to act with reasonable speed on a permit application. In some instances, this time period is set by state or local law. The building official must refuse to issue a permit when the application and accompanying documents do not conform to the code. In order to ensure effective communication and due process of law, the reasons for denial of an application for a permit are required to be in writing. Once the building official determines that the work described conforms with the code and other applicable laws, the permit must be issued on payment of the fees required by Section R108.

R105.3.1.1 Determination of substantially improved or substantially damaged existing buildings in flood hazard areas. For applications for reconstruction, rehabilitation, *addition*, alteration, repair or other improvement of existing buildings or structures located in a flood hazard area as established by Table R301.2(1), the *building official* shall examine or cause to be examined the *construction documents* and shall make a determination with regard to the value of the proposed work. For buildings that have sustained damage of any origin, the value of the proposed work shall include the cost to repair the building or structure to its predamaged condition. If the *building official* finds that the value of proposed work equals or exceeds 50 percent of the market value of the building or structure before the damage has occurred or the improvement is started, the proposed work is a substantial improvement or restoration of substantial damage and the building official shall require existing portions of the entire building or structure to meet the requirements of Section R322.

For the purpose of this determination, a substantial improvement shall mean any repair, reconstruction, rehabilitation, addition or improvement of a building or structure, the cost of which equals or exceeds 50 percent of the market value of the building or structure before the improvement or repair is started. Where the building or structure has sustained substantial damage, repairs necessary to restore the building or structure to its predamaged condition shall be considered substantial improvements regardless of the actual repair work performed. The term shall not include either of the following:

1. Improvements to a building or structure that are required to correct existing health, sanitary or safety code violations identified by the building official and that are the minimum necessary to ensure safe living conditions.
2. Any alteration of a historic building or structure, provided that the alteration will not preclude the continued designation as a historic building or structure. For the purposes of this exclusion, a historic building shall be any of the following:
 - 2.1. Listed or preliminarily determined to be eligible for listing in the National Register of Historic Places.
 - 2.2. Determined by the Secretary of the U.S. Department of Interior as contributing to the historical

significance of a registered historic district or a district preliminarily determined to qualify as an historic district.

- 2.3. Designated as historic under a state or local historic preservation program that is approved by the Department of Interior.
- ❖ The terms “Substantial damage” and “Substantial improvement” are defined in the IBC and the *International Existing Building Code*® (IEBC®).

Long-term reduction in exposure to flood hazards, including exposure of older buildings, is one of the purposes for regulating development in flood hazard areas. Existing buildings or structures located in flood hazard areas are to be brought into compliance with the flood-resistance provisions of Section R322 when the cost of improvements or the cost of repair of damage exceeds 50 percent of the market value before the improvement is started or before the damage occurred.

Section R105.3 requires the applicant to state the valuation of the proposed work as part of the information submitted to obtain a permit. If the proposed work will be performed on existing buildings or structures in flood hazard areas, including restoration of damage from any cause, the building official must compare the cost of the work to the market value of the building. For damaged buildings, the cost of the proposed work is the value of work necessary to restore the building to its predamage condition, even if the applicant is proposing less work. The cost of proposed work includes the value of the property owner’s labor, as well as the value of donated labor and materials.

To make a determination about whether a proposed repair, reconstruction, rehabilitation, addition or improvement of a building or structure will constitute a substantial improvement or repair of substantial damage, the cost of the proposed work is to be compared to the market value of the building or structure before the work is started. To determine market value, the building official may require the applicant to provide such information as allowed under Section R105.3.

If the building official determines the work is substantial improvement or repair of substantial damage, the existing building is to be brought into compliance with the flood-resistance provisions of Section R322. For additional guidance, refer to FEMA P-758.

R105.3.2 Time limitation of application. An application for a *permit* for any proposed work shall be deemed to have been abandoned 180 days after the date of filing unless such application has been pursued in good faith or a *permit* has been issued; except that the *building official* is authorized to grant one or more extensions of time for additional periods not exceeding 180 days each. The extension shall be requested in writing and justifiable cause demonstrated.

- ❖ The intent of this section is to limit the time between the review process and the issuance of a permit. Applications for permits are considered valid for 180 days. The permit application and review process must be done in a timely manner within that period. The applicant must

be responsive to requests for additional information made by the building department. The 180-day limitation is not intended to penalize an applicant for lack of action on the part of the jurisdiction. It is merely a measure used to void an application when it is no longer reasonable to keep it active because the applicant is delaying the process and is not responding to legitimate requests for information. The building official can extend the time limit of an application in increments of 180 days, provided the applicant can show a valid reason for an extension. The applicant must make this request in writing.

R105.4 Validity of permit. The issuance or granting of a *permit* shall not be construed to be a *permit* for, or an *approval* of, any violation of any of the provisions of this code or of any other ordinance of the *jurisdiction*. *Permits* presuming to give authority to violate or cancel the provisions of this code or other ordinances of the *jurisdiction* shall not be valid. The issuance of a *permit* based on *construction documents* and other data shall not prevent the *building official* from requiring the correction of errors in the *construction documents* and other data. The *building official* is authorized to prevent occupancy or use of a structure where in violation of this code or of any other ordinances of this *jurisdiction*.

❖ This section states the fundamental premise that the permit is only a license to proceed with the work. It is not a license to violate, cancel or set aside any provisions of the code. This is significant because it means that, despite any errors or oversights in the approval process, the permit applicant, not the building official, is responsible for code compliance. Also, the permit can be suspended or revoked in accordance with Section R105.6.

R105.5 Expiration. Every *permit* issued shall become invalid unless the work authorized by such *permit* is commenced within 180 days after its issuance, or if the work authorized by such *permit* is suspended or abandoned for a period of 180 days after the time the work is commenced. The *building official* is authorized to grant, in writing, one or more extensions of time, for periods not more than 180 days each. The extension shall be requested in writing and justifiable cause demonstrated.

❖ The permit becomes invalid under two distinct situations—both based on a 180-day period. The first situation is when no work was initiated 180 days from issuance of a permit. The second situation is when the authorized work has stopped for 180 days. The person who was issued the permit should be notified, in writing, that the permit is invalid and what steps must be taken to reinstate it and restart the work. The building official has the authority to extend this time limitation (in increments of 180 days), provided the extension is requested in writing and there is reasonable cause, which typically includes events beyond the permit holder's control.

R105.6 Suspension or revocation. The *building official* is authorized to suspend or revoke a *permit* issued under the provisions of this code wherever the *permit* is issued in error

or on the basis of incorrect, inaccurate or incomplete information, or in violation of any ordinance or regulation or any of the provisions of this code.

❖ A permit is a license to proceed with the work. The building official, however, can suspend or revoke permits shown to be based, all or in part, on any false statement or misrepresentation of fact. A permit can also be suspended or revoked if it was issued in error, such as an omitted prerequisite approval or code violation indicated on the construction documents. An applicant may subsequently apply for a reinstatement of the permit with the appropriate corrections or modifications made to the application and construction documents.

R105.7 Placement of permit. The building *permit* or a copy shall be kept on the site of the work until the completion of the project.

❖ The permit must be displayed at the work site until the certificate of occupancy has been issued. Because paperwork at a job site is sometimes lost, the code allows a copy of the permit to be kept at the site and the original to be retained in a more secure place. Keeping a record of permits at the project location satisfies the legal requirements set forth in the code, and any interested party can verify that a valid permit has been obtained.

R105.8 Responsibility. It shall be the duty of every person who performs work for the installation or repair of building, structure, electrical, gas, mechanical or plumbing systems, for which this code is applicable, to comply with this code.

❖ This is one of several code provisions that emphasize the required compliance for every aspect of the project. Although the permit holder is designated as having the primary responsibility for overall code compliance, it is the responsibility of each and every person working on the job to adhere to the requirements of the code.

R105.9 Preliminary inspection. Before issuing a *permit*, the *building official* is authorized to examine or cause to be examined buildings, structures and sites for which an application has been filed.

❖ This section provides the building official with a useful tool in the permit process, especially in cases of permits being issued for an existing building. While the construction documents may show the scope and nature of work to be done, there may be other existing conditions in the building that could affect the continued safety profile of the building and the approval of a permit, which could only be discovered by inspection.

SECTION R106 CONSTRUCTION DOCUMENTS

R106.1 Submittal documents. Submittal documents consisting of *construction documents*, and other data shall be submitted in two or more sets with each application for a *permit*. The *construction documents* shall be prepared by a registered *design professional* where required by the statutes of the *jurisdiction* in which the project is to be constructed. Where

special conditions exist, the *building official* is authorized to require additional *construction documents* to be prepared by a registered *design professional*.

Exception: The *building official* is authorized to waive the submission of *construction documents* and other data not required to be prepared by a registered *design professional* if it is found that the nature of the work applied for is such that reviewing of *construction documents* is not necessary to obtain compliance with this code.

- ❖ This section provides the minimum requirements for construction documents that an applicant must provide along with the permit application form for the application package to be considered complete. Construction documents are not just a set of drawings. Construction documents are the entire set of all submitted forms and information necessary to accurately communicate the scope of the construction. The submittals may include written special inspection and structural observation programs, construction drawings, and details, reports, calculations, specifications, shop drawings, manufacturer's installation instructions, site plans and other graphic and written forms that will describe the proposed work in detail. The building official can waive the submission of construction documents for types of work where the review of documents is not necessary to show compliance with the requirements of the code.

The code is prescriptive and makes possible the design of a dwelling or townhouse without the requirement for a licensed design professional. However, the construction documents must be prepared by a licensed design professional when required by the statutes of the state or jurisdiction. Additionally, the building official has the authority to require that plans be prepared by licensed design professionals when not otherwise required by the statutes of the jurisdiction if, in the opinion of the building official, special or unique conditions exist or if the design of a building does not meet the prescriptive provisions of the code.

R106.1.1 Information on construction documents. *Construction documents* shall be drawn upon suitable material. Electronic media documents are permitted to be submitted where *approved* by the *building official*. *Construction documents* shall be of sufficient clarity to indicate the location, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code and relevant laws, ordinances, rules and regulations, as determined by the *building official*.

- ❖ The emphasis of this section is on the clarity, completeness and accuracy of the construction documents. A wide variety of individuals will be using the construction documents to perform their specific tasks. Therefore, it is critical that there be no confusion about the intent of the designer based on the information in the plans and other documents.

Electronic submittal of construction documents is rapidly gaining popularity. Where the Department of Public Safety has the means to review plans electronically, it may request such submittals. Many departments continue to use hard-copy documents for the

plan review process, with a request for electronic media copies of documents for archival purposes.

R106.1.2 Manufacturer's installation instructions. Manufacturer's installation instructions, as required by this code, shall be available on the job site at the time of inspection.

- ❖ Throughout the code, it directs that materials or equipment be installed in accordance with the manufacturer's instructions. An example is the installation of modified bitumen roofing, as set forth in Section R905.11.3. The code recognizes that the manufacturer can best relate the specific installation requirements applicable to its specific product. Where the code mandates that the manufacturer's installation instructions be followed, those instructions must be available at the job site. In this way, both the installers and inspector are able to see that the directives of the manufacturer are being followed.

R106.1.3 Information on braced wall design. For buildings and structures utilizing braced wall design, and where required by the *building official*, braced wall lines shall be identified on the *construction documents*. Pertinent information including, but not limited to, bracing methods, location and length of *braced wall panels* and foundation requirements of braced wall panels at top and bottom shall be provided.

- ❖ This section mandates that the relevant wall bracing information required in Section R602.10 be clearly marked on the construction drawings. Those parts of the wall system that are designated bracing panels have potentially different panel attachment schedules, foundation requirements and specific connection requirements to other parts of the building than do other exterior and interior walls. Not only are braced walls often different from other walls, they are always required in every code-conforming structure. An extra burden is placed on building officials and plan checkers when they have to try to figure out which walls the designer has intended for use as bracing. Requiring such details on all submittals will ensure that bracing is being considered during the design process. It will further ensure that the building's structural detailing is being done by the person who draws the plans and not by the plan checker. It will also make it easier for the builder to properly construct the required bracing on the job site when the details are clearly spelled out on the drawings.

R106.1.4 Information for construction in flood hazard areas. For buildings and structures located in whole or in part in flood hazard areas as established by Table R301.2(1), *construction documents* shall include:

1. Delineation of flood hazard areas, floodway boundaries and flood zones and the design flood elevation, as appropriate.
2. The elevation of the proposed lowest floor, including *basement*; in areas of shallow flooding (AO Zones), the height of the proposed lowest floor, including *basement*, above the highest adjacent *grade*.

3. The elevation of the bottom of the lowest horizontal structural member in coastal high hazard areas (V Zone) and in Coastal A Zones where such zones are delineated on flood hazard maps identified in Table R301.2(1) or otherwise delineated by the jurisdiction.
 4. If design flood elevations are not included on the community's Flood Insurance Rate Map (FIRM), the *building official* and the applicant shall obtain and reasonably utilize any design flood elevation and floodway data available from other sources.
- ❖ This section details the information to be included in an application for a permit to build within a flood hazard area. The site plan is to show sufficient detail and information about the designated flood hazard area, including floodway and flood zones, to allow for a complete review of the proposed activities. Flood Insurance Rate Maps (FIRMs) are flood hazard maps prepared by the Federal Emergency Management Agency (FEMA). FIRMs may show specific base flood elevations (BFE). If the community adopts a flood hazard map other than the FIRM, the design flood elevations (DFE) must be at least as high as the BFEs [see Table R301.2(1)].

Construction documents are to include the proposed elevation of the lowest floor (in all Zone A other than Coastal A Zone) and the elevation of the bottom of the lowest horizontal structural member (in all Zone V and Coastal A Zone), which must be at or above the minimum elevation required in Section R322.

Basements below residential buildings are not to be constructed below the DFE, even if excavated into fill that is placed above the DFE. In flood hazard areas except coastal high-hazard areas, applicants may propose placing fill with the intent of later constructing buildings with excavated basements. When excavated into fill, basements may be subject to damage, especially where waters remain high for more than a few hours. Fill materials can become saturated and provide inadequate support, or water pressure can collapse below-grade walls. To address these concerns, building officials may require applicants to submit documentation outlined in FEMA TB #10.

If elevated in flood hazard areas, buildings will be surrounded by water during general conditions of flooding. Local emergency personnel responsible for evacuations should be consulted during the subdivision or building permit approval process. Many states and communities have provisions that require uninterrupted access to all buildings during a flood. These requirements may be administered by agencies responsible for permitting the construction of public rights-of-way or may be imposed as part of subdivision approval.

Many FIRMs show flood hazard areas without specifying the BFEs, indicating that engineering analyses have not been prepared for those areas. These flood hazard areas are often referred to as unnumbered A Zones or approximate A Zones. An important step in

regulating the development of these areas is the determination of the DFE. The building official and applicant are to search for, and use data from, other sources, which may include the U.S. Army Corps of Engineers, the Natural Resources Conservation Service, a state agency (transportation, water resources, environment), local planning or public works department, a flood control agency or district, or historical records. If flood elevation information is not available, the building official may require the applicant to develop the DFE in accordance with accepted engineering practices. Local officials unfamiliar with establishing DFEs are encouraged to contact the NFIP State Coordinator or the appropriate FEMA regional office. For additional guidance, refer to FEMA 265.

R106.2 Site plan or plot plan. The *construction documents* submitted with the application for *permit* shall be accompanied by a site plan showing the size and location of new construction and existing structures on the site and distances from *lot lines*. In the case of demolition, the site plan shall show construction to be demolished and the location and size of existing structures and construction that are to remain on the site or plot. The *building official* is authorized to waive or modify the requirement for a site plan where the application for *permit* is for *alteration* or repair or where otherwise warranted.

- ❖ One valuable part of the construction documents is the site plan. As a part of reviewing the building's location on the site for conformance to the code, the building official must know the size and location of any other structures on the lot, as well as their physical relationship to the new structure. The proximity of the new structure to lot lines and any public ways must also be shown. The distance between a building and the lot lines may trigger a variety of code requirements, the most notable being exterior wall fire-resistance rating and opening prohibition (see Section R302).

The code also requires that a site plan be submitted when a building or structure is to be demolished. The plan must identify the location of the building to be demolished, as well as any surrounding structures that will remain in place.

R106.3 Examination of documents. The *building official* shall examine or cause to be examined *construction documents* for code compliance.

- ❖ The requirements of this section are related to those found in Section R105.3.1 regarding the action of the building official in response to a permit application. The building official can delegate review of the construction documents to subordinates as provided for in Section R103.3.

R106.3.1 Approval of construction documents. Where the *building official* issues a *permit*, the *construction documents* shall be *approved* in writing or by a stamp that states "REVIEWED FOR CODE COMPLIANCE." One set of *construction documents* so reviewed shall be retained by the *building official*. The other set shall be returned to the appli-

cant, shall be kept at the site of work and shall be open to inspection by the *building official* or a duly authorized representative.

- ❖ Approval of the construction documents is the first in a series of reviews and approvals throughout the design and construction process. The building official or authorized representative must indicate that the construction documents are approved for construction, in writing or by a stamp that specifically states “REVIEWED FOR CODE COMPLIANCE,” and must include any additional information that is necessary for the project. A set of the documents must be retained by the building department as its record for the life of the project. It is not uncommon throughout the job for questions to arise that require referencing the approved set of plans in the office. An efficient filing system should be developed to make the retrieval of construction documents a simple process.

In addition to the set of construction documents retained by the Department of Building Safety, at least one set of approved plans is to be returned to the permit holder. These construction documents must be maintained at the job site for reference purposes throughout the project. To avoid confusion, the construction documents on the site must be the documents that were approved and stamped. They must be available for review by building department personnel during the numerous inspections that may take place. Additionally, the contractor cannot determine compliance with approved construction documents unless those approved documents are available. Another reason to have the documents available is that these plans will generally indicate any special items or issues identified by the plans examiner that may not be shown on any other construction documents. If the approved construction documents are not available, the inspection may be postponed and work on the project may be halted.

R106.3.2 Previous approvals. This code shall not require changes in the *construction documents*, construction or designated occupancy of a structure for which a lawful *permit* has been heretofore issued or otherwise lawfully authorized, and the construction of which has been pursued in good faith within 180 days after the effective date of this code and has not been abandoned.

- ❖ If, after a permit is issued and construction proceeds at a normal pace, a new edition of the code is adopted by the legislative body, requiring that the building be constructed to conform to the new code is unreasonable. This section provides for the continuity of permits issued under previous codes, as long as such permits are being “actively prosecuted” subsequent to the effective date of the ordinance adopting this edition of the code.

If the work is abandoned for 180 days or more, and an extension of the permit is not granted, the original permit is no longer valid, and a new permit must be

sought under the provisions of the latest edition of the code.

R106.3.3 Phased approval. The *building official* is authorized to issue a *permit* for the construction of foundations or any other part of a building or structure before the *construction documents* for the whole building or structure have been submitted, provided that adequate information and detailed statements have been filed complying with pertinent requirements of this code. The holder of such *permit* for the foundation or other parts of a building or structure shall proceed at the holder’s own risk with the building operation and without assurance that a *permit* for the entire structure will be granted.

- ❖ Phased approval is needed for projects that use the “fast track” construction method, which allows construction to begin before completion of all of the plans and specifications. Although it is preferable to issue permits for projects in their entirety, the building official has the authority to issue, at his or her discretion, a permit for a portion of the construction. The building official must be satisfied that the information provided shows, in sufficient detail, that the partial construction will conform to the requirements of the code. In such a case, the permit holder proceeds at his or her own risk with the construction and has no assurance of the entire permit ever being issued.

R106.4 Amended construction documents. Work shall be installed in accordance with the *approved construction documents*, and any changes made during construction that are not in compliance with the *approved construction documents* shall be resubmitted for approval as an amended set of *construction documents*.

- ❖ Any amendments to the approved construction documents must be filed before constructing the amended item. In the broadest sense, amendments include all addenda, change orders, revised drawings and marked-up shop drawings. Building officials should maintain a policy that all amendments be submitted for review. Otherwise, a significant amendment may not be submitted because of misinterpretation, resulting in an activity that is not approved and that causes a needless delay in obtaining approval of the finished work.

R106.5 Retention of construction documents. One set of *approved construction documents* shall be retained by the *building official* for a period of not less than 180 days from date of completion of the permitted work, or as required by state or local laws.

- ❖ A set of the approved construction documents must be kept by the building official as may be required by state or local laws, but for a period of not less than 180 days after the work is complete. Questions regarding an item shown on the approved documents may arise in the period immediately following completion of the work and the documents should be available for review. See Section R104.7 for requirements to retain other records that are generated as a result of the work.

SECTION R107 TEMPORARY STRUCTURES AND USES

R107.1 General. The *building official* is authorized to issue a *permit* for temporary structures and temporary uses. Such *permits* shall be limited as to time of service, but shall not be permitted for more than 180 days. The *building official* is authorized to grant extensions for demonstrated cause.

❖ The building official can authorize temporary use permits when the applicant has met all regulations governing such use. Permits for temporary structures may also be granted subject to the provisions of this section. Although the permit is to be granted for a time period consistent with the temporary use, 180 days is the maximum period of time for which a temporary use or structure can be valid. This code section often applies to structures that are commonly used for a short duration of time at a specific location, then easily dismantled and removed, often to be reconstructed at a different site. It is common for this type of structure to be used at events such as street fairs, carnivals, circuses, parades, sporting events, weddings, concerts or revivals, or they may also be used to house construction offices. These structures range in size from small tents or shade structures, which may house a vendor at a street fair, to large tents for circuses or religious revivals. Because of the large size, large occupant load and complexity that can result from smaller structures being grouped together, the fire safety and life safety concerns as covered in Section R107.2 must be duly considered before a permit is issued.

R107.2 Conformance. Temporary structures and uses shall conform to the structural strength, fire safety, means of egress, light, ventilation and sanitary requirements of this code as necessary to ensure the public health, safety and general welfare.

❖ This section gives the building official discretion in determining the specific criteria for conformance. The issues of structural strength, fire safety, egress, light, ventilation and sanitation are mentioned in this section as the key areas of concern for temporary structures or uses. The levels of required conformance must be determined by the building official to achieve the jurisdiction's required level of safety, health and welfare. Full compliance with the code is not required for a temporary structure or temporary use, but it is clear that the level of performance set forth by the code must be considered in the development of the requirements.

A certain level of conformance is required if temporary structures are permitted in flood hazard areas established by Table R301.2(1) in order to minimize the likelihood of increasing flood heights or flood damage. Measures to consider include anchoring to prevent flotation during conditions of the base flood and avoiding placement in floodways and coastal high-hazard areas (V Zones) to avoid impacts to downstream and adjacent properties.

R107.3 Temporary power. The *building official* is authorized to give permission to temporarily supply and use power

in part of an electric installation before such installation has been fully completed and the final certificate of completion has been issued. The part covered by the temporary certificate shall comply with the requirements specified for temporary lighting, heat or power in NFPA 70.

❖ Commonly, the electrical service on most construction sites is installed and energized long before all of the wiring is completed. This procedure allows the power supply to be increased as construction demands. However, temporary permission is not intended to waive the requirements set forth in NFPA 70. Construction power from the permanent wiring of the building does not require the installation of temporary ground-fault circuit interrupter (GFCI) protection or the Assured Equipment Grounding Conductor Program (AEGCP), because the building wiring installed as required by the code should be as safe for use during construction as it would be for use after completion of the building.

R107.4 Termination of approval. The *building official* is authorized to terminate such *permit* for a temporary structure or use and to order the temporary structure or use to be discontinued.

❖ This section provides the building official with the necessary authority to terminate the permit for a temporary structure or use. The building official can order that a temporary structure be removed or a temporary use be discontinued if conditions of the permit have been violated or the structure or use poses an imminent hazard to the public. This text is important because it allows the building official to act quickly when time is of the essence in order to protect public health, safety and welfare.

SECTION R108 FEES

R108.1 Payment of fees. A *permit* shall not be valid until the fees prescribed by law have been paid, nor shall an amendment to a *permit* be released until the additional fee, if any, has been paid.

❖ The code anticipates that jurisdictions will establish their own fee schedules. It is the intent that the fees collected by the department for building permit issuance, plan review and inspection be adequate to cover the costs to the department in these areas, including administration, plans examination and inspection. If the department has additional duties, then its budget will need to be supplemented from the general fund. This section requires that all fees be paid prior to permit issuance or release of an amendment to a permit. Since department operations are intended to be supported by fees paid by the user of department activities, it is important that these fees are received before incurring any expense. This philosophy has resulted in some departments having fees paid prior to the performance of two areas of work: plan review and inspection.

R108.2 Schedule of permit fees. On buildings, structures, electrical, gas, mechanical and plumbing systems or *alter-*

ations requiring a *permit*, a fee for each *permit* shall be paid as required, in accordance with the schedule as established by the applicable governing authority.

- ❖ The jurisdiction inserts its desired fee schedule at this location. The fees are established by law, such as in an ordinance adopting the code (see page xvii of the code for a sample), a separate ordinance or legally promulgated regulation, as required by state or local law. Fee schedules are often based on a valuation of the work to be performed. This concept is based on the proposition that the valuation of a project is related to the amount of work to be expended in plan review, inspections and administering the permit, plus an excess to cover the department overhead.

To assist jurisdictions in establishing uniformity in fees, building evaluation data are published twice each year in ICC's *Building Safety Journal Online*. An example of a building department fee schedule is shown in Appendix L.

R108.3 Building permit valuations. Building *permit* valuation shall include total value of the work for which a *permit* is being issued, such as electrical, gas, mechanical, plumbing *equipment* and other permanent systems, including materials and labor.

- ❖ Most jurisdictions develop a fee schedule based on the projected construction cost of the work to be done. Two methods are used to determine this cost valuation: 1. A "per-square-foot" factor based on the use or occupancy of the building and the type of construction involved; or 2. The "bid cost" factor based on the total accepted bid price for doing the work. The valuation is determined by including the value of the construction process, including both materials and labor. It is important that a realistic valuation be determined for every project so that permit fees are applied fairly and accurately. If the building official believes that the value provided by the applicant is underestimated, the permit should be denied unless the applicant can substantiate the value by providing detailed estimates of the work to the satisfaction of the building official.

R108.4 Related fees. The payment of the fee for the construction, *alteration*, removal or demolition for work done in connection to or concurrently with the work authorized by a building *permit* shall not relieve the applicant or holder of the *permit* from the payment of other fees that are prescribed by law.

- ❖ The fees for a building permit may be in addition to other fees required by the jurisdiction or others for related items, such as sewer connections, water service taps, driveways and signs. It cannot be construed that the building permit fee includes these other items. A building permit and the fees attached to that permit do not necessarily cover all aspects of the work to be performed. All fees of the jurisdiction, including those for additional permits, reinspections, investigations or other departmental functions, must be paid along with those for a building permit.

R108.5 Refunds. The *building official* is authorized to establish a refund policy.

- ❖ This section allows for a refund of fees, which may be full or partial, typically resulting from the revocation, abandonment or discontinuance of a building project for which a permit has been issued and fees have been collected. The refund of fees should be related to the cost of enforcement services not provided because of the termination of the project. The building official, when authorizing a fee refund, is authorizing the disbursement of public funds; therefore, the request for a refund must be in writing and for good cause.

R108.6 Work commencing before permit issuance. Any person who commences work requiring a *permit* on a building, structure, electrical, gas, mechanical or plumbing system before obtaining the necessary permits shall be subject to a fee established by the applicable governing authority that shall be in addition to the required *permit* fees.

- ❖ The building official will incur certain costs (e.g., inspection time and administrative) when investigating and citing a person who has commenced work without having obtained a permit. The building official is, therefore, entitled to recover these costs by establishing a fee, in addition to that collected when the required permit is issued, to be imposed on the responsible party.

SECTION R109 INSPECTIONS

R109.1 Types of inspections. For on-site construction, from time to time the *building official*, upon notification from the *permit* holder or his agent, shall make or cause to be made any necessary inspections and shall either approve that portion of the construction as completed or shall notify the *permit* holder or his or her agent wherein the same fails to comply with this code.

- ❖ Inspections are necessary to verify that the construction conforms to the code requirements, and this section outlines the minimum required inspections. Besides the minimum required inspections that are specifically listed, the building official has the authority to require additional inspections so that compliance with the code can be determined. It is the duty of the permit holder or an authorized agent of the permit holder to notify the building department that some or all of the work covered by the permit is ready and available for inspection. At that point, the appropriate jurisdictional inspector performs the necessary on-site inspection. The inspector then must inform the permit holder or agent that the work has been inspected. This may be by a telephone call, an electronic message or, in many cases, a written record of the inspection posted at the job site.

R109.1.1 Foundation inspection. Inspection of the foundation shall be made after poles or piers are set or trenches or *basement* areas are excavated and any required forms erected and any required reinforcing steel is in place and supported

prior to the placing of concrete. The foundation inspection shall include excavations for thickened slabs intended for the support of bearing walls, partitions, structural supports, or *equipment* and special requirements for wood foundations.

❖ The foundation inspection is typically the first inspection of the job site by a representative of the Building Safety Department. At that time, the inspector will verify that the foundation is located as shown on the approved plans and in accordance with the jurisdictional requirements for building setbacks and easements. Where a footing system is to be used, the footing trenches must be excavated and any required reinforcing steel must be in place. For foundation walls, the wall forms must be completely erected with the appropriate steel reinforcement placed within the forms.

Column pads, thickened slabs and other foundation work must also be ready for inspection prior to concrete placement.

R109.1.2 Plumbing, mechanical, gas and electrical systems inspection. Rough inspection of plumbing, mechanical, gas and electrical systems shall be made prior to covering or concealment, before fixtures or *appliances* are set or installed, and prior to framing inspection.

Exception: Backfilling of ground-source heat pump loop systems tested in accordance with Section M2105.28 prior to inspection shall be permitted.

❖ The various trade rough-in inspections must be completed prior to the framing inspection. The electrical, gas, mechanical and plumbing systems that are to be concealed must be inspected and approved prior to their concealment. In addition, the effect of these systems on the structural integrity of the building must be reviewed after they are completed and ready to be covered. All of the trades inspections must be completed and approvals granted prior to the inspection of the framing system.

R109.1.3 Floodplain inspections. For construction in flood hazard areas as established by Table R301.2(1), upon placement of the lowest floor, including *basement*, and prior to further vertical construction, the *building official* shall require submission of documentation, prepared and sealed by a registered *design professional*, of the elevation of the lowest floor, including *basement*, required in Section R322.

❖ For any building constructed in a flood hazard area, the elevation of the lowest floor level must be established immediately after the placement of the floor. Documentation of this elevation is evidence of compliance (also see commentary, Section R322.3.6). If the documentation is submitted when the lowest floor level is established and before further vertical construction, errors in elevation may be corrected at the least cost. The elevation of the lowest floor is used by insurance agents to compute federal flood insurance premium costs. An error in the minimum required elevation may significantly increase the cost of flood insurance. If the elevation of the lowest floor goes uncorrected, all

future owners will be exposed to flood hazards and incur the additional increase in recovery costs and insurance costs.

Documentation of elevations is also required by Section R109.1.6.1, prior to the final inspection. Most communities use the Elevation Certificate form developed by FEMA, FEMA Form 086-0-33. Insurance agents are required to use this form to write federal flood insurance policies. The Elevation Certificate is also used to record information that is useful during final inspections, including flood openings, garage floor elevations, and the elevation of equipment that serves buildings.

R109.1.4 Frame and masonry inspection. Inspection of framing and masonry construction shall be made after the roof, masonry, framing, firestopping, draftstopping and bracing are in place and after the plumbing, mechanical and electrical rough inspections are *approved*.

❖ The framing inspection is usually the final opportunity for the inspector to view all of the items that will be concealed within the structure. The inspection includes the structural frame work of the building, as well as any fireblocking or draftstopping that will be contained within concealed spaces. All of the electrical, mechanical, gas and plumbing inspections must be completed and approved prior to the framing inspection. This allows any framing members to be repaired while they are accessible.

R109.1.5 Other inspections. In addition to inspections in Sections R109.1.1 through R109.1.4, the *building official* shall have the authority to make or require any other inspections to ascertain compliance with this code and other laws enforced by the *building official*.

❖ Any item regulated by the code is subject to inspection by the building official to determine compliance with the applicable code provision, and no list can include all items in a given building. This section, therefore, gives the building official the authority to inspect any regulated items.

A variety of other inspections, such as those for gypsum board or insulation, may be mandated by the building department to verify compliance with the code or other city ordinances. These inspections are generally established as a result of local concern regarding a specific portion of the construction process. The procedure for these inspections should be consistent with the other provisions of this section.

R109.1.5.1 Fire-resistance-rated construction inspection. Where fire-resistance-rated construction is required between *dwelling units* or due to location on property, the *building official* shall require an inspection of such construction after lathing or gypsum board or gypsum panel products are in place, but before any plaster is applied, or before board or panel joints and fasteners are taped and finished.

❖ There are a limited number of situations in which fire-resistance-rated construction is required by the code. For example, where two or more dwelling units are

located within the same structure, they are required by Section R302 to be completely separated from each other by a specified level of fire resistance. This is the case for both two-family dwellings and townhouses. A second example would be the proximity of the building to an adjoining property line. Section R302 requires exterior walls located less than 3 feet (914 mm) from a property line (unless abutting a public way) to be of minimum 1-hour fire-resistance-rated construction. If either of these conditions should occur, an inspection of the fire-resistance-rated construction is required.

The inspection for compliance with the fire-resistance requirements of the code should be made at a point of construction when the membrane materials are in place, but the fasteners are still exposed. This allows the inspector to verify the appropriate fastener type and location based on the specific fire-resistance listing of the portion of the building under consideration.

R109.1.6 Final inspection. Final inspection shall be made after the permitted work is complete and prior to occupancy.

- ❖ The final inspection should occur after all of the work addressed by the code is complete, but prior to occupancy of the building. The issues addressed in the final inspection cover all aspects of construction, including fire safety, life safety and structural safety, as well as electrical, plumbing, gas and mechanical items. All violations of the approved construction documents and permit are to be noted and the holder of the permit is to be notified of the discrepancies. The final inspection must be approved before a certificate of occupancy can be issued.

R109.1.6.1 Elevation documentation. If located in a flood hazard area, the documentation of elevations required in Section R322.1.10 shall be submitted to the *building official* prior to the final inspection.

- ❖ Permittees must submit documentation of elevations before final inspection. Also see commentary for Sections R109.1.3 and R322.1.10.

R109.2 Inspection agencies. The *building official* is authorized to accept reports of *approved* agencies, provided such agencies satisfy the requirements as to qualifications and reliability.

- ❖ It is common for the building official to rely on other agencies for informational or inspection reports regarding various aspects covering methods of the construction process materials. This reliance should be based on the building official's approval of the qualifications and reliability of the third-party inspection or testing service.

R109.3 Inspection requests. It shall be the duty of the *permit* holder or their agent to notify the *building official* that such work is ready for inspection. It shall be the duty of the person requesting any inspections required by this code to provide access to and means for inspection of such work.

- ❖ It is the responsibility of the permit holder or other authorized person, such as the contractor performing

the work, to arrange for the required inspections when completed work is ready and to allow for sufficient time for the building official to schedule a visit to the site to prevent work from being concealed prior to being inspected.

Each building department establishes its own procedures on how and when requests should be made. Once an inspection has been scheduled, access to the work to be inspected must be provided, including any special means such as a ladder.

R109.4 Approval required. Work shall not be done beyond the point indicated in each successive inspection without first obtaining the approval of the *building official*. The *building official* upon notification, shall make the requested inspections and shall either indicate the portion of the construction that is satisfactory as completed, or shall notify the *permit* holder or an agent of the *permit* holder wherein the same fails to comply with this code. Any portions that do not comply shall be corrected and such portion shall not be covered or concealed until authorized by the *building official*.

- ❖ Work must not continue past the point of a required inspection until that inspection has been approved by the building department. It is possible that if the work progresses beyond this point and is not in total compliance with the code, some of the work may have to be removed. It is critical that each individual stage of the project be approved prior to continuance of construction.

As indicated in Section R109.1, inspections must be performed when requested, and the inspector must indicate whether the construction is satisfactory or is not compliant. If the work is not approved, it must be corrected, and a reinspection must be requested. Any item not approved cannot be concealed until it has been corrected and approved by the building official.

SECTION R110 CERTIFICATE OF OCCUPANCY

R110.1 Use and occupancy. A building or structure shall not be used or occupied, and a change in the existing use or occupancy classification of a building or structure or portion thereof shall not be made, until the *building official* has issued a certificate of occupancy therefor as provided herein. Issuance of a certificate of occupancy shall not be construed as an approval of a violation of the provisions of this code or of other ordinances of the *jurisdiction*. Certificates presuming to give authority to violate or cancel the provisions of this code or other ordinances of the *jurisdiction* shall not be valid.

Exceptions:

1. Certificates of occupancy are not required for work exempt from permits under Section R105.2.
 2. Accessory buildings or structures.
- ❖ The tool the building official employs to control the uses and occupancies of the various buildings in a jurisdiction is the certificate of occupancy. This section establishes the conditions of a certificate of occupancy

and identifies the information the certificate must contain. The building official must be satisfied that the structure meets the requirements of the code before a certificate of occupancy can be given, and the structure cannot be legally occupied until a certificate has been issued. If the occupancy classification of an existing building has changed, such as changing an old Victorian home to a small office building, a new certificate of occupancy must be issued. The certificate of occupancy is the legal notification from the Department of Building Safety that the building may be occupied for its intended purpose.

The granting of a certificate of occupancy does not necessarily indicate that no violations of the code or other jurisdictional laws exist. The building official should make every effort to determine compliance with all applicable code provisions and other ordinances of the jurisdiction. It is important that violations be corrected. It is possible that the certificate of occupancy will be revoked if it is found that the certificate was issued in error. Its issuance does not relieve the building owner from the responsibility for correcting any code violation that may exist.

The exceptions simply state that when work is not under the monitor of the building department, there is no need to deal with a certificate of occupancy.

R110.2 Change in use. Changes in the character or use of an existing structure shall not be made except as specified in Sections 407 and 408 of the *International Existing Building Code*.

❖ When an existing building's character or use is modified, the provisions of Sections 407 and 408 of the IEBC dealing with change of occupancy and historic buildings must be met. Because the code is limited in scope to specific residential occupancies, any change of occupancy to a use beyond the scope of Section R101.2 will be governed by the IBC.

R110.3 Certificate issued. After the *building official* inspects the building or structure and does not find violations

of the provisions of this code or other laws that are enforced by the department of building safety, the *building official* shall issue a certificate of occupancy containing the following:

1. The building *permit* number.
 2. The address of the structure.
 3. The name and address of the owner or the owner's authorized agent.
 4. A description of that portion of the structure for which the certificate is issued.
 5. A statement that the described portion of the structure has been inspected for compliance with the requirements of this code.
 6. The name of the *building official*.
 7. The edition of the code under which the *permit* was issued.
 8. If an automatic sprinkler system is provided and whether the sprinkler system is required.
 9. Any special stipulations and conditions of the building *permit*.
- ❖ Prior to the use or occupancy of the building, the building official shall perform a final inspection as described in Section R109.1.6. The building official is required to issue a certificate of occupancy after a successful final inspection has been completed and all deficiencies and violations have been resolved. This section lists the information that must be included on the certificate. This information is useful to both the building official and the owner because it indicates the criteria under which the structure was evaluated and approved at the time the certificate was issued. Commentary Figure R110.3 illustrates the information that must be provided on the certificate of occupancy.

R110.4 Temporary occupancy. The *building official* is authorized to issue a temporary certificate of occupancy

Figure R110.3
CERTIFICATE OF OCCUPANCY

before the completion of the entire work covered by the *permit*, provided that such portion or portions shall be occupied safely. The *building official* shall set a time period during which the temporary certificate of occupancy is valid.

❖ The building official is permitted to issue a temporary certificate of occupancy for all or a portion of a building prior to the completion of all work. Such certification is to be issued only when the building or portion in question can be safely occupied prior to full completion. The certification is intended to acknowledge that some building features may not be completed even though the building is safe for occupancy, or that a portion of the building can be safely occupied while work continues in another area. This provision precludes the occupancy of a building or structure that does not contain all of the required fire protection systems and means of egress. Temporary certificates should be issued only when incidental construction remains, such as site work and interior work that is not regulated by the code and exterior decoration not necessary to the integrity of the building envelope. The building official should recognize that the issuance of a temporary certificate of occupancy is as substantial an act as the issuance of the final certificate. Indeed, the issuance of a temporary certificate of occupancy offers a greater potential for conflict because once the building or structure is occupied, it is very difficult to remove the occupants through legal means. The certificate must specify the time period for which it is valid.

R110.5 Revocation. The *building official* shall, in writing, suspend or revoke a certificate of occupancy issued under the provisions of this code wherever the certificate is issued in error, or on the basis of incorrect information supplied, or where it is determined that the building or structure or portion thereof is in violation of any ordinance or regulation or any of the provisions of this code.

❖ In essence, the certificate of occupancy certifies that the described building or portion of that building complies with the requirements of the code for the intended use. However, any certificate of occupancy may be suspended or revoked by the building official under one of three conditions: 1. When the certificate is issued in error; 2. When incorrect information is supplied to the building official; or 3. When it is determined that the building or a portion of the building is shown to be in violation of the code or any other ordinance or regulation of the jurisdiction.

This section is needed to give the building official the authority to revoke a certificate of occupancy for the reasons indicated in the code text. The building official may also suspend the certificate of occupancy until all of the code violations are corrected.

SECTION R111 SERVICE UTILITIES

R111.1 Connection of service utilities. A person shall not make connections from a utility, source of energy, fuel or

power to any building or system that is regulated by this code for which a *permit* is required, until *approved* by the *building official*.

❖ This section establishes the authority of the building official to approve utility connections to a building for items such as water, sewer, electricity, gas and steam, and to require their disconnection when hazardous conditions or emergencies exist.

The approval of the building official is required before a connection can be made from a utility to a building system that is regulated by the code. This includes utilities supplying water, sewer, electricity, gas and steam services. For the protection of building occupants, including workers, such systems must have had final inspection approvals, except as allowed by Section R111.2 for temporary connections.

R111.2 Temporary connection. The *building official* shall have the authority to authorize the temporary connection of the building or system to the utility, source of energy, fuel or power.

❖ The building official is permitted to issue temporary authorization to make connections to the public utility system prior to the completion of all work. This acknowledges that, because of seasonal limitations, time constraints or the need for testing or partial operation of equipment, some building systems may be safely connected even though the building is not suitable for final occupancy. The temporary connection and utilization of connected equipment should be approved when the requesting permit holder has demonstrated to the building official's satisfaction that public health, safety and welfare will not be endangered.

R111.3 Authority to disconnect service utilities. The *building official* shall have the authority to authorize disconnection of utility service to the building, structure or system regulated by this code and the referenced codes and standards set forth in Section R102.4 in case of emergency where necessary to eliminate an immediate hazard to life or property or where such utility connection has been made without the approval required by Section R111.1 or R111.2. The *building official* shall notify the serving utility and where possible the owner or the owner's authorized agent and occupant of the building, structure or service system of the decision to disconnect prior to taking such action. If not notified prior to disconnection, the owner, the owner's authorized agent or occupant of the building, structure or service system shall be notified in writing as soon as practical thereafter.

❖ Disconnection of one or more of a building's utility services is the most radical method of hazard abatement available to the building official and should be reserved for cases in which all other lesser remedies have proven ineffective. Such an action must be preceded by written notice to the utility and the owner and occupants of the building. Disconnection must be accomplished within the time frame established by the building official in the notice. When the hazard to the

public health, safety or welfare is so imminent as to mandate immediate disconnection, the building official has the authority and even the obligation to cause disconnection without notice. In such cases, the owner or occupants must be given written notice as soon as possible.

SECTION R112 BOARD OF APPEALS

R112.1 General. In order to hear and decide appeals of orders, decisions or determinations made by the *building official* relative to the application and interpretation of this code, there shall be and is hereby created a board of appeals. The *building official* shall be an ex officio member of said board but shall not have a vote on any matter before the board. The board of appeals shall be appointed by the governing body and shall hold office at its pleasure. The board shall adopt rules of procedure for conducting its business, and shall render decisions and findings in writing to the appellant with a duplicate copy to the *building official*.

- ❖ This section holds that any aggrieved party with a material interest in the decision of the building official may appeal such a decision before a board of appeals. This provides a forum other than the court of the jurisdiction in which the building official's action can be reviewed.

A board of appeals is to be created by the jurisdiction. The primary functions of the board of appeals are hearing and acting on the appeal of orders or decisions the building official has made on the application or interpretation of the code. The building official is an ex officio member of the board of appeals, but he or she has no vote on any issue that comes before the board. The appellant is to be provided with a written copy of the board's findings and decisions, with a duplicate copy sent to the building official.

This section literally allows any person to appeal a decision of the building official. In practice, this section has been interpreted to permit appeals only by those aggrieved parties with a material or definitive interest in the decision of the building official. An aggrieved party may not appeal a code requirement per se. The intent of the appeal process is not to waive or set aside a code requirement; rather, it is intended to provide a means of reviewing a building official's decision on an interpretation or application of the code or to review the equivalency of protection to the code requirements. The members of the appeals board are appointed by the "governing body" of the jurisdiction, typically a council or administrator, such as a mayor or city manager, and remain members until removed from office. The board must establish procedures for electing a chairperson, scheduling and conducting meetings and administration. Note that Appendix B of the IBC contains complete, detailed requirements for creating an appeals board, including number of members, qualifications and administrative procedures.

R112.2 Limitations on authority. An application for appeal shall be based on a claim that the true intent of this code or the rules legally adopted thereunder have been incorrectly interpreted, the provisions of this code do not fully apply or an equally good or better form of construction is proposed. The board shall not have authority to waive requirements of this code.

- ❖ This section establishes the grounds for an appeal, which claims that the building official has misinterpreted or misapplied a code provision. The board is not allowed to set aside any of the technical requirements of the code; however, it is allowed to consider alternative methods of compliance with the technical requirements (see Section R104.11).

An appeal must be based on the claim that the provisions of the code have been misinterpreted, that the provisions do not apply to the appellant's circumstances, or that where an alternative method or technique of construction is used it has been shown to be at least equal to the code requirements.

R112.3 Qualifications. The board of appeals shall consist of members who are qualified by experience and training to pass judgement on matters pertaining to building construction and are not employees of the *jurisdiction*.

- ❖ It is important that the decisions of the appeals board are based purely on the technical merits involved in an appeal. It is not the place for policy or political deliberations. The members of the appeals board are, therefore, expected to have experience in building construction matters. The purpose of the board is to provide a review of the appeal independent from that of the building department, so no jurisdictional employee is permitted to be a member. Additional information on suggested qualifications of members of the board of appeals is contained in Appendix B of the IBC.

R112.4 Administration. The *building official* shall take immediate action in accordance with the decision of the board.

- ❖ Decisions made by the board of appeals must be enacted as quickly as possible. The building official is to take whatever action is necessary to see that the orders of the board are carried out.

SECTION R113 VIOLATIONS

R113.1 Unlawful acts. It shall be unlawful for any person, firm or corporation to erect, construct, alter, extend, repair, move, remove, demolish or occupy any building, structure or *equipment* regulated by this code, or cause same to be done, in conflict with or in violation of any of the provisions of this code.

- ❖ This section describes the citing, recording and subsequent actions to be taken when code violations are found.

R113.2 Notice of violation. The *building official* is authorized to serve a notice of violation or order on the person responsible for the erection, construction, *alteration*, extension, repair, moving, removal, demolition or occupancy of a building or structure in violation of the provisions of this code, or in violation of a detail statement or a plan *approved* thereunder, or in violation of a *permit* or certificate issued under the provisions of this code. Such order shall direct the discontinuance of the illegal action or condition and the abatement of the violation.

- ❖ The building official is required to notify the person responsible for the construction or use of a building found to be in violation of the code. The section of the code that is being violated must be cited so that the responsible party can respond to the notice.

R113.3 Prosecution of violation. If the notice of violation is not complied with in the time prescribed by such notice, the *building official* is authorized to request the legal counsel of the *jurisdiction* to institute the appropriate proceeding at law or in equity to restrain, correct or abate such violation, or to require the removal or termination of the unlawful occupancy of the building or structure in violation of the provisions of this code or of the order or direction made pursuant thereto.

- ❖ When the building owner, owner's agent or tenant does not correct the condition causing the violation as directed, the building official must pursue, through the use of legal counsel of the jurisdiction, legal means to correct the violation. This is not optional.

Any extensions that allow the violations to be corrected voluntarily must be for a reasonable, bona fide cause, or the building official may be subject to criticism for "arbitrary and capricious" actions. In general, it is better to have a standard time limitation for correction of violations. Departures from this standard must be for a clear and reasonable purpose, usually stated in writing by the violator.

R113.4 Violation penalties. Any person who violates a provision of this code or fails to comply with any of the requirements thereof or who erects, constructs, alters or repairs a building or structure in violation of the *approved construction documents* or directive of the *building official*, or of a *permit* or certificate issued under the provisions of this code, shall be subject to penalties as prescribed by law.

- ❖ The jurisdiction must establish penalties for a variety of violations that may occur. Violations specifically addressed by the code include failure to comply with the code, approved plans or directives of the building official.

Penalties for violating provisions of the code are typically contained in state law, particularly if the code is adopted at that level, and the building department must follow those procedures. If there is no such procedure already in effect, one must be established with the aid of legal counsel.

SECTION R114 STOP WORK ORDER

R114.1 Notice to owner or the owner's authorized agent.

Upon notice from the *building official* that work on any building or structure is being executed contrary to the provisions of this code or in an unsafe and dangerous manner, such work shall be immediately stopped. The stop work order shall be in writing and shall be given to the owner of the property involved, or to the owner's authorized agent or to the person performing the work and shall state the conditions under which work will be permitted to resume.

- ❖ The stop work order is a tool authorized by the code that enables the building official to demand that work on a building or structure be temporarily suspended. Typically used under rare circumstances, this order may be issued where the work being performed is dangerous, unsafe or significantly contrary to the provisions of the code.

The stop work order is to be a written document indicating the reason or reasons for the suspension of work, identifying those conditions where compliance is necessary before work is allowed to resume. All work addressed by the order must cease immediately. The stop work order must be presented to either the owner of the subject property, the agent of the owner or the individual doing the work. Commentary Figure R114.1 is an example of a stop work order.

R114.2 Unlawful continuance. Any person who shall continue any work in or about the structure after having been served with a stop work order, except such work as that person is directed to perform to remove a violation or unsafe condition, shall be subject to penalties as prescribed by law.

- ❖ The only activity permitted in a building or a portion of a building subject to a stop work order is that work necessary to eliminate the violation or unsafe condition. Otherwise, penalties prescribed by laws of the jurisdiction must be imposed for illegal construction activity in defiance of a stop work order.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

LEGAL NOTICE

Date _____

WHEREAS, VIOLATIONS OF Article _____, Section _____ of the Zoning Ordinance
Article _____, Section _____ of the Building Code have been found on
Article _____, Section _____ of the _____ Code
these premises, IT IS HEREBY ORDERED in accordance with the above Code that all persons cease, desist from, and

STOP WORK

at once pertaining to construction, alterations or repairs on these
premises known as _____

All persons acting contrary to this order or removing or mutilating this notice are liable to arrest unless such action is
authorized by the Department.

CODE OFFICIAL

**Figure R114.1
STOP WORK ORDER**

Part II—Definitions

Chapter 2: Definitions

Code change proposals to definitions in this chapter preceded by a bracketed letter are considered by the IRC-Building Code Development Committee [RB] or the IECC-Residential Code Development Committee [RE] during the Group B (2016) Code Development cycle.

General Comments

The code user should be familiar with the terms in this chapter because: 1. The definitions are essential to the correct interpretation of the *International Residential Code*[®] (IRC[®]); and 2. The user might not be aware that a particular term encountered in the text has the special definition found herein.

Section R201.1 contains the scope of the chapter. Section R201.2 establishes the inter-changeability of the terms in the code. Section R201.3 establishes the use of terms defined in other chapters. Section R201.4 establishes the use of undefined terms, and Section R202 lists terms and their definition according to this code.

Purpose

Codes are technical documents, so literally every word, term and punctuation mark can add to or change the meaning of the provision. Furthermore, the IRC, with its broad scope of applicability, includes terms inherent in a variety of construction disciplines. These terms can often have multiple meanings depending on the context or discipline being used at the time. For these reasons it is necessary to maintain a consensus on the specific meaning of terms contained in the IRC. Chapter 2 performs this function by stating clearly what specific terms mean for the purpose of this code.

SECTION R201 GENERAL

R201.1 Scope. Unless otherwise expressly stated, the following words and terms shall, for the purposes of this code, have the meanings indicated in this chapter.

- ❖ This section clarifies the terminology used in the IRC. The terms defined in the IRC often have very specific meanings, which can be different from their typical meanings. This section gives guidance to the use of the defined words relative to tense and gender and also provides the means to resolve those terms not defined.

R201.2 Interchangeability. Words used in the present tense include the future; words in the masculine gender include the feminine and neuter; the singular number includes the plural and the plural, the singular.

- ❖ Although the definitions contained in Chapter 2 are to be taken literally, gender and tense are considered to be interchangeable; thus, any gender and tense inconsistencies within the code text should not hinder the understanding or enforcement of the requirements.

R201.3 Terms defined in other codes. Where terms are not defined in this code such terms shall have the meanings

ascribed in other code publications of the International Code Council.

- ❖ When a word or term appears in the code that is not defined in this chapter, other code publications of the *International Code Council*[®] (ICC[®]) may be used to find its definition. These code documents include the *International Building Code*[®] (IBC[®]), *International Mechanical Code*[®] (IMC[®]), *International Plumbing Code*[®] (IPC[®]), *International Fuel Gas Code*[®] (IFGC[®]), *International Fire Code*[®] (IFC[®]) and others. These codes contain additional definitions (some parallel and duplicated) which may be used in the enforcement of this code or in the enforcement of the other ICC codes by reference. When using a definition from another code, keep in mind the admonition from “Purpose”: “These terms can often have multiple meanings depending on the context or discipline being used at the time.”

R201.4 Terms not defined. Where terms are not defined through the methods authorized by this section, such terms shall have ordinarily accepted meanings such as the context implies.

- ❖ Another possible source for the definitions of words or terms not defined in this code or in other codes is their

DEFINITIONS

“ordinarily accepted meanings.” Dictionary definitions may suffice, provided that the definitions are in context.

Sometimes construction terms used throughout the code may not be defined in Chapter 2, in another code, or in a dictionary. In such cases, one would first turn to the definitions contained in the referenced standards (see Chapter 43) and then to textbooks on the subject in question.

SECTION R202 DEFINITIONS

ACCESSIBLE. Signifies access that requires the removal of an access panel or similar removable obstruction.

❖ In general, where immediate access is not required because of the low level of hazard involved, an accessible method is all that is mandated, such as the removal of an access panel. The electrical definitions found in Chapter 34 contain two additional definitions for accessible that apply specifically to electrical wiring methods and electrical equipment (see Section 1102 of the IBC for the meaning of “accessible” as it applies to the requirements for “accessible” dwelling units in Section R320).

ACCESSIBLE, READILY. Signifies access without the necessity for removing a panel or similar obstruction.

❖ Where this term is designated as a requirement by other sections of the code, it is intended that access to the device, controls, shut-off valves or other element be extremely easy. “Readily accessible” means that the device must be reachable directly without a panel, door or equipment needing to be moved to gain access. Chapter 24, “Fuel Gas,” has a similar definition noted as “Ready access (to).”

[RB] ACCESSORY STRUCTURE. A structure that is accessory to and incidental to that of the *dwelling(s)* and that is located on the same *lot*.

❖ As it applies to the scope of the code in Section R101.2, this term describes structures that are designed for accessory use to one- or two-family dwellings and multiple single-family townhouses. These structures are commonly used as garages, carports, cabanas, storage sheds, tool sheds, playhouses and garden structures.

The structures all house uses that are incidental to the primary use, which is the dwelling unit, and the activities that take place in accessory structures occur as a result of the primary building. Their use is secondary or minor in importance to the primary residence.

[RB] ADDITION. An extension or increase in floor area or height of a building or structure.

❖ This term is used to describe the condition when the floor area or height of an existing building or structure is increased. This term is only applicable to existing buildings, never new ones. This would include additional floor area that is added within an existing building, such as adding a new mezzanine, or an increase in roof height (see also Section R102.7).

[RB] ADHERED STONE OR MASONRY VENEER. Stone or masonry veneer secured and supported through the adhesion of an *approved* bonding material applied to an *approved* backing.

❖ This is a common type of material used for a building façade. It is simply defined in order to allow use of the description to mean a specific type of material.

AIR ADMITTANCE VALVE. A one-way valve designed to allow air into the plumbing drainage system where a negative pressure develops in the piping. This device shall close by gravity and seal the terminal under conditions of zero differential pressure (no flow conditions) and under positive internal pressure.

❖ An air admittance valve is an alternative to traditional vent piping configurations. Such valves allow the venting of fixtures where conventional venting may be impractical. The valve is designed to open and admit air into the drainage system when negative pressures occur. The valve closes by gravity and seals the vent terminal when the internal drain pressure is equal to or exceeds atmospheric pressure. The seal prevents sewer gas from entering the building [see Commentary Figures R202(1) and R202(2)].

AIR BARRIER. See Section N1101.6 for definition applicable in Chapter 11.

❖ Air barriers are an integral part of the thermal envelope of a building for energy conservation.

AIR BREAK (DRAINAGE SYSTEM). An arrangement where a discharge pipe from a fixture, *appliance* or device drains indirectly into a receptor below the flood-level rim of the receptor and above the trap seal.

❖ An air break is an indirect drainage method by which waste discharges to the drainage system through piping that terminates below the flood level rim of an approved receptor. An air break is commonly used to protect mechanical equipment from sewage backup in the event that stoppage occurs. It also protects the drainage system from adverse pressure conditions caused by pumped discharge [see Commentary Figure R202(3)].

AIR CIRCULATION, FORCED. A means of providing space conditioning utilizing movement of air through ducts or plenums by mechanical means.

❖ Forced-air systems use a central heating or cooling unit equipped with a fan to return unconditioned air through return ducts and to deliver conditioned air through supply ducts or plenums to occupied spaces.

AIR-CONDITIONING SYSTEM. A system that consists of heat exchangers, blowers, filters, supply, exhaust and return-air systems, and shall include any apparatus installed in connection therewith.

❖ This definition is limited to the components commonly used in a mechanical air-conditioning system. Additional parts of the air-conditioning system include thermostats, humidistats, dampers and any other controls needed for the system to operate properly.

Figure R202(1)
AIR ADMITTANCE VALVE OPENS TO ADMIT AIR TO RELIEVE NEGATIVE PRESSURE

Figure R202(2)
AIR ADMITTANCE VALVE CLOSES AND SEALS VENT UNDER ZERO OR POSITIVE PRESSURE

AIR GAP, DRAINAGE SYSTEM. The unobstructed vertical distance through free atmosphere between the outlet of a waste pipe and the flood-level rim of the fixture or receptor into which it is discharging.

- ❖ In a drainage system air gap, waste is discharged to the drainage system through piping that terminates at a specified distance above the flood level rim of an approved receptor.

The air gap serves as an impossible barrier for sewage to overcome in the event that stoppage occurs in the receptor drain, because sewage backup would overflow in the receptor drain flood level before it

comes in contact with the drain line above [see Commentary Figure R202(3)].

AIR GAP, WATER-DISTRIBUTION SYSTEM. The unobstructed vertical distance through free atmosphere between the lowest opening from a water supply discharge to the flood-level rim of a plumbing fixture.

- ❖ An air gap is the most reliable and effective means of backflow protection. It is simply the vertical airspace between the potable water supply outlet and the possible source of contamination. This air gap prevents possible contamination of the potable water supply by preventing the supply outlet, such as a faucet, from

DEFINITIONS

backsiphoning waste water from a basin, for example. Many manufacturers have developed air gap fittings that provide a rigid connection to the drainage system while maintaining the minimum level of protection from contamination.

[RB] AIR-IMPERMEABLE INSULATION. An insulation having an air permeance equal to or less than 0.02 L/s-m^2 at 75 Pa pressure differential as tested in accordance with ASTM E2178 or E283.

❖ In all buildings, an air-impermeable layer is required to prevent air leakage into the building. In some cases, the insulation will serve that purpose, if it is insulation as defined here.

[RB] ALTERATION. Any construction, retrofit or renovation to an existing structure other than repair or addition that requires a permit. Also, a change in a building, electrical, gas, mechanical or plumbing system that involves an extension, addition or change to the arrangement, type or purpose of the original installation that requires a permit.

❖ The modification of an existing structure without adding any floor area or height to the structure is an alteration. Section R105 of the code specifies that a permit for the alteration work is required before work begins. The code utilizes this term to reflect construction operations intended for an existing building, but not within the scope of an addition or repair (see the definitions of "Addition" and "Repair"). The term "alteration" also applies to mechanical work where the original installation is altered in a manner requiring a permit. The repairs described in Section R105.2.2 are not alterations because a permit is not required.

[RB] ALTERNATING TREAD DEVICE. A device that has a series of steps between 50 and 70 degrees (0.87 and 1.22 rad) from horizontal, usually attached to a center support rail in an alternating manner so that the user does not have both feet on the same level at the same time.

❖ Alternating tread devices are regulated by Sections R311.7.11, R311.7.11.1 and R311.7.11.2.

[RB] ANCHORED STONE OR MASONRY VENEER. Stone or masonry veneer secured with *approved* mechanical fasteners to an *approved* backing.

❖ This is a common type of material used for a building façade. It is simply defined in order to allow use of the description to mean a specific type of material.

ANCHORS. See "Supports."

❖ Anchors are the same types of devices as supports. Any device, such as a hanger used to support or secure piping and fixtures, is an anchor.

ANTISIPHON. A term applied to valves or mechanical devices that eliminate siphonage.

❖ The term refers to the function of certain valves and devices used to break or prevent the siphon effect that can be created in plumbing systems.

APPLIANCE. A device or apparatus that is manufactured and designed to utilize energy and for which this code provides specific requirements.

❖ An appliance is a manufactured component or assembly of components that converts one form of energy into a different form of energy to serve a specific purpose. The term "appliance" generally refers to residential and commercial equipment that is manufactured in standardized sizes or types. The term is generally not associated with industrial equipment. For the application of the code provisions, the terms "appliance" and "equipment" are mutually exclusive.

Examples of appliances include furnaces; boilers; water heaters; room heaters; refrigeration units; cooking equipment; clothes dryers; wood stoves; pool, spa and hot tub heaters; unit heaters ovens; and similar fuel-fired or electrically operated appliances (see the definition of "Equipment").

[RB] APPROVED. Acceptable to the *building official*.

❖ Throughout the code, the term "approved" is used to describe a specific material or method of construction, such as the approved drainage system mentioned in

Figure R202(3)
AIR GAP, AIR BREAK

Section R405.1. Where “approved” is used, it means that the design, material or method of construction is acceptable to the building official. It is imperative that the building officials base their decision of approval on the result of investigations, tests or accepted principles or practices.

As related to the process of acceptance of building installations, including materials, equipment and construction systems, this definition identifies where the ultimate authority rests. Whenever this term is used, it intends that only the enforcing authority can accept a specific installation or component as complying with the code. The building official is identified as the person responsible for administering its provisions in this code. For the IFC, the fire code official is identified as the person responsible for administering IFC provisions. For the *International Property Maintenance Code*® (IPMC®), the code official is identified as the person responsible.

[RB] APPROVED AGENCY. An established and recognized agency that is regularly engaged in conducting tests or furnishing inspection services, where such agency has been *approved* by the building official.

- ❖ The building official will occasionally rely on the expertise of others to assist in plan review and inspection activities, or the owner will employ an individual or company to provide testing services for portions of the construction work. An agency qualified to perform such activities is an “approved agency.” The building official will review an agency’s qualifications, expertise and reliability to determine whether the agency should be granted approval for a specific activity.

The basis for the building official’s approval of any agency for a particular activity may include, but is not necessarily limited to, the capacity and capability of the agency to perform the work in accordance with applicable sections of the code. This is typically done through a review of the résumés and references of the agency and its personnel. For the IRC the building official is identified as the person responsible for approval.

[RB] ASPECT RATIO. The ratio of longest to shortest perpendicular dimensions, or for wall sections, the ratio of height to length.

- ❖ The shear wall or braced wall panel height divided by the width or length of the shear wall or braced wall panel is defined as the aspect ratio. Generally, the code places limits on shear wall aspect ratios to limit shear wall deformation.

[RB] ATTIC. The unfinished space between the ceiling assembly and the roof assembly.

- ❖ The unfinished space between the ceiling joists of the top story and the roof rafters.

Several provisions apply to the attic area of a building, such as those relating to ventilation of the attic space. The code identifies an attic as the unfinished space between the ceiling joists of the top story and the roof assembly. Such a space would be the top story, rather than the attic, if it is finished and occupiable,

except where it is in accordance with the definition for “Habitable attic.”

[RB] ATTIC, HABITABLE. A finished or unfinished area, not considered a *story*, complying with all of the following requirements:

1. The occupiable floor area is not less than 70 square feet (17 m²), in accordance with Section R304.
2. The occupiable floor area has a ceiling height in accordance with Section R305.
3. The occupiable space is enclosed by the roof assembly above, knee walls (if applicable) on the sides and the floor-ceiling assembly below.

- ❖ The code allows that an attic can contain habitable space. In such cases, the attic is not required to be considered as a story. Note that there is no limitation given for the area of the attic that contains habitable space.

BACKFLOW, DRAINAGE. A reversal of flow in the drainage system.

- ❖ Backflow is a condition found in plumbing systems where the contents of the piping flow in a direction opposite of the intended direction.

BACKFLOW PREVENTER. A backflow prevention assembly, a backflow prevention device or other means or method to prevent backflow into the potable water supply.

- ❖ There are three distinct classes of backflow equipment: assemblies, devices and other means or methods. This class distinction clarifies that an assembly is field testable, a device is not testable in the field and a mean or method is observable for their adequacy to protect the potable water supply from backflow. Table P2902.3 was reorganized to group backflow equipment into these three classes. This change should make the code user more aware of the suitability of particular backflow equipment after the initial installation. In other words, if a verification of the backflow protection is needed year after year, either an assembly would be chosen for its field testability or other means or methods would be chosen so that installation conditions can be observed.

BACKFLOW PREVENTER, REDUCED-PRESSURE-ZONE TYPE. A backflow-prevention device consisting of two independently acting check valves, internally force loaded to a normally closed position and separated by an intermediate chamber (or zone) in which there is an automatic relief means of venting to atmosphere internally loaded to a normally open position between two tightly closing shut-off valves and with means for testing for tightness of the checks and opening of relief means.

- ❖ This device is one of the most reliable mechanical devices (second only to an air gap) for the prevention of backflow. It uses two spring-loaded check valves with a relief valve in between that monitors the system pressure upstream and downstream of the device. The zone between the check valves is maintained at a pressure that is less than the water supply pressure.

DEFINITIONS

BACKFLOW, WATER DISTRIBUTION. The flow of water or other liquids into the potable water-supply piping from any sources other than its intended source. Backsiphonage is one type of backflow.

❖ There are primarily three types of backflow conditions that could occur in a water distribution system: 1. Backpressure; 2. Backpressure, low-head; and 3. Backsiphonage.

1. **Backpressure.** Liquid in a pipe flows from a high-pressure condition to a low-pressure condition, such as when the pressure within the water distribution system is greater than that in the water service. The water will reverse its intended direction of flow and return to the water supply unless a device to prevent backflow has been installed in the line. Elevated pressure can be created through mechanical means, such as a pumping system, or it can be the result of a loss of pressure within the main water supply. Backpressure often occurs in a system or a portion of a system that is closed (not open to the atmosphere).

2. **Backpressure, low-head.** This is the backpressure created where the source of backpressure comes from a hose elevated to a level that produces 10 feet (3048 mm) or less of water column at the outlet. Low-head backpressure typically occurs at a hose connection, such as a wall hydrant or sillcock. Certain types of backflow assemblies and devices are designed specifically for either backpressure or low-head backpressure.

3. **Backsiphonage.** See “Backsiphonage.”

BACKPRESSURE. Pressure created by any means in the water distribution system that by being in excess of the pressure in the water supply mains causes a potential backflow condition.

❖ Liquid in a pipe flows from a high-pressure condition to a low-pressure condition, such as when the pressure within the water distribution system is greater than that in the water service. The water will reverse its intended direction of flow and return to the water supply, unless a device to prevent backflow has been installed in the line. Elevated pressures can be created through mechanical means, such as a pumping system, or can be the result of a loss of pressure within the main water supply. Backpressure will often occur in a system or a portion of a system that is closed, i.e., it is not open to the atmosphere.

BACKPRESSURE, LOW HEAD. A pressure less than or equal to 4.33 psi (29.88 kPa) or the pressure exerted by a 10-foot (3048 mm) column of water.

❖ Low-head backpressure is created where the source of backpressure comes from a hose elevated to a level that produces 10 feet (3048 mm) or less of water column at the outlet. A hose connection, such as a wall

hydrant or faucet, is where “low-head backpressure” is typically experienced. (see also the commentary to “Backpressure”).

BACKSIPHONAGE. The flowing back of used or contaminated water from piping into a potable water-supply pipe due to a negative pressure in such pipe.

❖ Backsiphonage occurs when the pressure within a potable water distribution system drops below atmospheric pressure or negative gauge pressure. It, like backpressure, allows the normal direction of flow to reverse. A siphon can result in an unprotected cross connection, causing contamination or pollution of the potable water supply. The main difference between backsiphonage and backpressure is the pressure in the system. Water distribution systems having a pressure less than zero gauge have the potential to create a siphon, resulting in backsiphonage. Backpressure typically occurs in a closed system, and backsiphonage typically occurs in an open system (open to the atmosphere).

BACKWATER VALVE. A device installed in a drain or pipe to prevent backflow of sewage.

❖ A backwater valve is a type of check valve designed for installation in drainage piping. The valve has a lower invert downstream of the flapper than upstream to help prevent solids from interfering with valve closure.

[RB] BASEMENT. A *story* that is not a *story above grade plane*. (see “Story above grade plane”).

❖ Defined as “a story that is not a story above grade,” a basement is further identified in the provisions in Section R202 for a “story above grade.” Specific provisions, including the requirement for emergency escape and rescue openings in Section R310.1, are applicable for those floor levels meeting the criteria for basements. The presence of occupiable space below grade level causes various concerns that are addressed by the code.

[RB] BASEMENT WALL. The opaque portion of a wall that encloses one side of a *basement* and has an average below *grade* wall area that is 50 percent or more of the total opaque and nonopaque area of that enclosing side.

❖ A basement wall is defined in respect to the energy efficiency provisions of Chapter 11. A wall that encloses a basement and does not qualify as an exterior wall is a basement wall.

[RB] BASIC WIND SPEED. Three-second gust speed at 33 feet (10 058 mm) above the ground in Exposure C (see Section R301.2.1) as given in Figure R301.2(4)A.

❖ Basic wind speed, the basis for a number of structural decisions in the IRC, is the 3-second gust speed measured at a point 33 feet (10058 mm) above the ground. The assumed exposure used in determining the basic wind speed is that for generally open terrain having scattered obstructions. Ultimate design wind speed has replaced basic wind speed in most of the structural requirements in the code that address wind loads.

BATHROOM GROUP. A group of fixtures, including or excluding a bidet, consisting of a water closet, lavatory, and bathtub or shower. Such fixtures are located together on the same floor level.

❖ Special consideration is given to a bathroom group when sizing water distribution systems and drain, waste and vent piping because of fixture usage. “Bathroom group” has historically referred to a single water closet, a lavatory and a bathtub or shower, all located within a single room. Such an arrangement would normally allow only one occupant in the room; therefore, the likelihood of simultaneous fixture discharge is remote. For the fixture-usage theory of the bathroom group to be valid, the fixtures in the group must be located within the same bathroom. A bidet has been added to the group of fixtures constituting a bathroom group.

BEND. A drainage fitting, designed to provide a change in direction of a drain pipe of less than the angle specified by the amount necessary to establish the desired slope of the line (see “Elbow” and “Sweep”).

❖ This term denotes a one-way fitting (often referred to as an elbow) that is typically used in a drainage system to make a change in direction within a single run of pipe. Although bends (or elbows) are used in other plumbing and mechanical piping systems, in this instance the term refers to a drainage fitting that will meet the required radius of turn.

BOILER. A self-contained *appliance* from which hot water is circulated for heating purposes and then returned to the boiler, and that operates at water pressures not exceeding 160 pounds per square inch gage (psig) (1102 kPa gauge) and at water temperatures not exceeding 250°F (121°C).

❖ Boilers are usually manufactured of steel or cast iron, and are used to transfer heat (from the combustion of a fuel or from an electric-resistance element) to water for supplying steam or hot pressurized water for heating or other process or power purposes.

Boilers are usually installed in closed systems where the heat transfer medium is recirculated and retained within the system. Hot water supply boilers are normally part of open systems where the heated water is supplied and used externally to the boiler. Large domestic (potable) water heating systems often employ hot water supply boilers.

Boilers must be labeled and installed in accordance with the manufacturer’s instructions and the applicable sections of the code. Boilers are rated in accordance with standards published by the American Society of Mechanical Engineers (ASME), the Hydronics Institute, the Steel Boiler Institute (SBI), the American Gas Association (AGA) and the American Boiler Manufacturers Association (ABMA). Boilers can be classified in accordance with the following: working temperature, working pressure, type of fuel used (or electric boilers), materials of construction and whether or not the heat transfer medium changes phase from a liquid to a vapor.

[RB] BOND BEAM. A horizontal grouted element within masonry in which reinforcement is embedded.

❖ Composed of masonry, grout and reinforcement, a bond beam is a horizontal structural member constructed to transfer loads while tying the wall together.

[RB] BRACED WALL LINE. A straight line through the building plan that represents the location of the lateral resistance provided by the wall bracing.

❖ Commonly referred to as shear wall, a braced wall line is used to resist the lateral racking forces created by seismic or wind loading. A number of braced wall panels work together to form a braced wall line. The code has specific requirements for the method of constructing a braced wall line. Where a building does not comply with the bracing requirements of Chapter 6, those portions of the building not meeting the requirements must be designed in accordance with accepted engineering practice.

[RB] BRACED WALL LINE, CONTINUOUSLY SHEATHED. A *braced wall line* with structural sheathing applied to all sheathable surfaces including the areas above and below openings.

❖ A series of braced wall panels in a single story constructed in accordance with Section R602.10 for wood framing or Section R603.3.3 or R301.1.1 for cold-formed steel framing to resist racking from seismic and wind forces.

Commonly referred to as a shear wall, a braced wall line is used to resist the lateral racking forces created by seismic or wind loading. A number of braced wall panels work together to form a braced wall line. The code has specific requirements for the method of constructing a braced wall line. Where a building does not comply with the bracing requirements of Chapter 6, those portions of the building not meeting the requirements must be designed in accordance with accepted engineering practice.

[RB] BRACED WALL PANEL. A full-height section of wall constructed to resist in-plane shear loads through interaction of framing members, sheathing material and anchors. The panel’s length meets the requirements of its particular bracing method, and contributes toward the total amount of bracing required along its *braced wall line* in accordance with Section R602.10.1.

❖ A braced wall line is composed of a series of braced wall panels constructed in accordance with the provisions of Chapter 6. A braced wall panel must extend the full height of the wall.

BRANCH. Any part of the piping system other than a riser, main or stack.

❖ A branch refers to piping that connects to a riser, main or stack in a plumbing system. Branch piping is generalized as horizontal piping, can include vertical offsets and is smaller in size or capacity than the main artery or trunk from which it extends. It is analogous to branches of a tree.

DEFINITIONS

BRANCH, FIXTURE. See “Fixture branch, drainage.”

❖ See the commentary to “Fixture branch, drainage.”

BRANCH, HORIZONTAL. See “Horizontal branch, drainage.”

❖ See the commentary to “Horizontal branch, drainage.”

BRANCH INTERVAL. A vertical measurement of distance, 8 feet (2438 mm) or more in *developed length*, between the connections of horizontal branches to a drainage stack. Measurements are taken down the stack from the highest horizontal branch connection.

❖ A branch interval is the vertical distance between a drainage stack’s branch connections. In typical construction practice, the branch drain will connect to a stack near the floor level; therefore, the branch interval will correspond to the height of the story in which it is located. Depending on the design of the building, however, a branch interval may not correspond to the height of the story because stories are not limited in height. Therefore, the code requires a branch interval to be at least 8 feet (2438 mm) in developed length between the connections of the horizontal branches to the drainage stack.

Branch intervals are a design factor in drainage pipe sizing and venting design. Drain, waste and vent system design must consider the nature of waste and airflow in a stack and the effects that branch connections have on that flow.

BRANCH, MAIN. A water-distribution pipe that extends horizontally off a main or riser to convey water to branches or fixture groups.

❖ This applies to the primary water supply system piping that extends horizontally off a main or riser to supply water to branches or groups of fixtures.

BRANCH, VENT. A vent connecting two or more individual vents with a vent stack or stack vent.

❖ See Commentary Figure R202(4).

BTU/H. The *listed* maximum capacity of an *appliance*, absorption unit or burner expressed in British thermal units input per hour.

❖ This term stands for British thermal units per hour. Fuel-fired appliances and equipment are rated based on their Btu/h (W) input or output.

[RB] BUILDING. Building shall mean any one- and two-family dwelling or portion thereof, including *townhouses*, that is used, or designed or intended to be used for human habitation, for living, sleeping, cooking or eating purposes, or any combination thereof, and shall include *accessory structures* thereto.

❖ The code uses this term to identify those structures that provide shelter for a function or activity. More specifically, according to the code, a building is a single-family dwelling, a two-family dwelling, a townhouse or an accessory structure to such buildings. The use of a building, excluding an accessory structure, is human habitation, which specifically includes living, sleeping, cooking or eating.

BUILDING DRAIN. The lowest piping that collects the discharge from all other drainage piping inside the house and extends 30 inches (762 mm) in *developed length* of pipe, beyond the *exterior walls* and conveys the drainage to the *building sewer*.

❖ A building drain is usually the main drain of a system within a structure. Building drains are horizontal (including vertical offsets) and are the portion of the drainage system that is at the lowest elevation in the structure. All horizontal drains above the elevation of

the building drain are horizontal branches. The building drain terminates at the point where it exits the building [see Commentary Figure R202(5)].

[RB] BUILDING, EXISTING. Existing building is a building erected prior to the adoption of this code, or one for which a legal building *permit* has been issued.

❖ There are two definitions for an existing building. The most general use of the term is for a building that has been constructed prior to the adoption of the 2000 IRC. In other words, any building that is in existence at the time the current code is adopted by the jurisdiction is “existing.” A second definition relates to those buildings that have been issued a building permit. Once a building is under construction, it is an “existing building” and is regulated by the code under which the permit was issued.

[RB] BUILDING-INTEGRATED PHOTOVOLTAIC PRODUCT. A building product that incorporates photovoltaic modules and functions as a component of the building envelope.

❖ This term is used in Sections R324.5 and R902.3. This definition also appears in the IBC.

[RB] BUILDING LINE. The line established by law, beyond which a building shall not extend, except as specifically provided by law.

❖ The building line is not established by the code but rather by the jurisdiction as the point beyond which the construction of a building is not permitted. Often known as a setback line or a building setback, the building line is established to maintain order within the community’s building stock. The code does not regulate construction with regard to any jurisdictional building line.

[RB] BUILDING OFFICIAL. The officer or other designated authority charged with the administration and enforcement of this code.

❖ Regardless of title, the individual designated by the jurisdiction as the person who administers and enforces the code and is responsible for issuing permits is the building official. In addition, the building official may appoint various other individuals to assist in the activities of the Department of Building Safety. In many jurisdictions, the authority of the building official is extended to plans examiners and inspectors to some degree. Section R104 sets forth the duties and respon-

**Figure R202(5)
DRAINAGE SYSTEM COMPONENTS**

DEFINITIONS

sibilities of the building official. The statutory power to enforce the code is normally vested in a building department of a state, county or municipality that has a designated enforcement officer termed the “building official” (see Section 103.1).

BUILDING SEWER. That part of the drainage system that extends from the end of the *building drain* and conveys its discharge to a public sewer, private sewer, individual sewage-disposal system or other point of disposal.

❖ The building sewer is the extension of the building drain and is located entirely outside the building exterior walls.

[RE] BUILDING THERMAL ENVELOPE. The *basement walls, exterior walls, floor, roof* and any other building element that enclose *conditioned spaces*.

❖ The building thermal envelope includes the roof/ceiling assembly, wall assemblies and floor assemblies that surround a conditioned area, which is the space that is being intentionally heated and/or cooled. The building envelope is the assembly that separates conditioned space from unconditioned space or the outdoors. For example, a wall between a conditioned dwelling and an unconditioned garage is part of the building thermal envelope. Other elements of the building envelope include attic kneewalls, the perimeter foundation walls of basements, the perimeter joist between two conditioned floors and skylight wells.

[RB] BUILT-UP ROOF COVERING. Two or more layers of felt cemented together and surfaced with a cap sheet, mineral aggregate, smooth coating or similar surfacing material.

❖ A common roof covering for buildings with relatively flat roofs, built-up roof covering uses two or more felt layers with a cap-sheet surfacing. A number of materials standards regulate the wide variety of built-up roofing materials that are available.

[RB] CAP PLATE. The top plate of the double top plates used in structural insulated panel (SIP) construction. The cap plate is cut to match the panel thickness such that it overlaps the wood structural panel facing on both sides.

❖ Structural insulated panels (SIPs) have been in use in building construction for some time, but are relatively new. This term is defined to facilitate requirements for SIPs.

[RB] CEILING HEIGHT. The clear vertical distance from the finished floor to the finished ceiling.

❖ Ceiling height as regulated by Section R305 is measured from the finished floor surface to the finished ceiling. Depending on the space under consideration, the minimum ceiling height required by the IRC can vary greatly.

[RB] CEMENT PLASTER. A mixture of portland or blended cement, portland cement or blended cement and hydrated lime, masonry cement or plastic cement and aggregate and other *approved* materials as specified in this code.

❖ Cement plaster (often referred to as “stucco”) is a cementitious-based plaster material with excellent

water-resistant properties. It is the only type of plaster that is permitted by the code to be used as an exterior wall covering and as a base coat and finish coat. Cement plaster can also be used as an interior finish wall covering, but is required by the code to be used in all interior wet areas, such as toilet rooms, showers, saunas, steam rooms, indoor swimming pools or any other area that will be exposed to excessive amounts of moisture or humidity for prolonged periods of time.

[RB] CHIMNEY. A primary vertical structure containing one or more flues, for the purpose of carrying gaseous products of combustion and air from a fuel-burning *appliance* to the outside atmosphere.

❖ Chimneys differ from vents in the materials they are made of and the type of appliance they are designed to serve. Chimneys are capable of venting flue gases of much higher temperatures than vents.

CHIMNEY CONNECTOR. A pipe that connects a fuel-burning *appliance* to a chimney.

❖ Chimney connectors are sections of pipe used to convey combustion products from an appliance flue outlet to a chimney inlet. Factory-built chimneys can connect directly to some appliances without the need for a connector; however, masonry chimneys cannot connect directly to an appliance because of the chimney’s weight.

CHIMNEY TYPES.

Residential-type appliance. An *approved* chimney for removing the products of combustion from fuel-burning, residential-type *appliances* producing combustion gases not in excess of 1,000°F (538°C) under normal operating conditions, and capable of producing combustion gases of 1,400°F (760°C) during intermittent forces firing for periods up to 1 hour. All temperatures shall be measured at the *appliance* flue outlet. Residential-type *appliance* chimneys include masonry and factory-built types.

❖ The chimneys addressed in the IRC are generally for use with residential-type appliances. Such chimneys are limited in the temperature of the combustion gases they can exhaust. Both masonry and factory-built chimneys can be residential type.

CIRCUIT VENT. A vent that connects to a horizontal drainage branch and vents two traps to not more than eight traps or trapped fixtures connected into a battery.

❖ A circuit vent vents multiple fixtures using only one or two vents. The horizontal drainage branch actually serves as a wet vent for the fixtures located downstream of the circuit vent connection (see Section P3110).

CIRCULATING HOT WATER SYSTEM. A specifically designed water distribution system where one or more pumps are operated in the service hot water piping to circulate heated water from the water-heating equipment to fixtures and back to the water-heating equipment.

❖ This is a piping arrangement to provide hot (or tempered) water at plumbing fixtures in a manner that

does not require the user to wait any appreciable amount of time for the heated water to begin discharging from the water outlet. The hot (or tempered) water is circulated (by a pump) in a “loop” of piping that is routed in close proximity to each fixture and then back to the heated water source. Ideally, the fixture supply piping from this “loop” piping to the fixture is relatively short such that it only takes a few seconds for the heated water to arrive at the outlet when the faucet or mixing valve is opened. Large homes with centralized water heaters and hot water storage tanks are often piped in this manner so that the occupants do not have to wait for hot (or tempered) water to arrive. Wasting cool potable water down the drain (to get hot water to arrive) is costly and time consuming for the occupants. Generally, the hot (or tempered) water is only circulated in the piping “loop” for the hours that hot water is used in the home.

[RB] CLADDING. The exterior materials that cover the surface of the building envelope that is directly loaded by the wind.

❖ Sheathing, siding or other materials used on the exterior envelope of a building are “cladding” for the purpose of wind design.

CLEANOUT. An accessible opening in the drainage system used for the removal of possible obstruction.

❖ Cleanouts are broadly defined as any access point into the drainage system that allows the removal of a clog or other obstruction in the drain line. A cleanout provides convenient access to the piping interior without significant disassembly of the plumbing installation. A “P” trap with a removable U-bend is typically acceptable as a cleanout for the fixture drain or branch to which the trap discharges.

[RE] CLIMATE ZONE. A geographical region based on climatic criteria as specified in this code.

❖ Climate involves temperature, moisture, wind and sun and also includes both daily and seasonal patterns of variation of the parameters. To account for these variations, the code establishes climate zones that serve as the basis for the code provisions (see the commentary to Section N1101.7).

[RB] CLOSET. A small room or chamber used for storage.

❖ A closet is simply a small storage room. Closets are generally found throughout dwelling units but are not considered habitable spaces. The typical hazard related to closets is the probable storage of combustible materials.

COLLECTION PIPE. Unpressurized pipe used within the collection system that drains on-site nonpotable water or rainwater to a storage tank by gravity.

❖ A different term, other than drainage pipe, is used to describe piping that conveys, by gravity, on-site nonpotable water and rainwater to a storage tank to distinguish such piping from drainage piping that carries waste water.

COMBINATION WASTE AND VENT SYSTEM. A specially designed system of waste piping embodying the horizontal wet venting of one or more sinks, lavatories or floor drains by means of a common waste and vent pipe adequately sized to provide free movement of air above the flow line of the drain.

❖ This special system is employed when no other conventional system of separate waste and vent is practical. The combination waste and vent system is used only for venting floor drains, standpipes, sinks and lavatories. The drainage piping is larger than required for draining purposes only, and the drainage branch and stack should be provided with vent piping. The system is commonly used where floor drains are installed in large open areas that cannot accommodate vertical vent risers from the floor drains (see Section P3111).

[RB] COMBUSTIBLE MATERIAL. Any material not defined as noncombustible.

❖ Any material that (ASTM E136) does not qualify as a noncombustible material is considered combustible. The presence of sizable quantities of combustible material increases the potential fire hazard. Buildings containing or constructed of combustible materials are typically more highly regulated than those that are primarily noncombustible.

COMBUSTION AIR. The air provided to fuel-burning equipment including air for fuel combustion, draft hood dilution and ventilation of the equipment enclosure.

❖ The process of combustion requires a specific amount of oxygen to initiate and sustain the combustion reaction. Combustion air includes primary air, secondary air, draft hood dilution air and excess air. Combustion air is the amount of atmospheric air required for complete combustion of a fuel and is related to the molecular composition of the fuel being burned, the design of the fuel-burning equipment and the percentage of oxygen in the combustion air. Too little combustion air will result in incomplete combustion of a fuel and the possible formation of carbon deposits (soot), carbon monoxide, toxic alcohols, ketones, aldehydes, nitrous oxides and other byproducts. The required amount of combustion air is usually stated in terms of cubic feet per minute (m³/s) or pounds per hour (kg/h).

[CE] COMMERCIAL, BUILDING. See Section N1101.6.

COMMON VENT. A single pipe venting two trap arms within the same *branch interval*, either back-to-back or one above the other.

❖ Where two or more fixtures are connected to the same drainage pipe, a common vent could be installed. This common vent is sized and classified as an individual vent. Any two fixtures may be common vented to either a vertical or horizontal drainage pipe.

A typical form of common venting connects two fixtures at the same level. Two fixtures connecting at different levels but within the same story are also common vented. When one of the fixtures connected is at a different level, the vertical drain between the fix-

DEFINITIONS

tures is oversized because it functions as a drain for the upper fixture and a vent for the lower fixture.

CONDENSATE. The liquid that separates from a gas due to a reduction in temperature; for example, water that condenses from flue gases and water that condenses from air circulating through the cooling coil in air conditioning *equipment*.

❖ Condensate forms when the temperature of a vapor is lowered to its dew point temperature. Air conditioning systems produce condensate when an airstream contacts cooling coils. The moisture in the air condenses on the cold surface of the coils and the air is “dehumidified.” Condensate also forms within improperly designed chimneys and vents when the products of combustion (which contain water vapor) contact the colder walls of the flue. If the temperature of the products of combustion is lowered to the dew point temperature of the water vapor, condensate will form on the inside walls of the flue. Condensed steam in hydronic systems is also referred to as “condensate.”

CONDENSING APPLIANCE. An *appliance* that condenses water generated by the burning of fuels.

❖ Such units include compressors and condenser heat exchangers; they convert refrigerant vapor to liquid.

[RB] CONDITIONED AIR. Air treated to control its temperature, relative humidity or quality.

❖ Conditioned air is air that is heated, cooled, humidified, dehumidified or decontaminated.

[RE] CONDITIONED AREA. That area within a building provided with heating or cooling systems or *appliances* capable of maintaining, through design or heat loss or gain, 68°F (20°C) during the heating season or 80°F (27°C) during the cooling season, or has a fixed opening directly adjacent to a conditioned area.

❖ The conditioned area is the space within the building that receives conditioned air. The space can be directly conditioned or indirectly conditioned by an adjacent conditioned space.

[RE] CONDITIONED FLOOR AREA. The horizontal projection of the floors associated with the *conditioned space*.

❖ The conditioned floor area is the floor area in square feet (m²) of a conditioned space.

[RE] CONDITIONED SPACE. An area, room or space that is enclosed within the building thermal envelope and that is directly heated or cooled or that is indirectly heated or cooled. Spaces are indirectly heated or cooled where they communicate thru openings with conditioned spaces, where they are separated from conditioned spaces by uninsulated walls, floors or ceilings or where they contain uninsulated ducts, piping or other sources of heating or cooling.

❖ If a space is directly and intentionally heated or cooled, it is obviously a conditioned space. A space that is indirectly heated or cooled, by intent or not, is also a conditioned space. A space is indirectly heated or cooled

where it: connects to a directly or indirectly conditioned space through openings; is separated from a directly or indirectly conditioned space by one or more uninsulated walls, an uninsulated ceiling or an uninsulated floor; or contains uninsulated heating or cooling ductwork or piping. Unconditioned spaces become conditioned, whether by intent or not, where they are affected by adjacent conditioned spaces or HVAC system components.

[RB] CONSTRUCTION DOCUMENTS. Written, graphic and pictorial documents prepared or assembled for describing the design, location and physical characteristics of the elements of a project necessary for obtaining a building *permit*. Construction drawings shall be drawn to an appropriate scale.

❖ To determine whether or not proposed construction is in compliance with code requirements, it is necessary that sufficient information be submitted to the building official for review. This typically consists of the drawings (such as floor plans, elevations, sections and details), specifications and product information describing the proposed work. Addressed in Section R106, construction documents are required at the time of permit application unless the work is of such a minor nature that the documents are not necessary to provide compliance with the code. The construction documents must be drawn to an appropriate scale so they may be easily interpreted.

CONTAMINATION. A high hazard or health hazard impairment of the quality of the potable water that creates an actual hazard to the public health through poisoning or through the spread of disease by sewage, industrial fluids or waste.

❖ The Environmental Protection Agency (EPA) sets maximum levels for various chemicals and bacteria in drinking water. When an unacceptable level of one or more contaminants is present, the water is considered to be nonpotable. One of the primary purposes of the code is to protect potable water supplies from contamination. Contamination consists of either hazardous chemicals or raw sewage, and is considered by the code to represent a high hazard when present in the water supply. Refer to Table P2902.2 for the required potable protection requirements related to high-hazard situations.

The code and other related regulations, such as those from the EPA, are intended to reduce, if not totally eliminate, the risk to the general public of poisoning or health impairment through sewage, industrial fluids or waste entering the potable water supply. Note that these contaminants would have a harmful effect on the occupants of a building should the water be consumed. Contamination is quite different from pollution, which is a situation where the water supply is still considered to be nonpotable, but would not kill or harm if ingested. Refer to the definition of “Pollution” for additional information on that term.

[RE] CONTINUOUS INSULATION (ci). Insulating material that is continuous across all structural members without thermal bridges other than fasteners and service openings. It is installed on the interior or exterior or is integral to any opaque surface of the building envelope.

- ❖ The need for more insulation on exterior walls has created the need to specify continuous insulation on the exterior side of the wall, thus the need for this definition.

CONTINUOUS WASTE. A drain from two or more similar adjacent fixtures connected to a single trap.

- ❖ Continuous waste is the piping described and regulated in Section P3201.6. The most common occurrences are where multiple compartments of a kitchen sink or double lavatories are connected to a single trap.

CONTROL, LIMIT. An automatic control responsive to changes in liquid flow or level, pressure, or temperature for limiting the operation of an *appliance*.

- ❖ Limit controls are safety devices used to protect equipment, appliances, property, and persons. Such controls act at their set point to limit a condition such as temperature or pressure and include high and low limits. This definition applies to controls for all types of fuel: gas, liquid and solid.

CONTROL, PRIMARY SAFETY. A safety control responsive directly to flame properties that senses the presence or absence of flame and, in event of ignition failure or unintentional flame extinguishment, automatically causes shutdown of mechanical *equipment*.

- ❖ This is a device designed to shut down mechanical equipment in response to changes in liquid or gas flow rates that could extinguish a flame.

CONVECTOR. A system-incorporating heating element in an enclosure in which air enters an opening below the heating element, is heated and leaves the enclosure through an opening located above the heating element.

- ❖ See Commentary Figure R202(6) for an illustration of an electric hydronic convector.

CORE. The lightweight middle section of a structural insulated panel, composed of foam plastic insulation that provides the link between the two facing shells.

- ❖ Structural insulated panels (SIPs) have been in use in building construction for some time, but are relatively new. This term is defined to facilitate requirements for SIPs.

[RB] CORROSION RESISTANCE. The ability of a material to withstand deterioration of its surface or its properties where exposed to its environment.

- ❖ Under those conditions where corrosion of materials is detrimental to the integrity of the building's construction and use, the code mandates corrosion-resistant materials. Corrosion-resistant materials control or withstand the deterioration of their surfaces and retain their physical properties in their intended environment.

Corrosion resistance can be provided by the material or by a process applied to the material.

[RB] COURT. A space, open and unobstructed to the sky, located at or above *grade* level on a *lot* and bounded on three or more sides by walls or a building.

- ❖ An exterior area is a court if it is enclosed on at least three sides by exterior walls of the building or other enclosing elements and is open and unobstructed to the sky above. By virtue of being substantially open to the exterior and to the sky, a court may be used to obtain natural light and ventilation for the building.

[RB] CRIPPLE WALL. A framed wall extending from the top of the foundation to the underside of the floor framing of the first *story above grade plane*.

- ❖ Cripple walls are built on the top of footings or foundation walls. They can typically be found along the top of stepped foundation walls where the grade adjoining the structure changes height. Cripple walls must be properly braced to resist lateral forces. They are often treated the same as a first-story wall. Provisions for the bracing of cripple walls are in Section R602.10.2.

CROSS CONNECTION. Any connection between two otherwise separate piping systems that allows a flow from one system to the other.

- ❖ Cross connections are the links through which it is possible for contaminated materials to enter a potable water supply. The contaminant enters the potable water supply when the pressure of the polluted source exceeds the pressure of the potable source. The action may be called backsiphonage or backpressure.

Many serious outbreaks of illnesses and disease have been traced to cross connections. The intent of the code is to eliminate cross connections or prevent backflow where cross connections cannot be eliminated. Refer to the definitions of and the commentary to "Backflow" and "Backsiphonage."

Figure R202(6)
ELECTRIC HYDRONIC CONVECTOR

DEFINITIONS

[RB] CROSS-LAMINATED TIMBER. A prefabricated engineered wood product consisting of not less than three layers of solid-sawn lumber or *structural composite lumber* where the adjacent layers are cross-oriented and bonded with structural adhesive to form a solid wood element.

- ❖ Cross-laminated timber is a specific type of engineered wood product. The important thing to remember is that it must be manufactured in accordance with ANSI/APA PRG320 to be in compliance with this code. (see the commentary to Section 502.1.6).

[RE] CURTAIN WALL. See Section N1101.6 for definition applicable in Chapter 11.

[RB] DALLE GLASS. A decorative composite glazing material made of individual pieces of glass that are embedded in a cast matrix of concrete or epoxy.

- ❖ Various types of decorative glazing materials are exempt from the safety glazing provisions when installed in side-hinged doors, adjacent to doors, or in large glazed openings. Dalle glass is one such material. Made up of multiple individual pieces of glass, Dalle glass is exempt because of its decorative function.

DAMPER, VOLUME. A device that will restrict, retard or direct the flow of air in any duct, or the products of combustion of heat-producing *equipment*, vent connector, vent or chimney.

- ❖ A damper is used in an air distribution system as a restrictor to regulate airflow through duct work. When used in flues venting combustion gases, a damper is used to regulate draft.

[RB] DEAD LOADS. The weight of the materials of construction incorporated into the building, including but not limited to walls, floors, roofs, ceilings, stairways, built-in partitions, finishes, cladding, and other similarly incorporated architectural and structural items, and fixed service *equipment*.

- ❖ Dead loads are considered in the structural design of a building and are used in the span tables for sizing floor joists, ceiling joists and rafters. The weight of the materials of construction joists, sheathing, studs and gypsum board is counted as the dead load, as are stairways, cladding and fixed service equipment. The dead loads make up the fixed load placed in the building and are independent from the live loads.

[RB] DECORATIVE GLASS. A carved, leaded or Dalle glass or glazing material with a purpose that is decorative or artistic, not functional; with coloring, texture or other design qualities or components that cannot be removed without destroying the glazing material; and with a surface, or assembly into which it is incorporated, that is divided into segments.

- ❖ Decorative glass is not designed for functional purposes such as a vision panel, but rather is used for artistic reasons. Some types of decorative glass include carved, leaded, and Dalle glass. Decorative glass is typically made up of multiple pieces of glass arranged in some design or pattern. Fixed-in-place decorative glass is exempt from some of the requirements for glazing in hazardous locations.

[RE] DEMAND RECIRCULATION WATER SYSTEM. See Section N1101.6 for definition applicable in Chapter 11.

DESIGN PROFESSIONAL. See “*Registered design professional*.”

- ❖ “Design professional” is another term for registered design professional (see the definition of “Registered design professional”).

DEVELOPED LENGTH. The length of a pipeline measured along the center line of the pipe and fittings.

- ❖ This term identifies a concept necessary for computing the actual length of piping in a plumbing system. The developed length is measured along the actual flow path of piping and includes the piping lengths in all offsets and changes in direction. Several code requirements are dependent on the actual length of plumbing piping.

DIAMETER. Unless specifically stated, the term “diameter” is the nominal diameter as designated by the *approved* material standard.

- ❖ “Diameter” is the length of a line passing through the center of a pipe from one side to the other. Depending on the pipe standard, this distance can be measured to the inside portions (inside diameter, or ID) or the outside portions (outside diameter, or OD) of the pipe.

[RB] DIAPHRAGM. A horizontal or nearly horizontal system acting to transmit lateral forces to the vertical resisting elements. Where the term “*diaphragm*” is used, it includes horizontal bracing systems.

- ❖ In the load path for forces transmitted through a building or structure, the diaphragm is that horizontal portion of the path where lateral forces are transferred to the vertical resisting elements. Roof diaphragms and floor diaphragms carry lateral loads to the shear walls.

DILUTION AIR. Air that enters a draft hood or draft regulator and mixes with flue gases.

- ❖ Dilution air is associated with draft-hood-equipped Category I appliances. Fan-assisted Category I appliances do not use dilution air; all of the air brought in by the fan passes directly through the combustion chamber of the appliance. Dilution air causes lowering of the dew point and cooling of flue gases, but to a point that is still above the point when condensation will occur inside the vent.

DIRECT SYSTEM. A solar thermal system in which the gas or liquid in the solar collector loop is not separated from the load.

- ❖ Direct systems do not utilize a heat exchanger between the solar collectors and the load served. The heat transfer medium is not separated from the water or air that is being heated by the solar collector loop. For example, the most common type of direct system is a potable water heating system where the potable water passes through the collectors. The majority of solar systems use a heat transfer medium that is separated from what is ultimately being heated.

DIRECT-VENT APPLIANCE. A fuel-burning *appliance* with a sealed combustion system that draws all air for combustion from the outside atmosphere and discharges all flue gases to the outside atmosphere.

- ❖ Such appliances are equipped with independent exhaust and combustion air intake pipes, or they have concentric pipes that vent through the inner pipe and convey combustion air in the annular space between pipe walls (see the commentary to Sections G2427.2.1 and G2427.8).

DRAFT. The pressure difference existing between the *appliance* or any component part and the atmosphere, that causes a continuous flow of air and products of combustion through the gas passages of the *appliance* to the atmosphere.

Induced draft. The pressure difference created by the action of a fan, blower or ejector, that is located between the *appliance* and the chimney or vent termination.

Natural draft. The pressure difference created by a vent or chimney because of its height, and the temperature difference between the flue gases and the atmosphere.

- ❖ Draft is the negative static pressure measured relative to atmospheric pressure that is developed in chimneys and vents and in the flueways of fuel-burning appliances. Draft can be produced by hot flue-gas buoyancy (“stack effect”), mechanically by fans and exhausters or by a combination of both natural and mechanical means.

DRAFT HOOD. A device built into an *appliance*, or a part of the vent connector from an *appliance*, that is designed to provide for the ready escape of the flue gases from the *appliance* in the event of no draft, backdraft or stoppage beyond the draft hood; prevent a backdraft from entering the *appliance*; and neutralize the effect of stack action of the chimney or gas vent on the operation of the *appliance*.

- ❖ Draft hoods are integral to or supplied with natural-draft, atmospheric-burner gas-fired appliances. Appliances equipped with draft hoods are classified by the manufacturer as Category I appliances. Because of new minimum-efficiency standards and the popularity of mechanical and other special proprietary venting systems, draft-hood-equipped appliances are becoming rare in the marketplace.

DRAFT REGULATOR. A device that functions to maintain a desired draft in the *appliance* by automatically reducing the draft to the desired value.

- ❖ Excessive draft reduces the efficiency of an appliance because of energy loss in the form of heat loss out the vent. Draft regulators automatically adjust the draft by allowing cooler air to enter the vent at a preset flow rate, reducing the draft.

[RB] DRAFT STOP. A material, device or construction installed to restrict the movement of air within open spaces of concealed areas of building components such as crawl spaces, floor-ceiling assemblies, roof-ceiling assemblies and *attics*.

- ❖ Draft stops divide a large concealed space into smaller compartments in wood-frame floor construction. They limit the movement of air within the cavity, reducing the potential for rapid fire spread. Draftstopping materials include gypsum board, wood structural panels, particleboard or other substantial materials that are adequately supported.

DRAIN. Any pipe that carries soil and water-borne wastes in a building drainage system.

- ❖ A drain is any pipe in a plumbing system that carries sanitary waste, clear-water waste or storm water. In the case of wet vents, common vents, waste stack vents, circuit vents and combination drain and vents, the drain may also be conducting airflow.

DRAIN-BACK SYSTEM. A solar thermal system in which the fluid in the solar collector loop is drained from the collector into a holding tank under prescribed circumstances.

- ❖ Drain-back systems are a simple type of closed loop thermal solar energy system that automatically drains the heat transfer medium from the solar collector components of the system. The heat transfer medium is commonly water or a water/antifreeze solution and the medium is drained into a receiver or reservoir to prevent it from freezing or to stop the collection of energy when the system reaches a high limit temperature setting. Typically a pump draws the medium from the reservoir and lifts it up to the collectors and when the pump shuts off, the medium drains by gravity back into the reservoir.

DRAINAGE FITTING. A pipe fitting designed to provide connections in the drainage system that have provisions for establishing the desired slope in the system. These fittings are made from a variety of both metals and plastics. The methods of coupling provide for required slope in the system.

- ❖ These fittings will accommodate the necessary slope and sweep required for a drain line (see Section P3005.1).

DUCT SYSTEM. A continuous passageway for the transmission of air that, in addition to ducts, includes duct fittings, dampers, plenums, fans and accessory air-handling *equipment* and *appliances*.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ Duct systems are part of an air distribution system and include supply, return and relief/exhaust air systems.

DEFINITIONS

[RB] DWELLING. Any building that contains one or two *dwelling units* used, intended, or designed to be built, used, rented, leased, let or hired out to be occupied, or that are occupied for living purposes.

- ❖ A dwelling is a building that contains either one or two dwelling units. The purpose of a dwelling is occupation for living purposes, regardless of the manner of ownership. Single-family houses and duplexes fall under the definition of dwelling (see also “Dwelling unit”).

[RB] DWELLING UNIT. A single unit providing complete independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

- ❖ The specific purpose of a dwelling unit is to provide the essential amenities necessary for complete and independent facilities. Commonly, dwelling units are thought of as single-family houses or individual living units in duplexes or townhouses.

DWV. Abbreviated term for drain, waste and vent piping as used in common plumbing practice.

- ❖ This term is used extensively to identify systems and materials suitable for drain, waste and vent installations. It will often be labeled on specific materials approved for such use.

EFFECTIVE OPENING. The minimum cross-sectional area at the point of water-supply discharge, measured or expressed in terms of diameter of a circle and if the opening is not circular, the diameter of a circle of equivalent cross-sectional area. (This is applicable to air gap.)

- ❖ An effective opening is used to determine the minimum air gap required between a potable water supply outlet or opening and the flood level rim of a receptacle, fixture or other potential source of contamination.

ELBOW. A pressure pipe fitting designed to provide an exact change in direction of a pipe run. An elbow provides a sharp turn in the flow path (see “Bend” and “Sweep”).

- ❖ See the definition of “Bend.”

[RB] EMERGENCY ESCAPE AND RESCUE OPENING. An operable exterior window, door or similar device that provides for a means of escape and access for rescue in the event of an emergency.

- ❖ In the case of an emergency, particularly a fire, immediate action must be taken. Quick evacuation of the dwelling unit is often required. If occupants are sleeping at the time of the incident, the time for evacuation is extended, often to the point where normal egress is not possible. In such situations, a door or window to the exterior can be used. It is also possible to use such an exterior opening for rescue. See Section R310 for code requirements.

[RB] ENGINEERED WOOD RIM BOARD. A full-depth structural composite lumber, wood structural panel, structural glued laminated timber or prefabricated wood I-joist member

designed to transfer horizontal (shear) and vertical (compression) loads, provide attachment for *diaphragm* sheathing, siding and exterior deck ledgers and provide lateral support at the ends of floor or roof joists or rafters.

- ❖ This is a specific type of engineered wood product designed and manufactured to serve a specific function in a building, as a rim board. Sections R502.1.7, R602.1.7 and R802.1.7 require that this product meet ANSI/APA PRR410. See the commentary to those sections.

EQUIPMENT. Piping, ducts, vents, control devices and other components of systems other than *appliances* that are permanently installed and integrated to provide control of environmental conditions for buildings. This definition shall also include other systems specifically regulated in this code.

- ❖ Throughout the code, the terms “equipment” and “appliance” have been used as necessary to match the terms with the intent and context of the code text. Appliances are not referred to as equipment and vice versa. Traditionally, the term “equipment” meant large machinery and specialized hardware not thought of as an “appliance” (see the definition of “Appliance”).

EQUIVALENT LENGTH. For determining friction losses in a piping system, the effect of a particular fitting equal to the friction loss through a straight piping length of the same nominal diameter.

- ❖ Fluid flow through a round, straight conduit is resisted by friction of the fluid against the inside wall of the conduit. Turns (elbows) and junctures (tees) in the conduit resist flow of the fluid because of the energy that it takes to make the fluid change direction. A turn (elbow) or a juncture (tee) can be “equated” to a length of straight conduit. For example, one 90-degree bend (elbow) in a 1-inch pipe is equivalent to 2.5 feet of straight 1-inch pipe. Using equivalent lengths for fittings makes it easy to determine the friction loss for a piping system. Appendix P uses equivalent lengths of fittings for determination of pressure losses in a water distribution system.

[RE] ERI REFERENCE DESIGN. A version of the rated design that meets the minimum requirements of the 2006 *International Energy Conservation Code*.

- ❖ This is an index used in the Energy Rating Index Compliance Alternative for energy conservation design. (See Section N1106).

[RB] ESCARPMENT. With respect to topographic wind effects, a cliff or steep slope generally separating two levels or gently sloping areas.

- ❖ This is a term to describe a topographical area where wind speed-up can occur. In cases where there is known to be structural damage due to this type of wind speed-up, the code requires consideration of topographical wind effects (see Section 301.2.1.5).

ESSENTIALLY NONTOXIC TRANSFER FLUIDS. Fluids having a Gosselin rating of 1, including propylene glycol; mineral oil; polydimethyl oil oxane; hydrochlorofluorocarbon, chlorofluorocarbon and hydrofluorocarbon refrigerants; and FDA-approved boiler water additives for steam boilers.

- ❖ Transfer fluids are liquids or gases that transfer heat to or remove heat from another fluid, such as water. The exchange of heat energy takes place through a heat exchange material, which separates the transfer fluid from the fluid being heated or cooled.

ESSENTIALLY TOXIC TRANSFER FLUIDS. Soil, water or gray water and fluids having a Gosselin rating of 2 or more including ethylene glycol, hydrocarbon oils, ammonia refrigerants and hydrazine.

- ❖ See the commentary to the definition of “Essentially nontoxic transfer fluids.”

EVAPORATIVE COOLER. A device used for reducing air temperature by the process of evaporating water into an airstream.

- ❖ Also known as “swamp coolers,” such units are used in arid climates and use water as a refrigerant. Such units substantially increase the humidity of the air being conditioned.

EXCESS AIR. Air that passes through the combustion chamber and the *appliance* flue in excess of what is theoretically required for complete combustion.

- ❖ The nature of natural-draft, fuel-fired appliances is such that the introduction and efficient intermixing of primary and secondary combustion air is not precise and is coupled with the induced air inflow caused by the internal draft. To achieve complete oxidation (com-

bustion), there will always be more air (excess) introduced into the appliances than is theoretically necessary for the complete combustion of the fuel.

EXHAUST HOOD, FULL OPENING. An exhaust hood with an opening not less than the diameter of the connecting vent.

- ❖ See Commentary Figure R202(7) for an illustration of a full opening exhaust hood.

EXISTING INSTALLATIONS. Any plumbing system regulated by this code that was legally installed prior to the effective date of this code, or for which a *permit* to install has been issued.

- ❖ “Existing installations” is a term that applies to all plumbing work that has been legally installed prior to the effective date of the code, as well as to all plumbing work for which a permit to install has been issued prior to the effective date of the code. Plumbing that has been illegally installed prior to the effective date of the code is not “existing” and is subject to all of the code requirements for new installations.

[RB] EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS). EIFS are nonstructural, nonload-bearing *exterior wall* cladding systems that consist of an insulation board attached either adhesively or mechanically, or both, to the substrate; an integrally reinforced base coat; and a textured protective finish coat.

- ❖ A variety of popular exterior finish systems have been developed, with the typical construction consisting of five layers of material. The code has relatively few provisions regulating EIFS; most of the requirements are those of the manufacturer.

DEFINITIONS

[RB] EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS) WITH DRAINAGE. An EIFS that incorporates a means of drainage applied over a water-resistive barrier.

- ❖ This type of EIFS system typically contains a water impermeable barrier underneath to prevent accumulation of water in the exterior façade.

[RB] EXTERIOR WALL. An above-grade wall that defines the exterior boundaries of a building. Includes between-floor spandrels, peripheral edges of floors, roof and *basement* knee walls, dormer walls, gable end walls, walls enclosing a mansard roof and *basement walls* with an average below-grade wall area that is less than 50 percent of the total opaque and nonopaque area of that enclosing side.

- ❖ An exterior wall is any wall located above grade level enclosing conditioned space. Regulated by this definition for the purpose of energy efficiency, a basement wall is exterior where less than 50 percent of its enclosing surface area is below grade.

[RB] EXTERIOR WALL COVERING. A material or assembly of materials applied on the exterior side of exterior walls for the purpose of providing a weather-resistive barrier, insulation or for aesthetics, including but not limited to, veneers, siding, exterior insulation and finish systems, architectural trim and embellishments such as cornices, soffits, and fascias.

- ❖ The definition of “Exterior wall covering” from Chapter 14 of the IBC is introduced to the IRC for appropriate and consistent usage.

Section R602.3 applies this definition to clarify requirements for sheathing installation on exterior walls. Wall sheathing that is used for structural purposes (e.g., bracing) is addressed in Chapter 6, “Wall Construction,” while wall sheathing that is used solely for exterior wall covering purposes is appropriately addressed in Chapter 7, “Wall Covering.” The special reference to wood structural panels at the exclusion of listing specific requirements for other sheathing types is deleted because the requirements for applicable wall sheathing materials, including wood structural panels, are adequately addressed by reference to Tables R602.3(1) through R602.3(4).

[RB] FACING. The wood structural panel facings that form the two outmost rigid layers of the structural insulated panel.

- ❖ Structural insulated panels are relatively new to the code. Terminology describing components of the panel are necessary to facilitate provisions to regulate the material.

FACTORY-BUILT CHIMNEY. A *listed* and *labeled* chimney composed of factory-made components assembled in the field in accordance with the manufacturer’s instructions and the conditions of the *listing*.

- ❖ A factory-built chimney is a manufactured, listed and labeled chimney that has been tested by an approved agency to determine its performance characteristics.

Factory-built chimneys are manufactured in two basic designs: a double-wall insulated design or a triple-wall air-cooled design. Both designs use stainless steel inner liners to resist the corrosive effects of combustion products.

FACTORY-MADE AIR DUCT. A *listed* and *labeled* duct manufactured in a factory and assembled in the field in accordance with the manufacturer’s instructions and conditions of the *listing*.

- ❖ The definition is not material specific, but is normally associated with fibrous glass ducts and flexible ducts. Such ducts are typically round and are sold in standardized lengths that are field connected to duct system components and other ducts. Factory-made ducts are available in insulated and uninsulated types.

[RE] FENESTRATION. Skylights, roof windows, vertical windows (whether fixed or moveable); opaque doors; glazed doors; glass block; and combination opaque and glazed doors.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ Exterior windows and doors are fenestrations in the exterior wall. Skylights and other sloped glazing are also included in the definition, as are glass doors, opaque doors and opaque/glazed doors. Chapter 11 regulates fenestrations for energy efficiency.

FIBER-CEMENT (BACKERBOARD, SIDING, SOFFIT, TRIM AND UNDERLAYMENT) PRODUCTS. Manufactured thin section composites of hydraulic cementitious matrices and discrete nonasbestos fibers.

- ❖ Fiber cement products are used as backerboard, siding, soffit, trim and underlayment. They are produced from flat nonasbestos fiber cement sheets. Fiber cement sheets consist of fiber-reinforced cement which is formed either with or without pressure and cured either under natural or accelerated conditions. The surface of the sheet to be exposed is either smooth, granular or textured. Specific standards are applicable to this material depending upon its use. These standards are referenced in the corresponding location of the code.

FIREBLOCKING. Building materials or materials *approved* for use as fireblocking, installed to resist the free passage of flame to other areas of the building through concealed spaces.

- ❖ Fireblocking materials include lumber; wood structural panels, particleboard, gypsum board, cement-based millboard, batts or blankets of mineral wool or glass fiber, or any other approved material that will resist the passage of flame from one concealed area to another. Regulated by Sections R302.11 and R602.8 for wood-frame construction, fireblocking is often used to isolate vertical cavities such as stud spaces from horizontal concealed areas such as attics or floor-ceiling assemblies.

[RB] FIREPLACE. An assembly consisting of a hearth and fire chamber of noncombustible material and provided with a chimney, for use with solid fuels.

- ❖ Fireplaces burn solid fuels such as wood and coal and are not referred to as appliances in the code. Both masonry and factory-built fireplaces are regulated by the IRC.

Factory-built fireplace. A *listed* and *labeled* fireplace and chimney system composed of factory-made components, and assembled in the field in accordance with manufacturer's instructions and the conditions of the listing.

- ❖ Factory-built fireplaces are solid-fuel burning units having a fire chamber that is either open to the room or, if equipped with doors, operated with the doors either open or closed. The term "fireplace" describes a complete assembly, which includes the hearth, fire chamber and chimney. A factory-built fireplace is composed of factory-built components representative of the prototypes tested, and it is to be installed in accordance with the manufacturer's instructions to form a completed fireplace.

Masonry fireplace. A field-constructed fireplace composed of *solid masonry* units, bricks, stones or concrete.

- ❖ Masonry fireplaces must be constructed in accordance with the requirements found in Section R1001. These specific requirements are based on tradition and field experience and describe the conventional fireplace that has proven to be reliable where properly constructed, used and maintained.

FIREPLACE STOVE. A free-standing, chimney-connected solid-fuel-burning heater designed to be operated with the fire chamber doors in either the open or closed position.

- ❖ Fireplace stoves are generally of the free-standing type and heat a space by direct radiation. There are various types of fireplace stoves, and their installation must be in compliance with the listing of the stove.

[RB] FIREPLACE THROAT. The opening between the top of the firebox and the smoke chamber.

- ❖ The fireplace throat is the point where the combustion products from the fireplace pass into the chimney.

[RB] FIRE-RETARDANT-TREATED WOOD. Pressure-treated lumber and plywood that exhibit reduced surface burning characteristics and resist propagation of fire.

Other means during manufacture. A process where the wood raw material is treated with a fire-retardant formulation while undergoing creation as a finished product.

Pressure process. A process for treating wood using an initial vacuum followed by the introduction of pressure above atmospheric.

- ❖ Fire-retardant-treated wood (FRTW) is a specific type of material that is made to be fire retardant by the infu-

sion of chemicals into the wood using a pressure process. It is important to apply the code provisions that allow FRTW to products that are pressure treated in accordance with referenced standards. Other products will not necessarily perform in the same manner.

[RB] FIRE SEPARATION DISTANCE. The distance measured from the building face to one of the following:

1. To the closest interior *lot line*.
2. To the centerline of a street, an alley or public way.
3. To an imaginary line between two buildings on the *lot*.

The distance shall be measured at a right angle from the face of the wall.

- ❖ This is the distance between the exterior surface of a building and one of the following three locations: the nearest interior lot line; the centerline of a street, alley, or public way; or an imaginary line placed between two buildings on the same lot. The measurement is perpendicular to the lot line [see Commentary Figure R202(8)]. The fire separation distance is important in determining exterior wall protection and the potential prohibition of exterior openings based on the proximity to the lot lines.

FIXTURE. See "Plumbing fixture."

FIXTURE BRANCH, DRAINAGE. A drain serving two or more fixtures that discharges into another portion of the drainage system.

- ❖ See Commentary Figure R202(9).

FIXTURE BRANCH, WATER-SUPPLY. A water-supply pipe between the fixture supply and a main water-distribution pipe or fixture group main.

- ❖ See the definition of "Branch."

FIXTURE DRAIN. The drain from the trap of a fixture to the junction of that drain with any other drain pipe.

- ❖ Commonly referred to as a trap arm, a fixture drain is the horizontal section of pipe connecting the outlet weir of a trap to a stack, fixture branch or any other drain [see Commentary Figures R202(9) and (10)].

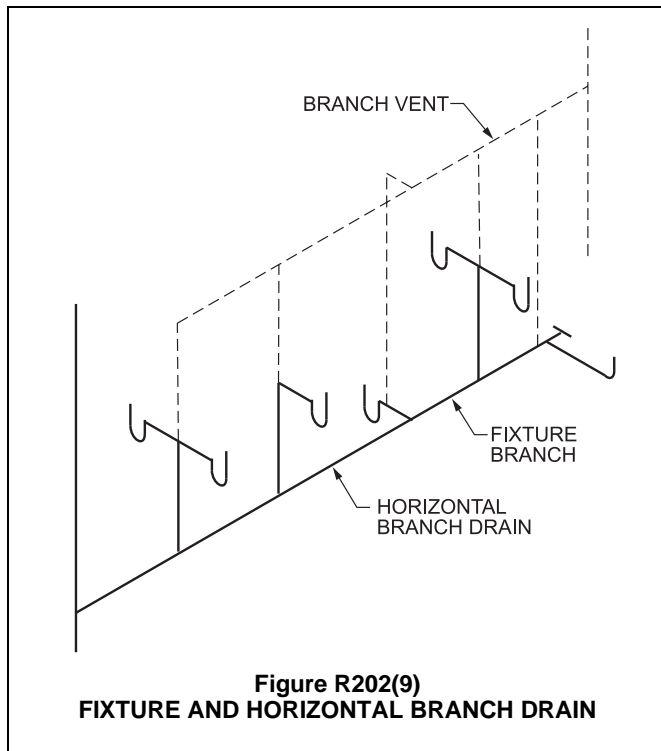

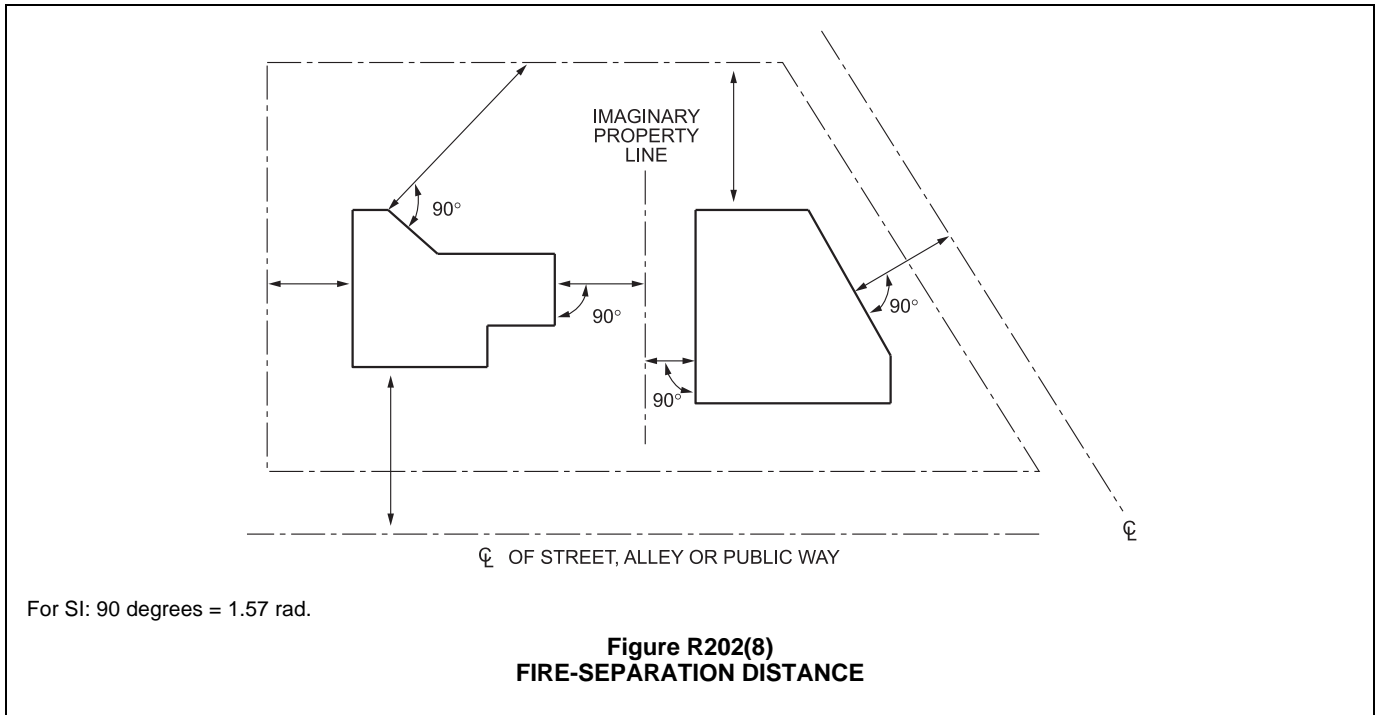

FIXTURE FITTING.

Supply fitting. A fitting that controls the volume or directional flow or both of water and that is either attached to or accessible from a fixture or is used with an open or atmospheric discharge.

Waste fitting. A combination of components that conveys the sanitary waste from the outlet of a fixture to the connection of the sanitary drainage system.

- ❖ This includes the various portions of a faucet from its connecting supply lines to the termination point where water is delivered. When applied to waste components, it includes tubing, fittings and traps used for the connection to the drainage system.

DEFINITIONS

FIXTURE GROUP, MAIN. The main water-distribution pipe (or secondary branch) serving a plumbing fixture grouping such as a bath, kitchen or laundry area to which two or more individual fixture branch pipes are connected.

- ❖ This is the main or branch water-distribution pipe that extends to a group of fixtures (i.e., bathroom, laundry or kitchen).

FIXTURE SUPPLY. The water-supply pipe connecting a fixture or fixture fitting to a fixture branch.

- ❖ A fixture supply is a water supply pipe serving a single fixture.

FIXTURE UNIT, DRAINAGE (d.f.u.). A measure of probable discharge into the drainage system by various types of plumbing fixtures, used to size DWV piping systems. The

drainage fixture-unit value for a particular fixture depends on its volume rate of drainage discharge, on the time duration of a single drainage operation and on the average time between successive operations.

❖ The conventional method of designing a sanitary drainage system is based on drainage fixture unit (d.f.u.) load values. The fixture-unit approach takes into consideration the probability of load on a drainage system. The d.f.u. is an arbitrary loading factor assigned to each fixture relative to its impact on the drainage system. Drainage fixture unit values are determined based on the average rate of water discharge by a fixture, the duration of a single operation, and the frequency of use or interval between each operation.

Because d.f.u. values have a built-in probability factor, they cannot be directly translated into flow rates or discharge rates.

A d.f.u. is not the same as the water supply fixture unit (w.s.f.u.) described in Chapter 29 and below.

FIXTURE UNIT, WATER-SUPPLY (w.s.f.u.). A measure of the probable hydraulic demand on the water supply by various types of plumbing fixtures used to size water-piping systems. The water-supply fixture-unit value for a particular fixture depends on its volume rate of supply, on the time duration of a single supply operation and on the average time between successive operations.

❖ When estimating peak demand for water supply systems, sizing methods use water-supply fixture units (w.s.f.u.). This is a numerical factor on an arbitrary scale assigned to intermittently used fixtures to calculate their load-producing effects on the water supply system.

The use of fixture units makes it possible to simplify the difficult task of calculating load-producing characteristics of any fixture to a common basis. The fixture units of different kinds of fixtures can be applied to a single basic probability curve found in various sizing methods.

[RB] FLAME SPREAD. The propagation of flame over a surface.

❖ During a fire, flames will travel across a building's interior surfaces in different forms and at different speeds. The movement of the flames along the surface material is the flame spread.

[RB] FLAME SPREAD INDEX. A comparative measure, expressed as a dimensionless number, derived from visual measurements of the spread of flame versus time for a material tested in accordance with ASTM E84 or UL723.

❖ To regulate the spread of fire over an interior surface material, limitations are imposed on the characteristics of the material. The standardized test procedure described in ASTM E84 or UL 723 measures the flame spread under specified conditions, and a numerical value is assigned to the material being tested. This value is the flame spread index.

FLEXIBLE AIR CONNECTOR. A conduit for transferring air between an air duct or plenum and an air terminal unit, an air inlet or an air outlet. Such conduit is limited in its use, length and location.

❖ Flexible air connectors are factory made and are very similar to flexible ducts to the point of being almost indistinguishable, other than the label. Such connectors are typically in standardized lengths and typically have termination collars attached on each end from the factory. Flexible connectors are listed to UL 181, but are not subjected to all of the testing required for flexible ducts. Unlike flexible ducts, flexible connectors are limited in length.

[RB] FLIGHT. A continuous run of rectangular treads or winders or combination thereof from one landing to another.

❖ Two points of clarification for stairways have been addressed by the definition of flight. For one, a flight is made up of the treads and risers that occur between landings. Therefore, a stairway connecting two stories that includes an intermediate landing consists of two flights. Secondly, the inclusion of winders within a stairway does not create multiple flights. Winders are simply treads within a flight and are often combined with rectangular treads within the same flight.

FLOOD-LEVEL RIM. The edge of the receptor or fixture from which water overflows.

❖ The flood-level rim is the highest elevation that liquid can be contained in a receptacle without spilling over the side of the fixture or receptor.

FLOOR DRAIN. A plumbing fixture for recess in the floor having a floor-level strainer intended for the purpose of the collection and disposal of waste water used in cleaning the floor and for the collection and disposal of accidental spillage to the floor.

❖ Floor drains are typically installed as emergency fixtures, preventing the flooding of a room or space.

FLOOR FURNACE. A self-contained furnace suspended from the floor of the space being heated, taking air for combustion from outside such space, and with means for lighting the *appliance* from such space.

❖ Such units supply heat through a floor grille placed directly over the unit's heat exchanger. Typically floor furnaces are classified as gravity-type furnaces. The circulation of air from a gravity-type floor furnace is accomplished by convection. Floor furnaces may be equipped with factory fans to circulate the air.

FLOW PRESSURE. The static pressure reading in the water-supply pipe near the faucet or water outlet while the faucet or water outlet is open and flowing at capacity.

❖ Each fixture requiring water has a minimum flow pressure necessary for the fixture to operate properly and to help protect the potable water supply from contamination. "Flow pressure" is a factor used in sizing the water supply system. The flow pressure of a plumbing

DEFINITIONS

system is less than the static pressure because energy is lost in putting the fluid in motion.

FLUE. See “Vent.”

FLUE, APPLIANCE. The passages within an *appliance* through which combustion products pass from the combustion chamber to the flue collar.

❖ This is the passage through an appliance used for the removal of combustion products.

FLUE COLLAR. The portion of a fuel-burning *appliance* designed for the attachment of a draft hood, vent connector or venting system.

❖ See the commentary to the definition of “Draft hood.”

FLUE GASES. Products of combustion plus excess air in *appliance* flues or heat exchangers.

❖ The exact composition of flue gases depends on the materials being burned. The primary components of flue gases are nitrogen, carbon dioxide, water vapor, particulates, carbon monoxide and myriad compounds and trace elements that vary with the nature of the fuel.

FLUSH VALVE. A device located at the bottom of a flush tank that is operated to flush water closets.

❖ A flush valve consists of the flapper and the flush-valve seat in a flush-tank type water closet.

FLUSHOMETER TANK. A device integrated within an air accumulator vessel that is designed to discharge a predetermined quantity of water to fixtures for flushing purposes.

❖ This device is a hybrid between a flushometer valve and a gravity flush tank. A flushometer tank employs a compression tank that holds water under a pressure equivalent to the water-supply pressure. The flushing action created by the flushometer tank is similar to that of the flushometer valve, and the amount of water used is limited as it is with a gravity flush tank.

FLUSHOMETER VALVE. A flushometer valve is a device that discharges a predetermined quantity of water to fixtures for flushing purposes and is actuated by direct water pressure.

❖ This flushing device is a type of metering valve that is used primarily in public occupancy applications because of its powerful flushing action.

[RB] FOAM BACKER BOARD. Foam plastic used in siding applications where the foam plastic is a component of the siding.

❖ Products that combine an exterior siding material and foam plastic are available in the marketplace. The foam plastic component used in these products is referred to as a foam backer board. By using a foam layer in addition to the siding, the thermal properties can be enhanced.

[RB] FOAM PLASTIC INSULATION. A plastic that is intentionally expanded by the use of a foaming agent to produce a reduced-density plastic containing voids consisting of open or closed cells distributed throughout the plastic for thermal insulating or acoustic purposes and that has a density

less than 20 pounds per cubic foot (320 kg/m³) unless it is used as interior trim.

❖ An expanded plastic produced through use of a foaming agent that has a reduced density. This plastic contains voids consisting of open or closed cells distributed throughout the plastic, which provide thermal insulation and/or acoustic control. The density of the material is to be less than 20 pounds per cubic foot (320 kg/m³) unless it is used as interior trim. Foam plastic used in siding applications where the foam plastic is a component of the siding.

[RB] FOAM PLASTIC INTERIOR TRIM. Exposed foam plastic used as picture molds, chair rails, crown moldings, baseboards, handrails, ceiling beams, door trim and window trim and similar decorative or protective materials used in fixed applications.

❖ An expanded plastic used as a decorative trim which is produced through use of a foaming agent. This foam plastic contains voids consisting of open or closed cells distributed throughout the material with a minimum density of at least 20 pounds (320 kg/m³) per cubic foot (pcf). The foam plastic trim is left exposed in applications such as picture moldings, chair rails, crown moldings, baseboards, handrails, ceiling beams, door trim, window trim and similar decorative or protective applications.

FUEL-PIPING SYSTEM. All piping, tubing, valves and fittings used to connect fuel utilization *equipment* to the point of fuel delivery.

❖ As used in this code, this term includes the tubing and pipe used to convey fuel gas from the point of delivery to the appliance.

FULLWAY VALVE. A valve that in the full open position has an opening cross-sectional area that is not less than 85 percent of the cross-sectional area of the connecting pipe.

❖ Gate valves and ball valves are typical fullway (full-open) valves. Unlike a globe valve, a fullway valve will provide the most open and straight run for the contents to flow through because the closing portion is perpendicular to the run of pipe.

FURNACE. A vented heating *appliance* designed or arranged to discharge heated air into a *conditioned space* or through a duct or ducts.

❖ The single most distinguishing characteristic of furnaces is that they use air as the heat transfer medium. Furnaces can be fueled by gas, oil, solid fuel or electricity and can use fans, blowers and gravity (convection) to circulate the heated air to and from the unit. In the context of the code, the primary use of the term “furnace” refers to heating appliance units that combine a combustion chamber with related components, one or more heat exchangers and an air-handling system.

[RB] GLAZING AREA. The interior surface area of all glazed fenestration, including the area of sash, curbing or other framing elements, that enclose *conditioned space*.

Includes the area of glazed fenestration assemblies in walls bounding conditioned *basements*.

- ❖ The glazing area includes not only the surface area of the exposed glazing but also the framing elements, including the sash and curbing. The amount of glazing area is regulated for natural light by Section R303; however, this definition applies to the energy efficiency provisions of Chapter 11.

[RB] GRADE. The finished ground level adjoining the building at all *exterior walls*.

- ❖ This is the point at which the finished exterior ground level intersects the exterior wall of the building. The grade around a building may remain relatively constant, such as on a flat site, or may change dramatically from one point to the next if the site is steeply sloping.

[RB] GRADE FLOOR OPENING. A window or other opening located such that the sill height of the opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening.

- ❖ In the requirements for emergency escape and rescue openings found in Section R310, the size of the openings may be reduced if they are grade floor openings. These are windows or other openings that are located within close proximity to the finished ground level. The sill of a grade floor opening may be located either above or below the adjacent ground level, provided it is located no more than 44 inches (1118 mm) vertically from the level of the ground.

GRADE, PIPING. See “Slope.”

[RB] GRADE PLANE. A reference plane representing the average of the finished ground level adjoining the building at all *exterior walls*. Where the finished ground level slopes away from the *exterior walls*, the reference plane shall be established by the lowest points within the area between the building and the *lot line* or, where the *lot line* is more than 6 feet (1829 mm) from the building between the structure and a point 6 feet (1829 mm) from the building.

- ❖ This definition can be important in determining the number of stories within a building as well as its height in feet. In some cases, the finished surface of the ground may be artificially raised with imported fill to create a higher grade plane around a building to decrease the number of stories or height. The definition requires that the lowest elevation within 6 feet (1829 mm) of the exterior wall be used to determine the grade plane.

GRAY WATER. Waste discharged from lavatories, bathtubs, showers, clothes washers and laundry trays.

- ❖ This definition was added for the 2012 edition to support the new Section 3009, “Gray Water Recycling Systems.” The collection of gray water must be kept separate from blackwater (waste water from water closets, urinals and kitchen sinks), therefore requiring separate drainage and vent systems. Although the code does not require marking of gray-water collection piping, it may be prudent to mark such systems to

avoid future cross connection to blackwater collection piping.

GRIDDED WATER DISTRIBUTION SYSTEM. A water distribution system where every water distribution pipe is interconnected so as to provide two or more paths to each fixture supply pipe.

- ❖ These systems offer the advantage of a simplistic design, typically smaller sized distribution lines and aid water conservation. In a traditional water distribution system, the water contained in the larger diameter piping is wasted when the line is opened and the user has to wait until the water reaches the desired temperature.

Parallel or gridded water distribution systems differ from branch systems which have individual supply pipes that extend to each fixture or outlet from a central supply point. The central supply point is a multiple-outlet manifold to which the distribution lines connect.

[RB] GROSS AREA OF EXTERIOR WALLS. The normal projection of all *exterior walls*, including the area of all windows and doors installed therein.

- ❖ The calculation for determining the gross area of exterior walls for energy efficiency purposes is based on the total area of the entire exterior surface, including openings such as windows and doors.

GROUND-SOURCE HEAT PUMP LOOP SYSTEM. Piping buried in horizontal or vertical excavations or placed in a body of water for the purpose of transporting heat transfer liquid to and from a heat pump. Included in this definition are closed loop systems in which the liquid is recirculated and open loop systems in which the liquid is drawn from a well or other source.

- ❖ This definition assists the user with a ready means of distinguishing ground-source heat pump loop systems from other hydronic systems.

[RB] GUARD. A building component or a system of building components located near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to the lower level.

- ❖ A guard is a component or system of components whose function is the prevention of falls from an elevated area. Placed adjacent to an elevation change, a guard must be of adequate height, strength and configuration to help prevent people, especially small children, from falling over or through the guard to the area below.

[RB] GUESTROOM. Any room or rooms used or intended to be used by one or more guests for living or sleeping purposes.

- ❖ Section 101.2 provides an exception to allow lodging houses to be built in accordance with the code. A common example of a lodging house is a bed and breakfast. To support this provision (Section 101.2, Exception 2), the code includes a definition of “Lodging house,” which includes the term “guestroom.” Therefore, it is necessary to define the term guestroom as well.

DEFINITIONS

[RB] GYPSUM BOARD. The generic name for a family of sheet products consisting of a noncombustible core primarily of gypsum with paper surfacing. Gypsum wallboard, gypsum sheathing, gypsum base for gypsum *vener* plaster, exterior gypsum soffit board, predecorated gypsum board and water-resistant gypsum backing board complying with the standards listed in Section R702.3 and Part IX of this code are types of gypsum board.

[RB] GYPSUM PANEL PRODUCT. The general name for a family of sheet products consisting essentially of gypsum.

[RB] HABITABLE SPACE. A space in a building for living, sleeping, eating or cooking. Bathrooms, toilet rooms, closets, halls, storage or utility spaces and similar areas are not considered *habitable spaces*.

❖ An area within a building used for living, sleeping, dining or cooking is a habitable space. Those areas not meeting this definition include bathrooms, closets, hallways and utility rooms. Habitable spaces are typically occupied, and as such they are more highly regulated than accessory use areas.

[RB] HANDRAIL. A horizontal or sloping rail intended for grasping by the hand for guidance or support.

❖ Typically used in conjunction with a ramp or stairway, a handrail provides support for the user along the travel path. Through its height, size, shape, continuity and structural stability, a handrail assists users at elevation changes inside and outside a building. A handrail may also be used as a guide to direct the user in a specified direction.

HANGERS. See “Supports.”

HAZARDOUS LOCATION. Any location considered to be a fire hazard for flammable vapors, dust, combustible fibers or other highly combustible substances.

❖ The environment in which mechanical equipment and appliances operate plays a significant role in the safe performance of the equipment installation. Locations that may contain ignitable or explosive atmospheres are classified as hazardous locations with respect to the installation of mechanical equipment and appliances. For example, repair garages can be classified as hazardous locations because they can contain gasoline vapors from vehicles stored within them as well as other volatile chemicals. Public and private garages can be considered as hazardous locations because of the presence of motor vehicles and because of the owners' propensity for storing paint, varnish, thinners, lawn and home maintenance products and other chemicals within the space.

HEAT PUMP. An *appliance* having heating or heating and cooling capability and that uses refrigerants to extract heat from air, liquid or other sources.

❖ Heat pumps are referred to as reverse-cycle refrigeration systems. Special controls and valves allow the system to be used as a comfort heating system, comfort cooling system and potable water heating system. Auxiliary heat is often installed in heat pumps in the form of electric resistance heat or fuel-fired furnaces.

In most cases, the design and installation of heat pumps is more critical than for other types of comfort air-conditioning systems because of the heat-transfer process and the amount of air that must be circulated. Heat-pump types include water source (hydronic), ground source (earth loop), water source (wells) and air source.

[RE] HEATING DEGREE DAYS (HDD). The sum, on an annual basis, of the difference between 65°F (18°C) and the mean temperature for each day as determined from “NOAA Annual Degree Days to Selected Bases Derived from the 1960-1990 Normals” or other weather data sources acceptable to the code official.

❖ Heating degree days (HDDs) are a measure of the heating requirements for buildings in a particular climate. The greater the number of HDD, the colder the climate. HDD is calculated by first determining the average temperature for each day of the year over a 24-hour period. The average temperature for each day is then subtracted from a base temperature of 65°F (18°C) to determine the HDD value for the day. For days on which the average temperature is over 65°F (18°C), the HDD is zero. The HDD for each day are then totaled to determine the HDD value for the particular area. The average temperatures are calculated over a number of years. These values are published in the *ASHRAE Handbook of Fundamentals*. They can also be found in the NOAA Annual Degree Days to Selected Bases Derived from the 1960-1990 Normals.

Climate Zone numbers listed in Table N1101.2 can also be used to approximate the HDD value for a particular county. Each climate zone is equal to 500 HDD. For example, Climate Zone 1 is equal to 0-499 HDD, and Climate Zone 2 is equal to 500-999 HDD.

[RB] HEIGHT, BUILDING. The vertical distance from *grade plane* to the average height of the highest roof surface.

❖ Once the elevation of the grade plane has been calculated, it is possible to determine a building's height, which is measured vertically from the grade plane to the average height of the highest roof surface. Commentary Figure R202(11) contains examples of this measurement.

If the building is stepped or terraced, it is logical that the height is the maximum height of any segment of the building. It may be appropriate under certain circumstances that the number of stories in a building be determined in the same manner. Each case should be judged individually based on the characteristics of the site and construction.

[RB] HEIGHT, STORY. The vertical distance from top to top of two successive tiers of beams or finished floor surfaces; and, for the topmost *story*, from the top of the floor finish to the top of the ceiling joists or, where there is not a ceiling, to the top of the roof rafters.

❖ Within the building itself, the height of an individual story is determined by measuring the vertical distance between two successive finished floor surfaces. In a single-story building or for the uppermost floor in a mul-

tistory structure, the measurement is taken from the finished floor surface to the top of the ceiling joists or to the underside of the roof deck (top of the roof rafters) where a ceiling is not provided [see Commentary Figure R202(12)].

[RE] HIGH-EFFICACY LAMPS. See Section N1101.6 for definition applicable in Chapter 11.

- ❖ The energy conservation requirements of this code now contain a requirement to use high-efficacy lamps in permanently installed lighting fixtures. These lamps are considerably more energy efficient than normal lamps.

HIGH-TEMPERATURE (H.T.) CHIMNEY. A high temperature chimney complying with the requirements of UL 103. A Type H.T. chimney is identifiable by the markings “Type H.T.” on each chimney pipe section.

- ❖ This is a factory-built chimney used to vent solid-fuel-burning appliances when a masonry chimney is not available [see Commentary Figure R202(13) for an illustration of a Type H.T. chimney].

[RB] HILL. With respect to topographic wind effects, a land surface characterized by strong relief in any horizontal direction.

- ❖ This is a term to describe a topographical area where wind speed-up can occur. In cases where there is

known to be structural damage due to this type of wind speed-up, the code requires consideration of topographical wind effects (see Section R301.2.1.5).

[RB] HISTORIC BUILDING. Buildings that are listed in or eligible for listing in the National Register of Historic Places, or designated as historic under an appropriate state or local law.

- ❖ This term is used in Sections R105.3.1.1, N1101.6 and N1107.6. The definitions for this term here and in Section N1101.6 are identical.

HORIZONTAL BRANCH, DRAINAGE. A drain pipe extending laterally from a soil or waste stack or *building drain*, that receives the discharge from one or more *fixture drains*.

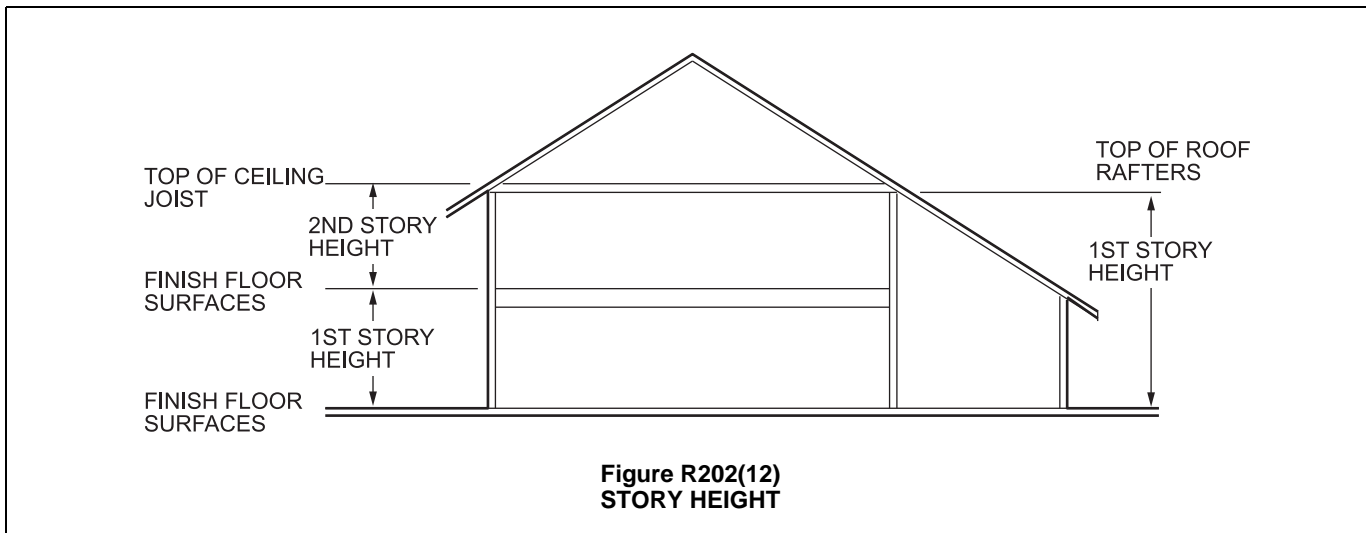

- ❖ See Commentary Figure R202(9).

HORIZONTAL PIPE. Any pipe or fitting that makes an angle of less than 45 degrees (0.79 rad) with the horizontal.

- ❖ This definition is needed for the application of many code provisions that apply only to horizontal piping.

HOT WATER. Water at a temperature greater than or equal to 110°F (43°C).

- ❖ The code does not specify a maximum temperature for hot water; however, it should be limited to a tempera-

DEFINITIONS

ture that will minimize: 1. The risk of a user's burn; and 2. Thermal stress to plumbing system components. The designer, installer or owner has the choice of determining the temperature. Most water heaters are now shipped with a factory-set temperature of 120°F (49°C). The minimum temperature is established to determine what is considered as hot water. Water temperature below the minimum temperature is either tempered or cold. Care must be used when installing a system that has temperature capability of exceeding 120°F (49°C) because of the possibility of a user being scalded.

[RB] HURRICANE-PRONE REGIONS. Areas vulnerable to hurricanes, defined as the U.S. Atlantic Ocean and Gulf of Mexico coasts where the ultimate design wind speed, V_{ult} , is greater than 115 miles per hour (51 m/s), and Hawaii, Puerto Rico, Guam, Virgin Islands and America Samoa.

- ❖ Those geographical areas subject to hurricanes are "hurricane-prone regions." The specific areas include those having a minimum basic wind speed exceeding 110 miles per hour (177 km/h or 49 m/s) along the United States coastline of the Atlantic Ocean and the coasts bordering the Gulf of Mexico, as well as the indicated islands.

For SI: 1 inch = 25.4 mm, 1 degree = 0.01745 rad.

**Figure R202(13)
HIGH-TEMPERATURE CHIMNEY**

HYDROGEN-GENERATING APPLIANCE. A self-contained package or factory-matched packages of integrated systems for generating gaseous hydrogen. Hydrogen-generating *appliances* utilize electrolysis, reformation, chemical or other processes to generate hydrogen.

- ❖ Hydrogen is being generated to fuel a new line of developmental vehicles and to generate electric power in fuel cell power systems. Several different processes are being used to generate hydrogen. One such process removes hydrogen from tap water (H₂O) in an electrically powered appliance.

Installation requirements for these appliances are found in Chapter 7 of the IFGC and ventilation requirements for spaces containing the appliances are found in Section M1307.4 of this code.

IGNITION SOURCE. A flame, spark or hot surface capable of igniting flammable vapors or fumes. Such sources include *appliance* burners, burner ignitions and electrical switching devices.

- ❖ Any component of an appliance that can generate a spark or heat sufficient to ignite flammable gasses or vapors is an ignition source. Open flames (such as a pilot light) and appliance burners are also an ignition source.

INDIRECT SYSTEM. A solar thermal system in which the gas or liquid in the solar collector loop circulates between the solar collector and a heat exchanger and such gas or liquid is not drained from the system or supplied to the load during normal operation.

- ❖ Indirect systems do not directly heat the water or air that they are intended to heat. Rather, such systems heat a transfer medium such as an antifreeze solution and that solution is passed through a heat exchanger that separates the solar side (loop) of the system from the air or water intended to be heated. Indirect systems are commonly used to heat potable water.

INDIRECT WASTE PIPE. A waste pipe that discharges into the drainage system through an *air gap* into a trap, fixture or receptor.

- ❖ Often referred to as “open site” or “safe waste,” indirect waste pipe installations protect fixtures, equipment and systems from the backflow or backsiphonage of waste.

INDIVIDUAL SEWAGE DISPOSAL SYSTEM. A system for disposal of sewage by means of a septic tank or mechanical treatment, designed for use apart from a public sewer to serve a single establishment or building.

- ❖ When installed in accordance with the *International Private Sewage Disposal Code*[®] (IPSDC[®]) and approved by the administrative authority, these systems are acceptable as a point of disposal for sewage when a public sewer system is not available.

INDIVIDUAL VENT. A pipe installed to vent a single *fixture drain* that connects with the vent system above or terminates independently outside the building.

- ❖ An individual vent is the simplest and most common method of venting a single plumbing fixture.

INDIVIDUAL WATER SUPPLY. A supply other than an approved public water supply that serves one or more families.

- ❖ This type of water supply includes wells, springs, streams and cisterns. Surface bodies of water and land cisterns can be used when properly treated and approved.

[RB] INSULATED SIDING. A type of continuous insulation, with manufacturer-installed insulating material as an integral part of the cladding product, having a minimum *R*-value of R-2.

[RB] INSULATED VINYL SIDING. A vinyl cladding product, with manufacturer-installed foam plastic insulating material as an integral part of the cladding product, having a thermal resistance of not less than R-2.

[RB] INSULATING CONCRETE FORM (ICF). A concrete forming system using stay-in-place forms of rigid foam plastic insulation, a hybrid of cement and foam insulation, a hybrid of cement and wood chips, or other insulating material for constructing cast-in-place concrete walls.

- ❖ This is a relatively new construction technique for foundation/basement walls and above-grade walls that uses stay-in-place insulation forms and concrete. A wide variety of systems are available, with several types of insulating materials used for the formwork. Sections R404.1.3 (foundation walls) and R610 (above-grade walls) address three different systems consisting of insulating concrete forms: flat, waffle grid, and screen grid.

[RE] INSULATING SHEATHING. An insulating board having a thermal resistance of not less than R-2 of the core material.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ A sheathing board having an insulating core material is insulating sheathing if its thermal resistance is at least R-2.

[RB] JURISDICTION. The governmental unit that has adopted this code under due legislative authority.

- ❖ The governmental entity that adopts and enforces the IRC is the “jurisdiction.” A jurisdiction can take on a variety of forms such as a state, city, town, county, fire district, improvement district or federal department. The jurisdiction appoints a building official to administer and enforce the provisions of the code.

DEFINITIONS

[RB] KITCHEN. Kitchen shall mean an area used, or designated to be used, for the preparation of food.

- ❖ This is an area designed to be used for the preparation of food. A kitchen is a habitable space and is subject to a number of requirements.

[RB] LABEL. An identification applied on a product by the manufacturer that contains the name of the manufacturer, the function and performance characteristics of the product or material, and the name and identification of an *approved agency* and that indicates that the representative sample of the product or material has been tested and evaluated by an *approved agency*. (See also “Manufacturer’s designation” and “Mark.”)

- ❖ A label provides verification of testing and inspection of materials, products or assemblies, identifies a product or material and provides other information that can be investigated if there is a question about the suitability of the product or material for a specific installation.

The applicable referenced standard often states the minimum identifying information required on a label. The information on a label as mandated by the code includes the name of the manufacturer, the product’s function or performance characteristics, the name and identification of the approved labeling agency and the approval of the testing agency. The product name, serial number, installation specifications or applicable tests and standards might be additional information that is provided (see also the commentary for the definitions of “Listed,” “Mark,” “Labeled” and “Manufacturer’s designation”).

[RB] LABELED. *Equipment*, materials or products to which have been affixed a *label*, seal, symbol or other identifying *mark* of a nationally recognized testing laboratory, inspection agency or other organization concerned with product evaluation that maintains periodic inspection of the production of the *labeled* items and whose labeling indicates either that the *equipment*, material or product meets identified standards or has been tested and found suitable for a specified purpose.

- ❖ The term is an adjective applied to equipment, materials and products that have been tested or otherwise determined to meet the intended purpose or meet a standard. The label is that of a laboratory or other agency qualified to do the evaluations (see also the commentary for definitions of “Listed,” “Mark,” “Label” and “Manufacturer’s designation”).

When a product is labeled, the label indicates that the material has been tested for conformance to an applicable standard and that the component is subject to a third-party inspection that verifies that the minimum level of quality required by the appropriate standard is maintained. Labeling provides a readily available source of information that is useful for field inspection of installed products.

The labeling agency performing the third-party inspection must be approved by the building official, and the basis for this approval may include, but is not necessarily limited to, the capacity and capability of the agency to perform the specific testing and inspection.

[RB] LIGHT-FRAME CONSTRUCTION. A type of construction with vertical and horizontal structural elements that are primarily formed by a system of repetitive wood or cold-formed steel framing members.

- ❖ Light-frame construction is by far the predominant construction technique used for dwelling units. Consisting primarily of repetitive framing members such as studs, floor joists, ceiling joists and rafters, light-frame construction can use wood or light-gage steel as framing members. The repetitive members work together as a system to provide the structural integrity of the building. The IRC devotes most of its structural provisions to structures of light-frame construction.

[RB] LISTED. *Equipment*, materials, products or services included in a list published by an organization acceptable to the code official and concerned with evaluation of products or services that maintains periodic inspection of production of *listed equipment* or materials or periodic evaluation of services and whose listing states either that the *equipment*, material, product or service meets identified standards or has been tested and found suitable for a specified purpose.

- ❖ When a product is listed and labeled, it indicates that it has been tested for conformance to an applicable standard and is subject to a third-party inspection quality assurance (QA) program. The QA verifies that the minimum level of quality required by the appropriate standard is maintained. Labeling provides a readily available source of information that is useful for field inspection of installed products. The label identifies the product or material and provides other information that can be further investigated if there is any question as to its suitability for the specific installation. The labeling agency performing the third-party inspection must be approved by the building official, and the basis for this approval may include, but is not limited to, the capacity and capability of the agency to perform the specific testing and inspection (see also the commentary for definitions of “Mark,” “Label,” “Labeled” and “Manufacturer’s designation”).

The question is often asked whether the listing of a product can be voided or violated. The use of a listing mark applied to a product is authorized by the listing agency and is a “statement” by the product manufacturer that the product, as manufactured, met all appropriate requirements (such as the criteria contained in a test standard) at the time of manufacture and shipment to a point-of-use or point-of-sale. After that point in time, any alteration or modification makes it impossible for the building official or the listing agency to determine if the product continues to meet the criteria by which its listing was originally attained. Listed products are subject to the review and approval of the building official and, where the building official determines that a field modification or alteration to the product is significant enough to call its impact on the listing into question, an evaluation in the field by representatives of the listing agency may be required in order to verify the continued compliance of the product with the original listing criteria. Such field evaluations or tests would be

the responsibility of the permit holder and conducted at no cost to the jurisdiction (see Section R104.11.1).

[RB] LIVE LOADS. Those loads produced by the use and occupancy of the building or other structure and do not include construction or environmental loads such as wind load, snow load, rain load, earthquake load, flood load or dead load.

- ❖ A variety of loads are imposed on a structure that must be considered in the building design. One group is live loads, produced through the use of the building. Different types of uses or occupancies result in different live loads, due primarily to the number of people involved, the type of activity that takes place and the movable furnishings and equipment that are typically a part of the use.

Design loads that are not live loads include environmental loads such as wind loads, snow loads, rain loads, earthquake loads and flood loads, as well as construction loads. Fixed-in-place equipment is a dead load rather than a live load.

LIVING SPACE. Space within a *dwelling unit* utilized for living, sleeping, eating, cooking, bathing, washing and sanitation purposes.

- ❖ The living space within a dwelling extends beyond what is defined as habitable space. Living space includes not only those areas used for living, sleeping, eating and cooking but also includes bathing and washing areas such as bathrooms. Storage areas such as closets and garages are not a portion of the living space.

LOCAL EXHAUST. An exhaust system that uses one or more fans to exhaust air from a specific room or rooms within a dwelling.

- ❖ The most common example of local exhaust in a dwelling is the bathroom fan that exhausts air directly to the outside of the house. This definition was installed to clarify the intent of the exception to Section R303.3. The exception allows for a light and local exhaust to be used in lieu of the required amount of glazing to the exterior in a bathroom.

[RB] LODGING HOUSE. A one-family dwelling where one or more occupants are primarily permanent in nature, and rent is paid for guestrooms.

- ❖ Section 101.2 now provides an exception to allow lodging houses to be built in accordance with this code. A common example of a lodging house is a bed and breakfast. To support this new provision (Section 101.2, Exception 2), the code now includes this definition of "Lodging house." Note that this definition includes the term "guestroom," which is also a defined term in this code.

[RB] LOT. A portion or parcel of land considered as a unit.

- ❖ A lot is a legally recorded parcel of land, the boundaries of which are described in a deed. When code requirements are based on some element of a lot (such as yard area or lot line location), it is the physical

attributes of the parcel of land that the code is addressing, not issues of ownership. Adjacent lots owned by the same party are treated as if they were owned by different parties because ownership can change at any time. However, a group of platted lots or subdivision lots could be joined together and "considered as a unit" for the purposes of the code. For example, a collection of platted lots could be used as a single building lot for the construction of a covered mall and its associated anchor buildings. Local jurisdictions may require for taxing or other purposes that the lots be legally joined, or merged, as well.

A condominium form of building ownership, whether a residential or commercial condominium, does not create separate lots (i.e., parcels of land) and such unit owners are treated as separate tenants, not separate lot owners. The lines separating one part of a condominium from another are not lot lines but lines indicating the limits of ownership. As such, walls constructed on lines separating condominium ownership would not need to be fire (or party) walls.

Legal property lines do not always constitute site boundaries (e.g., malls, condominiums, townhouses). A site could contain multiple legal "lot" divisions.

[RB] LOT LINE. A line dividing one *lot* from another, or from a street or any public place.

- ❖ The lot line defines the exterior perimeter of the lot. It is used in several provisions of the code as the basis for requirements dealing with the proximity of an exterior wall or opening to the lot line.

Lot lines are legally recorded divisions between two adjacent land parcels or lots. They are the reference point for the location of buildings for exterior separation and other code purposes (see also the definition of "Lot").

MACERATING TOILET SYSTEMS. A system comprised of a sump with macerating pump and with connections for a water closet and other plumbing fixtures, that is designed to accept, grind and pump wastes to an *approved* point of discharge.

- ❖ See Section P2723.

MAIN. The principal pipe artery to which branches may be connected.

- ❖ This generic term applies to the primary or principal pipe artery in either water-supply systems or drainage systems to which branches may be connected.

MAIN SEWER. See "Public sewer."

MANIFOLD WATER DISTRIBUTION SYSTEMS. A fabricated piping arrangement in which a large supply main is fitted with multiple branches in close proximity in which water is distributed separately to fixtures from each branch.

- ❖ A manifold is a multiple-opening header to which one or more branch lines connect (see Section P2903.8).

[RB] MANUFACTURED HOME. *Manufactured home* means a structure, transportable in one or more sections, that in the traveling mode is 8 body feet (2438 body mm) or more

DEFINITIONS

in width or 40 body feet (12 192 body mm) or more in length, or, where erected on site, is 320 square feet (30 m²) or more, and that is built on a permanent chassis and designed to be used as a *dwelling* with or without a permanent foundation where connected to the required utilities, and includes the plumbing, heating, air-conditioning and electrical systems contained therein; except that such term shall include any structure that meets all the requirements of this paragraph except the size requirements and with respect to which the manufacturer voluntarily files a certification required by the secretary (HUD) and complies with the standards established under this title. For mobile homes built prior to June 15, 1976, a *label* certifying compliance to the Standard for Mobile Homes, NFPA 501, in effect at the time of manufacture is required. For the purpose of these provisions, a mobile home shall be considered to be a *manufactured home*.

- ❖ Appendix E contains provisions for the use of manufactured housing as dwellings. Appendix E is applicable only if so specified in the adoption ordinance of the jurisdiction. The provisions of this appendix are limited to three areas: 1. The construction, alteration or repair of a foundation system used to support a manufactured home unit; 2. The construction, installation, addition, alteration, repair or maintenance of building services equipment necessary for connecting the manufactured home to water, fuel, power supplies or sewage systems; and 3. Alterations, additions or repairs to existing manufactured homes.

The code describes a manufactured home as being transportable in one or more sections, sets forth minimum dimensions for the home and indicates that a manufactured home is constructed on a permanent chassis. Under the provisions of the IRC, a mobile home is a manufactured home.

[RB] MANUFACTURER'S DESIGNATION. An identification applied on a product by the manufacturer indicating that a product or material complies with a specified standard or set of rules. (See also "Mark" and "Label.")

- ❖ Identification applied on a product by the manufacturer indicating that a product or material complies with a specified standard or set of rules (see also "Mark" and "Label").

[RB] MANUFACTURER'S INSTALLATION INSTRUCTIONS. Printed instructions included with *equipment* as part of the conditions of their *listing* and *labeling*.

- ❖ A set of instructions provided by the manufacturer of a product that guides the user or installer through the steps necessary to ensure a complying installation. These instructions help ensure that an installer does not violate the listing of a product.

[RB] MARK. An identification applied on a product by the manufacturer indicating the name of the manufacturer and the function of a product or material. (See also "Manufacturer's designation" and "Label.")

- ❖ A mark represents the manufacturer's identification placed on a product, stating who made the product and describing its function. There is, however, no certification of compliance to any particular standard and no

third-party quality control (see also the commentary to definitions of "Listed," "Label," "Labeled" and "Manufacturer's designation").

[RB] MASONRY CHIMNEY. A field-constructed chimney composed of solid masonry units, bricks, stones or concrete.

- ❖ Masonry chimneys can have one or more flues within them and are field constructed of brick, stone, concrete, or fire-clay materials. Masonry chimneys can stand alone or be part of a masonry fireplace.

[RB] MASONRY HEATER. A masonry heater is a solid fuel burning heating *appliance* constructed predominantly of concrete or solid masonry having a mass of not less than 1,100 pounds (500 kg), excluding the chimney and foundation. It is designed to absorb and store a substantial portion of heat from a fire built in the firebox by routing exhaust gases through internal heat exchange channels in which the flow path downstream of the firebox includes not less than one 180-degree (3.14-rad) change in flow direction before entering the chimney and that deliver heat by radiation through the masonry surface of the heater.

- ❖ Masonry heaters are appliances designed to absorb and store heat from a relatively small fire and to radiate that heat into the building interior. They are thermally more efficient than traditional fireplaces because of their design. Interior passageways through the heater allow hot exhaust gases from the fire to transfer heat into the masonry, which then radiates into the building.

[RB] MASONRY, SOLID. Masonry consisting of solid masonry units laid contiguously with the joints between the units filled with mortar.

- ❖ In solid masonry construction, walls are made up of solid masonry units. The joints between the units are also solid because they must be filled with mortar. Solid masonry walls may be either single-wythe or multiple-wythe construction. Where multiple wythes are used, the space between the wythes is filled with mortar or grout.

[RB] MASONRY UNIT. Brick, tile, stone, architectural cast stone, glass block or concrete block conforming to the requirements specified in Section 2103 of the *International Building Code*.

- ❖ The IBC contains the material requirements for masonry units. Various materials are used to construct masonry units, including brick, tile, stone, architectural cast stone, glass and concrete.

Clay. A building unit larger in size than a brick, composed of burned clay, shale, fire clay or mixtures thereof.

- ❖ Clay masonry units are composed of burned clay, shale, fire clay or a combination of these materials. A clay masonry unit is somewhat larger than a brick.

Concrete. A building unit or block larger in size than 12 inches by 4 inches by 4 inches (305 mm by 102 mm by 102 mm) made of cement and suitable aggregates.

- ❖ Masonry units constructed of cement, aggregates, water and suitable admixtures are concrete masonry

units. The minimum size for a concrete masonry unit is 4 inches by 4 inches by 12 inches.

Glass. Nonload-bearing masonry composed of glass units bonded by mortar.

- ❖ Glass masonry units are unique in that they are permitted for use only in nonload-bearing conditions. The units, either solid or hollow, are connected with mortar in the manner described in Section R610.

Hollow. A masonry unit with a net cross-sectional area in any plane parallel to the loadbearing surface that is less than 75 percent of its gross cross-sectional area measured in the same plane.

- ❖ The net cross-sectional area of a hollow masonry unit is less than 75 percent of its gross cross-sectional area measured in the same plane and parallel to the loadbearing surface. A unit having a greater ratio of net area to gross area than a hollow masonry unit is considered a solid masonry unit.

Solid. A masonry unit with a net cross-sectional area in every plane parallel to the loadbearing surface that is 75 percent or more of its cross-sectional area measured in the same plane.

- ❖ The net cross-sectional area of a solid masonry unit is at least 75 percent of its gross cross-sectional area measured in the same plane and parallel to the loadbearing surface. A unit having a ratio of net area to gross area below 75 percent is a hollow masonry unit.

[RE] MASS WALL. Masonry or concrete walls having a mass greater than or equal to 30 pounds per square foot (146 kg/m²), solid wood walls having a mass greater than or equal to 20 pounds per square foot (98 kg/m²), and any other walls having a heat capacity greater than or equal to 6 Btu/ft² · °F [123 J/(m² · K)].

- ❖ A mass wall must have a heat capacity of 6 Btu/ft² · °F. In general terms, the heat capacity is a measure of how well a material stores heat. The higher the heat capacity the greater amount of heat stored. For example, a 6-inch, heavyweight concrete wall has a heat capacity of 14 Btu/ft² · °F (286 kJ/m² · K) compared to a conventional 2-inch by 4-inch wood framed wall with a heat capacity of approximately 3 Btu/ft² · °F (63 kJ/m² · K). The code defines a mass wall as a masonry or concrete wall having a mass greater than or equal to 30 lb/ft², a solid wood wall (e.g., a log house) having a mass of greater than 20 lb/ft², or any other walls having a heat capacity of greater than or equal to 6 Btu/ft² · °F (123 kJ/m² · K).

[RB] MEAN ROOF HEIGHT. The average of the roof eave height and the height to the highest point on the roof surface, except that eave height shall be used for roof angle of less than or equal to 10 degrees (0.18 rad).

- ❖ For a relatively flat roof (up to 10 degrees slope), the mean roof height is the height of the eave. For steeper roofs, the mean roof height is measured to the average point between the eave and the highest point on the roof surface, typically the highest ridge.

MECHANICAL DRAFT SYSTEM. A venting system designed to remove flue or vent gases by mechanical means, that consists of an induced draft portion under nonpositive static pressure or a forced draft portion under positive static pressure.

- ❖ Mechanical draft systems do not depend on draft; they use fans or blowers.

Forced-draft venting system. A portion of a venting system using a fan or other mechanical means to cause the removal of flue or vent gases under positive static pressure.

- ❖ Power exhausters and some power-burner systems are examples of forced-draft systems. Vents and chimneys must be listed for positive pressure applications where used with forced-draft systems.

Induced draft venting system. A portion of a venting system using a fan or other mechanical means to cause the removal of flue or vent gases under nonpositive static vent pressure.

- ❖ Induced-draft venting is commonly accomplished with field-installed inducer fans designed to supplement natural-draft chimneys or vents.

Power venting system. A portion of a venting system using a fan or other mechanical means to cause the removal of flue or vent gases under positive static vent pressure.

- ❖ See the commentary to "Forced-draft venting system" above.

MECHANICAL EXHAUST SYSTEM. A system for removing air from a room or space by mechanical means.

- ❖ A mechanical exhaust system uses a fan or other air-handling equipment to exhaust air to the outdoors. Mechanical exhaust systems include those used for hazardous exhaust and commercial kitchen exhaust. Mechanical exhaust systems may or may not use ductwork as part of the system and may include air-cleaning or air-filtering equipment and fire-suppression equipment.

MECHANICAL JOINT.

1. A connection between pipes, fittings or pipes and fittings that is not welded, brazed, caulked, soldered, solvent cemented or heat-fused.
 2. A general form of gas- or liquid-tight connections obtained by the joining of parts through a positive holding mechanical construction such as, but not limited to, flanged, screwed, clamped or flared connections.
- ❖ Mechanical joints form a seal by compressing a ferrule or seal around the outside circumference of the pipe or tube or by compressing the tubing around a fitting inserted into the tubing. Mechanical joints are often proprietary and must be installed in accordance with the manufacturers' instructions. Heat-fused joints are not considered to be a mechanical joint.

DEFINITIONS

MECHANICAL SYSTEM. A system specifically addressed and regulated in this code and composed of components, devices, *appliances* and *equipment*.

❖ Mechanical systems include, among others, refrigeration systems, air-conditioning systems, exhaust systems, piping systems, duct systems, venting systems, hydronic systems and ventilation systems. A mechanical system may be any of the above systems or incorporate one or more of the systems. The system includes all of the equipment and appliances required to perform the function for which the system is designed.

[RB] METAL ROOF PANEL. An interlocking metal sheet having an installed weather exposure of not less than 3 square feet (0.28 m²) per sheet.

❖ A metal roof panel is specifically defined here in order to identify its difference from a metal roof shingle. Metal roof panels are each at least 3 square feet in surface area and interlock to provide a suitable roof covering. The provisions of Section R905.10 address roof coverings consisting of metal roof panels.

[RB] METAL ROOF SHINGLE. An interlocking metal sheet having an installed weather exposure less than 3 square feet (0.28 m²) per sheet.

❖ Section R905.4 regulates roof coverings consisting of metal roof shingles, which are smaller than 3 square feet (0.28 m²) per sheet.

[RB] MEZZANINE. An intermediate level or levels between the floor and ceiling of any *story*.

❖ Floor levels consisting of relatively small floor areas opening into larger rooms are mezzanines. Located at an intermediate level within a high-ceiling space, a mezzanine is limited to one-third of the area of the room in which it is located in accordance with Section R325.3. Because of its openness and relatively small size, a loft mezzanine is not considered an additional story (see Section R325 for further mezzanine requirements).

[RB] MODIFIED BITUMEN ROOF COVERING. One or more layers of polymer modified asphalt sheets. The sheet materials shall be fully adhered or mechanically attached to the substrate or held in place with an *approved* ballast layer.

❖ Polymer-modified asphalt sheets, applied in one or more layers, may be used as a roof covering when installed in accordance with Section R905.11. There are several approved methods for attaching the asphalt sheets, including: 1. Full adhesion to the substrate; 2. Mechanical attachment to the substrate; and 3. Use of a layer of ballast.

[RB] MULTIPLE STATION SMOKE ALARM. Two or more single station alarm devices that are capable of interconnection such that actuation of one causes all integral or separate audible alarms to operate.

❖ A multiple station smoke alarm consists of two or more interconnected single station smoke alarms. When one of the smoke alarms is actuated, all of the audible

alarms sound. Most dwelling units will require several smoke alarms throughout the unit; Section R314.4 requires that they be interconnected.

[RB] NAILABLE SUBSTRATE. A product or material such as framing, sheathing or furring, composed of wood or wood-based materials, or other materials and fasteners providing equivalent fastener withdrawal resistance.

❖ Throughout this code, the integrity of a nail or fastener connection is dependent upon the product or material that a nail or fastener penetrates. This definition simply states that the nailable substrate must produce an equivalent withdrawal resistance as a wood substrate.

NATURAL DRAFT SYSTEM. A venting system designed to remove flue or vent gases under nonpositive static vent pressure entirely by natural draft.

❖ Natural-draft chimneys and vents do not rely on any mechanical means to convey combustion products to the outdoors. Draft is produced by the temperature difference between the combustion gases (flue gases) and the ambient atmosphere. Hot gases are less dense and more buoyant; therefore, they rise or produce a draft.

[RB] NATURALLY DURABLE WOOD. The heartwood of the following species with the exception that an occasional piece with corner sapwood is permitted if 90 percent or more of the width of each side on which it occurs is heartwood.

❖ Because of their natural ability to resist deterioration, the harder portions of some species of wood are considered to be naturally durable. The code specifies that "occasional" sapwood is permitted if heartwood constitutes 90 percent of each side.

Decay resistant. Redwood, cedar, black locust and black walnut.

❖ Redwood, cedar, black locust and black walnut lumber are known to resist deterioration caused by the action of microbes that enter the wood fibers. The code defines these species of lumber as being decay resistant.

Termite resistant. Alaska yellow cedar, redwood, Eastern red cedar and Western red cedar including all sapwood of Western red cedar.

❖ Redwood and eastern red cedar are considered to be resistant to infestation by termites and are thus listed as naturally durable. The Formosan Termite, however, is capable of destroying all naturally durable species of wood.

[RB] NONCOMBUSTIBLE MATERIAL. Materials that pass the test procedure for defining noncombustibility of elementary materials set forth in ASTM E136.

❖ A material that successfully passes the ASTM E136 test is considered to be noncombustible. The test determines whether a building material will act to aid combustion or add appreciable heat to a fire. A material may have a limited combustible content but not contribute appreciably to a fire; thus, it may still qualify as noncombustible.

[RB] NOSING. The leading edge of treads of stairs and of landings at the top of stairway flights.

- ❖ The code must limit the depth of stair tread nosing. Limiting the extent of the tread nosings results in a stair that is easy to use. If too large, they are a tripping hazard when walking up a stairway, and reduce the effective tread depth when walking down the stairway.

[RB] OCCUPIED SPACE. The total area of all buildings or structures on any *lot* or parcel of ground projected on a horizontal plane, excluding permitted projections as allowed by this code.

- ❖ The entire floor area of a building is generally the occupied space. It encompasses all floor levels, including basements. Any exterior space without exterior walls that is covered by a roof or floor above is occupied space. Only those areas beneath roof projections commonly known as eaves or overhangs, including, but not limited to those permitted by Section R302, do not contribute to the total occupied space.

OFFSET. A combination of fittings that makes two changes in direction, bringing one section of the pipe out of line and into a line parallel with the other section.

- ❖ Offsets are necessary to route piping around or through structural elements such as beams, joists, trusses and columns. An offset always involves at least two changes in direction; this is necessary to keep the piping heading in the same direction as the pipe before the offset. Any other arrangement would be considered a bend.

ON-SITE NONPOTABLE WATER REUSE SYSTEMS.

Water systems for the collection, treatment, storage, distribution, and reuse of nonpotable water generated on site, including but not limited to graywater systems. This definition does not include rainwater harvesting systems.

- ❖ There are a number of water sources that can be generated by the operation or occupancy of a building. The first source that comes to mind is usually gray water (see definition for “Gray water”). But there could be many other sources such as heat exchanger cooling water and air-conditioning condensate. If it is water-based liquid and is not black water (that which contains fecal matter or urine), it could possibly be used for another purpose. Whether or not all sources can be used depends on how much the water needs to be treated to make it suitable for an end use, the feasibility of collecting the water and the jurisdiction’s allowances for using such water for end uses.

[RB] OWNER. Any person, agent, firm or corporation having a legal or equitable interest in the property.

- ❖ This term defines the person or other legal entity who is responsible for a building and its compliance with code requirements. The code places certain responsibilities on the owner in the construction and maintenance of a building. The owner is considered the individual, firm or corporation who, under applicable laws, has a legal interest in the property.

[RB] PAN FLASHING. Corrosion-resistant flashing at the base of an opening that is integrated into the building exterior wall to direct water to the exterior and is premanufactured, fabricated, formed or applied at the job site.

- ❖ Pan flashing is the code-prescribed method of flashing for fenestration. It is required if there are no manufacturer’s instructions for any other type of flashing (see Section R703.8.5).

[RB] PANEL THICKNESS. Thickness of core plus two layers of structural wood panel facings.

- ❖ Structural insulated panels (SIPs) have been in use in building construction for some time, but are relatively new. This term is defined to facilitate requirements for SIPs.

PELLET FUEL-BURNING APPLIANCE. A closed combustion, vented *appliance* equipped with a fuel feed mechanism for burning processed pellets of solid fuel of a specified size and composition.

- ❖ This is an appliance that uses solid fuel in the form of pellets in a closed combustion system. The pellets consist of a blend of wood waste products (sawdust and chips) mixed with resin (binders) and compressed into small pellets. The pellets are fed into the appliance in a regulated manner to provide consistent burning.

PELLET VENT. A vent *listed* and *labeled* for use with a *listed* pellet fuel-burning *appliance*.

- ❖ See the commentary to the definition for “Vent.”

[RB] PERFORMANCE CATEGORY. A designation of wood structural panels as related to the panel performance used in Chapters 4, 5, 6 and 8.

- ❖ This is a nomenclature that reflects the newest versions of National Standards DOC PS 1 and PS 2 for wood structural panels. Wood structural panels are required to be in conformance to DOC PS 1 and PS 2 in the code. The DOC PS 1 and PS 2 consensus standards now include the terminology of “performance category” to reference the thicknesses tolerance consistent with the nominal panel thicknesses in the IBC.

[RB] PERMIT. An official document or certificate issued by the authority having jurisdiction that authorizes performance of a specified activity.

- ❖ The Department of Building Safety is authorized to require a permit according to Section R105. The permit constitutes a license issued by the building official to proceed with a specific activity, such as construction of a building, in accordance with all applicable laws.

For the IRC, the building official is identified as the person responsible for issuing the permit.

[RB] PERSON. An individual, heirs, executors, administrators or assigns, and a firm, partnership or corporation, its or their successors or assigns, or the agent of any of the aforesaid.

- ❖ As used in the IRC, a person is not only an individual but also any heirs, executors, administrators, firm, partnership or corporation, including its or their suc-

DEFINITIONS

cessors or assigns. An agent for any person as described is also a “person.” Corporations and other organizations listed in the definition are treated as persons under the law. Also, when the code provides for a penalty (see Section R113.4), the definition makes it clear that the individuals responsible for administering the activities of these various organizations are subject to these penalties.

[RB] PHOTOVOLTAIC MODULE. A complete, environmentally protected unit consisting of solar cells, optics and other components, exclusive of a tracker, designed to generate DC power where exposed to sunlight.

- ❖ Technologies for generation of electricity from solar power include photovoltaic modules or shingles (see Section R902.4).

[RB] PHOTOVOLTAIC PANEL. A collection of photovoltaic modules mechanically fastened together, wired, and designed to provide a field-installable unit.

- ❖ See the definition of “Photovoltaic panel system” and Sections R324, R902.4, R907 and R909.

[RB] PHOTOVOLTAIC PANEL SYSTEM. A system that incorporates discrete photovoltaic panels that convert solar radiation into electricity, including rack support systems.

- ❖ See the definition of “Photovoltaic panel” and Sections R324, R907 and R909.

[RB] PHOTOVOLTAIC SHINGLES. A *roof covering* that resembles shingles and that incorporates photovoltaic modules.

- ❖ See Sections R324.5.1 and R905.16.

PITCH. See “Slope.”

- ❖ The pitch of a pipe run is the fall of the pipe in relationship to a horizontal plane. It is also known as the slope and is measured as a ratio between change in horizontal units and vertical units along a length of pipe.

[RB] PLASTIC COMPOSITE. A generic designation that refers to wood-plastic composites and plastic lumber.

[RB] PLATFORM CONSTRUCTION. A method of construction by which floor framing bears on load bearing walls that are not continuous through the *story* levels or floor framing.

- ❖ In light-frame construction, platform construction is the technique of stacking floor systems on load-bearing stud walls. As opposed to walls in balloon construction, the load-bearing walls in platform construction do not continue beyond each individual story level. Platform construction is by far the most popular framing method in use today.

PLENUM. A chamber that forms part of an air-circulation system other than the *occupied space* being conditioned.

- ❖ A plenum is part of an HVAC air circulation system and is typically a box built from ductwork material. Plenums commonly connect to the inlet and outlet side of furnaces and air handlers. Plenums can also be cavities in stud walls, spaces between solid joists and similar interstitial spaces (see Section M1601).

PLUMBING. For the purpose of this code, plumbing refers to those installations, repairs, maintenance and *alterations* regulated by Chapters 25 through 33.

- ❖ This term refers to the collective system of piping, fixtures, fittings, components, devices or appurtenances that transport potable water and liquid and solid wastes associated with cleaning, washing, bathing, food preparation, drinking and the elimination of bodily wastes. Plumbing also includes appliances, equipment and systems such as water conditioners, water heaters, storm drainage systems, water coolers, water filters and waste treatment systems.

The word “plumbing” comes from the Latin word for the element lead (plumbum), because lead was used extensively in the construction of piping systems. The practice of installing piping systems and the materials used in such systems became known as plumbing.

Piping systems such as fuel gas, fuel oil, heating, cooling, air conditioning, lawn irrigation and fire suppression systems are not plumbing, even though plumbers often perform the work necessary to install these systems. Chapters 25 to 32 regulate plumbing.

PLUMBING APPLIANCE. An energized household *appliance* with plumbing connections, such as a dishwasher, food waste disposer, clothes washer or water heater.

- ❖ Examples of plumbing appliances include water heaters, hot water dispensers, garbage disposals, dishwashers, clothes washers, water purifiers and water softeners. Typically, an appliance is dependent on a source of energy for its operation.

PLUMBING APPURTENANCE. A device or assembly that is an adjunct to the basic plumbing system and does not demand additional water supply or add any discharge load to the system. It is presumed that it performs some useful function in the operation, maintenance, servicing, economy or safety of the plumbing system. Examples include filters, relief valves and aerators.

- ❖ Examples of plumbing appurtenances include water closet seats, hand-held showers, manifolds, backflow preventers, water-hammer arrestors, strainers and filters. An appurtenance by default becomes part of the entire fixture.

PLUMBING FIXTURE. A receptacle or device that is connected to a water supply system or discharges to a drainage system or both. Such receptacles or devices require a supply of water; or discharge liquid waste or liquid-borne solid waste; or require a supply of water and discharge waste to a drainage system.

- ❖ This definition encompasses the variety of plumbing fixtures that could be installed in a building. The most common type of plumbing fixture has a supply of water connected to it and is connected to the drain system. Examples are water closets, lavatories and bathtubs. Nonwater-supplied (waterless) urinals, floor sinks and floor drains are fixtures that only require connection to the drain system. An outdoor shower discharging to the ground is an example of a plumbing fixture that is connected only to a supply of water.

PLUMBING SYSTEMS. Includes the water distribution pipes; plumbing fixtures and traps; water-treating or water-using *equipment*; soil, waste and vent pipes; and building drains; in addition to their respective connections, devices and appurtenances within a structure or premises; and the water service, building sewer and building storm sewer serving such structure or premises.

- ❖ The plumbing system includes all piping, fixtures and components that transport potable water and convey liquid and liquid-borne solid wastes (see “Plumbing”). Devices that treat the water prior to its use are also included.

POLLUTION. A low-hazard or non-health hazard impairment of the quality of the potable water to a degree that does not create a hazard to the public health and that does adversely and unreasonably affect the aesthetic qualities of such potable water for domestic use.

- ❖ Books have been written trying to define the term “pollution.” For use in the code, pollution is anything that reduces the quality of the potable water supply so that it is undesirable for consumption or use. A pollutant in the water supply causes the water to look, smell or taste bad, but drinking the water would not be harmful. This does not change the fact that polluted water is still considered to be nonpotable. Pollutants are thus not considered potentially harmful, whereas a contaminant would be considered potentially harmful. Refer to the definition of the term “Contamination” to find additional information and the differences between pollution and contamination.

The methods for determining potable and nonpotable water supplies are very closely regulated by the EPA. For the purposes of protecting a water supply, the code considers a polluted source to represent a low hazard when selecting a backflow preventer.

[RB] POLYPROPYLENE SIDING. A shaped material, made principally from polypropylene homopolymer, or copolymer, that in some cases contains fillers or reinforcements, that is used to clad *exterior walls* or buildings.

- ❖ For information on the material standards and installation for this product (see the commentary to Section R703.14).

PORTABLE-FUEL-CELL APPLIANCE. A fuel cell generator of electricity that is not fixed in place. A portable-fuel-cell *appliance* utilizes a cord and plug connection to a grid-isolated load and has an integral fuel supply.

- ❖ These appliances are a smaller version of the stationary fuel cell power plants in Section M1903 of this code. Fuel cells generate electricity from hydrocarbon fuels and, when pure hydrogen is used, release water and heat as the only by-products. Portable fuel cell appliances are generally fueled by gas tanks or some other local source and are connected to the house current or are used only to charge the batteries of electric cars. Connecting the appliance to the local electrical

power grid or hard-piping fuel to the appliance would constitute a permanent installation and require permitting in accordance with Section 105.

[RB] POSITIVE ROOF DRAINAGE. The drainage condition in which consideration has been made for the loading deflections of the roof deck, and additional slope has been provided to ensure drainage of the roof within 48 hours of precipitation.

- ❖ Unless a roof is designed to support a specified amount of water, adequate drainage must be provided to approved locations. In considering the appropriate drainage pattern, all of the possible roof deck deflections should be included. The code mandates that the water be removed from the roof within a period of 48 hours from the time of deposit.

POTABLE WATER. Water free from impurities present in amounts sufficient to cause disease or harmful physiological effects and conforming in bacteriological and chemical quality to the requirements of the public health authority having jurisdiction.

- ❖ In the United States, the EPA Clean Drinking Water Act defines the quality requirements for potable water. “Potable” means fit to drink.

[RB] PRECAST CONCRETE. A structural concrete element cast elsewhere than its final position in the structure.

- ❖ Precast concrete members may be cast on site and subsequently lifted into place (e.g., tilt-up wall construction) or cast off site, usually in a plant out of the outside weather and transported to the construction site when needed. Precast concrete which has been manufactured under plant conditions has closer controlled tolerances than cast-in-place concrete construction. This results in the need for lesser minimum concrete cover for reinforcement versus that needed for cast-in-place concrete (see ACI 318, Sections 7.7.1 and 7.7.2).

[RB] PRECAST CONCRETE FOUNDATION WALLS. Pre-engineered, precast concrete wall panels that are designed to withstand specified stresses and used to build below-*grade* foundations.

- ❖ Foundation walls are required to carry specific loads. Often, the foundation wall can be constructed of precast concrete. Precast concrete foundation walls therefore are addressed specifically in several areas of the code.

PRESSURE-RELIEF VALVE. A pressure-actuated valve held closed by a spring or other means and designed to automatically relieve pressure at the pressure at which it is set.

- ❖ This valve is designed to be actuated by excessive pressures for the purpose of preventing the rupture or explosion of tanks, vessels or piping. The degree of valve opening is directly proportional to the pressure acting on the valve disk.

DEFINITIONS

PUBLIC SEWER. A common sewer directly controlled by public authority.

- ❖ A public sewer is the piping system that receives the discharge from building sewers and conveys it to treatment facilities.

PUBLIC WATER MAIN. A water-supply pipe for public use controlled by public authority.

- ❖ A water main is owned and operated by municipalities, rural water districts, privately owned water purveyors and other such entities.

[RB] PUBLIC WAY. Any street, alley or other parcel of land open to the outside air leading to a public street, that has been deeded, dedicated or otherwise permanently appropriated to the public for public use and that has a clear width and height of not less than 10 feet (3048 mm).

- ❖ A public way is essentially a street, alley or any parcel of land that is permanently appropriated to the public for public use. Therefore, the public's right to use such a parcel of land is guaranteed. A public way is open to the exterior and available for use as an egress path if necessary. To qualify as a public way, the space must be at least 10 feet (3048 mm) wide and must have a clear height of at least 10 feet (3048 mm).

PURGE. To clear of air, gas or other foreign substances.

- ❖ This term applies to a process used for clearing piping systems of impurities, making the system pure prior to the introduction of a desired substance. Although the practice of flushing a system to remove debris is sometimes referred to as purging the system, true purging involves a specific process of forcing a product into a system until impurities are completely removed. One such method would be the introduction of nitrous gas within a copper system serving a medical gas installation. Such a purge is required to clear the system of impurities that may have been left during installation.

QUICK-CLOSING VALVE. A valve or faucet that closes automatically when released manually or controlled by mechanical means for fast-action closing.

- ❖ A quick-closing valve is any type of solenoid-actuated valve; spring-loaded, self-closing faucets; or any other device capable of instantaneously reducing water flow from full flow to no flow. This rapid change from a full-flow to a no-flow condition can cause water-hammer-related damage. Although most faucets can be manually closed fast enough to produce water hammer, the code does not designate manually closed valves or faucets as "quick closing."

Typical quick-closing valves include electrically actuated valves such as those found in dishwashing machines, clothes washing machines and boiler makeup-water feeders. Some self-closing valves and faucets are not quick closing. For example, typical metering faucets and typical flushometer valves are slowly, automatically closed by a diaphragm/bleed ori-

fice or pilot valve assembly. Also, a typical float-actuated valve is automatic yet slow in closing.

[RE] R-VALUE, THERMAL RESISTANCE. The inverse of the time rate of heat flow through a *building thermal envelope* element from one of its bounding surfaces to the other for a unit temperature difference between the two surfaces, under steady state conditions, per unit area ($h \cdot ft^2 \cdot ^\circ F/Btu$).

- ❖ The *R*-value is a unit of thermal resistance used for comparing insulating values of different materials. The higher the *R*-value of a material, the greater its insulating properties and the slower heat flows through it. *R*-values are used to rate roof/ceiling, wall and floor insulation.

[RB] RAMP. A walking surface that has a running slope steeper than 1 unit vertical in 20 units horizontal (5-percent slope).

- ❖ A pedestrian travel surface that has a slope of 1:20 (5 percent) or less is a walking surface. A surface that is steeper than 1 unit vertical in 20 units horizontal is a ramp. Because steeply sloping walking surfaces present a considerable hazard to users, ramps are regulated for maximum slope, handrails and landings by Section R311.8 and its subsections.

[RE] RATED DESIGN. A description of the proposed *building*, used to determine the energy rating index.

- ❖ This is the description of a proposed building in the application of the Energy Rating Index Compliance Alternative in Section N1106 (see the commentary to Section N1106).

RECEPTOR. A fixture or device that receives the discharge from indirect waste pipes.

- ❖ This term applies to a fixture used for collecting drainage from fixtures that are not directly connected to the drainage system. A floor sink is the most common type of receptor. However, a laundry sink that is used for collecting the drainage from a clothes washer could be defined as a receptor.

RECLAIMED WATER. Nonpotable water that has been derived from the treatment of waste water by a facility or system licensed or permitted to produce water meeting the *jurisdiction's* water requirements for its intended uses. Also known as "Recycled Water."

- ❖ For many decades, reclaimed water has been used for golf course irrigation in many jurisdictions. In the early days, those jurisdictions prohibited the use of reclaimed water for any purpose inside of buildings because of concerns about disinfection, the potential for the spread of what was thought to be "harmful" components in the water and the uncertainty about how to prevent such water from being inadvertently used for a potable water application. Many studies have been performed to allay the initial concerns and the color purple has been chosen to identify the piping and components that convey nonpotable water.

[RE] REFLECTIVE DUCT INSULATION. A thermal insulation assembly consisting of one or more surfaces that have an emittance of 0.1 or less, and that bound an enclosed air space or spaces.

- ❖ This type of insulation material is an assembly consisting of two membranes separated by a layer of closed cell plastic insulation. The two membranes are made of highly reflective metal foil or metalized plastic. The insulation value is created by the air trapped in the plastic bubbles of the center layer combined with the reflective nature of the outer membranes.

REFRIGERANT. A substance used to produce refrigeration by its expansion or evaporation.

- ❖ The refrigerant is the working fluid in refrigeration and air-conditioning systems. In vapor-refrigeration cycles, refrigerants absorb heat from the load side at the evaporator and reject heat at the condenser. The selection of a refrigerant must take into consideration suitable thermodynamic properties, chemical stability, flammability, toxicity and environmental compatibility. Refrigeration is a result of the physical laws of vaporization (evaporation) of liquids. Basically, evaporation of liquid refrigerant is an endothermic process, and condensing of vapors is an exothermic process.

REFRIGERANT COMPRESSOR. A specific machine, with or without accessories, for compressing a given refrigerant vapor.

- ❖ A compressor is the heart of mechanical refrigeration systems. It is used in a vapor-refrigeration cycle to raise the pressure and enthalpy of the refrigerant into the superheated vapor state, at which point the refrigerant vapor enters the condenser and transfers heat energy to a cooler medium.

REFRIGERATING SYSTEM. A combination of interconnected parts forming a closed circuit in which refrigerant is circulated for the purpose of extracting, then rejecting, heat. A direct refrigerating system is one in which the evaporator or condenser of the refrigerating system is in direct contact with the air or other substances to be cooled or heated. An indirect refrigerating system is one in which a secondary coolant cooled or heated by the refrigerating system is circulated to the air or other substance to be cooled or heated.

- ❖ Such systems include at minimum a pressure-imposing element or generator, an evaporator, a condenser and interconnecting piping. A single piece of equipment can contain multiple refrigeration systems (circuits).

[RB] REGISTERED DESIGN PROFESSIONAL. An individual who is registered or licensed to practice their respective design profession as defined by the statutory requirements of the professional registration laws of the state or *jurisdiction* in which the project is to be constructed.

- ❖ Legal qualifications for engineers and architects are established by the state having jurisdiction. Licensing and registration of engineers and architects are accomplished by written or oral examinations offered by states or by reciprocity (licensing in other states).

An individual who meets the statutory requirements in the laws of the state, and possibly even an individual jurisdiction, is a registered design professional.

RELIEF VALVE, VACUUM. A device to prevent excessive buildup of vacuum in a pressure vessel.

- ❖ This device will automatically open to allow air into a vessel or system in the event of backsiphonage. Such a device is used where a water heater without an anti-siphon drip tube is installed above the fixtures served. Where the water supply to the water heater is closed and the lower fixtures opened, the vacuum relief valve will open, thus breaking the siphoning effect.

[RB] REPAIR. The reconstruction or renewal of any part of an existing building for the purpose of its maintenance or to correct damage.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ When an existing building undergoes some form of remodel, reconstruction, renewal or maintenance to correct damage, the work is defined as a repair. A repair maintains a portion of the building in safe and sound working order, without reducing the intended level of protection or structural safety. Major repair work may be subject to a permit where required by Section R105.

As indicated in Section R105.2.2, the repair of an item typically does not require a permit. This definition makes it clear that repair is limited to work on the item, and does not include complete or substantial replacement or other new work.

[RB] REROOFING. The process of recovering or replacing an existing roof covering. See “Roof recover.”

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ The description of reroofing includes two different processes: 1. Recovering an existing roof covering; and 2. Replacing an existing roof covering. Recovering involves the installation of an additional roof covering over an existing roof covering without the removal of the existing roof covering. Replacement addresses those cases where the existing roof covering is completely removed prior to installation of the new roof covering.

RETURN AIR. Air removed from an *approved conditioned space* or location and recirculated or exhausted.

- ❖ Return air is air that is being returned to the air handler. Only air in excess of the required ventilation air can be recirculated.

[RB] RIDGE. With respect to topographic wind effects, an elongated crest of a hill characterized by strong relief in two directions.

- ❖ This is a term to describe a topographical area where wind speed-up can occur. In cases where there is known to be structural damage due to this type of wind speed-up, the code requires consideration of topographical wind effects (see Section R301.2.1.5).

DEFINITIONS

[RB] RISER.

1. The vertical component of a step or stair.
2. A water pipe that extends vertically one full *story* or more to convey water to branches or to a group of fixtures.

[RB] ROOF ASSEMBLY. A system designed to provide weather protection and resistance to design loads. The system consists of a roof covering and roof deck or a single component serving as both the roof covering and the roof deck. A roof assembly includes the roof deck, vapor retarder, substrate or thermal barrier, insulation, vapor retarder, and roof covering.

- ❖ A roof assembly may be either a single component serving as both the roof covering and the deck or, as typically occurs, a combination of individual roof deck and roof covering components used together to form a complete assembly. A roof assembly may include the roof deck, vapor retarder, substrate, thermal barrier, insulation and roof covering.

[RB] ROOF COVERING. The covering applied to the roof deck for weather resistance, fire classification or appearance.

- ❖ Roof covering provides a building with weather protection, fire retardancy or decoration.

ROOF COVERING SYSTEM. See “Roof assembly.”

- ❖ “Roof covering system” is another term for “Roof assembly.”

[RB] ROOF DECK. The flat or sloped surface not including its supporting members or vertical supports.

- ❖ Often composed of wood structural panels, a roof deck is the flat or sloped surface on which roof covering is typically attached. Roof decks assist in both the weather protection and structural integrity of the building. The rafters and associated structural roof members are not a part of the roof deck, nor is the insulation or roof covering that is placed on the deck.

[RB] ROOF RECOVER. The process of installing an additional roof covering over a prepared existing roof covering without removing the existing roof covering.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ Under the provisions of Section R908, it is acceptable under specific conditions to install new roof covering over an existing roof without first removing the old roof covering. In a roof recover, the existing roof covering must be prepared in an approved manner prior to installation of the new roof covering.

[RB] ROOF REPAIR. Reconstruction or renewal of any part of an existing roof for the purposes of its maintenance.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ A roof repair occurs when only minor reconstruction or renewal work to an existing roof is necessary. The extent of a roof repair is limited by Section R908.1.

[RB] ROOF REPLACEMENT. The process of removing the existing *roof covering*, repairing any damaged substrate and installing a new *roof covering*.

- ❖ Roof replacement refers to the replacement of the roof covering.

[RB] ROOFTOP STRUCTURE. An enclosed structure on or above the roof of any part of a building.

- ❖ Often used to house mechanical equipment or installed for decorative purposes, a rooftop structure is any enclosed structure on or above the roof. A rooftop structure must be adequately supported and comply with the construction provisions applicable to the remainder of the building.

ROOM HEATER. A freestanding heating *appliance* installed in the space being heated and not connected to ducts.

- ❖ Room heaters are space-heating appliances that are not connected to ducts. They are also called “unvented room heaters.”

ROUGH-IN. The installation of the parts of the plumbing system that must be completed prior to the installation of fixtures. This includes DWV, water supply and built-in fixture supports.

- ❖ Rough-in refers to that stage of construction prior to the installation of any building materials that would conceal plumbing installations in the building structure. This term generally refers to the installation of drain, waste, vent and water supply piping that will be concealed in floor, ceiling and wall cavities or concealed underground or under slab. At this stage of construction, the plumbing systems are tested for leaks and the entire plumbing “rough-in” is inspected for code compliance.

[RB] RUNNING BOND. The placement of masonry units such that head joints in successive courses are horizontally offset not less than one-quarter the unit length.

- ❖ A common method of placing masonry units, running bond describes the type of masonry construction where the units are horizontally offset on each successive course. The length of the offset must be at least one-fourth the length of the masonry unit, otherwise it is considered as stack bond. Commentary Figure R202(14) shows an example of running bond.

SANITARY SEWER. A sewer that carries sewage and excludes storm, surface and groundwater.

- ❖ A sanitary sewer extends from the sanitary building drain to the public sewer system or to a private sewage disposal system. Most jurisdictions arbitrarily set a distance such as 3 or 5 feet (914 or 1524 mm) outside of the building foundation as the point at which the building drain becomes the building sewer.

SCUPPER. An opening in a wall or parapet that allows water to drain from a roof.

- ❖ Various design methods are used to drain water from a roof. A common approach is to slope the roof toward one or more exterior walls and provide drainage over the edge of the roof, often into a gutter and downspout system. Another method is the use of roof drains that capture water from numerous low points of the roof and use interior drain lines to remove the water. A third procedure is the use of scuppers, which are openings in the exterior wall surface that allow water to flow off the roof.

Where scuppers are used, the code specifies their size and height above the roof. Scuppers are often included as a portion of the overflow or emergency drain system, a system required by the code and designed to shed water when the primary roof drains are blocked.

[RB] SEISMIC DESIGN CATEGORY (SDC). A classification assigned to a structure based on its occupancy category and the severity of the design earthquake ground motion at the site.

- ❖ The structural provisions of the IRC vary based on several factors, one of which is the probability of an earth-

quake causing damage to the building. The term used by the code to assign a rating or level of seismic risk is "Seismic design category." Classification into one of the categories is based on two factors: 1. The Seismic Group; and 2. The severity of the ground motion at the site. The Seismic Group is the classification assigned based upon use of the structure. Residential construction is considered in Seismic Group I, with Groups II and III assigned to structures whose loss would create a substantial public hazard or those structures considered as essential facilities. The ground-motion criterion used in the IRC is based on Short Period Design Spectral Response Accelerations (0.2 second). Section 1613 of the IBC contains further explanation of the seismic considerations.

SEPTIC TANK. A water-tight receptor that receives the discharge of a building sanitary drainage system and is constructed so as to separate solids from the liquid, digest organic matter through a period of detention, and allow the liquids to discharge into the soil outside of the tank through a system of open joint or perforated piping or a seepage pit.

- ❖ This type of tank is typically used in private sewage disposal systems (see Appendix I).

SEWAGE. Any liquid waste containing animal matter, vegetable matter or other impurity in suspension or solution.

- ❖ This term refers to the discharge from all plumbing fixtures, which includes human bodily wastes and the wastes associated with cleaning, washing, bathing and food preparation.

SEWAGE PUMP. A permanently installed mechanical device for removing sewage or liquid waste from a sump.

- ❖ Sewage pumps are designed to transport liquid/solid mixtures without clogging and are typically equipped with large suction and discharging ports.

[RB] SHALL. The term, where used in the code, is construed as mandatory.

- ❖ The term "shall" means that the requirement is a mandatory provision. Where a provision is allowed but not required, the term "is permitted" generally appears in the code.

[RB] SHEAR WALL. A general term for walls that are designed and constructed to resist racking from seismic and wind by use of masonry, concrete, cold-formed steel or wood framing in accordance with Chapter 6 of this code and the associated limitations in Section R301.2 of this code.

- ❖ Shear walls are walls designed to carry lateral loads such as seismic or wind loads. Shear walls may be of a variety of materials; however, they must be designed in the specific manner required by the code. Shear walls are typically used in conjunction with diaphragms to provide a load path for transmitting lateral loads through the structure.

DEFINITIONS

[RB] SINGLE PLY MEMBRANE. A roofing membrane that is field applied using one layer of membrane material (either homogeneous or composite) rather than multiple layers.

- ❖ In contrast to a built-up roof, a single-ply membrane roof system consists of one layer of membrane material. Chapter 9 addresses both thermoset and thermoplastic single-ply roofing systems.

[RB] SINGLE STATION SMOKE ALARM. An assembly incorporating the detector, control *equipment* and alarm sounding device in one unit that is operated from a power supply either in the unit or obtained at the point of installation.

- ❖ A single-station smoke alarm contains all components for operation of the device, including the power supply in battery-operated units. For a hard-wired unit, the power is available directly at the alarm device. Where two or more single-station smoke alarms are interconnected, they are multiple-station alarms.

[RB] SHINGLE FASHION. A method of installing roof or wall coverings, water-resistive barriers, flashing or other building components such that upper layers of material are placed overlapping lower layers of material to provide drainage and protect against water intrusion at unsealed penetrations and joints or in combination with sealed joints.

- ❖ This term and definition is also used in the IBC to describe the required method of applying moisture control layers such as roof underlayment and water-resistive barriers (WRBs) to the building. The intent is to direct the builder, contractor or installer to place upper layers of material lapping over lower layers of material, in the fashion of placing roof shingles, so moisture is provided with a clear path to drain down and away from the building. In field investigations of buildings with mold and moisture issues, it is frequently discovered that flashing, WRBs or underlayment have been placed in reverse shingle fashion, with the upper layer tucked behind the lower layer. This permits moisture to drain behind or below the intended protective layer or material where it can be trapped and lead to mold and decay of building components.

[RE] SKYLIGHT. See Section N1101.6 for definition applicable in Chapter 11.

[RB] SKYLIGHT AND SLOPED GLAZING. Glass or other transparent or translucent glazing material installed at a slope of 15 degrees (0.26 rad) or more from vertical. Glazing materials in skylights, including unit skylights, tubular daylighting devices, solariums, sunrooms, roofs and sloped walls are included in this definition.

- ❖ Any glass or other transparent or translucent glazing installed in the building construction at a slope greater than 15 degrees from the vertical is sloped glazing. Skylights are the most common type of sloped glazing, which may also include tubular daylighting devices, solariums, sun rooms, roofs and sloped walls.

[RB] SKYLIGHT, UNIT. A factory assembled, glazed fenestration unit, containing one panel of glazing material, that allows for natural daylighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof.

[RE] SLEEPING UNIT. See Section N1101.6 for definition applicable in Chapter 11.

SLIP JOINT. A mechanical-type joint used primarily on fixture traps. The joint tightness is obtained by compressing a friction-type washer such as rubber, nylon, neoprene, lead or special packing material against the pipe by the tightening of a (slip) nut.

- ❖ A slip joint is commonly found in fixture tailpieces and in “P” traps (see the commentary to Section P2704).

SLOPE. The fall (pitch) of a line of pipe in reference to a horizontal plane. In drainage, the slope is expressed as the fall in units vertical per units horizontal (percent) for a length of pipe.

- ❖ Commonly referred to as pitch, fall or grade, slope is the gradual change in elevation of horizontal piping. Slope is necessary to cause waste flow by gravity.

[RB] SMOKE-DEVELOPED INDEX. A comparative measure, expressed as a dimensionless number, derived from measurements of smoke obscuration versus time for a material tested in accordance with ASTM E84 or UL 723.

- ❖ The ASTM E84 (or UL 723) test standard for flame spread also addresses the potential for smoke development of specific materials. The numerical value assigned to the material being tested, based on the density of the smoke produced during the test, is the smoke-developed rating, which is typically regulated in conjunction with the flame spread index.

SOIL STACK OR PIPE. A pipe that conveys sewage containing fecal material.

- ❖ In the plumbing trade, “soil pipe” is a common name for cast-iron drainage pipe. The term, however, is not specific to cast-iron pipe and refers to any drainpipe that conveys the discharge of water closets, urinals or any other fixture that receives human waste.

[RE] SOLAR HEAT GAIN COEFFICIENT (SHGC). The solar heat gain through a fenestration or glazing assembly relative to the incident solar radiation ($\text{Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}$).

- ❖ The solar heat gain coefficient (SHGC) measures the ratio of the solar radiation that passes through the window to the total solar radiation that strikes the window. Sunlight, or solar radiation, striking a window contains visible light and heat. As the sunlight strikes the window, a portion of the visible light and heat passes through into the building. A portion of the heat is absorbed by the glass and window sash. Moreover, a portion of the visible light and heat is reflected to the outdoors. The lower the SHGC, the lower the solar radiation that is allowed to pass through the window. For example, a window with an SHGC value of 0.40 allows only 40 percent of the total solar radiation that strikes the window to pass through.

[RB] SOLID MASONRY. Load-bearing or nonload-bearing construction using masonry units where the net cross-sectional area of each unit in any plane parallel to the bearing surface is not less than 75 percent of its gross cross-sectional area. Solid masonry units shall conform to ASTM C55, C62, C73, C145 or C216.

❖ Solid masonry can consist of either load-bearing or nonload-bearing construction made up of masonry units. Although not required to be totally of solid material, solid masonry must have a net cross-sectional area equal to at least 75 percent of its gross cross-sectional area. The percentage must be maintained in any plane parallel to the bearing surface.

[RB] SPLINE. A strip of wood structural panel cut from the same material used for the panel facings, used to connect two structural insulated panels. The strip (spline) fits into a groove cut into the vertical edges of the two structural insulated panels to be joined. Splines are used behind each facing of the structural insulated panels being connected as shown in Figure R613.8.

❖ Structural insulated panels are relatively new to the code. Terminology describing components of the panel is necessary to facilitate provisions to regulate the material.

STACK. Any main vertical DWV line, including offsets, that extends one or more stories as directly as possible to its vent terminal.

❖ Traditionally, the term “stack” has been used to describe vertical piping [90 degrees (1.57 rad) from the horizontal] that extends through one or more stories of a building and that constitutes a main to which branch piping connects. Vertical vent branch piping that extends to the open air or through two or more stories is a stack.

[RB] STACK BOND. The placement of masonry units in a bond pattern is such that head joints in successive courses are vertically aligned. For the purpose of this code, requirements for stack bond shall apply to all masonry laid in other than running bond.

❖ Where the head joints in successive courses of masonry construction are not offset horizontally by at least one-fourth of the unit length, the method of placement is a stack bond. Vertical joints directly aligned on each course are typical in stack bond masonry.

STACK VENT. The extension of soil or waste stack above the highest horizontal drain connected.

❖ A stack vent is the dry extension of a soil or waste stack. Generally, a stack vent extends to the open air and can serve as a main vent to which branch vents connect.

[RB] STAIR. A change in elevation, consisting of one or more risers.

❖ All steps, even a single step, are defined as a stair. This makes the stair requirements applicable to all steps unless specifically exempt in the code.

[RB] STAIRWAY. One or more flights of stairs, either interior or exterior, with the necessary landings and connecting platforms to form a continuous and uninterrupted passage from one level to another within or attached to a building, porch or deck.

❖ It is important to note that this definition characterizes a stairway as connecting one level to another. The term “level” is not to be confused with “story.” Steps that connect two levels, one of which is not considered a “story” of the structure, would be considered a stairway. For example, a set of steps between the basement level in an areaway and the outside ground level would be considered a stairway. A series of steps between the floor of a story and a mezzanine within that story would also be considered a stairway.

[RB] STAIRWAY, SPIRAL. A stairway with a plan view of closed circular form and uniform section-shaped treads radiating from a minimum-diameter circle.

❖ This definition determines the specific plan view geometry for the type of stairs that are to be regulated by Section R311.7.10.1. These space-saving stairs have a preferred walking path at the outside perimeter. This definition is not intended to restrict the use of a center column in spiral stairs.

[RB] STANDARD TRUSS. Any construction that does not permit the roof-ceiling insulation to achieve the required *R*-value over the *exterior walls*.

❖ The term “standard truss” describes typical roof truss construction where the insulation cannot achieve the necessary *R*-value mandated for the roof-ceiling assembly.

STATIONARY FUEL CELL POWER PLANT. A self-contained package or factory-matched packages that constitute an automatically-operated assembly of integrated systems for generating useful electrical energy and recoverable thermal energy that is permanently connected and fixed in place.

❖ Fuel cells generate electricity from hydrocarbon fuels and, when pure hydrogen is used, release water and heat as the only by-products (see commentary to Section M1903 for a description of the conversion process). Stationary fuel cell appliances cannot exceed 1000 kW of power output, listed and tested in accordance with ANSI Z21.83 and installed in accordance with NFPA 853 and the manufacturer’s instructions. These appliances may be independent of or connected to the local electrical power grid and may be fueled by fuel tanks or permanent piping systems.

STORM SEWER, DRAIN. A pipe used for conveying rainwater, surface water, subsurface water and similar liquid waste.

❖ This is the general term used to describe the piping that conducts rainwater or surface-water waste from structures to the point of disposal.

DEFINITIONS

[RB] STORY. That portion of a building included between the upper surface of a floor and the upper surface of the floor or roof next above.

❖ A story is that portion of a building from a floor surface to the floor surface or roof above. In the case of the top-most story, the height of the story is measured from the floor surface to the top of the ceiling joists of an attic. Where a ceiling does not create an attic, such as a cathedral ceiling, the story height is measured to the top of the roof rafters. (see the definition of “Story above grade plane”).

[RB] STORY ABOVE GRADE PLANE. Any story having its finished floor surface entirely above *grade plane*, or in which the finished surface of the floor next above is either of the following:

1. More than 6 feet (1829 mm) *above grade plane*.
2. More than 12 feet (3658 mm) above the finished ground level at any point.

❖ The code defines a “Story above grade plane” as any story having its finished floor surface entirely above grade. However, the critical part of the definition involves whether or not a basement is a story above grade. A level that is a story above grade may be either an inhab-

ited story or unused under-floor space. Two criteria are important to the determination of whether a given floor level is either a story above grade or a basement:

1. If the finished floor above the level under consideration or above the under-floor space is more than 6 feet (1829 mm) above the grade plane as defined in Section R202, the level under consideration is a story above grade.
2. If the finished floor level above the level under consideration or above the under-floor space is more than 12 feet (3658 mm) above the finished ground level at any point, the floor level under consideration or the under-floor space is a story above grade.

Conversely, if the finished floor level above the level under consideration is 6 feet (1829 mm) or less above the grade plane, and is 6 feet (1829 mm) or less above the finished ground level for more than 50 percent of the perimeter and does not exceed 12 feet (3658 mm) at any point, the floor level under consideration is a basement. Or, described a bit differently, a basement is a floor level that does not qualify as a story above grade. Commentary Figure R202(15) illustrates the definition of “Story above grade plane.”

[RB] STRUCTURAL COMPOSITE LUMBER. Structural members manufactured using wood elements bonded together with exterior adhesives.

Examples of structural composite lumber are:

Laminated veneer lumber (LVL). A composite of wood veneer elements with wood fibers primarily oriented along the length of the member, where the veneer element thicknesses are 0.25 inches (6.4 mm) or less.

Parallel strand lumber (PSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member, where the least dimension of the wood strand elements is 0.25 inch (6.4 mm) or less and their average lengths are not less than 300 times the least dimension of the wood strand elements.

Laminated strand lumber (LSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member, where the least dimension of the wood strand elements is 0.10 inch (2.54 mm) or less and their average lengths are not less than 150 times the least dimension of the wood strand elements.

Oriented strand lumber (OSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member, where the least dimension of the wood strand elements is 0.10 inch (2.54 mm) or less and their average lengths are not less than 75 times and less than 150 times the least dimension of the wood strand elements.

- ❖ ASTM D5456 is the standard by which structural composite lumber is evaluated. This definition is consistent with the types of structural composite lumber defined in ASTM D5456. These products are being used as beams, headers, long length studs, floor and roof framing and other applications where high strength, long length and/or dimensional stability make the use of structural composite lumber more desirable than sawn lumber.

[RB] STRUCTURAL INSULATED PANEL (SIP). A structural sandwich panel that consists of a light-weight foam plastic core securely laminated between two thin, rigid wood structural panel facings.

- ❖ Structural insulated panels are construction elements composed of solid-core insulation panels enclosed within structural wood-panel membranes. These panels are fabricated at the factory, then brought to the job site and installed.

[RB] STRUCTURE. That which is built or constructed.

- ❖ This definition is intentionally broad so as to include within its scope—and therefore the scope of the code (see Section R101.2)—everything that is built as an improvement to real property. See also the definition for “Building” for the difference between a building and structure.

[RB] SUBSOIL DRAIN. A drain that collects subsurface water or seepage water and conveys such water to a place of disposal.

- ❖ These drains are generally installed adjacent to the foundation footing of a building. They are intended to

alleviate problems caused by subsurface (ground) water. Additionally, any other piping that collects either subsurface water or seepage would be termed a subsoil drain as well.

SUMP. A tank or pit that receives sewage or waste, located below the normal *grade* of the gravity system and that must be emptied by mechanical means.

- ❖ This is the receiving tank or vessel used to collect and store waste from drainage systems that are incapable of draining by gravity. A sump generally houses an ejector or pump used to evacuate the contents. A sump can refer to a receiver for either waste water or storm water.

SUMP PUMP. A pump installed to empty a sump. These pumps are used for removing storm water only. The pump is selected for the specific head and volume of the load and is usually operated by level controllers.

- ❖ A typical sump pump [see Commentary Figure R202(16)] receives its primary power from the building primary wiring system; however, some are models equipped with a battery or natural-gas-activated backup system. This backup system is helpful during electrical storms or any condition where there is an unexpected loss of power.

[RB] SUNROOM. A one-story structure attached to a *dwelling* with a *glazing area* in excess of 40 percent of the gross area of the structure’s *exterior walls* and roof.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ Sunrooms are unique attached rooms that create a space which differs in character from that provided by conventional additions. Sunrooms and other highly glazed structures are sometimes called conservatories or solariums. This definition distinguishes a sunroom from other conventional structures because they are limited to one-story in height and the total glazing area needs to be at least 40 percent of the exterior wall and roof area. This definition is important because Section R303.2 permits a sunroom addition to be considered for light and ventilation. Sunroom additions are discussed in Section R303.9.1 (see the commentary to “Thermal isolation”).

SUPPLY AIR. Air delivered to a *conditioned space* through ducts or plenums from the heat exchanger of a heating, cooling or ventilating system.

- ❖ As opposed to return air, supply air is delivered to the conditioned space by an air handler and may or may not be returned to the air handler. Supply air can include ventilation air.

SUPPORTS. Devices for supporting, hanging and securing pipes, fixtures and *equipment*.

- ❖ Types of supports include hangers, anchors, braces, brackets, strapping and any other material or device used to support plumbing piping and components.

Figure R202(16)
SUMP PUMP

SWEEP. A drainage fitting designed to provide a change in direction of a drain pipe of less than the angle specified by the amount necessary to establish the desired slope of the line. Sweeps provide a longer turning radius than bends and a less turbulent flow pattern (see “Bend” and “Elbow”).

❖ See the definition of “Bend.”

TEMPERATURE- AND PRESSURE-RELIEF (T AND P) VALVE. A combination relief valve designed to function as both a temperature-relief and pressure-relief valve.

❖ These devices combine the components of pressure-relief and temperature-relief valves and are designed to discharge automatically at excessive pressures or temperatures or both.

TEMPERATURE-RELIEF VALVE. A temperature-actuated valve designed to discharge automatically at the temperature at which it is set.

❖ This valve is designed to discharge at excessive temperatures to prevent dangerously high water temperatures that can cause tank, vessel or pipe explosions.

[RB] TERMITE-RESISTANT MATERIAL. Pressure-preserved treated wood in accordance with the AWPA standards in Section R318.1, naturally durable termite-resistant wood, steel, concrete, masonry or other *approved* material.

❖ Section R318.1 allows for termite-resistant materials as protection against termites. Typical materials include steel, concrete and masonry.

[RB] THERMAL ISOLATION. Physical and space conditioning separation from *conditioned space(s)* consisting of existing or new walls, doors or windows. The *conditioned space(s)* shall be controlled as separate zones for heating and cooling or conditioned by separate *equipment*.

For definition applicable in Chapter 11, see Section N1101.6.

❖ This term is conceptually somewhat similar to the separation provided by the “building envelope” but instead of being between conditioned space and the exterior or conditioned space and unconditioned space, this separation occurs between two conditioned spaces, the separation between the existing dwelling and the new sunroom addition. Unless a new wall is constructed, the existing “exterior wall” of the dwelling will generally provide the thermal isolation between the dwelling and the sunroom.

[RE] THERMAL RESISTANCE, R-VALUE. The inverse of the time rate of heat flow through a body from one of its bounding surfaces to the other for a unit temperature difference between the two surfaces, under steady state conditions, per unit area ($h \cdot ft^2 \cdot ^\circ F/Btu$) ($m^2 \cdot K/W$).

❖ *R*-value is a unit of thermal resistance used for comparing insulating values of different materials. The greater the *R*-value of a material, the greater its insulating properties and the slower heat flows through it. *R*-values are used to rate roof/ceiling, wall and floor insulation.

[RE] THERMAL TRANSMITTANCE, U-FACTOR. The coefficient of heat transmission (air to air) through a building envelope component or assembly, equal to the time rate of heat flow per unit area and unit temperature difference between the warm side and cold side air films ($Btu/h \cdot ft^2 \cdot ^\circ F$) $W/(m^2 \cdot K)$.

❖ *U*-factor is the rate of heat transfer in Btu per hour through a square foot of a surface when the difference between the air temperatures on either side is one Fahrenheit degree. The *U*-factor is the reciprocal of the

R-value. Vertical windows, skylights and doors are rated with *U*-factors. The lower the *U*-factor, the more thermally efficient the material or assembly.

[RB] THIRD-PARTY CERTIFICATION AGENCY. An approved agency operating a product or material certification system that incorporates initial product testing, assessment and surveillance of a manufacturer's quality control system.

❖ The code contains requirements for materials such as pipe, fittings, mechanical equipment and structural items that require either testing by a third-party agency or certification by a third-party agency. A "third party" is an agency independent of the product manufacturer.

[RB] THIRD PARTY CERTIFIED. Certification obtained by the manufacturer indicating that the function and performance characteristics of a product or material have been determined by testing and ongoing surveillance by an approved third-party certification agency. Assertion of certification is in the form of identification in accordance with the requirements of the third-party certification agency.

❖ The code contains requirements for materials such as pipe, fittings, mechanical equipment and structural items that require either testing by a third-party agency or certification by a third-party agency. A "third party" is an agency independent of the product manufacturer.

[RB] THIRD-PARTY TESTED. Procedure by which an approved testing laboratory provides documentation that a product material or system conforms to specified requirements.

❖ The code contains requirements for materials such as pipe, fittings, mechanical equipment and structural items that require either testing by a third-party agency or certification by a third-party agency. A "third party" is an agency independent of the product manufacturer.

[RB] TOWNHOUSE. A single-family *dwelling unit* constructed in a group of three or more attached units in which each unit extends from foundation to roof and with a *yard* or public way on not less than two sides.

❖ A configuration of three or more single-family dwellings attached together in a single structure constitutes a townhouse if all of the following conditions exist:

1. Each unit extends vertically from the foundation to the roof (townhouses cannot be stacked, though two-family dwellings can be),
2. Each unit is open to the exterior on at least two sides, providing some degree of independence from other units.
3. Not more than three stories in height above grade plan, and
4. Each unit must have independent egress to the exterior.

A townhouse structure that does not meet all of the preceding four criteria is regulated by the IBC, not the IRC.

It should also be noted that townhouses within the IRC must be separated by a wall or walls meeting specific criteria. A townhouse structure could be built with

any number of attached units on the same lot, or it could be developed such that a property line lies at each common wall separating dwelling units (see the definition for "Lot").

TRAP. A fitting, either separate or built into a fixture, that provides a liquid seal to prevent the emission of sewer gases without materially affecting the flow of sewage or waste water through it.

❖ The sole purpose of a trap is to isolate the interior of occupiable spaces from the sanitary drainage and vent system. It traps liquid waste and retains it to form a seal or barrier through which gases and vapors in the drainage and vent system cannot pass under normal operating conditions. Traps are either separate devices or are integral with fixtures. Other than a grease trap or a trap that is integral with a fixture, the only type of trap permitted by the code is the "P" type (see Commentary Figure R202(17) and "Fixture drain").

TRAP ARM. That portion of a *fixture drain* between a trap weir and the vent fitting.

❖ This is the common name for a "fixture drain."

TRAP PRIMER. A device or system of piping to maintain a water seal in a trap, typically installed where infrequent use of the trap would result in evaporation of the trap seal, such as floor drains.

❖ This is a device or system of piping that maintains a water seal in a trap (see Section P3201.2).

TRAP SEAL. The trap seal is the maximum vertical depth of liquid that a trap will retain, measured between the crown weir and the top of the dip of the trap.

❖ A trap seal is the vertical depth of liquid held in the dip of a trap. Trap seals are required to have a minimum depth.

DEFINITIONS

[RB] TRIM. Picture molds, chair rails, baseboards, handrails, door and window frames, and similar decorative or protective materials used in fixed applications.

- ❖ Where limited amounts of decorative or protective materials are installed as a part of the building construction, they are regulated as trim. Examples include chair rails, door and window frames, handrails, baseboards and cove molding.

[RB] TRUSS DESIGN DRAWING. The graphic depiction of an individual truss, that describes the design and physical characteristics of the truss.

- ❖ If a floor or roof truss system is to be used in a building's construction, truss design drawings must be prepared and submitted to the building official prior to truss installation. The truss design drawings should graphically illustrate each specific type of truss to be installed and include a variety of other information as required in the code.

[RE] TUBULAR DAYLIGHTING DEVICE (TDD). A nonoperable fenestration unit primarily designed to transmit daylight from a roof surface to an interior ceiling via a tubular conduit. The basic unit consists of an exterior glazed weathering surface, a light-transmitting tube with a reflective interior surface, and an interior-sealing device such as a translucent ceiling panel. The unit may be factory assembled, or field assembled from a manufactured kit.

- ❖ This device functions just as a skylight does. The code includes this with skylights in specifying proper use and application.

TYPE L VENT. A *listed* and *labeled* vent conforming to UL 641 for venting oil-burning *appliances listed* for use with Type L vents or with gas *appliances listed* for use with Type B vents.

- ❖ See the commentary to the definition of "Vent."

[RE] U-FACTOR, THERMAL TRANSMITTANCE. See Section N1101.6 for definition applicable in Chapter 11.

- ❖ See "Thermal transmittance, U-factor."

[RB] UNDERLAYMENT. One or more layers of felt, sheathing paper, nonbituminous saturated felt, or other *approved* material over which a roof covering, with a slope of 2 to 12 (17-percent slope) or greater, is applied.

- ❖ Underlayment for roof covering is the initial layer of weather protection installed over a roof deck. The underlayment may consist of a single or multiple layers of material and is to be used on roofs having a minimum slope of 2 to 12. Examples of underlayment include felt, sheathing paper and nonbituminous saturated felt.

VACUUM BREAKER. A device that prevents back-siphonage of water by admitting atmospheric pressure through ports to the discharge side of the device.

- ❖ A vacuum breaker is a device used as a backflow preventer. The device neutralizes (breaks) the negative pressures (vacuum) in closed systems by allowing atmospheric pressure to enter the system.

[RB] VAPOR PERMEABLE. The property of having a moisture vapor permeance rating of 5 perms (2.9×10^{-10} kg/Pa · s · m²) or greater, where tested in accordance with the desiccant method using Procedure A of ASTM E96. A vapor permeable material permits the passage of moisture vapor.

- ❖ A vapor permeable membrane can consist of breather paper or other materials that allow the passage of moisture vapor. An acceptable vapor permeable membrane can be any material that has a vapor permeance of no less than 5 perm ($2.9 \cdot 10^{-10}$ kg/Pa · s · m²) when tested in accordance with the desiccant method using Procedure A of ASTM E96.

[RB] VAPOR RETARDER CLASS. A measure of the ability of a material or assembly to limit the amount of moisture that passes through that material or assembly. Vapor retarder class shall be defined using the desiccant method with Procedure A of ASTM E96 as follows:

Class I: 0.1 perm or less

Class II: $0.1 < \text{perm} \leq 1.0$ perm

Class III: $1.0 < \text{perm} \leq 10$ perm

- ❖ The code contains detail requirements for moisture control in Section R702.7. This section calls out requirements for vapor retarders with different levels of vapor permeance. This defines each class.

VENT. A passageway for conveying flue gases from fuel-fired *appliances*, or their vent connectors, to the outside atmosphere.

- ❖ In code terminology, vents are distinguished from chimneys and usually are constructed of factory-made listed and labeled components intended to function as a system. Type B and BW vents are constructed of galvanized steel and aluminum sheet metal and are double-wall and air insulated. Such vents are designed to vent gas-fired appliances and equipment that are equipped with draft hoods or specifically listed (labeled) for use with Type B or BW vents. Type L vents are typically constructed of sheet steel and stainless steel. They are double-wall, air insulated and designed to vent gas and oil-fired appliances and equipment. Mid- to high-efficiency appliances are designed for use with corrosion-resistant vents such as those made of plastic pipe and special alloys of stainless steel. Pellet vents (PL) are specialized vents similar in design and construction to Type L vents. Pellet vents must not be used with any appliances other than pellet-burning appliances.

VENT COLLAR. See "Flue collar."

VENT CONNECTOR. That portion of a venting system that connects the flue collar or draft hood of an *appliance* to a vent.

- ❖ In most cases, appliances are not located directly in line with the vertically rising chimney or vent; therefore, a vent connector is necessary to connect the appliance flue outlet with the vent. Vent connectors can be single- or double-wall pipes and are usually made from galvanized steel, stainless steel or aluminum sheet

metal. In many installations, the vent connectors must be constructed of the same material as the vent, as is typically done with Type B vent systems.

VENT DAMPER DEVICE, AUTOMATIC. A device intended for installation in the venting system, in the outlet of an individual, automatically operated fuel burning *appliance* and that is designed to open the venting system automatically where the *appliance* is in operation and to close off the venting system automatically where the *appliance* is in a standby or shutdown condition.

- ❖ The purpose of this device is the conservation of energy by preventing the cooling of the combustion chamber of the appliance and by preventing the loss of conditioned air through the venting system during the appliance off cycle. This is accomplished by preventing the flow of air (by means of venting system draft) through the combustion chamber when the appliance is not in operation.

VENT GASES. Products of combustion from fuel-burning *appliances*, plus excess air and dilution air, in the venting system above the draft hood or draft regulator.

- ❖ Vent gases are combustion products within the venting system, whereas flue gases are combustion products within the fuel-burning appliance. Vent gases are combustion products being conveyed to the outdoors by chimneys, vents and venting systems.

VENT STACK. A vertical vent pipe installed to provide circulation of air to and from the drainage system and that extends through one or more stories.

- ❖ This is a dry vent that extends from the base of a waste or soil stack and typically runs parallel and adjacent to the waste or soil stack it serves. The vent stack can connect to the horizontal drain downstream of the drain stack, or it can connect directly to the drainage stack.

VENT SYSTEM. Piping installed to equalize pneumatic pressure in a drainage system to prevent trap seal loss or blow-back due to siphonage or back pressure.

- ❖ This system is a piping arrangement designed to maintain pressure fluctuation at fixture traps to within plus or minus 2 inches of water column (249 Pa).

VENTILATION. The natural or mechanical process of supplying conditioned or unconditioned air to, or removing such air from, any space.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ Ventilation can be used for comfort cooling, the control of air contaminants, equipment cooling and replenishing oxygen levels.

VENTING. Removal of combustion products to the outdoors.

- ❖ This is the desired result of the venting system.

VENTING SYSTEM. A continuous open passageway from the flue collar of an *appliance* to the outside atmosphere for

the purpose of removing flue or vent gases. A venting system is usually composed of a vent or a chimney and vent connector, if used, assembled to form the open passageway.

- ❖ Venting systems operate by gravity (natural draft) or mechanical means. Venting systems include both vents and chimneys.

VERTICAL PIPE. Any pipe or fitting that makes an angle of 45 degrees (0.79 rad) or more with the horizontal.

- ❖ Vertical pipes are angled 45 degrees (0.79 rad) or more above the horizontal.

[RB] VINYL SIDING. A shaped material, made principally from rigid polyvinyl chloride (PVC), that is used to cover exterior walls of buildings.

- ❖ Vinyl siding is a manufactured plastic product whose primary component is polyvinyl chloride (PVC). Vinyl siding is either coextruded in layers or thermoformed, depending on the style or profile of the product. Additives are used to improve weathering performance. Vinyl siding products are available in a wide range of sizes, shapes, colors and textures and are intended for exterior wall and related applications.

[RB] WALL, RETAINING. A wall not laterally supported at the top, that resists lateral soil load and other imposed loads.

- ❖ Retaining walls are discussed in Section R404.4 of this code. These walls retain soil that would otherwise slump or cave to a more natural slope. The lateral pressure of soil against a retaining wall is greatly influenced by soil moisture and it is this lateral pressure that constitutes the largest part of the load that the wall must withstand.

[RB] WALLS. Walls shall be defined as follows:

Load-bearing wall. A wall supporting any vertical load in addition to its own weight.

Nonbearing wall. A wall which does not support vertical loads other than its own weight.

- ❖ Walls are either load-bearing or nonbearing. A load-bearing wall supports not only its own weight but also an additional vertical load. An example is a wood stud wall supporting roof rafters and ceiling joists. A non-bearing wall does not support any vertical load other than its own weight.

WASTE. Liquid-borne waste that is free of fecal matter.

- ❖ Waste is any plumbing fixture discharge other than the discharge from a water closet or urinal. This material does not contain human fecal matter.

WASTE PIPE OR STACK. Piping that conveys only liquid sewage not containing fecal material.

- ❖ A waste pipe or stack is any waste-conducting pipe not falling under the definition of soil pipe. Waste pipes do not convey human fecal matter.

DEFINITIONS

WASTE RECEPTOR. A floor sink, standpipe, hub drain or a floor drain that receives the discharge of one or more indirect waste pipes.

- ❖ A common assumption was that only floor sinks and hub drains were waste receptors. Standpipes and floor drains were rarely thought of as being waste receptors but they are commonly installed for capturing the flow from indirect waste pipes. A floor drain is only considered to be a waste receptor where it receives the discharge of one or more indirect waste pipes.

WATER DISTRIBUTION SYSTEM. Piping that conveys water from the service to the plumbing fixtures, *appliances*, appurtenances, *equipment*, devices or other systems served, including fittings and control valves.

- ❖ This is all the water piping within a building from the point of connection to the water service to the various connections of the fixture supplies or outlets.

WATER HEATER. Any heating *appliance* or *equipment* that heats potable water and supplies such water to the potable hot water distribution system.

- ❖ The types of water heaters include storage (tank), circulating and instantaneous. Point-of-use water heaters typically supply hot water to a single fixture or outlet and are located in close proximity to the fixture or outlet.

WATER MAIN. A water supply pipe for public use.

- ❖ Water mains are owned and operated by municipalities, rural water districts, privately owned water purveyors or other such entities.

WATER OUTLET. A valved discharge opening, including a hose bibb, through which water is removed from the potable water system supplying water to a plumbing fixture or plumbing *appliance* that requires either an *air gap* or back-flow prevention device for protection of the supply system.

- ❖ A water outlet is a discharge opening through which water is supplied to a fixture, into the atmosphere (except into an open tank that is part of the water supply system), to a boiler or heating system or to any device or equipment requiring water to operate but which is not part of the plumbing system.

[RB] WATER-RESISTIVE BARRIER. A material behind an *exterior wall* covering that is intended to resist liquid water that has penetrated behind the exterior covering from further intruding into the *exterior wall* assembly.

- ❖ Protection of the building envelope is a primary concern. The ability of the water-resistive barrier to provide weather resistance and maintain the integrity of the building envelope is key to controlling water based issues like mold, decay and deterioration of a structure. Water-resistive barriers are discussed in Section R703.2 of the code and in Section 1404.2 of the IBC.

WATER SERVICE PIPE. The outside pipe from the water main or other source of potable water supply to the water distribution system inside the building, terminating at the service valve.

- ❖ Water service pipe is any acceptable piping that conveys potable water.

WATER SUPPLY SYSTEM. The water service pipe, the water-distributing pipes and the necessary connecting pipes, fittings, control valves and appurtenances in or adjacent to the building or premises.

- ❖ The water supply system includes all piping and components that convey potable water from the public main or other source to the points of water usage.

WET VENT. A vent that receives the discharge of wastes from other fixtures.

- ❖ Although Section P3108 describes “wet venting” systems, the term “wet vent” applies to any pipe that is used concurrently as both a drain and a vent. This arrangement can be found in the following systems: Common Vent (Section P3107), Wet Venting (Section P3108), Waste Stack Vent (Section P3109), Circuit Venting (Section P3110), and Combination Waste and Vent System (Section P3111).

WHOLE-HOUSE MECHANICAL VENTILATION SYSTEM. An exhaust system, supply system, or combination thereof that is designed to mechanically exchange indoor air for outdoor air where operating continuously or through a programmed intermittent schedule to satisfy the whole-house ventilation rate.

For definition applicable in Chapter 11, see Section N1101.6.

- ❖ See Section M1507.3.

[RB] WINDBORNE DEBRIS REGION. Areas within *hurricane-prone regions* located in accordance with one of the following:

1. Within 1 mile (1.61 km) of the coastal mean high water line where the ultimate design wind speed, V_{ult} , is 130 mph (58 m/s) or greater.
2. In areas where the ultimate design wind speed, V_{ult} , is 140 mph (63.6 m/s) or greater; or Hawaii.

- ❖ The code regulates the exterior openings of a building where there is a concern about the extensive damage that can be caused by debris carried through the air by extremely high winds. Wind-borne debris regions are those areas where the potential for such damage is high. The code identifies these areas by means of this definition and its application to Figures R301.2(4)A and R301.2(4)B.

[RB] WINDER. A tread with nonparallel edges.

- ❖ A winder is a tread in a winding stairway. Winder treads are used as components of stairs that change direc-

tion, just as straight treads are components in straight stairs. A winder serves as a tread but its shape allows the additional function of a gradual turning of the stairway direction. The tread depth of a winder at the walk line and the minimum tread depth at the narrow end can control the turn made by each winder.

[RB] WOOD STRUCTURAL PANEL. A panel manufactured from veneers; or wood strands or wafers; bonded together with waterproof synthetic resins or other suitable bonding systems. Examples of wood structural panels are plywood, OSB or composite panels.

❖ Wood structural panels are sheet products commonly known as plywood, wafer board, oriented strand board (OSB) or chip board manufactured to meet the United States Department of Commerce (DOC) standards for Construction and Industrial Plywood, PS 1, and Performance Standards for Wood-Based Structural-Use Panels, PS 2.

[RB] YARD. An open space, other than a court, unobstructed from the ground to the sky, except where specifically provided by this code, on the *lot* on which a building is situated.

❖ Used throughout the code to describe an open space at the exterior of a building, a yard must be unobstructed from the ground to the sky and located on the same lot on which the building is situated. The openness of a yard allows it to be used to supply buildings with natural light and ventilation. A court, which is bounded on three or more sides by the exterior walls of the building, is not a yard.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

ANSI Z21.83–1998, *Fuel Cell Power Plants*. New York, NY: American National Standards Institute, 1998.

ASTM C55–03, *Standard Specification for Concrete Brick*. West Conshohocken, PA: ASTM International, 2003.

ASTM C62–03, *Standard Specification for Building Brick (Solid Masonry Units Made from Clay or Shale)*. West Conshohocken, PA: ASTM International, 2003.

Part III—Building Planning and Construction

Chapter 3: Building Planning

General Comments

Chapter 3 is a compilation of the code requirements specific to the building planning sector of the design and construction process. The provisions address a wide variety of issues important to designing a building that is both safe and usable. The limitations placed on the materials and methods of construction contribute to the development of a structurally sound building. Snow, wind and seismic design and flood-resistant construction are regulated, as are the live and dead loads, in Chapter 3.

Fire-resistance-rated assemblies are necessary under two different conditions: 1. Where a building is situated very close to a property line, the code addresses the concern for radiant heat exposure in a fire; and 2. Where two or more dwelling units are housed in a single structure, the code mandates a minimum level of fire separation between all units. Other concerns related to fires include the limitations on wall and ceiling finishes, the requirement for emergency escape and rescue openings, the required installation of smoke alarms throughout the dwelling unit and limitations on the use of foam plastics and other insulation materials. In addition, the specific construction requirements for the common wall between the house and garage and the ceiling assembly between the garage and habitable space are addressed in Chapter 3.

This chapter sets forth traditional code requirements dealing with light, ventilation, sanitation, room size, ceiling height and environmental comfort. Life-safety provisions include limitations on glazing used in hazardous areas, specifications on the use of guards at elevated surfaces, fall protection for open windows, and basic rules for the egress system. This chapter also contains most of the regulations found in the code that deal with the planning and design of dwelling units.

- Section R301 establishes the design criteria, including dead loads, live loads, roof loads, floor loads, snow loads, wind loads and seismic loads.
- Section R302 identifies the requirements for the fire-resistant construction for residential buildings.
- Section R303 establishes the light, ventilation and heating requirements for dwelling units.
- Section R304 establishes the minimum requirements for room areas in dwelling units.
- Section R305 establishes the ceiling height requirements for dwelling units.
- Section R306 contains requirements for sanitation.
- Section R307 contains requirements for toilets and bath and shower spaces.
- Section R308 contains requirements for glazing, hazardous locations of glazing, site-built windows and sky-lights.
- Section R309 contains provisions for garages and carports.
- Section R310 contains provisions for emergency escape and rescue openings.
- Section R311 establishes the means of egress requirements, including provisions for egress doors, hallways, stairways and ramps.
- Section R312 addresses guards and fall prevention for open windows.
- Section R313 provides requirements for an automatic sprinkler system with the option of complying with NFPA 13D or Section P2904.
- Section R314 contains the requirements for smoke alarms.
- Section R315 provides criteria for the installation and location of carbon monoxide (CO) alarms.
- Section R316 addresses the use of foam plastic.
- Section R317 contains requirements for decay protection for wood and wood-based products.
- Section R318 contains requirements for termite protection.
- Section R319 provides the requirements for premise identification (site address).
- Section R320 provides a reference to the *International Building Code*[®] (IBC[®]) for accessibility requirements.
- Section R321 addresses elevators and platform lifts.
- Section R322 establishes flood-resistant construction provisions.
- Section R323 references ICC/NSSA 500 for when someone chooses to construct a storm shelter within their home or building.

- Section R324 provides requirements for photovoltaic solar energy systems and references Chapter 23 and the *International Fire Code*® (IFC®) for solar thermal energy systems.
- Section R325 contains requirements for mezzanines.
- Section R326 references the *International Swimming Pool and Spa Code*® (ISPSC®) for the design and construction of pools and spas.

Purpose

Chapter 3 provides guidelines for a minimum level of structural integrity, life safety, fire safety and livability for inhabitants of dwelling units regulated by the code. The chapter sets forth the requirements that affect the most basic planning and design aspects of dwelling construction. It identifies the various structural loads that are imposed on a building, and it establishes criteria that address each of the imposed loads. In the design of residential structures scoped by the code, there are many climatic and geographical issues that must be considered. This chapter provides guidance in the determination of all appropriate design criteria. In addition, it sets

forth the limiting conditions under which a building may be designed and constructed using the code.

Fundamental issues of livability and sanitation are satisfied through the regulation of minimum room sizes and ceiling heights, as well as basic requirements for toilet rooms, kitchens, swimming pools, spas and hot tubs. Life safety concerns are addressed in a number of areas, including provisions regulating emergency escape and rescue openings, glazing in areas subject to human impact and exiting. The chapter establishes minimum specifications for a number of different building components and systems, including stairways, ramps, landings, handrails, guards, mezzanines, solar energy systems and fall protection for open windows. It deals with fire-safety issues, such as automatic sprinkler systems, early fire detection by smoke alarms, exterior wall protection for proximity to property lines, separation of dwelling units in multiple-family buildings, and control of fire spread across wall and ceiling finishes. Other life safety concerns are dealt with by requirements for CO detectors and guidance for the design of storm shelters. Property protection is also a concern, with provisions established for protection against decay and termites.

SECTION R301 DESIGN CRITERIA

R301.1 Application. Buildings and structures, and parts thereof, shall be constructed to safely support all loads, including dead loads, live loads, roof loads, flood loads, snow loads, wind loads and seismic loads as prescribed by this code. The construction of buildings and structures in accordance with the provisions of this code shall result in a system that provides a complete load path that meets the requirements for the transfer of loads from their point of origin through the load-resisting elements to the foundation. Buildings and structures constructed as prescribed by this code are deemed to comply with the requirements of this section.

❖ This section specifies the minimum design loads required for structures built in accordance with the provisions of the code. In structural design, loads are generally divided into two categories: gravity loads, which act vertically; and lateral loads, which act horizontally. Lateral loads typically result from either wind (see Section R301.2.1), earthquakes (see Section R301.2.2) or flood loads (see Section R301.2.4). Although wind, flood and earthquake design are concerned with lateral loads, there are also vertical force components that must be considered.

All structures must be designed to support these loads and provide a complete load path capable of transferring these loads from their point of origin through the appropriate load-resisting elements and

foundation and, ultimately, to the supporting soil. The charging statement specifically states that any building or structure that has been built in strict compliance with the code provides a complete load path that meets all requirements for load transfer from the point of origin to the foundation. A load path that is either incomplete or inadequate will expose the structure to damage just as surely as an undersized structural member will. The concept of a complete load path is a fundamental principle in structural engineering, and the code makes it clear that a complete load path must be provided.

R301.1.1 Alternative provisions. As an alternative to the requirements in Section R301.1, the following standards are permitted subject to the limitations of this code and the limitations therein. Where engineered design is used in conjunction with these standards, the design shall comply with the *International Building Code*.

1. AF&PA *Wood Frame Construction Manual* (WFCM).
2. AISI *Standard for Cold-Formed Steel Framing—Prescriptive Method for One- and Two-Family Dwellings* (AISI S230).
3. ICC *Standard on the Design and Construction of Log Structures* (ICC 400).

❖ This section permits the use of alternative prescriptive framing methods. Wood framing is permitted to comply with the provisions of the American Forest and Paper Association's (AF&PA) WFCM, *Wood Frame Con-*

struction Manual for One- and Two-family Dwellings. Cold-formed steel framing is permitted to comply with American Iron and Steel Institute's (AISI) S230, *Standard for Cold-formed Steel Framing-prescriptive Method for One- and Two-family Dwellings*. Log homes can be constructed using ICC 400, *Standard on the Design and Construction of Log Structures*. Engineered design in accordance with the IBC is required when a building is beyond (or exceeds) the applicability limits of these standards.

R301.1.2 Construction systems. The requirements of this code are based on platform and balloon-frame construction for light-frame buildings. The requirements for concrete and masonry buildings are based on a balloon framing system. Other framing systems must have equivalent detailing to ensure force transfer, continuity and compatible deformations.

- ❖ The requirements of the code are based on platform or balloon-frame construction for light-frame buildings (see the definitions of "Platform construction" and "Light-frame construction" in Chapter 2) and on a balloon-framing system for concrete and masonry buildings.

R301.1.3 Engineered design. Where a building of otherwise conventional construction contains structural elements exceeding the limits of Section R301 or otherwise not conforming to this code, these elements shall be designed in accordance with accepted engineering practice. The extent of such design need only demonstrate compliance of nonconventional elements with other applicable provisions and shall be compatible with the performance of the conventional framed system. Engineered design in accordance with the *International Building Code* is permitted for buildings and structures, and parts thereof, included in the scope of this code.

- ❖ Generally, proper application of the code requires a clear understanding of and adherence to its prescriptive limitations, which are based on conventional construction. However, a building may contain structural elements that are either unconventional or exceed the prescriptive limitations of the code. This is acceptable, if these elements are designed in accordance with accepted engineering practice by a design professional.

R301.2 Climatic and geographic design criteria. Buildings shall be constructed in accordance with the provisions of this code as limited by the provisions of this section. Additional criteria shall be established by the local *jurisdiction* and set forth in Table R301.2(1).

- ❖ This section establishes the design criteria that vary based on location and/or climate. Some of the criteria reflect loading, such as earthquake, flood and wind; others reflect susceptibility to damage from hazards, such as weather exposure or termites. Additional criteria may be established by local jurisdictions as neces-

sary. These would include, for example, whether a site is within a wind-borne debris region as described in Section R301.2.1.2, of this commentary. Table R301.2(1) lists the criteria that must be established within each jurisdiction for any project constructed under the code. The table must be filled in by the jurisdiction adopting the code for their particular area. In reality, the information required to be inserted into the table is typically included in the adopting ordinance, and may not actually appear in the code. For this reason, it may be wise for designers, contractors, manufacturers and other code users to acquire a copy of the adopting ordinance for the code for each jurisdiction in which they do business.

Note that some of these criteria (e.g., wind exposure category or flood hazard) can vary within a given jurisdiction and may need to be established on a site-by-site (or project-by-project) basis. The table serves as a useful reminder for code enforcement personnel, builders, designers and owners. Verifying this information up front aids compliance with the code.

TABLE R301.2(1). See Page 3-6.

- ❖ Table R301.2(1) is designed so that jurisdictions recognize certain climatic and geographic design criteria that vary from location to location. Communities are directed to complete the table with a variety of factors. See the table footnotes for the sources of the information to be determined by the local jurisdiction to complete the table.

The required information includes the date of the jurisdictions entry into the National Flood Insurance Program (NFIP), which is typically the date of adoption of the first code or ordinance for management of flood hazard areas. With respect to the official map that shows flood hazard areas, the community inserts the date of the currently effective Flood Insurance Study and the panel numbers and dates of all currently effective Flood Insurance Rate Maps (FIRM) [and Flood Boundary and Floodway Maps (FBFM), if applicable] or the date of other maps that are adopted. Another flood hazard map may be specified if it shows flood hazard areas that are larger than those shown on the FIRM, as may be the case if a community elects to define its flood plains based on higher standards, such as the "flood of record," "ultimate development" of an upstream watershed, or "no-rise" rules to define the floodway.

From time to time, the Federal Emergency Management Agency (FEMA) may revise and republish Federal Insurance Studies (FISs) and FIRMs. In recent years, revised FIRMs have been produced in a digital format for some communities. Communities that prefer to cite the digital data should obtain a legal opinion whether such maps and data are acceptable. Digital map products are registered to the primary coordinate system of the state or community. FEMA advises that

the horizontal location of flood hazard areas relative to specific sites should be determined using the coordinate grid, rather than planimetric base map features, such as streets.

When maps are revised and flood hazard areas are changed, FEMA involves the community and provides a formal opportunity to review the documents. Once the revisions are finalized, FEMA requires adoption of the new maps by the community. Communities may be able to minimize having to adopt each revision by referencing the date of the map and study, as amended. This is a method by which subsequent revisions to flood maps and studies may be automatically adopted administratively without requiring legislative action on the part of the community. Communities will need to determine whether this automatic adoption-by-reference approach is allowed under their state's enabling authority and due process requirements. If not allowed, communities are to follow their state's requirements, which normally require public notices, hearings and specific adoption of revised maps by the community's legislative body.

Table R301.2(1) requires the local municipality or code user to insert a frost line depth entry for the particular geographical area they are located in. Commentary Figure R301.2(8) provides some guidance to do this more accurately based on the US Weather Bureau information. Since elevation above sea level may increase frost depth, another local resource for frost depth is often the local graveyard owners.

In Table R301.2(1), under the title of Wind Design, Topographic effects, a jurisdiction must enter "yes" or "no." This is in consideration of historical information indicating unusually high wind speeds due to local topography (see commentary, Section R301.2.1.5).

TABLE R301.2(2). See page 3-7.

- ❖ This table lists wind pressures for components or cladding building elements. For the 2015 edition, the table has been revised to reflect ultimate design wind speed basis, as opposed to the basic wind speed basis used in previous editions.

The term "Cladding" is defined in Section R202. Although the ultimate design wind speed from Figure R301.2(4)A is applicable to the structure as a whole, this table applies to elements of the building that typically are not part of the wind-force-resisting system. Wind pressures on these elements vary depending on the tributary area, the location/orientation (i.e., a wall that is typically vertical versus a roof and its slope), the region or zone, as well as the ultimate design wind speed.

"Zones" refer to various portions of a structure as illustrated in Figure R301.2(7). Some zones, such as at roof edges and the ends of a wall, represent discontinuities in the exterior building surfaces. Discontinuities

interrupt the flow of wind and result in higher wind pressures at these locations. How to determine the appropriate "effective wind area" is defined in Note a. This approach is taken from ASCE 7 and modified editorially to fit the table.

For each combination of these various factors there are two entries in the table, one positive and one negative. The positive number denotes the pressure acting inward or toward the exterior surface of the building; the negative number denotes the pressure acting outward or away from the building surface. The latter is of interest in designing roof elements and their hold-downs that must resist wind uplift.

Unlike the IBC, the code does not elaborate on the distinctions between wind loads on the main wind-force-resisting system versus components and cladding wind loads. Instead, compliance with the components and cladding pressures is necessary only where code provisions explicitly refer to this table. This occurs in the establishment of design wind loads for skylights, exterior windows and doors (see Sections R301.2.1 and R612.2), and setting the threshold for requiring rafter ties (see Sections R608.9.3, R802.11 and R804.3.8).

TABLE R301.2(3). See page 3-8.

- ❖ This table provides adjustment factors for the components and cladding wind pressure of Table R301.2(2), which are based on a mean roof height of 30 feet (9144 mm) and wind Exposure Category B (see the commentary to Section R301.2.1.4 for a discussion of exposure). For mean roof heights and exposure categories that vary from those assumed in Table R301.2(2), the resulting pressure will change accordingly. Thus, adjustments to the pressures are required by the factors given in this table.

FIGURE R301.2(1). See page 3-8.

- ❖ This figure establishes the winter design temperature, which is a criteria for determining the need for dwelling unit heating (see Section R303.10), as well as determining the need for freeze protection of piping (see Sections M2301.2.6, P2603.5 and P3001.2).

FIGURE R301.2(2). See pages 3-9 through 3-14.

- ❖ This figure establishes the seismic design category for a site as presented in Section R301.2.2.1. It provides the most direct determination of the seismic design category in the code. The earthquake-related provisions of the code state requirements as a function of the seismic design category.

This figure reflects seismic hazard data developed by the U.S. Geological Survey (USGS) as part of its National Seismic Hazard Mapping Project and related technical changes developed by the Building Seismic Safety Council's (BSSC) Seismic Design Procedures

Reassessment Group (SDPRG) as part of its work for the Federal Emergency Management Agency (FEMA).

The USGS and the FEMA-funded SDPRG worked together to update the seismic design maps and procedures for the 2009 edition of the NEHRP (National Earthquake Hazards Reduction Program) *Recommended Seismic Provisions for New Buildings and Other Structures*. The design maps are based on USGS updates to their seismic hazard data and ground motion attenuation formulas as well as the SDPRG's use of risk-targeted ground motions, maximum direction ground motions, and near-source 84th percentile ground motions.

These IRC maps are different from earlier versions in that the division between Seismic Design Categories D₂ and E has been changed from 118 percent g to 125 percent g. The 125 percent g contour would have been used in earlier maps but the mapping technology then available for drawing the IRC maps did not permit this to be done. The result of this change and the improved seismic hazard data generated by the USGS over the years is that the geographic region affected by the Seismic Design Category E designation is smaller. This occurs primarily in the region around Charleston, South Carolina, but is also evident in Seismic Design Category E regions in other parts of the United States. Maps developed on the same basis have been incorporated into the IBC which will allow engineers to design components of the building that are outside of the scope of the IRC with compatible seismic loads.

FIGURE R301.2(3). See page 3-14.

❖ See the commentary to Section R301.2.1.

FIGURE R301.2(4)A. See page 3-15.

❖ See the commentary to Section R301.2.1.

FIGURE R301.2(4)B. See page 3-16.

❖ See the commentary to Section R301.2.1.

FIGURE R301.2(5). See pages 3-17 and 3-18.

❖ The ground snow-load map is taken from the ASCE 7 snow-load provisions and is based on statistical analysis of ground snow data. This map provides ground snow loads for direct use in the prescriptive provisions and tables of the code. Snow loads may increase due to lake effect or elevations. Check with local authorities for more refined snow-load maps.

FIGURE R301.2(6). See page 3-19.

❖ This figure establishes the potential for termite damage in areas of the continental United States. The boundaries for the various classifications are approximate, and local experience should be relied on either to affirm or to modify the classification determined from this map.

FIGURE R301.2(7). See page 3-20.

❖ This figure depicts the zones for the components and cladding wind pressures that are given in Table R301.2(2). See the commentary to this table for a discussion of components and cladding.

TABLE R301.2(1)
CLIMATIC AND GEOGRAPHIC DESIGN CRITERIA

GROUND SNOW LOAD	WIND DESIGN			SEISMIC DESIGN CATEGORY ^f	SUBJECT TO DAMAGE FROM		WINTER DESIGN TEMP ^g	ICE BARRIER UNDERLAYMENT REQUIRED ^h	FLOOD HAZARDS ^g	AIR FREEZING INDEX ⁱ	MEAN ANNUAL TEMP ^j
	Speed ^d (mph)	Topographic effects ^a	Special wind region ^l		Wind-borne debris zone ^m	Weathering ^a					

For SI: 1 pound per square foot = 0.0479 kPa, 1 mile per hour = 0.447 m/s.

- a. Weathering may require a higher strength concrete or *grade* of masonry than necessary to satisfy the structural requirements of this code. The weathering column shall be filled in with the weathering index, “negligible,” “moderate” or “severe” for concrete as determined from Figure R301.2(3). The *grade* of masonry units shall be determined from ASTM C34, C55, C62, C73, C90, C129, C145, C216 or C652.
- b. The frost line depth may require deeper footings than indicated in Figure R403.1(1). The *jurisdiction* shall fill in the frost line depth column with the minimum depth of footing below finish *grade*.
- c. The *jurisdiction* shall fill in this part of the table to indicate the need for protection depending on whether there has been a history of local subterranean termite damage.
- d. The *jurisdiction* shall fill in this part of the table with the wind speed from the basic wind speed map [Figure R301.2(4)A]. Wind exposure category shall be determined on a site-specific basis in accordance with Section R301.2.1.4.
- e. The outdoor design dry-bulb temperature shall be selected from the columns of 97 $\frac{1}{2}$ -percent values for winter from Appendix D of the *International Plumbing Code*. Deviations from the Appendix D temperatures shall be permitted to reflect local climates or local weather experience as determined by the *building official*.
- f. The *jurisdiction* shall fill in this part of the table with the seismic design category determined from Section R301.2.2.1.
- g. The *jurisdiction* shall fill in this part of the table with (a) the date of the *jurisdiction*'s entry into the National Flood Insurance Program (date of adoption of the first code or ordinance for management of flood hazard areas), (b) the date(s) of the Flood Insurance Study and (c) the panel numbers and dates of the currently effective FIRMs and FBFMs or other flood hazard map adopted by the authority having *jurisdiction*, as amended.
- h. In accordance with Sections R905.1.2, R905.4.3.1, R905.5.3.1, R905.6.3.1, R905.7.3.1 and R905.8.3.1, where there has been a history of local damage from the effects of ice damming, the *jurisdiction* shall fill in this part of the table with “YES.” Otherwise, the *jurisdiction* shall fill in this part of the table with “NO.”
- i. The *jurisdiction* shall fill in this part of the table with the 100-year return period air freezing index (BF-days) from Figure R403.3(2) or from the 100-year (99 percent) value on the National Climatic Data Center data table “Air Freezing Index-USA Method (Base 32°F).”
- j. The *jurisdiction* shall fill in this part of the table with the mean annual temperature from the National Climatic Data Center data table “Air Freezing Index-USA Method (Base 32°F).”
- k. In accordance with Section R301.2.1.5, where there is local historical data documenting structural damage to buildings due to topographic wind speed-up effects, the *jurisdiction* shall fill in this part of the table with “YES.” Otherwise, the *jurisdiction* shall indicate “NO” in this part of the table.
- l. In accordance with Figure R301.2(4)A, where there is local historical data documenting unusual wind conditions, the *jurisdiction* shall fill in this part of the table with “YES” and identify any specific requirements. Otherwise, the *jurisdiction* shall indicate “NO” in this part of the table.
- m. In accordance with Section R301.2.1.2.1, the *jurisdiction* shall indicate the wind-borne debris wind zone(s). Otherwise, the *jurisdiction* shall indicate “NO” in this part of the table.

TABLE R301.2(2)
COMPONENT AND CLADDING LOADS FOR A BUILDING WITH A MEAN
ROOF HEIGHT OF 30 FEET LOCATED IN EXPOSURE B (ASD) (psf)^{a, b, c, d, e}

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa.

- a. The effective wind area shall be equal to the span length multiplied by an effective width. This width shall be permitted to be not less than one-third the span length. For cladding fasteners, the effective wind area shall not be greater than the area that is tributary to an individual fastener.
- b. For effective areas between those given, the load shall be interpolated or the load associated with the lower effective area shall be used.
- c. Table values shall be adjusted for height and exposure by multiplying by the adjustment coefficient in Table R301.2(3).
- d. See Figure R301.2(7) for location of zones.
- e. Plus and minus signs signify pressures acting toward and away from the building surfaces.

a. Alaska and Hawaii are classified as severe and negligible, respectively.
 b. Lines defining areas are approximate only. Local conditions may be more or less severe than indicated by region classification. A severe classification is where weather conditions result in significant snowfall combined with extended periods during which there is little or no natural thawing causing deicing salts to be used extensively.

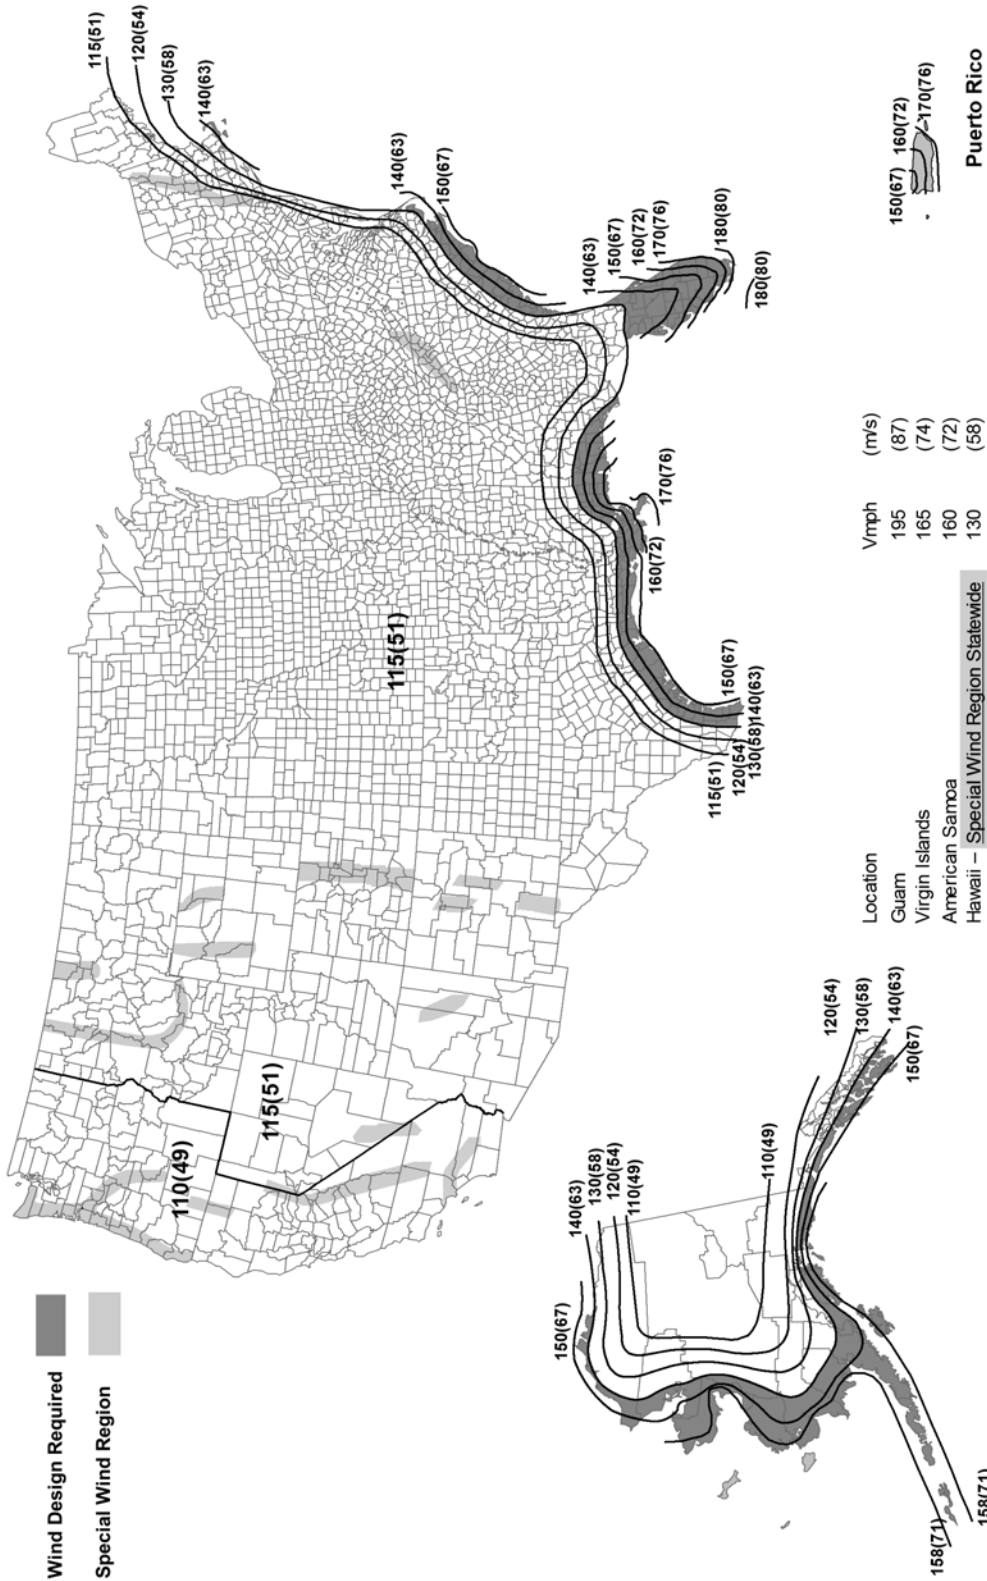

FIGURE R301.2(3)
WEATHERING PROBABILITY MAP FOR CONCRETE^{a, b}

Notes:

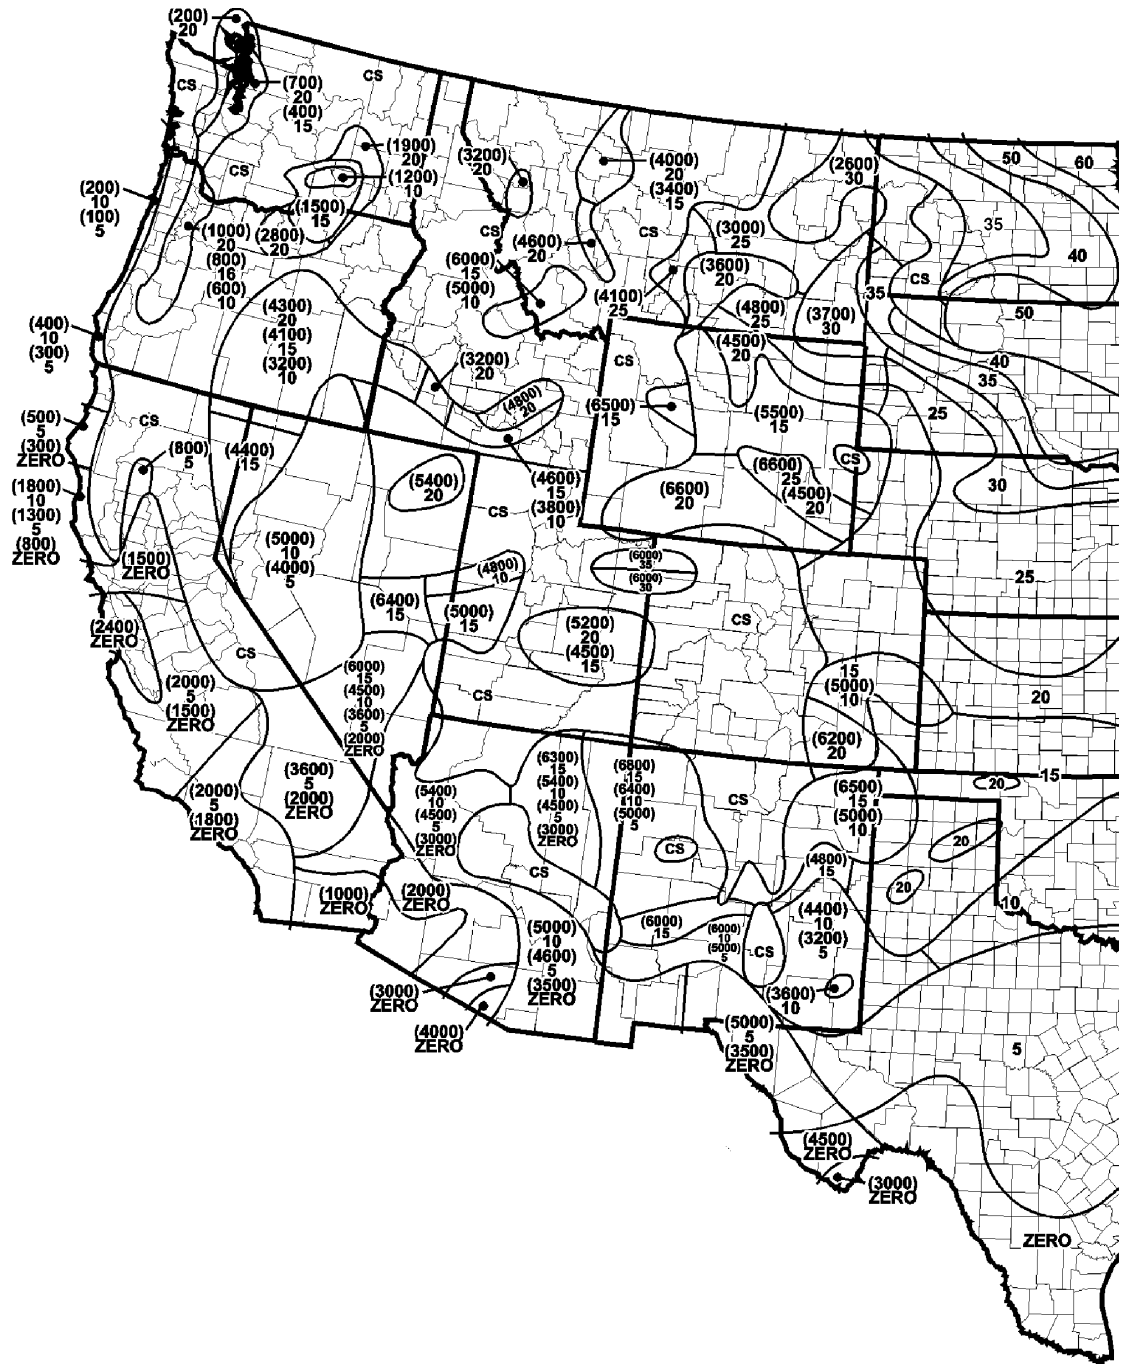

1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation between contours is permitted.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years (Annual Exceedance Probability = 0.00143, MRI = 700 Years).

FIGURE R301.2(4)A

R301.2.1 Wind design criteria. Buildings and portions thereof shall be constructed in accordance with the wind provisions of this code using the ultimate design wind speed in Table R301.2(1) as determined from Figure R301.2(4)A. The structural provisions of this code for wind loads are not permitted where wind design is required as specified in Section R301.2.1.1. Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where not otherwise specified, the wind loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.4. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 from the roof assembly to the foundation.

- ❖ Buildings must be capable of withstanding the wind loads based on the wind speed specified in Table R301.2(1). Jurisdictions determine the wind speeds used for entry in the table by the application of Figure R301.2(4)A. The structural provisions in the code are limited, however, and do not apply where wind design or structural engineering is required in accordance with Section R301.2.1.1. As buildings typically contain multiple construction methods and structural materials, the code's wind criteria that are applicable to each of the methods and materials that are incorporated in a building must be complied with. Wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors must be capable of withstanding the component and cladding wind pressures of Table R301.2(2) adjusted by the height and exposure coefficients given in Table R301.2(3).

Section R905.2.6 addresses the attachment details for asphalt shingles. Roofs with higher slopes or in

areas subject to higher wind speeds may require special methods of attachment (see commentary, Section R905.2.6).

Wind loads are a major consideration in designing a structure's lateral-force-resisting system. See Commentary Figure R301.2.1 for a schematic representation of the lateral component of wind loading on a building. Wind loads affect more than the lateral load system, as evidenced by provisions such as the roof tie-down requirements of Section R802.11. A continuous load path must be provided to transmit the roof uplift forces to the foundation.

For the 2015 edition, the wind design provisions of the *International Residential Code*® (IRC®) have been brought in line with the 2012 IBC and ASCE 7-10. New maps based on the ASCE 7-10 ultimate wind speed data, but converted back down to nominal (ASD) basis, were provided in previous editions of the IRC, which led to some confusion among those stakeholders who work with both the IRC and the IBC.

A working group of stakeholders including the National Association of Home Builders (NAHB), the major material associations, the American Society of Civil Engineers (ASCE), and the Insurance Institute for Business and Home Safety developed a new ultimate wind speed basis for design. Thus the Chapter 3 wind design criteria and the corresponding definitions (see the definitions for "Hurricane-prone regions" and "Windborne debris region" in Section R202) have been updated. Further updates include:

- A new ultimate wind speed map [Figure R301.2(4)A].
- A new map of the regions where special high-wind design is required [Figure R301.2(4)B].
- A revised table (Table R301.2.1.3) for conversion of ultimate design wind speeds to nominal design (ASD) wind speeds, for use with those standards that have not updated their provisions.
- A revised table [Table R301.2(2)] for component and cladding pressures.
- The addition of Section R301.2.1.2.1 for substitutions and modifications to ASTM E1886.
- Revisions to Table R301.2.1.5.1 to reflect the change to the ultimate design basis, including the addition of a footnote indicating that buildings must be considered as "wind design required" where the ultimate design wind speed, as modified by the table, is 140 mph or more, as also required by Section R301.2.1.1.

While the code does not provide any specific guidance on the topic, one should take note of the areas identified as "special wind regions" in the ultimate wind speed map [Figure R301.2(4)A], as well as other areas described in the footnotes to the figure where wind anomalies are observed. As the footnotes explain, these areas must be examined for unusual wind conditions. ASCE 7 discusses the use of

Figure R301.2.1
WIND FORCES ACTING ON AREA

regional climatic data in these areas. Section R301.2.1.5 provides greater detail for scenarios where topography causes a wind speed-up effect, which may overlap some of the special wind region considerations.

The region in Figure R301.2(4)B where the use of alternate prescriptive high-wind standards or engineered design is required is defined using the 130 mph contour along the Gulf Coast and along the southern portions of the Atlantic coast from Florida up to North Carolina. The 140-mph contour is used for the northern portions of the Atlantic coast from Virginia up to Maine, and for Alaska. A 130-mph trigger is also used for the assorted Caribbean and Pacific islands that are also considered part of the “hurricane-prone” region. This creates a region that approximately equals the region defined by the 110-mph contour under the wind map used in the 2000 through 2009 IRC, maintains areas of Florida and the Gulf Coast traditionally outside of the prescriptive limits of the IRC, and maintains areas of New England traditionally included within the prescriptive limits of the IRC.

Code users desiring a more accurate determination in areas near or along a particular contour (or in general) can make use of the Applied Technology Council’s (ATC) Windspeed by Location web site (<http://www.atcouncil.org/windspeed/>) to obtain site-specific wind speeds using latitude/longitude or site address. This site was developed by ATC using the same data used to develop the wind maps for ASCE 7, the IBC and the IRC.

Note that component and cladding pressure Table R301.2(2) uses ultimate design wind speed, but reports pressures at an ASD level. That is, the listed pressures incorporate the 0.6 multiplier on wind loads per the allowable stress design load combinations shown in Section 1605.3 of the IBC and Section 2.3.2 of ASCE 7-10. This is done here and throughout the updated code requirements to allow for easy adaptation of existing stock designs, construction documents and guidelines to the 2015 IRC, as the loads and pressures will be comparable to previous editions of the code for most sites.

R301.2.1.1 Wind limitations and wind design required.

The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(4)B.

Exceptions:

1. For concrete construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R404 and R608.
2. For structural insulated panels, the wind provisions of this code shall apply in accordance with the limitations of Section R610.

3. For cold-formed steel light-frame construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R505, R603 and R804.

In regions where wind design is required in accordance with Figure R301.2(4)B, the design of buildings for wind loads shall be in accordance with one or more of the following methods:

1. *AF&PA Wood Frame Construction Manual (WFCM)*.
2. *ICC Standard for Residential Construction in High-Wind Regions (ICC 600)*.
3. *ASCE Minimum Design Loads for Buildings and Other Structures (ASCE 7)*.
4. *AISI Standard for Cold-Formed Steel Framing—Prescriptive Method For One- and Two-Family Dwellings (AISI S230)*.
5. *International Building Code*.

The elements of design not addressed by the methods in Items 1 through 5 shall be in accordance with the provisions of this code.

Where ASCE 7 or the *International Building Code* is used for the design of the building, the wind speed map and exposure category requirements as specified in ASCE 7 and the *International Building Code* shall be used.

❖ With the exception of concrete construction, structural insulated panel (SIP) construction and cold-formed steel light-frame construction, the prescriptive structural provisions in the code do not apply where wind design is required in accordance with Figure R301.2(4)B. The prescriptive provisions for concrete exterior walls are applicable in regions with design wind speeds up to 160 mph (72 m/s), where the site is classified as Exposure B, 136 mph (61 m/s) for Exposure C and 125 mph (56 m/s) for Exposure D (see commentary, Section R608.2). The prescriptive SIP provisions are applicable in regions with ultimate design wind speeds of less than or equal to 155 mph (69 m/s), where the site is classified as Exposure B and 140 mph (63 m/s) where the site is classified as Exposure C (see commentary, Section R610.2).

Where the ultimate design wind speed exceeds the limitations given in the code, the prescriptive provisions of the code are not applicable. In such regions, structures must be designed or engineered for wind loads. For this purpose, the code expressly allows the use of AF&PA WFCM; ICC 600, *Standard for Residential Construction in High-Wind Regions*; ASCE 7, *Minimum Design Loads for Buildings and Other Structures*; and AISI S230, *Standard for Cold-formed Steel Framing—Prescriptive Method for One- and Two-family Dwellings for International Building Code (IBC)*. Some of these referenced standards have prescriptive provisions for regions that the code does not.

The building elements not addressed by Methods 1 through 5 must be in accordance with the provisions of the code. Only the structural design of the building to resist wind loads or seismic loads, and the selection of certain critical components such as window or roofing that is prone to wind damage, must be performed in accordance with Methods 1 through 5. The remaining provisions of the code including, but not limited to, architectural, mechanical, electrical and plumbing still apply to the building (see also the commentary to Section R301.2.1).

R301.2.1.1.1 Sunrooms. Sunrooms shall comply with AAMA/NPEA/NSA 2100. For the purpose of applying the criteria of AAMA/NPEA/NSA 2100 based on the intended use, sunrooms shall be identified as one of the following categories by the permit applicant, design professional or the property owner or owner's agent in the construction documents. Component and cladding pressures shall be used for the design of elements that do not qualify as main windforce-resisting systems. Main windforce-resisting system pressures shall be used for the design of elements assigned to provide support and stability for the overall *sunroom*.

Category I: A thermally isolated sunroom with walls that are open or enclosed with insect screening or 0.5 mm (20 mil) maximum thickness plastic film. The space is nonhabitable and unconditioned.

Category II: A thermally isolated sunroom with enclosed walls. The openings are enclosed with translucent or transparent plastic or glass. The space is nonhabitable and unconditioned.

Category III: A thermally isolated sunroom with enclosed walls. The openings are enclosed with translucent or transparent plastic or glass. The sunroom fenestration complies with additional requirements for air infiltration resistance and water penetration resistance. The space is nonhabitable and unconditioned.

Category IV: A thermally isolated sunroom with enclosed walls. The sunroom is designed to be heated or cooled by a separate temperature control or system and is thermally isolated from the primary structure. The sunroom fenestration complies with additional requirements for water penetration resistance, air infiltration resistance and thermal performance. The space is nonhabitable and conditioned.

Category V: A sunroom with enclosed walls. The sunroom is designed to be heated or cooled and is open to the main structure. The sunroom fenestration complies with additional requirements for water penetration resistance, air infiltration resistance and thermal performance. The space is habitable and conditioned.

- ❖ The code defines a sunroom in Section R202 as "A one-story structure attached to a dwelling with a glazing area in excess of 40 percent of the gross area of the structure's exterior walls and roof." These structures are typically constructed in one of two manners: 1. Using typical wood framing techniques; or 2. Using a stick system that consists of prefabricated framing of

aluminum, fiberglass, wood or other materials, with glass or opaque wall or roof panels, and steel or aluminum connections.

The first technique can be done in accordance with the provisions of the IRC for wood-framed construction. This section addresses the second method of constructing a sunroom. The provisions clarify the requirements for such sunrooms by referencing the provisions of AAMA/NPEA/NSA 2100-12, *Specifications for Sunrooms*. Sunrooms designed and constructed in accordance with AAMA/NPEA/NSA 2100 are required within the standard to meet the structural provisions of the IRC or the IBC; therefore, the appropriate engineering analysis has already been conducted for these structures. In addition, the standard establishes the specific requirements for these unique structures based on one of five designated categories. The intended category must be indicated in the construction documents. Those portions of the sunroom that are not part of the main wind-force-resisting system must be designed using component and cladding pressures. Main wind-force-resisting-system pressures must be considered in the design of the structural elements of the sunroom.

In 2002 the American Architectural Manufacturers Association (AAMA), the National Sunroom Association (NSA) and the National Patio Enclosure Association (NPEA) published the first U.S. standard for the design and specification of sunrooms—AAMA/NPEA/NSA 2100-02. The standard established five categories of sunrooms based on the intended use of the space, and established specific design and performance criteria for them based on the end use.

As the document began to be used and referenced in various local codes (such as the *Florida Building Code*) the members of the AAMA Sunroom Council and NSA became aware that improvements and updates were needed. These improvements included revisions that would bring the document in line with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440 for the design, testing and labeling of windows, glass doors and skylights, and revisions that would bring the foundation requirements more closely in line with the requirements of the IRC.

Commentary Figure R301.2.1.1.1 provides an overview of the requirements of AAMA/NPEA/NSA 2100 as they apply to the various categories of sunrooms.

R301.2.1.2 Protection of openings. Exterior glazing in buildings located in windborne debris regions shall be protected from windborne debris. Glazed opening protection for windborne debris shall meet the requirements of the Large Missile Test of ASTM E1996 and ASTM E1886 as modified in Section 301.2.1.2.1. Garage door glazed opening protection for windborne debris shall meet the requirements of an *approved* impact-resisting standard or ANSI/DASMA 115.

Exception: Wood structural panels with a thickness of not less than $\frac{7}{16}$ inch (11 mm) and a span of not more than 8 feet (2438 mm) shall be permitted for opening protection. Panels

shall be precut and attached to the framing surrounding the opening containing the product with the glazed opening. Panels shall be predrilled as required for the anchorage method and shall be secured with the attachment hardware provided. Attachments shall be designed to resist the component and cladding loads determined in accordance with either Table R301.2(2) or ASCE 7, with the permanent corrosion-resistant attachment hardware provided and anchors permanently installed on the building. Attachment in accordance with Table R301.2.1.2 is permitted for buildings with a mean roof height of 45 feet (13, 728 mm) or less where the ultimate design wind speed, V_{ult} , is 180 mph (290 kph) or less.

- ❖ Exterior glazing in buildings located in windborne debris regions must have openings that provide protection from windborne debris. The definition of “Windborne debris region” in Section R202 indicates that such regions are areas within hurricane-prone regions that are also located either:
 1. Within 1 mile of the coastal mean high water line and where the ultimate design wind speed, V_{ult} , is 130 mph (58 m/s) or more, or
 2. In Hawaii or where the ultimate design wind speed is 140 mph (63.6 m/s) or more.

The ultimate design wind speed, V_{ult} , is determined in accordance with Figure R301.2(4)A.

The opening protection, usually in the form of permanent shutters or laminated glass, must meet the requirements of the Large Missile Test of ASTM E1996 and ASTM E1886, as listed in Chapter 44. Section R301.2.1.2.1 contains code-required modifications to ASTM E1886. Glazing in garage doors must meet the protection requirements for garage doors in ANSI/DSMA 115, *Standard Method for Testing Sectional Garage Doors and Rolling Doors: Determination of Structural Performance Under Missile Impact and Cyclic Wind Pressure*.

The exception to Section R301.2.1.2 provides a prescriptive and more economical method for one- and two-story buildings. This method of opening protection uses wood structural panels that are limited to a maximum span of 8 feet (2438 mm), with fastening as specified in Table R301.2.1.2. The method is applicable to buildings with a mean roof height of 45 feet (13 728 mm) or less that are located where the ultimate design wind speed, V_{ult} , is 180 mph or less, as determined in accordance with Figure R301.2(4)A. The builder must precut the opening protection panels to fit each glazed opening and provide the necessary attachment hardware so that panels can be adequately anchored and installed quickly.

MINIMUM REQUIREMENTS	CATEGORY I	CATEGORY II	CATEGORY III	CATEGORY IV	CATEGORY V
Structural design in accordance with the code.	X	X	X	X	X
Fenestration products must comply with AAMA/WDMA/CSA 101/I.S.2/A440 (includes resistance to air leakage, water penetration, forced entry, etc., as well as structural design pressure rating).		X	X	X	X
Comply with the <i>International Energy Conservation Code</i> ® (IECC®) or IRC Chapter 11.				X	X
Comply with the foundation/footings, site location, and emergency escape and rescue openings requirements of the code.	X	X	X	X	X
Emergency escape and rescue openings are permitted to open onto a sunroom.	X				
Comply with the natural lighting requirements of the code.	X	X	X	X	X
Openings for natural lighting are permitted to open onto a sunroom.	X				
Comply with the requirements of the code for stairway and egress illumination.		X	X	X	X
Required to have exit lighting.		X	X	X	X
Receptacle outlets as required by NFPA 70, Article 314.				X	X

**Figure R301.2.1.1.1
SUNROOM MINIMUM REQUIREMENTS**

TABLE R301.2.1.2
WINDBORNE DEBRIS PROTECTION FASTENING
SCHEDULE FOR WOOD STRUCTURAL PANELS^{a, b, c, d}

FASTENER TYPE	FASTENER SPACING (inches) ^{a, b}		
	Panel span ≤ 4 feet	4 feet < panel span ≤ 6 feet	6 feet < panel span ≤ 8 feet
No. 8 wood screw based anchor with 2-inch embedment length	16	10	8
No. 10 wood screw based anchor with 2-inch embedment length	16	12	9
1/4-inch lag screw based anchor with 2-inch embedment length	16	16	16

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 4.448 N, 1 mile per hour = 0.447 m/s.

- a. This table is based on 180 mph ultimate design wind speeds, V_{ult} , and a 33-foot mean roof height.
- b. Fasteners shall be installed at opposing ends of the wood structural panel. Fasteners shall be located not less than 1 inch from the edge of the panel.
- c. Anchors shall penetrate through the exterior wall covering with an embedment length of not less than 2 inches into the building frame. Fasteners shall be located not less than 2 1/2 inches from the edge of concrete block or concrete.
- d. Panels attached to masonry or masonry/stucco shall be attached using vibration-resistant anchors having an ultimate withdrawal capacity of not less than 1,500 pounds.

❖ The fastening schedule provided in this table allows for the selection of the appropriate fasteners size and spacing when the prescriptive alternative is applied to a tested assembly, as required by Section R301.2.1.2. Installing the specified fasteners at both ends of the wood structural panel provides the necessary panel support. Hardware must be permanently mounted when using wood structural panel shutters for window protection for new construction. Using wood structural panels as window protection is basically an emergency option for the protection of existing buildings where the homeowner does not have some permanent shutter system in place.

While the code requires the panels to be precut and the attachment hardware provided, there are potentially many logistical problems with homeowners actually installing the panels when attachment hardware is not permanent. It is not clear that the homeowners will be sufficiently instructed on (or remember at a later date) how to attach the panels, in particular using the prescribed minimum spacing. Additionally, it can be extremely cumbersome to attempt to nail a sheet of plywood over a window, particularly on the second story of a building. There are also concerns about the capacity of nailed connections where the nails are

installed in the same hole repeatedly.

The minimum required capacity of masonry anchors is 1,500 pounds (6672 N). Evaluation reports (ICC, NES and SBCCI) for masonry anchors require a Factor of Safety (FS) of 4.0 if a special inspection is performed on the anchor installation. The required capacity of the masonry anchors to 1,500 pounds (6672 N) provides an FS more in line with the evaluation reports for masonry anchors.

R301.2.1.2.1 Application of ASTM E1996. The text of Section 2.2 of ASTM E1996 shall be substituted as follows:

2.2 ASCE Standard:

ASCE 7-10 American Society of Civil Engineers *Minimum Design Loads for Buildings and Other Structures*

The text of Section 6.2.2 of ASTM E1996 shall be substituted as follows:

6.2.2 Unless otherwise specified, select the wind zone based on the ultimate design wind speed, V_{ult} , as follows:

6.2.2.1 Wind Zone 1–130 mph ≤ ultimate design wind speed, $V_{ult} < 140$ mph.

6.2.2.2 Wind Zone 2–140 mph ≤ ultimate design wind speed, $V_{ult} < 150$ mph at greater than 1 mile (1.6 km) from the coastline. The coastline shall be measured from the mean high water mark.

6.2.2.3 Wind Zone 3–150 mph (58 m/s) ≤ ultimate design wind speed, $V_{ult} ≤ 170$ mph (76 m/s), or 140 mph (54 m/s) ≤ ultimate design wind speed, $V_{ult} ≤ 170$ mph (76 m/s) and within 1 mile (1.6 km) of the coastline. The coastline shall be measured from the mean high water mark.

6.2.2.4 Wind Zone 4–ultimate design wind speed, $V_{ult} > 170$ mph (76 m/s).

❖ See commentary to Section R301.2.1.

R301.2.1.3 Wind speed conversion. Where referenced documents are based on nominal design wind speeds and do not provide the means for conversion between ultimate design wind speeds and nominal design wind speeds, the ultimate design wind speeds, V_{ult} , of Figure R301.2(4)A shall be converted to nominal design wind speeds, V_{asd} , using Table R301.2.1.3.

❖ See commentary to Section R301.2.1.

TABLE R301.2.1.3. See below.

❖ Where referenced documents are based on nominal design wind speeds, the appropriate wind speed can be selected directly from this table using the ultimate design wind speed determined from Figure

TABLE R301.2.1.3
WIND SPEED CONVERSIONS^a

V_{ult}	110	115	120	130	140	150	160	170	180	190	200
V_{asd}	85	89	93	101	108	116	124	132	139	147	155

For SI: 1 mile per hour = 0.447 m/s.

- a. Linear interpolation is permitted.

R301.2(4)A. For example, if the ultimate design wind speed, V_{ult} , for a site is determined to be 110 mph (49.2 m/s), and it is necessary to design using one of the referenced standards in Section R301.2.1.1, the corresponding nominal design wind velocity would be 85 mph (38 m/s).

R301.2.1.4 Exposure category. For each wind direction considered, an exposure category that adequately reflects the characteristics of ground surface irregularities shall be determined for the site at which the building or structure is to be constructed. For a site located in the transition zone between categories, the category resulting in the largest wind forces shall apply. Account shall be taken of variations in ground surface roughness that arise from natural topography and vegetation as well as from constructed features. For a site where multiple detached one- and two-family *dwelling*s, *townhouses* or other structures are to be constructed as part of a subdivision or master-planned community, or are otherwise designated as a developed area by the authority having jurisdiction, the exposure category for an individual structure shall be based upon the site conditions that will exist at the time when all adjacent structures on the site have been constructed, provided that their construction is expected to begin within one year of the start of construction for the structure for which the exposure category is determined. For any given wind direction, the exposure in which a specific building or other structure is sited shall be assessed as being one of the following categories:

1. Exposure B. Urban and suburban areas, wooded areas or other terrain with numerous closely spaced obstructions having the size of single-family *dwelling*s or larger. Exposure B shall be assumed unless the site meets the definition of another type exposure.
 2. Exposure C. Open terrain with scattered obstructions, including surface undulations or other irregularities, having heights generally less than 30 feet (9144 mm) extending more than 1,500 feet (457 m) from the building site in any quadrant. This exposure shall also apply to any building located within Exposure B type terrain where the building is directly adjacent to open areas of Exposure C type terrain in any quadrant for a distance of more than 600 feet (183 m). This category includes flat, open country and grasslands.
 3. Exposure D. Flat, unobstructed areas exposed to wind flowing over open water, smooth mud flats, salt flats and unbroken ice for a distance of not less than 5,000 feet (1524 m). This exposure shall apply only to those buildings and other structures exposed to the wind coming from over the unobstructed area. Exposure D extends downwind from the edge of the unobstructed area a distance of 600 feet (183 m) or 20 times the height of the building or structure, whichever is greater.
- ❖ Wind loading on structures is a function of a site exposure category, which reflects the characteristics of ground surface irregularities and accounts for variations in ground surface roughness that arise from natural topography and vegetation, as well as from

constructed features. These categories range from Exposure B for the least severe exposure category to Exposure D for the most severe exposure category. Exposure B should be used wherever the site does not meet the definition for another category of exposure, as well as for urban and suburban areas, wooded areas and other terrain with numerous, closely spaced obstructions having the size of single-family dwellings or larger. The commentary of ASCE 7 contains a detailed discussion of wind exposure categories. The exposure category of homes constructed on a large residential development site should be based upon the exposure condition that will exist for the vast majority of the structure's life, not the temporary condition that may exist during build-out of the development. Residential construction frequently involves the construction of multiple detached homes and/or townhouses on a large residential development site. Such sites are often cleared creating a temporary situation where Exposure Category C exists until a significant number of the homes are constructed.

The commentary to ASCE 7 indicates that in a recent study, the majority of buildings are in Exposure Category B—as many as 60 to 80 percent. Even a higher percentage is likely for residential construction as jurisdictions push for higher density development and homes are constructed on smaller lots to reduce the impact of rapidly escalating land costs

R301.2.1.5 Topographic wind effects. In areas designated in Table R301.2(1) as having local historical data documenting structural damage to buildings caused by wind speed-up at isolated hills, ridges and escarpments that are abrupt changes from the general topography of the area, topographic wind effects shall be considered in the design of the building in accordance with Section R301.2.1.5.1 or in accordance with the provisions of ASCE 7. See Figure R301.2.1.5.1(1) for topographic features for wind speed-up effect.

In these designated areas, topographic wind effects shall apply only to buildings sited on the top half of an isolated hill, ridge or escarpment where all of the following conditions exist:

1. The average slope of the top half of the hill, ridge or escarpment is 10 percent or greater.
2. The hill, ridge or escarpment is 60 feet (18 288 mm) or greater in height for Exposure B, 30 feet (9144 mm) or greater in height for Exposure C, and 15 feet (4572 mm) or greater in height for Exposure D.
3. The hill, ridge or escarpment is isolated or unobstructed by other topographic features of similar height in the upwind direction for a distance measured from its high point of 100 times its height or 2 miles (3.2 km), whichever is less. See Figure R301.2.1.5.1(3) for upwind obstruction.
4. The hill, ridge or escarpment protrudes by a factor of two or more above the height of other upwind topo-

graphic features located in any quadrant within a radius of 2 miles (3.2 km) measured from its high point.

- ❖ These requirements are for consideration of topographic wind effects. Historically, consideration of wind speed-up due to topographic effects has been ignored in the United States for the design and construction of new homes. Provisions calling for consideration of topographic effects on wind were first included in the 1995 edition of ASCE 7.

The procedures for determining wind speed-up due to topographic effects require the services of a structural engineer with experience in wind analysis and design. Topographic configurations can be quite complex and any resulting speed-up can be difficult, at best, to determine. In fact, modeling the ground topography and testing in a wind tunnel is probably the only means of getting an accurate estimate of the wind speed-up. Using engineering calculations will likely give an overly conservative estimate of the resulting speed-up for an idealized topographic configuration.

A jurisdiction would require an investigation of topographic wind effects when historical data for the area documents structural damage to buildings due to wind speed-up at isolated hills, ridges and escarpments. The jurisdiction would indicate the need for this additional design requirement in Table R301.2(1).

Additionally, Figures R301.2.1.5.1(1), R301.2.1.5.1(2) and R301.2.1.5.1(3) provide guidance to aid builders and designers in designated areas requiring consideration of topographic wind effects on where wind speed-up will likely occur and needs to be considered. These provisions are based on the requirements of ASCE 7, with one exception. ASCE 7 requires consideration of wind speed-up for a building located on the top half of a hill, ridge or escarpment in Exposure Category C when its height is 15 feet (4572 mm) or greater.

This section sets the height at 30 feet (9144 mm) or greater for Exposure C, which is consistent with earlier

editions of ASCE 7. If left at 15 feet (4572 mm) or greater, every isolated farmhouse located on a small hill surrounded by flat, cleared farmland would be subjected to wind speed-up due to topographic effects. The 15-foot (4572 mm) trigger was considered to be simply too low and does not reflect what is occurring in the built environment.

An alternative simplified method of designing for topographic wind speed-up effects is offered in Section R301.2.1.5.1, which can be used with the prescriptive methods, and thus does not require engineering design.

TABLE R301.2.1.5.1. See below.

- ❖ See the commentary to Sections R301.2.1.5 and R301.2.1.5.1.

FIGURE R301.2.1.5.1(1). See page 3-28.

- ❖ This figure provides guidance to aid builders and designers in designated areas requiring consideration of topographic wind effects on where wind speed-up will likely occur and needs to be considered (see commentary, Sections R301.2.1.5 and R301.2.1.5.1).

FIGURE R301.2.1.5.1(2). See page 3-28.

- ❖ This figure provides guidance to aid builders and designers in designated areas requiring consideration of topographic wind effects on where wind speed-up will likely occur and needs to be considered (see commentary, Sections R301.2.1.5 and R301.2.1.5.1).

FIGURE R301.2.1.5.1(3). See page 3-28.

- ❖ This figure provides guidance to aid builders and designers in designated areas requiring consideration of topographic wind effects on where wind speed-up will likely occur and needs to be considered (see commentary, Sections R301.2.1.5 and R301.2.1.5.1).

TABLE R301.2.1.5.1
ULTIMATE DESIGN WIND SPEED MODIFICATION FOR TOPOGRAPHIC WIND EFFECT^{a, b}

ULTIMATE DESIGN WIND SPEED FROM FIGURE R301.2(4)A (mph)	AVERAGE SLOPE OF THE TOP HALF OF HILL, RIDGE OR ESCARPMENT (percent)						
	0.10	0.125	0.15	0.175	0.20	0.23	0.25
	Required ultimate design wind speed-up, modified for topographic wind speed-up (mph)						
110	132	137	142	147	152	158	162
115	138	143	148	154	159	165	169
120	144	149	155	160	166	172	176
130	156	162	168	174	179	N/A	N/A
140	168	174	181	N/A	N/A	N/A	N/A
150	180	N/A	N/A	N/A	N/A	N/A	N/A

For SI: 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm.

a. Table applies to a feature height of 500 feet or less and dwellings sited a distance equal or greater than half the feature height.

b. Where the ultimate design wind speed as modified by Table R301.2.1.5.1 equals or exceeds 140 miles per hour, the building shall be considered as “wind design required” in accordance with Section R301.2.1.1.

Note: $H/2$ determines the measurement point for L_h . L is twice L_h .

FIGURE R301.2.1.5.1(1)
TOPOGRAPHIC FEATURES FOR WIND SPEED-UP EFFECT

FIGURE R301.2.1.5.1(2)
ILLUSTRATION OF WHERE ON A TOPOGRAPHIC FEATURE, WIND SPEED INCREASE IS APPLIED

FIGURE R301.2.1.5.1(3)
UPWIND OBSTRUCTION

R301.2.1.5.1 Simplified topographic wind speed-up method. As an alternative to the ASCE 7 topographic wind provisions, the provisions of Section R301.2.1.5.1 shall be permitted to be used to design for wind speed-up effects, where required by Section R301.2.1.5.

Structures located on the top half of isolated hills, ridges or escarpments meeting the conditions of Section R301.2.1.5 shall be designed for an increased basic wind speed as determined by Table R301.2.1.5.1. On the high side of an escarpment, the increased basic wind speed shall extend horizontally downwind from the edge of the escarpment 1.5 times the horizontal length of the upwind slope (1.5L) or 6 times the height of the escarpment (6H), whichever is greater. See Figure R301.2.1.5.1(2) for where wind speed increase is applied.

❖ Section R301.2.1.5.1 is an alternative for compliance with ASCE 7 as specified in Section R301.2.1.5. The methodology proposed is an outgrowth of the wind simplification process developed by the Structural Engineers of Washington (SEAW) and the Applied Technology Council (ATC), and is an attempt at simplifying the wind design process in the code for areas with extreme topography.

R301.2.2 Seismic provisions. The seismic provisions of this code shall apply as follows:

1. *Townhouses* in Seismic Design Categories C, D₀, D₁ and D₂.
2. Detached one- and two-family *dwelling*s in Seismic Design Categories, D₀, D₁ and D₂.

❖ Earthquakes generate internal forces in a structure caused by inertia. This is depicted in Commentary Figure R301.2.2. These forces can cause a building to be distorted and severely damaged. The objective of earthquake-resistant construction is to resist these forces and the resulting distortions.

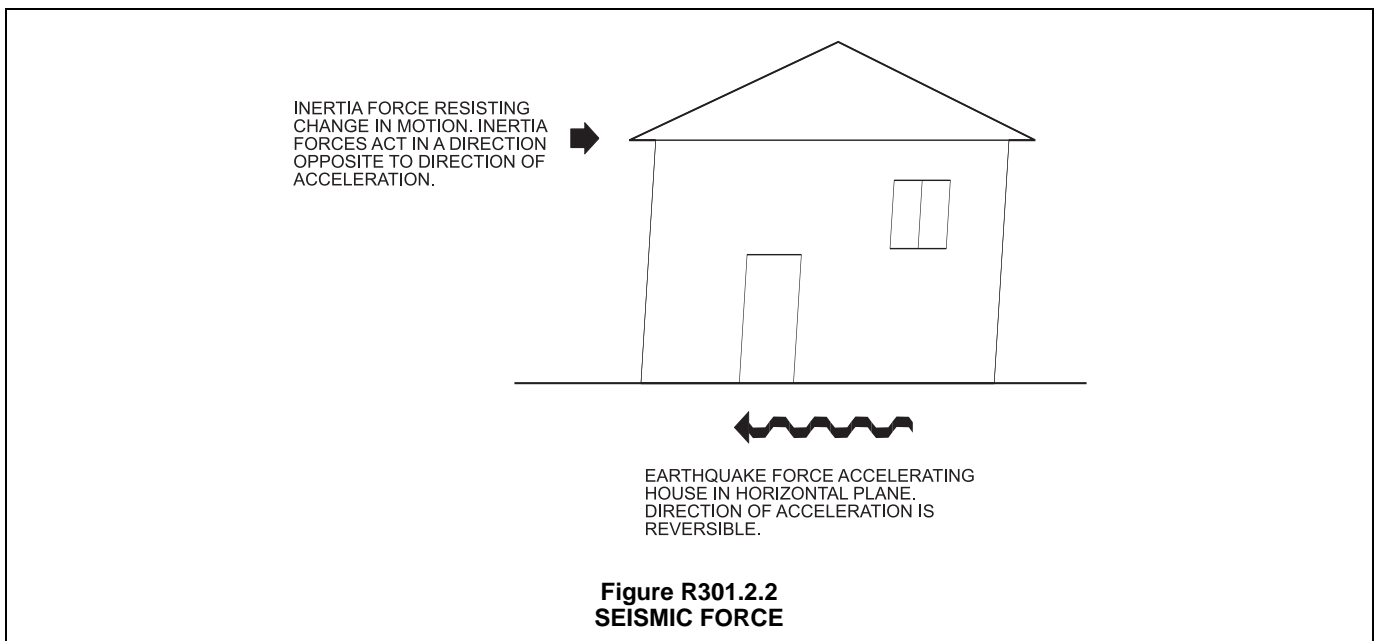

Providing for the adequate earthquake performance

of any structure begins with assessing the degree of hazard at the proposed site. As in the IBC, this is accomplished in the code by assigning a seismic design category (see Section R301.2.2.1 and the definition in Chapter 2). These range from Seismic Design Category A, representing the lowest level of seismic hazard, to Seismic Design Category E, representing the highest hazard. Buildings in Seismic Design Category E must be designed in accordance with the IBC, except as allowed in Section R301.2.2.1. Under the code, the seismic design category depends on the building location according to Figure R301.2(2), unless one of the options permitting a more precise determination is exercised.

The code's seismic provisions apply to buildings classified as Seismic Design Category C, D₀, D₁ or D₂. Detached one- and two-family dwellings need to comply with only the seismic requirements of the code when classified as Seismic Design Category D₀, D₁ or D₂. In other words, only townhouses constructed under Section R101.2 need to comply with Seismic Design Category C requirements. All buildings classified as Seismic Design Category A or B, as well as detached one- and two-family dwellings classified as Seismic Design Category C, will perform satisfactorily when constructed in accordance with the basic prescriptive requirements of the code.

Values for seismic loads on structures are based on a percentage of the dead load, and the code prescriptive provisions for structural elements that resist seismic forces are based on an assumed dead load. Generally, the building dead loads as described in Section R301.4 are reflected in the prescriptive design tables throughout the code.

FEMA 232, *Home Builder's Guide to Seismic-resistant Construction*, is an excellent source of additional information on seismic-resistant construction, particularly as it pertains to residential buildings.

R301.2.2.1 Determination of seismic design category. Buildings shall be assigned a seismic design category in accordance with Figure R301.2(2).

❖ Unlike the IBC, the code does not require a calculation to determine the seismic design category of a structure. Instead, the seismic design category is taken directly from Figure R301.2(2). The seismic design categories shown in Figure R301.2(2) are based solely on the Short Period Design Spectral Response Accelerations, SDS, assuming soil Site Class D, as defined in Section 1613 of the IBC.

A convenient alternative to the maps of Figure R301.2(2) and the calculations described in Section R301.2.2.1.1 is the Seismic Design Parameters program prepared by USGS and the USGS National Seismic Hazard Mapping Project web site (<http://earthquake.usgs.gov/hazards>). Either of these allows a computer user to view the seismic hazard map of the code in more detail. The Seismic Design Parameters program also provides determination of a site's seismic design category using either the zip code or the longitude and latitude of the site. Because use of longitude and latitude is more precise, this approach is preferable.

The seismic design category classification provides a relative scale of earthquake risk to structures. The seismic design category considers not only the seismicity of the site in terms of the mapped spectral response accelerations, but also the site soil profile and the nature of the structure's occupancy category. Housing, in areas that have a low seismic risk and are classified as Seismic Design Categories A and B, need not go through the seismic design consideration. Structures in Seismic Design Categories C and D are considered moderate to high risk and should be designed in accordance with this section. In an area that is close to a major active fault, where S_1 is greater than or equal to 1.17g, there is deemed to be considerable seismic risk, and the seismic design category is classified as E. Dwellings in Seismic Category E must be designed in accordance with the IBC (see Section R301.2.2.4). The seismic design category classification is a key criterion in using and understanding the seismic requirements because the analysis method, general design, structural material detailing, and the structure's component and system design requirements are determined, at least in part, by the seismic design category.

R301.2.2.1.1 Alternate determination of seismic design category. The seismic design categories and corresponding short-period design spectral response accelerations, S_{DS} shown in Figure R301.2(2) are based on soil Site Class D, as defined in Section 1613.3.2 of the *International Building Code*. If soil conditions are other than Site Class D, the short-period design spectral response accelerations, S_{DS} , for a site can be determined in accordance with Section 1613.3 of the *International Building Code*. The value of S_{DS} determined in accordance with Section 1613.3 of the *International Building*

Code is permitted to be used to set the seismic design category in accordance with Table R301.2.2.1.1, and to interpolate between values in Tables R602.10.3(3), R603.9.2(1) and other seismic design requirements of this code.

❖ In recognition that there may be an advantage to determining a building's seismic design category using the more detailed procedure of the IBC, the code allows this as an option. If soil conditions are other than Site Class D, for instance, the Short Period Design Spectral Response Acceleration (SDS) for a site may be determined using Section 1613 of the IBC. This value of SDS can then be used to establish the seismic design category according to Table R301.2.2.1.1. Determining SDS in this manner, although requiring more work, will provide the benefit of reducing the amount of wall bracing that would otherwise be required by the provisions in Chapter 6, based solely on seismic design category. This is accomplished, in Table R602.10.3(3) for instance, by interpolating between the tabulated values using the values of SDS determined as described above.

**TABLE R301.2.2.1.1
SEISMIC DESIGN CATEGORY DETERMINATION**

CALCULATED S_{DS}	SEISMIC DESIGN CATEGORY
$S_{DS} \leq 0.17g$	A
$0.17g < S_{DS} \leq 0.33g$	B
$0.33g < S_{DS} \leq 0.50g$	C
$0.50g < S_{DS} \leq 0.67g$	D ₀
$0.67g < S_{DS} \leq 0.83g$	D ₁
$0.83g < S_{DS} \leq 1.25g$	D ₂
$1.25g < S_{DS}$	E

❖ This table lists the seismic design category for ranges of Short Period Design Spectral Response Acceleration, SDS. These numbers correspond exactly to the legend in the Seismic Design Category Map, Figure R301.2(2). Use of this table is necessary only if the alternative seismic design category determination is used.

R301.2.2.1.2 Alternative determination of Seismic Design Category E. Buildings located in Seismic Design Category E in accordance with Figure R301.2(2) are permitted to be reclassified as being in Seismic Design Category D₂ provided that one of the following is done:

1. A more detailed evaluation of the seismic design category is made in accordance with the provisions and maps of the *International Building Code*. Buildings located in Seismic Design Category E in accordance with Table R301.2.2.1.1, but located in Seismic Design Category D in accordance with the *International Building Code*, shall be permitted to be designed using the Seismic Design Category D₂ requirements of this code.
2. Buildings located in Seismic Design Category E that conform to the following additional restrictions are per-

mitted to be constructed in accordance with the provisions for Seismic Design Category D_2 of this code:

- 2.1. All exterior shear wall lines or *braced wall panels* are in one plane vertically from the foundation to the uppermost *story*.
- 2.2. Floors shall not cantilever past the *exterior walls*.
- 2.3. The building is within the requirements of Section R301.2.2.2.5 for being considered as regular.

❖ The code permits construction of buildings classified as Seismic Design Category E in Figure R301.2(2) in accordance with the provisions for Seismic Design Category D_2 if the building has no irregular features as described in Section R301.2.2.2.5. In addition, out-of-plane offsets in the exterior shear-wall lines or braced wall panels are not allowed, and floors are not permitted to cantilever beyond the exterior walls. In other words, this reclassification to a lower seismic design category is limited to very regular, “box-like” structures.

Also, a building classified as Seismic Design Category E using Figure R301.2(2) may possibly be reclassified to Seismic Design Category D_2 if a more detailed evaluation in accordance with the provisions of the IBC is undertaken. If application of the IBC provisions results in a classification of Seismic Design Category D, then the building may be constructed as Seismic Design Category D_2 under the code.

R301.2.2.2 Seismic Design Category C. Structures assigned to Seismic Design Category C shall conform to the requirements of this section.

❖ This section establishes the limitations for weights, irregularity and structures in Seismic Design Category C. This would also be applicable for Seismic Design Categories D_0 , D_1 and D_2 by the reference in Section R301.2.2.3.

R301.2.2.2.1 Weights of materials. Average dead loads shall not exceed 15 pounds per square foot (720 Pa) for the combined roof and ceiling assemblies (on a horizontal projection) or 10 pounds per square foot (480 Pa) for floor assemblies, except as further limited by Section R301.2.2. Dead loads for walls above *grade* shall not exceed:

1. Fifteen pounds per square foot (720 Pa) for exterior light-frame wood walls.
2. Fourteen pounds per square foot (670 Pa) for exterior light-frame cold-formed steel walls.
3. Ten pounds per square foot (480 Pa) for interior light-frame wood walls.
4. Five pounds per square foot (240 Pa) for interior light-frame cold-formed steel walls.
5. Eighty pounds per square foot (3830 Pa) for 8-inch-thick (203 mm) masonry walls.
6. Eighty-five pounds per square foot (4070 Pa) for 6-inch-thick (152 mm) concrete walls.

7. Ten pounds per square foot (480 Pa) for SIP walls.

Exceptions:

1. Roof and ceiling dead loads not exceeding 25 pounds per square foot (1190 Pa) shall be permitted provided that the wall bracing amounts in Section R602.10.3 are increased in accordance with Table R602.10.3(4).
2. Light-frame walls with stone or masonry veneer shall be permitted in accordance with the provisions of Sections R702.1 and R703.
3. Fireplaces and chimneys shall be permitted in accordance with Chapter 10.

❖ As stated in Section R301.2.2, the dead loads of structures in seismic design categories regulated by the code must be within the limits listed in this section. Exceeding these limits would necessitate a design of the lateral-force-resisting system as described in Section R301.1.2. In some cases, these dead load limits are more restrictive than the dead load allowances in the prescriptive tables of the code [e.g., Table R502.3.1(1) for floor joist and Table R802.5(1) for rafters].

Exception 1 permits the use of roof/ceiling assemblies that exceed the 15 pounds per square foot (psf) (720 Pa) dead load limit if additional wall bracing is installed as determined using the adjustment factors of Table R602.10.3(4). This would permit the use of heavier roof coverings, such as tile. The additional wall bracing compensates for the additional seismic force that would be attributed to the added dead load.

Exception 2 directly references Sections R702.1 and R703. Section R702.1 specifically addresses interior stone and masonry veneer and Section R703 contains the requirements for the support and anchorage of masonry veneer.

Exception 3 references Chapter 10 for the seismic limitations for chimneys and fireplaces. Seismic reinforcing requirements for masonry fireplaces are found in Section R1001.3 and seismic anchorage of masonry fireplaces is covered in Section R1001.4.

R301.2.2.2.2 Stone and masonry veneer. Anchored stone and masonry veneer shall comply with the requirements of Sections R702.1 and R703.

❖ Stone and masonry veneer are addressed in Chapter 7 of the code. Table R703.7(1) lists the stone and masonry veneer limitations based on the seismic design category.

R301.2.2.2.3 Masonry construction. Masonry construction shall comply with the requirements of Section R606.12.

❖ This section provides a cross reference to the masonry sections in the code for seismic requirements.

R301.2.2.2.4 Concrete construction. Detached one- and two-family *dwellings* with exterior above-*grade* concrete walls shall comply with the requirements of Section R608, PCA 100 or shall be designed in accordance with ACI 318.

Townhouses with above-grade exterior concrete walls shall comply with the requirements of PCA 100 or shall be designed in accordance with ACI 318.

❖ This section provides a cross reference to the prescriptive provisions for concrete construction in Seismic Design Category C. Townhouses, by nature of being multiple-family housings, and exterior above-grade concrete walls, may not use the simplified approach in Section R608. As an alternative, concrete construction may be designed in accordance with accepted engineering practice.

R301.2.2.2.5 Irregular buildings. The seismic provisions of this code shall not be used for irregular structures located in Seismic Design Categories C, D₀, D₁ and D₂. Irregular portions of structures shall be designed in accordance with accepted engineering practice to the extent the irregular features affect the performance of the remaining structural system. Where the forces associated with the irregularity are resisted by a structural system designed in accordance with accepted engineering practice, design of the remainder of the building shall be permitted using the provisions of this code. A building or portion of a building shall be considered to be irregular where one or more of the following conditions occur:

1. Where exterior shear wall lines or *braced wall panels* are not in one plane vertically from the foundation to the uppermost *story* in which they are required.

Exception: For wood light-frame construction, floors with cantilevers or setbacks not exceeding four times the nominal depth of the wood floor joists are permitted to support *braced wall panels* that are out of plane with *braced wall panels* below provided that:

1. Floor joists are nominal 2 inches by 10 inches (51 mm by 254 mm) or larger and spaced not more than 16 inches (406 mm) on center.
2. The ratio of the back span to the cantilever is not less than 2 to 1.
3. Floor joists at ends of *braced wall panels* are doubled.
4. For wood-frame construction, a continuous rim joist is connected to ends of cantilever joists. When spliced, the rim joists shall be spliced using a galvanized metal tie not less than 0.058 inch (1.5 mm) (16 gage) and 1½ inches (38 mm) wide fastened with six 16d nails on each side of the splice or a block of the same size as the rim joist of sufficient length to fit securely between the joist space at which the splice occurs fastened with eight 16d nails on each side of the splice; and
5. Gravity loads carried at the end of cantilevered joists are limited to uniform wall and roof loads and the reactions from headers having a span of 8 feet (2438 mm) or less.

2. Where a section of floor or roof is not laterally supported by shear walls or *braced wall lines* on all edges.

Exception: Portions of floors that do not support shear walls or *braced wall panels* above, or roofs, shall be permitted to extend not more than 6 feet (1829 mm) beyond a shear wall or *braced wall line*.

3. Where the end of a *braced wall panel* occurs over an opening in the wall below and ends at a horizontal distance greater than 1 foot (305 mm) from the edge of the opening. This provision is applicable to shear walls and *braced wall panels* offset in plane and to *braced wall panels* offset out of plane as permitted by the exception to Item 1.

Exception: For wood light-frame wall construction, one end of a *braced wall panel* shall be permitted to extend more than 1 foot (305 mm) over an opening not more than 8 feet (2438 mm) in width in the wall below provided that the opening includes a header in accordance with the following:

1. The building width, loading condition and framing member species limitations of Table R602.7(1) shall apply; and
 2. Not less than one 2 × 12 or two 2 × 10 for an opening not more than 4 feet (1219 mm) wide; or
 3. Not less than two 2 × 12 or three 2 × 10 for an opening not more than 6 feet (1829 mm) in width; or
 4. Not less than three 2 × 12 or four 2 × 10 for an opening not more than 8 feet (2438 mm) in width; and
 5. The entire length of the *braced wall panel* does not occur over an opening in the wall below.
4. Where an opening in a floor or roof exceeds the lesser of 12 feet (3658 mm) or 50 percent of the least floor or roof dimension.
 5. Where portions of a floor level are vertically offset.

Exceptions:

1. Framing supported directly by continuous foundations at the perimeter of the building.
 2. For wood light-frame construction, floors shall be permitted to be vertically offset when the floor framing is lapped or tied together as required by Section R502.6.1.
6. Where shear walls and *braced wall lines* do not occur in two perpendicular directions.
 7. Where stories above *grade plane* partially or completely braced by wood wall framing in accordance with Section R602 or cold-formed steel wall framing in accordance with Section R603 include masonry or concrete construction. Where this irregularity applies, the

entire story shall be designed in accordance with accepted engineering practice.

Exception: Fireplaces, chimneys and masonry veneer as permitted by this code.

- ❖ Conventional light-frame construction typically allows cantilevers, offsets, etc., within certain limits in order to accommodate common design features and options. These features are not well suited to resisting earthquake forces. This becomes more of a concern in areas of higher seismic hazard. Where this is the case, it is preferable that the building, or more importantly the lateral-force-resisting system, be more “box-like” or regular.

Accordingly, this section identifies building features that are irregular and are not permitted under the concrete or conventional light-frame construction provisions in Seismic Design Categories C, D₀, D₁ and D₂. These irregular portions of structures must be designed in accordance with accepted engineering practice. A portion of a building is classified as “irregular” when one of the several conditions described in the code occurs.

Out-of-plane offsets in exterior braced wall lines have been recognized as a factor in buildings damaged by earthquakes. Where an offset occurs, the

earthquake forces must be transferred through the floor framing. Thus, Item 1 stipulates that exterior shear wall lines or braced wall panels that are not in one plane vertically from the foundation to the uppermost story in which they are required constitute an irregularity as illustrated in Commentary Figure R301.2.2.2.5(1). The exception, illustrated in Commentary Figure R301.2.2.2.5(2), allows out-of-plane offsets not exceeding four times the nominal depth of the wood floor joists supporting the braced wall line above. There are five additional limitations that must be met to ensure the adequacy of the supporting floor framing. Use of this exception is limited to wood light-frame construction.

Typically, braced wall lines are located around the perimeter of floors and walls where forces are greatest. As Item 2 indicates, an irregularity occurs where a portion of a floor or roof is not laterally supported by shear walls or braced wall lines on all edges. This is shown in Commentary Figure R301.2.2.2.5(3). The exception permits a floor or roof to extend beyond a braced wall line as illustrated in Commentary Figure R301.2.2.2.5(4).

Where the end of a braced wall panel occurs over an opening in the wall below, an irregularity will be present if the panel extends a horizontal distance greater than

1 foot (305 mm) from the edge of the opening. As Commentary Figure R301.2.2.2.5(5) illustrates, this applies to braced wall panels offset out of plane, as well as in plane. An exception for wood light-frame construction permits a braced wall panel to extend more than 1 foot (305 mm) over an opening in the wall below if the opening includes a header, in accordance with this exception, and the entire length of the braced wall panel does not occur over the opening. Openings in floors are required in most buildings to provide for stairways, equipment chases, etc. If the size of the opening is large compared to the size of the floor diaphragm, earthquake forces may overstress portions of the diaphragm. Because this could result in premature failure of the diaphragm and, thus, constitute an incomplete load path, the code limits the size of such openings allowed under conventional light-frame construction. Commentary Figure R301.2.2.2.5(6) illustrates the irregularity created by an opening in a floor or roof that

exceeds the lesser of 12 feet (3657 mm) or 50 percent of the least floor or roof dimension.

Commentary Figure R301.2.2.2.5(7) illustrates Item 5. An irregularity results where portions of a floor level are vertically offset. This limitation does not apply to framing that is supported directly by continuous foundations at the perimeter of the building. Also, in wood light-frame construction, floors may be vertically offset if the floor framing is lapped or tied together as required by Section R502.6.1.

More often than not, the shape of conventional light-frame buildings is regular with wall lines perpendicular to one another. Commentary Figure R301.2.2.2.5(8) depicts a nonorthogonal system. This type of irregularity occurs where shear walls or braced wall lines are not oriented perpendicular to each other.

In addition, an irregularity occurs if shear walls or braced wall lines are constructed of dissimilar bracing systems on any story level above grade plane. This

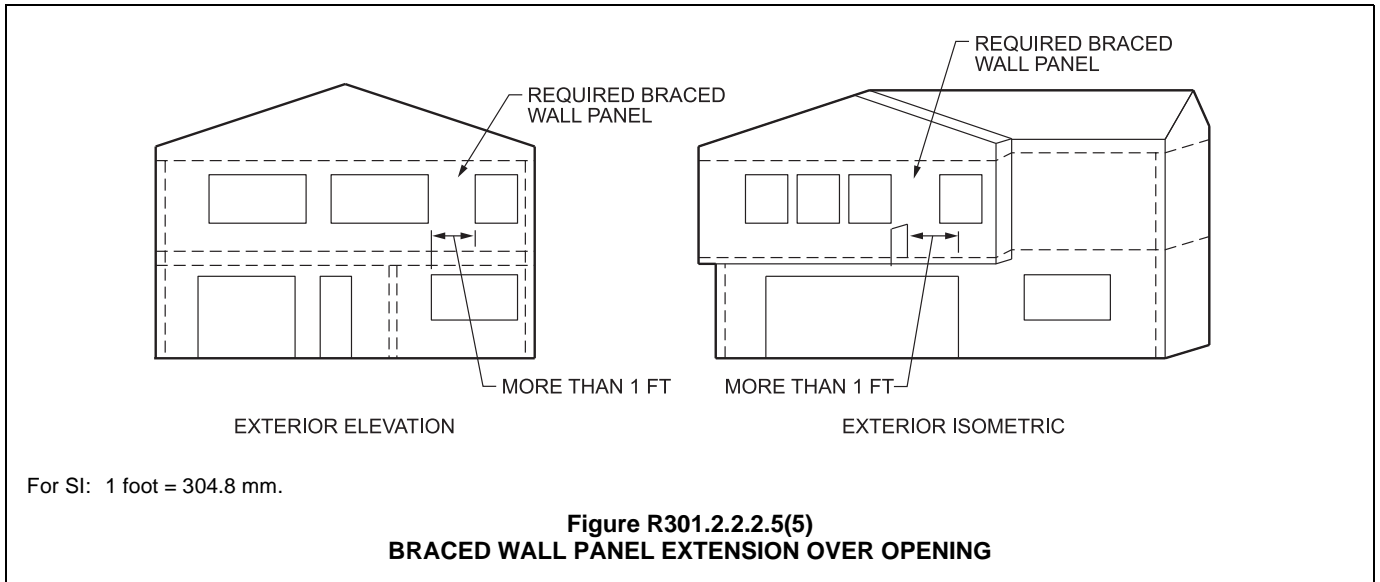

For SI: 1 foot = 304.8 mm.

requirement applies to the underlying framing system material, such as steel-framed shear walls or wood-framed braced wall panels combined with masonry or concrete construction in the same story.

Where this condition occurs, the entire story must be

designed in accordance with accepted engineering practice.

Masonry or concrete fireplaces, chimneys and masonry veneer can be combined with steel or wood framing and not be considered irregular.

R301.2.2.3 Seismic Design Categories D₀, D₁ and D₂. Structures assigned to Seismic Design Categories D₀, D₁ and D₂ shall conform to the requirements for Seismic Design Category C and the additional requirements of this section.

- ❖ Seismic requirements are cumulative as the seismic design category becomes higher. A structure that is assigned to Seismic Design Category D₀, D₁ or D₂ must comply with all the seismic requirements for Seismic Design Category C structures (see Section R301.2.2.2, in addition to those for Seismic Design Categories D₀, D₁ and D₂).

R301.2.2.3.1 Height limitations. Wood-framed buildings shall be limited to three stories above *grade plane* or the limits given in Table R602.10.3(3). Cold-formed, steel-framed buildings shall be limited to less than or equal to three stories above *grade plane* in accordance with AISI S230. Mezzanines as defined in Section R202 that comply with Section R325 shall not be considered as stories. Structural insulated panel buildings shall be limited to two stories above *grade plane*.

- ❖ This section limits the building height so that the lateral-force-resisting elements will not be overloaded during an earthquake. It provides a cross reference to other sections that limit the height of structures. Wood-framed buildings are generally limited to three stories. Floor levels meeting the limitations for mezzanines (see the definition in Chapter 2) need not be counted as a story.

R301.2.2.3.2 Stone and masonry veneer. Anchored stone and masonry veneer shall comply with the requirements of Sections R702.1 and R703.

- ❖ This section limits the height of stone and masonry veneer so that the bracing capacity will not be exceeded during an earthquake. This section references Sections R702.1 and R703. Tables R703.8.1(1) and R703.8(2) provide specific information on the maximum allowed height of veneer and the maximum allowed thickness and weight of veneer.

R301.2.2.3.3 Masonry construction. Masonry construction in Seismic Design Categories D₀ and D₁ shall comply with the requirements of Section R606.12.1. Masonry construction in Seismic Design Category D₂ shall comply with the requirements of Section R606.12.4.

- ❖ This is a cross reference to the section that is applicable to masonry seismic requirements.

R301.2.2.3.4 Concrete construction. Buildings with exterior above-*grade* concrete walls shall comply with PCA 100 or shall be designed in accordance with ACI 318.

- ❖ In Seismic Design Categories D₀, D₁ and D₂, exterior above-*grade* concrete walls must be engineered in accordance with PCA 100, *Prescriptive Design for Exterior Concrete Walls for One- and Two-family Dwellings*, or ACI 318, *Building Code Requirements for Structural Concrete*.

R301.2.2.3.5 Cold-formed steel framing in Seismic Design Categories D₀, D₁ and D₂. In Seismic Design Categories D₀, D₁ and D₂ in addition to the requirements of this code, cold-formed steel framing shall comply with the requirements of AISI S230.

- ❖ The prescriptive requirements for cold-formed steel framing in Seismic Design Category C are contained in the code. In addition to the seismic requirements found in the code, the cold-formed steel framing must comply with AISI S230.

R301.2.2.3.6 Masonry chimneys. Masonry chimneys shall be reinforced and anchored to the building in accordance with Sections R1003.3 and R1003.4.

- ❖ This is a cross reference to the section that is applicable to masonry chimney requirements.

R301.2.2.3.7 Anchorage of water heaters. Water heaters shall be anchored against movement and overturning in accordance with Section M1307.2.

- ❖ This is a cross reference to the section that is applicable to water heater anchorage.

R301.2.2.4 Seismic Design Category E. Buildings in Seismic Design Category E shall be designed to resist seismic loads in accordance with the *International Building Code*, except where the seismic design category is reclassified to a lower seismic design category in accordance with Section R301.2.2.1. Components of buildings not required to be designed to resist seismic loads shall be constructed in accordance with the provisions of this code.

❖ In an area that is close to a major active fault, where S_1 is greater than or equal to 1.25g, there is deemed to be considerable seismic risk, and the seismic design category is classified as E. Dwellings in Seismic Design Category E must be designed in accordance with Section 1613 of the IBC. The seismic design category classification is a key criterion in using and understanding the seismic requirements because the analysis method, general design, structural material detailing, and the structure's component and system design requirements are determined, at least in part, by the seismic design category. See the commentary to Section R301.2.2.1.2 for the alternative design of buildings in Seismic Design Category E.

R301.2.3 Snow loads. Wood-framed construction, cold-formed, steel-framed construction and masonry and concrete construction, and structural insulated panel construction in regions with ground snow loads 70 pounds per square foot (3.35 kPa) or less, shall be in accordance with Chapters 5, 6 and 8. Buildings in regions with ground snow loads greater than 70 pounds per square foot (3.35 kPa) shall be designed in accordance with accepted engineering practice.

❖ This section specifies the maximum ground snow load where the prescriptive provisions in Chapters 5, 6 and 8 apply.

The prescriptive provisions for floors, walls and roofs in Chapters 5, 6 and 8 apply in regions with ground snow loads of 70 psf (3.35 kPa) or less. Structures in regions with ground snow loads exceeding 70 psf (3.35 kPa) are beyond the limitations of these prescriptive provisions and, as stated in Section R301.1, a design would be required for all elements that carry snow loads. The ground snow load is to be determined using Figure R301.2(5) or by site-specific case studies as discussed in Section 7.0 of ASCE 7.

R301.2.4 Floodplain construction. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones) as established in Table R301.2(1), and substantial improvement and restoration of substantial damage of buildings and structures in flood hazard areas, shall be designed and constructed in accordance with Section R322. Buildings and structures that are located in more than one flood hazard area shall comply with the provisions associated with the most restrictive flood hazard area. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

❖ Buildings in flood hazard areas must meet certain requirements. The requirements are intended to reduce flood damage and improve resistance to flood

loads and other effects of flooding, such as saturation. See commentary for Section R105.3.1.1 regarding substantial improvement and substantial damage requirements. Some riverine flood plains are mapped to show floodways. Because floodways typically are characterized by deeper and faster moving water, it is appropriate that the design of buildings in these areas explicitly account for flood loads as called for in ASCE 24 (see commentary, Section R322). Where portions of buildings are located in different flood hazard areas, the entire building must comply with the most restrictive requirements.

R301.2.4.1 Alternative provisions. As an alternative to the requirements in Section R322, ASCE 24 is permitted subject to the limitations of this code and the limitations therein.

❖ This section provides an alternative for buildings and structures in all flood hazard areas to be designed and constructed according to ASCE 24.

R301.3 Story height. The wind and seismic provisions of this code shall apply to buildings with *story heights* not exceeding the following:

1. For wood wall framing, the *story height* shall not exceed 11 feet 7 inches (3531 mm) and the laterally unsupported bearing wall stud height permitted by Table R602.3(5).
2. For cold-formed steel wall framing, the *story height* shall be not more than 11 feet 7 inches (3531 mm) and the unsupported bearing wall stud height shall be not more than 10 feet (3048 mm).
3. For masonry walls, the *story height* shall be not more than 13 feet 7 inches (4140 mm) and the bearing wall clear height shall be not greater than 12 feet (3658 mm).

Exception: An additional 8 feet (2438 mm) of bearing wall clear height is permitted for gable end walls.
4. For insulating concrete form walls, the maximum *story height* shall not exceed 11 feet 7 inches (3531 mm) and the maximum unsupported wall height per *story* as permitted by Section R608 tables shall not exceed 10 feet (3048 mm).
5. For structural insulated panel (SIP) walls, the *story height* shall be not greater than 11 feet 7 inches (3531 mm) and the bearing wall height per *story* as permitted by Section R610 tables shall not exceed 10 feet (3048 mm).

Individual walls or wall studs shall be permitted to exceed these limits as permitted by Chapter 6 provisions, provided that *story heights* are not exceeded. An engineered design shall be provided for the wall or wall framing members where the limits of Chapter 6 are exceeded. Where the *story height* limits of this section are exceeded, the design of the building, or the noncompliant portions thereof, to resist wind and seismic loads shall be in accordance with the *International Building Code*.

❖ This section defines the *story height* and wall height limits. These *story heights* are the basis for the wind- and seismic-force-resisting system. The wall heights

are based on the materials used for wall construction. The wall height limits are prescribed for wood, steel, masonry and concrete. The story height permitted is the wall height including floor framing [not to exceed 16 inches (406 mm)]. The story height may vary depending on the material used for wall construction. Individual walls or wall studs are permitted to exceed these limits as permitted by Chapter 6 provisions, provided story heights are not exceeded. An engineered design must be provided for the wall or wall framing members when they exceed the limits of Chapter 6. However, if the story heights of this section are exceeded, an engineered design in accordance with the IBC must be provided for the building, or noncompliant portion thereof, for wind and seismic lateral forces.

R301.4 Dead load. The actual weights of materials and construction shall be used for determining dead load with consideration for the dead load of fixed service *equipment*.

- ❖ The actual weights of the materials used in the construction of a structure must be used to determine the dead loads. The code requires the weight of fixed service equipment (see the definition in Chapter 2) to be included, as well. It is important to verify that the actual dead loads of proposed buildings are within the limits of the dead load allowance in the prescriptive design tables of subsequent chapters. Otherwise, in accordance with Section R301.1, an engineered design is required. Also, the dead load limits of Section R301.2.2.2.1 must be met where required by a structure's seismic design category as explained in the commentary to Section R301.2.2.

The dead load of a building or other structure is the weight of all permanent construction, such as floors, roofs, permanent partitions, stairways and walls. The actual weights of materials and construction should be considered in the building design along with the dead

load of fixed service equipment. Commentary Figure R301.4 lists the weight of typical residential building components. Sources of information for weights of fixed service equipment include manufacturer's literature and trade association publications.

R301.5 Live load. The minimum uniformly distributed live load shall be as provided in Table R301.5.

- ❖ Table R301.5 lists the minimum uniformly distributed live loads (see the definition in Chapter 2) required for design of various portions of a residence. These loads are the basis for the prescriptive tables for floor systems in Chapter 5.

TABLE R301.5. See page 3-40.

- ❖ The uniform live loads of this table are consistent with Table 1607.1 of the IBC, which in turn is similar to ASCE 7. The table provides the minimum loads based on the use of a particular area or portion of a structure that must be considered for the design of corresponding structural elements of any residence constructed under the code. For instance, bedrooms (sleeping rooms) require use of a 30-psf (1.48 kN/m²) live load, while all other rooms must be designed for 40-psf (1915 kN/m²) uniform live load.

Attics with limited storage must be designed for 20-psf (957.6 N/m²) live loads, while a 10-psf (0.48 kN/m²) live load is required without storage. Note b provides criteria for when an attic is to be considered too small to provide adequate space for storage. Also, attics not required to have access in accordance with Section R807 may be considered as attics without storage. Habitable attics and attics accessed by fixed stairs, as they may be finished later, must be designed for a 30 psf (1.44 kN/m²) live load. Note g provides criteria for when the attic space is considered large enough to become potential storage or living space.

BUILDING PLANNING

COMPONENT	LOAD (psf)	COMPONENT	LOAD (psf)
CEILING		FLOORS AND FLOOR FINISHES	
Acoustical fiber tile	1	Asphalt block (2-inch), 1/2-inch mortar	30
Gypsum board (per 1/8-inch thickness)	0.55	Cement finish (1-inch) on stone-concrete fill	32
Mechanical duct allowance	4	Ceramic or quarry tile (3/4-inch) on 1/2-inch mortar bed	16
Plaster on tile or concrete	5	Ceramic or quarry tile (3/4-inch) on 1-inch mortar bed	23
Plaster on wood lath	8	Concrete fill finish (per thickness)	12
Suspended steel channel system	2	Hardwood flooring, 7/8-inch	4
Suspended metal lath and cement plaster	15	Linoleum or asphalt tile, 1/4-inch	1
Suspended metal lath and gypsum plaster	10	Marble and mortar on stone-concrete fill	33
Wood-furring suspension system	2.5	Slate (per inch thickness)	15
COVERINGS, ROOF AND WALL		Solid flat tile on 1-inch mortar base	23
Asbestos-cement shingles	4	Subflooring, 3/4-inch	3
Asphalt shingles	2	Terrazzo (12-inch) directly on slab	19
Cement tile	16	Terrazzo (1-inch) on stone-concrete fill	32
Clay tile (for mortar add 10 lb)		Terrazzo (1-inch) 2-inch stone concrete	32
Book tile, 2-inch	12	Wood block (3-inch) on mastic, no fill	10
Book tile, 3-inch	20	Wood block (3-inch) on 2-inch mortar base	16
Ludowici	10	FLOOR, WOOD-JOIST (NO PLASTER) DOUBLE WOOD FLOOR	
Roman	12	Joint Sizes (inches)	12-inch spacing (lb/ft²)
Spanish	19		16-inch spacing (lb/ft²)
Composition:			24-inch spacing (lb/ft²)
Three-ply ready roofing	1	2 x 6	5
Four-ply felt and gravel	5.5	2 x 8	5
Five-ply felt and gravel	6	2 x 10	6
Copper or tin	1	2 x 12	7
Corrugated asbestos-cement roofing	4		6
Deck, metal 20 gage	2.5	FRAME PARTITIONS	
Deck, metal, 18 gage	3	Moveable steel partitions	4
Decking, 2-inch wood (Douglas fir)	5	Wood or steel studs, 2-inch gypsum board each side	8
Decking, 3-inch wood (Douglas fir)	8	Wood studs, 2 x 4 unplastered	4
Fiberboard, 2-inch	0.75	Wood studs, 2 x 4, plastered one side	12
Gypsum sheathing, 2-inch	2	Wood studs, 2 x 4, plastered two sides	20
Insulation, roof boards (per inch thickness)		FRAME WALLS	
Cellular glass	0.7	Exterior stud walls:	
Fibrous glass	1.1	2 x 4 @ 16 inches, 5/8-inch gypsum insulated, 3/8-inch siding	
Fiberboard	1.5		
Perlite	0.8	2 x 6 @ 16 inches, 5/8-inch gypsum insulated, 3/8-inch siding	
Polystyrene foam	0.2		
Urethane foam with skin	0.5		
Plywood (per 1/8-inch thickness)	0.4	Exterior stud walls, with brick veneer	48
Rigid insulation, 2-inch	0.75	Windows, glass, frame and sash	8
Skylight, metal frame, 3/8-inch wired glass	8	MASONRY PARTITIONS AND WALLS	
Slate, 3/16-inch	7	Clay tile:	
		4-inch	18
		6-inch	24
		8-inch	24
Slate, 1/4-inch	10		
Structural insulated panels (SIPs)		Concrete block, heavy aggregate:	
4 1/2-inch thick	3	4-inch	30
6 1/2-inch thick	3.5	6-inch	42
8 1/2-inch thick	3.5	8-inch	55
10 1/2-inch thick	4.0	12-inch	85
12 1/2-inch thick	4.5		
Waterproofing members		Concrete block, light aggregate:	
Bituminous, gravel-covered	5.5	4-inch	20
Bituminous, smooth surface	1.5	6-inch	28
Liquid applied	1.0	8-inch	38
Single-ply, sheet	0.7	12-inch	55
Wood sheathing (per 1-inch thickness)	3		
Wood shingles	3		

For Sl: 1 pound per square foot = 0.0479 kPa, 1 inch = 25.4 mm, 1 pound = 0.4536 kg.

Note: Weights of masonry include mortar but not plaster. For plaster add 5 lb/ft² for each inch of plaster. Values given represent averages. In some cases there is considerable range for the same construction.

**Figure R301.4
MINIMUM DESIGN DEAD LOADS FOR TYPICAL RESIDENTIAL COMPONENTS**

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS
(in pounds per square foot)

USE	LIVE LOAD
Uninhabitable attics without storage ^b	10
Uninhabitable attics with limited storage ^{b, g}	20
Habitable attics and attics served with fixed stairs	30
Balconies (exterior) and decks ^c	40
Fire escapes	40
Guards and handrails ^d	200 ^h
Guard in-fill components ^f	50 ^h
Passenger vehicle garages ^a	50 ^a
Rooms other than sleeping rooms	40
Sleeping rooms	30
Stairs	40 ^c

For SI: 1 pound per square foot = 0.0479 kPa, 1 square inch = 645 mm²,
 1 pound = 4.45 N.

- a. Elevated garage floors shall be capable of supporting a 2,000-pound load applied over a 20-square-inch area.
- b. Uninhabitable *attics* without storage are those where the clear height between joists and rafters is not more than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
- c. Individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches, whichever produces the greater stresses.
- d. A single concentrated load applied in any direction at any point along the top.
- e. See Section R507.1 for decks attached to *exterior walls*.
- f. *Guard* in-fill components (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds on an area equal to 1 square foot. This load need not be assumed to act concurrently with any other live load requirement.
- g. Uninhabitable *attics* with limited storage are those where the clear height between joists and rafters is not greater than 42 inches, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The *attic* area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the *attic* is not less than 30 inches.
2. The slopes of the joists or truss bottom chords are not greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 pounds per square foot.

- h. Glazing used in handrail assemblies and *guards* shall be designed with a safety factor of 4. The safety factor shall be applied to each of the concentrated loads applied to the top of the rail, and to the load on the in-fill components. These loads shall be determined independent of one another, and loads are assumed not to occur with any other live load.

R301.6 Roof load. The roof shall be designed for the live load indicated in Table R301.6 or the snow load indicated in Table R301.2(1), whichever is greater.

- ❖ The basic 20-psf (0.96 kN/m²) roof live load indicated in Table R301.6 is a severe enough loading condition on the roof to address the support live loads created by

maintenance workers, including their equipment and materials. The code permits reduction of this basic live load based on the tributary area supported by any structural member of the roof. The rationale for this reduction of the roof live load is that it is highly improbable that structural members with large tributary areas would be loaded over the entire area with the full live load. In addition, the reduction of the basic roof live load for roofs is also a function of the slope of the roof because it becomes less probable that the loads on the roof members would be at maximum levels as the roof slope increases.

The code requires that the roof be designed to resist snow loading and does not permit a reduction of snow loads based on the tributary area, as it does for the roof live load. Be aware, however, that snow on the roof rarely accumulates evenly. The design should account for unbalanced snow loading. One case would be the loading of one slope of a gable roof with snow while the other slope is unloaded. Many roofs fail from accumulation of snow at valleys, parapets, roof structures and offsets in roofs. However, the code does not specify criteria for the determination of how these potential accumulations are to be handled. Snow loading provisions in the IBC may be consulted for these loading scenarios.

TABLE R301.6
MINIMUM ROOF LIVE LOADS IN POUNDS-FORCE PER SQUARE FOOT OF HORIZONTAL PROJECTION

ROOF SLOPE	TRIBUTARY LOADED AREA IN SQUARE FEET FOR ANY STRUCTURAL MEMBER		
	0 to 200	201 to 600	Over 600
Flat or rise less than 4 inches per foot (1:3)	20	16	12
Rise 4 inches per foot (1:3) to less than 12 inches per foot (1:1)	16	14	12
Rise 12 inches per foot (1:1) and greater	12	12	12

For SI: 1 square foot = 0.0929 m², 1 pound per square foot = 0.0479 kPa,
 1 inch per foot = 83.3 mm/m.

- ❖ See the commentary to Section R301.6.

R301.7 Deflection. The allowable deflection of any structural member under the live load listed in Sections R301.5 and R301.6 or wind loads determined by Section R301.2.1 shall not exceed the values in Table R301.7.

- ❖ The allowable deflection of structural members from the design live load must not exceed the values in Table R301.7. These limits are expressed in terms of the span length. Brittle finishes, such as plaster ceilings and exterior stucco walls, are protected by limiting the deflection of those elements.

Commentary Figure R301.7 shows a simply supported beam with dead load deflection before the live load has been applied. It also shows the same beam after the live load has been applied. The vertical distance that the center of the beam has moved from the initial dead load deflection position is called the live

load deflection. If a finish material is applied to this beam, the finish material is subject to distortion in proportion to this deflection.

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS^{b, c}

STRUCTURAL MEMBER	ALLOWABLE DEFLECTION
Rafters having slopes greater than 3:12 with finished ceiling not attached to rafters	$L/180$
Interior walls and partitions	$H/180$
Floors	$L/360$
Ceilings with brittle finishes (including plaster and stucco)	$L/360$
Ceilings with flexible finishes (including gypsum board)	$L/240$
All other structural members	$L/240$
Exterior walls—wind loads ^a with plaster or stucco finish	$H/360$
Exterior walls—wind loads ^a with other brittle finishes	$H/240$
Exterior walls—wind loads ^a with flexible finishes	$H/120^d$
Lintels supporting masonry veneer walls ^e	$L/600$

Note: L = span length, H = span height.

- a. For the purpose of the determining deflection limits herein, the wind load shall be permitted to be taken as 0.7 times the component and cladding (ASD) loads obtained from Table R301.2(2).
- b. For cantilever members, L shall be taken as twice the length of the cantilever.
- c. For aluminum structural members or panels used in roofs or walls of sunroom additions or patio covers, not supporting edge of glass or sandwich panels, the total load deflection shall not exceed $L/60$. For continuous aluminum structural members supporting edge of glass, the total load deflection shall not exceed $L/175$ for each glass lite or $L/60$ for the entire length of the member, whichever is more stringent. For sandwich panels used in roofs or walls of sunroom additions or patio covers, the total load deflection shall not exceed $L/120$.
- d. Deflection for exterior walls with interior gypsum board finish shall be limited to an allowable deflection of $H/180$.
- e. Refer to Section R703.8.2.

❖ Generally, it is not necessary to calculate the deflection indicated in Table R301.7, since the deflection limit is typically accounted for in the prescriptive design tables of the code. Since this is not the case for elements that required design in accordance with Section R301.1.2, the following example illustrates this requirement.

Example:

What is the maximum allowable deflection of a 20-foot (6096 mm) span with the following conditions?

- a. Rafter with no ceiling load having a slope of 5 units vertical in 12 units horizontal (42 percent).
- b. Rafters with no ceiling load having a slope of 2 units in 12 units horizontal (17 percent).
- c. A floor joist supporting a finished floor.

Solution:

Length = Span = 20-feet (6096 mm)

- a. $D_{MAX} = L/180 = 20 \text{ feet } 12 \text{ inches} / 180 = 1.33 \text{ inches}$ or approx. $1\frac{3}{8} \text{ inches}$ (35 mm)
- b. $D_{MAX} = L/240 = 20 \text{ feet } 12 \text{ inches} / 240 = 1.00 \text{ inches}$ or approx. 1 inch (25.4 mm)
- c. $D_{MAX} = L/360 = 20 \text{ feet } 12 \text{ inches} / 360 = 0.67 \text{ inches}$ or approx. $\frac{5}{8} \text{ inch}$ (15.9 mm)

R301.8 Nominal sizes. For the purposes of this code, dimensions of lumber specified shall be deemed to be nominal dimensions unless specifically designated as actual dimensions.

❖ Because solid-sawn lumber sizes are normally referred to using the nominal lumber dimensions, this clarification explains that any code references to lumber dimensions are to be taken as nominal dimensions unless explicitly stated otherwise.

SECTION R302 FIRE-RESISTANT CONSTRUCTION

❖ This section groups the fire-resistant construction requirements for building elements that are located between and within dwelling units and within close proximity of lot lines. This section addresses exterior wall location; townhouse separation; two-family dwellings separation; rated penetrations; garage penetrations; garage separation; under-stair protection; flame spread and smoke development; insulation; fireblocking; draft stopping required and insulation clearance from heat-producing devices.

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory

Figure R301.7
BEAM DEFLECTION

buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
 2. Walls of *dwelling*s and *accessory structures* located on the same *lot*.
 3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
 4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
 5. Foundation vents installed in compliance with this code are permitted.
- ❖ This section provides details for issues related to building location on the property, including the fire rating of exterior walls, permitted openings and projections. Tables R302.1(1) and R302.1(2) provide a tabular overview of the requirements of this section.

Concerning exterior wall protection, the code assumes that an owner has no control over an adjoining property. Thus, the location of buildings on the owner's property relative to the property line requires regulation. In addition, Section R302.6, which lists the separation requirements for garages and carports, specifically requires garages located less than 3 feet (914 mm) from a dwelling unit on the same lot to have not less than 1/2-inch (12.7 mm) gypsum board applied to the interior side of the walls. Opening protection for these walls is regulated by Section R302.5.

The property line concept is a convenient means of protecting one building from another as far as exposure is concerned. Exposure is the potential for heat to be transmitted from one building to another during a fire in the exposing building. Radiation is the primary means of heat transfer.

Table R302.1(1) specifies the exterior wall elements, fire separation distance and fire-resistance rating for dwellings without sprinkler systems. Walls less than 5 feet (1525 mm) from the property line must be of 1-hour fire-resistant construction. The fire-resistance rating also requires the rating exposure to be for both sides. The exterior rated walls are required to be an assembly that has been tested in accordance with either ASTM E119 or UL 263. This is not intended to limit fire-resistance-rated assemblies solely to the test criteria contained in these standards. Section R104.11 still allows the building official to approve alternative fire-resistance methodologies, such as those described in Section 703.3 of the IBC. This would still allow a builder to use acceptable engineering analysis, calculations in

accordance with Section 721 of the IBC or prescriptive assemblies permitted by Section 720 of the IBC as alternatives to the standards contained within the code.

Projections cannot be closer than 2 feet (610 mm) from the lot line. Projections that have a fire separation distance of less than 5 feet (1525 mm) from the lot line in unsprinklered buildings, or less than 3 feet in sprinklered buildings, are required to be protected on the underside with 1-hour fire-resistant construction in accordance with Tables R302.1(1) and R302.1(2), respectively [see Commentary Figure R302.1(1)]. Footnotes to the tables allow the underside protection to be omitted where fireblocking is provided or gable vents openings are not present.

Unlike the IBC, the code does not set a distance from the property line at which openings must be protected. Openings are not permitted in exterior walls where the exterior wall has a fire separation distance of less than 3 feet (914 mm) from the lot line. Openings in a wall with a fire separation distance that is equal to or greater than 3 feet (914 mm), but less than 5 feet (1525 mm) from the lot line, cannot exceed 25 percent of the maximum wall area [see Commentary Figures R302.1(2) and R302.1(3)]. The consensus as to the minimum distance necessary to provide a sufficient buffer against the spread of fire has changed somewhat over the years. For example, the 2000 and 2003 editions of the IRC required a 3-foot (914 mm) minimum fire separation distance for unrated exterior walls. In the 2006 edition, that distance was increased to 5 feet (1525 mm) to provide a higher level of safety and to correlate with the provisions for residential occupancies regulated by the IBC. The 2009 IRC introduced requirements for automatic fire sprinkler systems in all new one- and two-family dwellings and townhouses. Table R302.1(2) permits nonrated walls that have a 3-foot (914 mm) minimum fire separation distance, a dimension previously prescribed in earlier editions of the code. The 3-foot (914 mm) dimension specified in Table R302.1(2) is the new threshold for exterior wall construction, projections, openings and penetrations for dwellings that are sprinklered in accordance with Section P2904 or NFPA 13D. For dwellings without sprinkler systems, the 5-foot (1525 mm) separation distance still applies.

The reduced clearances are intended to provide design flexibility and reduce costs associated with fire-resistant construction, while maintaining a reasonable level of safety based on past performance of dwelling fire sprinkler systems. A dwelling automatic sprinkler system installed in accordance with Section P2904 or NFPA 13D aids in the detection and control of fires in residential occupancies regulated by the IRC. The design criteria of these sprinkler systems are for life safety to buy time for occupants to escape a fire; dwelling fire sprinklers are not designed for property protection. Sprinklers in accordance with Section P2904 or NFPA 13D are not required throughout the dwelling—they generally may be omitted in concealed spaces, closets, bathrooms, garages, and attics and crawl spaces without gas-fired appliances, for example.

However, the automatic sprinkler system is expected to prevent total fire involvement (flashover) in the room of fire origin if the room is sprinklered. In addition to increasing the likelihood of occupants escaping or being evacuated, sprinklers often provide some measure of property protection as well.

Note a to Table R302.1(2) allows exterior walls in subdivisions where all dwellings are equipped with sprinkler systems to be placed on the lot line if the adjacent lot maintains a 6-foot (1829 mm) setback for buildings on the opposite side of the lot line. This provision allows flexibility in placing buildings on the lot for maximum effective use of the buildable area while still maintaining a minimum 6 feet (1829 mm) of clearance between buildings. Commentary Figure R302.1 summarizes the fire separation distance requirements for exterior walls that are not fire-resistance rated.

Exception 1 permits walls, openings, projections or penetrations that are 90 degrees (1.57 rad) (perpendicular) to the line used to determine the fire separation distance to be exempt from the requirements of Tables R302.1(1) and R302.1(2). Section R302.4 describes through penetrations and membrane penetrations in detail (see the definition of “Fire separation distance” in Chapter 2) [see Commentary Figures R302.1(2) and R302.1(3)].

Exception 2 allows dwellings and accessory structures, on the same lot, to be considered one building such that the requirements of Tables R302.1(1) and R302.1(2) will not apply to the exterior walls facing each other. This exception eliminates the imaginary line between two buildings on the lot when measuring the fire separation distance. Tables R302.1(1) and R302.1(2) will apply to the other exterior walls of the buildings.

Exception 3 applies to detached tool and storage sheds, playhouses and similar structures that are exempt from permits. Projections from these structures, however, are not permitted to extend over the property line.

Exception 4 will allow roof eave projection for detached garages to be closer than 2 feet (610 mm) from the lot line, but limits the roof eave projection to 4 inches (102 mm). This projection cannot extend over the property line.

Exception 5 allows foundation vents installed in compliance with the code in areas where openings are otherwise prohibited.

TABLE R302.1(1). See below.

❖ See the commentary to Section R302.1.

TABLE R302.1(2). See page 3-44.

❖ See the commentary to Section R302.1.

R302.2 Townhouses. Common walls separating *townhouses* shall be assigned a fire-resistance rating in accordance with Section R302.2, Item 1 or 2. The common wall shared by two *townhouses* shall be constructed without plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be in accordance with Chapters 34 through 43. Penetrations of the membrane of common walls for electrical outlet boxes shall be in accordance with Section R302.4.

1. Where a fire sprinkler system in accordance with Section P2904 is provided, the common wall shall be not less than a 1-hour fire-resistance-rated wall assembly tested in accordance with ASTM E119 or UL 263.
2. Where a fire sprinkler system in accordance with Section P2904 is not provided, the common wall shall be

**TABLE R302.1(1)
EXTERIOR WALLS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E119 or UL 263 with exposure from both sides	< 5 feet
	Not fire-resistance rated	0 hours	≥ 5 feet
Projections	Not allowed	N/A	< 2 feet
	Fire-resistance rated	1 hour on the underside ^{a, b}	≥ 2 feet to < 5 feet
	Not fire-resistance rated	0 hours	≥ 5 feet
Openings in walls	Not allowed	N/A	< 3 feet
	25% maximum of wall area	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable.

- a. Roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave if fireblocking is provided from the wall top plate to the underside of the roof sheathing.
- b. Roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave provided that gable vent openings are not installed.

not less than a 2-hour fire-resistance-rated wall assembly tested in accordance with ASTM E119 or UL 263.

- ❖ The application of this section has its basis in the exterior wall requirements found in Section R302.1 that deal with the building's location on the lot. The defini-

tion of a townhouse in Section R202 should be reviewed, as well as the requirement for structural independence in Section R302.2.4. In general, because the "exterior wall" of the townhouse is essentially being constructed with no fire separation distance where one

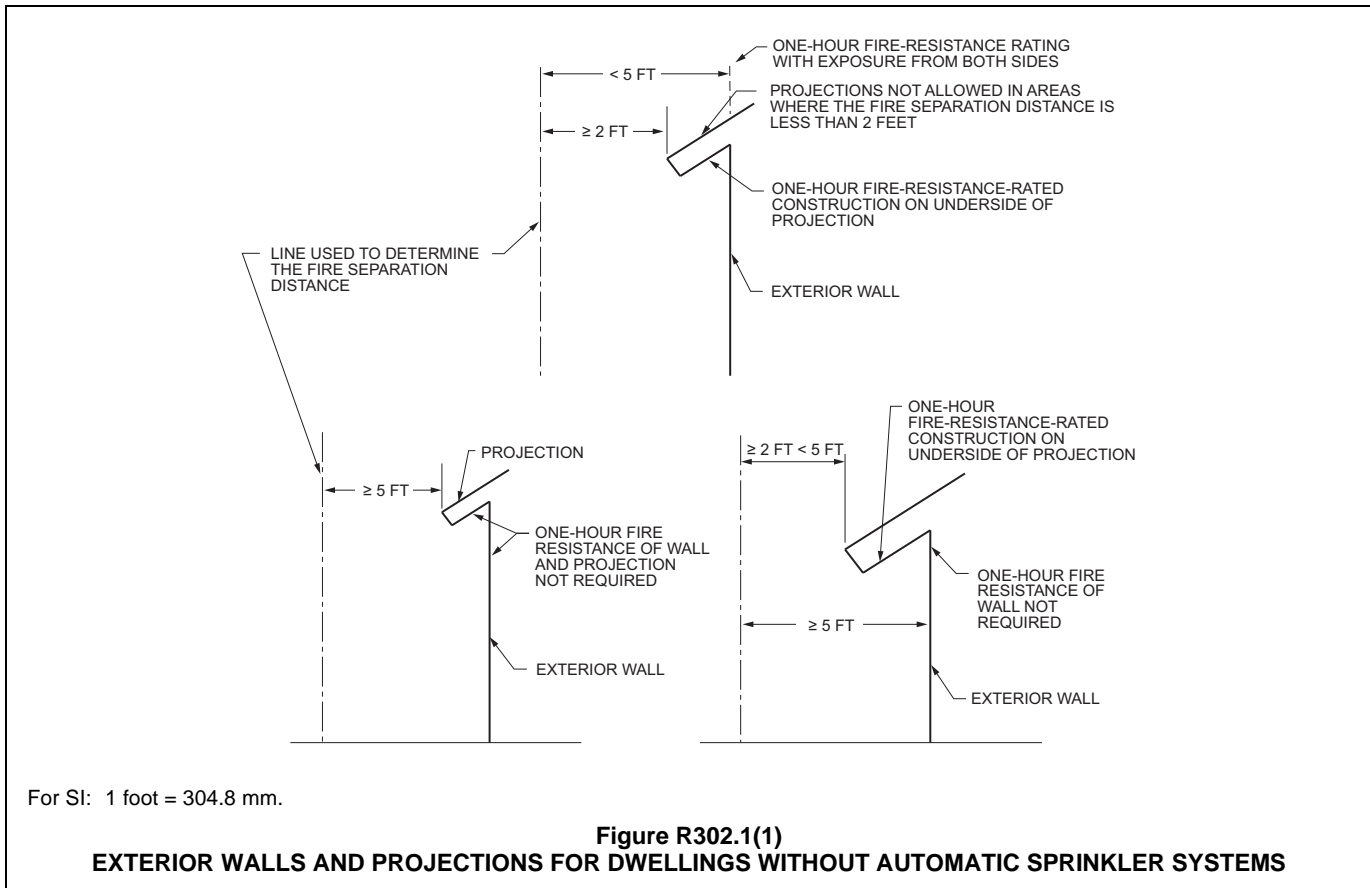

TABLE R302.1(2)
EXTERIOR WALLS—DWELLINGS WITH FIRE SPRINKLERS

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E119 or UL 263 with exposure from the outside	0 feet
	Not fire-resistance rated	0 hours	3 feet ^a
Projections	Not allowed	N/A	< 2 feet
	Fire-resistance rated	1 hour on the underside ^{b, c}	2 feet ^a
	Not fire-resistance rated	0 hours	3 feet
Openings in walls	Not allowed	N/A	< 3 feet
	Unlimited	0 hours	3 feet ^a
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet ^a

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

- For residential subdivisions where all *dwelling*s are equipped throughout with an automatic sprinkler system installed in accordance with Section P2904, the *fire separation distance* for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining *lot* provides an open setback *yard* that is 6 feet or more in width on the opposite side of the property line.
- The roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave if fireblocking is provided from the wall top plate to the underside of the roof sheathing.
- The roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave provided that gable vent openings are not installed.

townhouse adjoins another, the code requires, by Section R302.1, that the wall have not less than a 1-hour fire-resistance rating. The adjacent townhouse would have the same requirement. Therefore, the general requirement at this location (based on Sections R302.1

and R302.3) would be that each townhouse has its own fire-resistance rated "exterior wall." This would result in the construction of two separate 1-hour walls located side by side where one townhouse adjoins another. Because of the difficulties involved in construction

and the potential for unnecessary duplication, Item 1 offers an alternative to the two separate 1-hour walls by permitting the construction of a shared or “common” wall between the townhouses. The common wall must be 1-hour fire-resistance rated in sprinklered buildings or 2-hour fire-resistance rated in unsprinklered buildings, as tested in accordance with ASTM E119 or UL 263 (see the discussion of Section R104.11 in the commentary for Section R302.1).

See Commentary Figure R302.2 for an illustration of the two separate 1-hour walls and the common 2-hour wall. Because the common wall has the potential to create an interconnection between the adjacent dwelling units and reduce the clear separation that would exist if two separate walls were constructed, the code places limits on services being located within the wall. This exception does not permit the inclusion of any type of plumbing, mechanical equipment, ducts or vents within the cavity of the common wall. This prohibition is applicable even if the penetrations or openings are protected by the penetration provisions of Section R302.4 or if a damper is installed in the duct or vent. The pro-

hibition on plumbing includes all types of plumbing materials and systems, as well as water supply and drainage piping of either combustible or noncombustible materials. However, the exception permits the cavity of the wall to be used for electrical installations if they comply with the electrical provisions of the code and the penetrations are properly protected.

R302.2.1 Continuity. The fire-resistance-rated wall or assembly separating townhouses shall be continuous from the foundation to the underside of the roof sheathing, deck or slab. The fire-resistance rating shall extend the full length of the wall or assembly, including wall extensions through and separating attached enclosed accessory structures.

❖ This section addresses the continuity of the fire-resistance-rated wall or assembly separating townhouses using the exception in Section R302.2. The requirements are conceptually similar to the continuity issues that exist in Section R302.3. These provisions, by regulating the extensions and terminations of the wall, can make possible the separation of dwelling units from each other.

EXTERIOR WALL ELEMENT (Not fire-resistance rated)	MINIMUM FIRE SEPARATION DISTANCE		
	Without Sprinkler System	With Sprinkler System	With Sprinkler System in all Dwellings of Subdivision and 6-foot Setback for Building on Adjoining Lot
Walls	5 feet	3 feet	0 feet
Projections	5 feet	3 feet	0 feet
Unlimited openings in walls	5 feet	3 feet	0 feet
Penetrations (no restrictions)	3 feet	3 feet	0 feet

For SI: 1 foot = 304.8 mm.

Figure R302.1
MINIMUM FIRE SEPARATION DISTANCE COMPARISON (NONRATED CONSTRUCTION)

R302.2.2 Parapets for townhouses. Parapets constructed in accordance with Section R302.2.3 shall be constructed for *townhouses* as an extension of exterior walls or common walls in accordance with the following:

1. Where roof surfaces adjacent to the wall or walls are at the same elevation, the parapet shall extend not less than 30 inches (762 mm) above the roof surfaces.
2. Where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is not more than 30 inches (762 mm) above the lower roof, the parapet shall extend not less than 30 inches (762 mm) above the lower roof surface.

Exception: A parapet is not required in the preceding two cases where the roof covering complies with a minimum Class C rating as tested in accordance with ASTM E108 or UL 790 and the roof decking or sheathing is of noncombustible materials or *approved* fire-retardant-treated wood for a distance of 4 feet (1219 mm) on each side of the wall or walls, or one layer of $\frac{5}{8}$ -inch (15.9 mm) Type X gypsum board is installed directly beneath the roof decking or sheathing, supported by not less than nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members, for a distance of not less than 4 feet (1219 mm) on each side of the wall or walls and any openings or penetrations in the roof are not within 4 feet (1219 mm) of the common walls.

3. A parapet is not required where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is more than 30 inches (762 mm) above the lower roof. The common wall construction from the lower roof to the underside of the higher roof deck shall have not less than a 1-hour fire-resistance rating. The wall shall be rated for exposure from both sides.
- ❖ This section provides for the continuation of the dwelling-unit separation by requiring that a parapet be constructed above the common wall or the two “exterior walls” that occur between adjacent townhouses. This parapet requirement is applicable only to the wall or walls between townhouses and does not apply to the separation in a two-family dwelling, nor does it apply to other exterior walls on either townhouses or dwellings.

The code states three requirements that address the details of the parapet depending on the height of the adjacent roofs. The code also has an exception that can be used to eliminate the need for the parapet in the two conditions that require them. In general, parapets must extend at least 30 inches (762 mm) above the roof surfaces of the adjacent townhouses. This standard requirement is found in Item 1 and is applicable where the roof surfaces of the adjacent dwelling units are at the same level, unless the exception is satisfied.

The second item requires a parapet where the roofs are at different levels, but the difference is less than 30 inches (762 mm), unless the exception is satisfied. Under this condition, the parapet height must still be 30 inches (762 mm), but it is measured only from the roof

surface of the lower roof. The exception to this item indicates that a parapet is not required in this scenario if the roof is covered with a roof covering that have a minimum Class C rating as tested in accordance with ASTM E108 or UL 790 and the roof sheathing is noncombustible or fire-retardant-treated wood. Compliance with this item is not required, however, where the exception is satisfied.

The third item requires a parapet where the height difference between roofs above the common wall is more than 30 inches (762 mm) unless the common wall between the units is rated to the height of the upper roof deck. The required minimum fire-resistance rating for this portion of the wall is 1 hour. See Commentary Figure R302.2.2(1) for an illustration of the three requirements.

See Commentary Figure R302.2.2(2) for an illustration of the exception. Openings or penetrations through the roof are prohibited within 4 feet of the common wall or walls. It does not apply where the height difference between the roofs is more than 30 inches (762 mm) and the provisions of Item 3 have been satisfied.

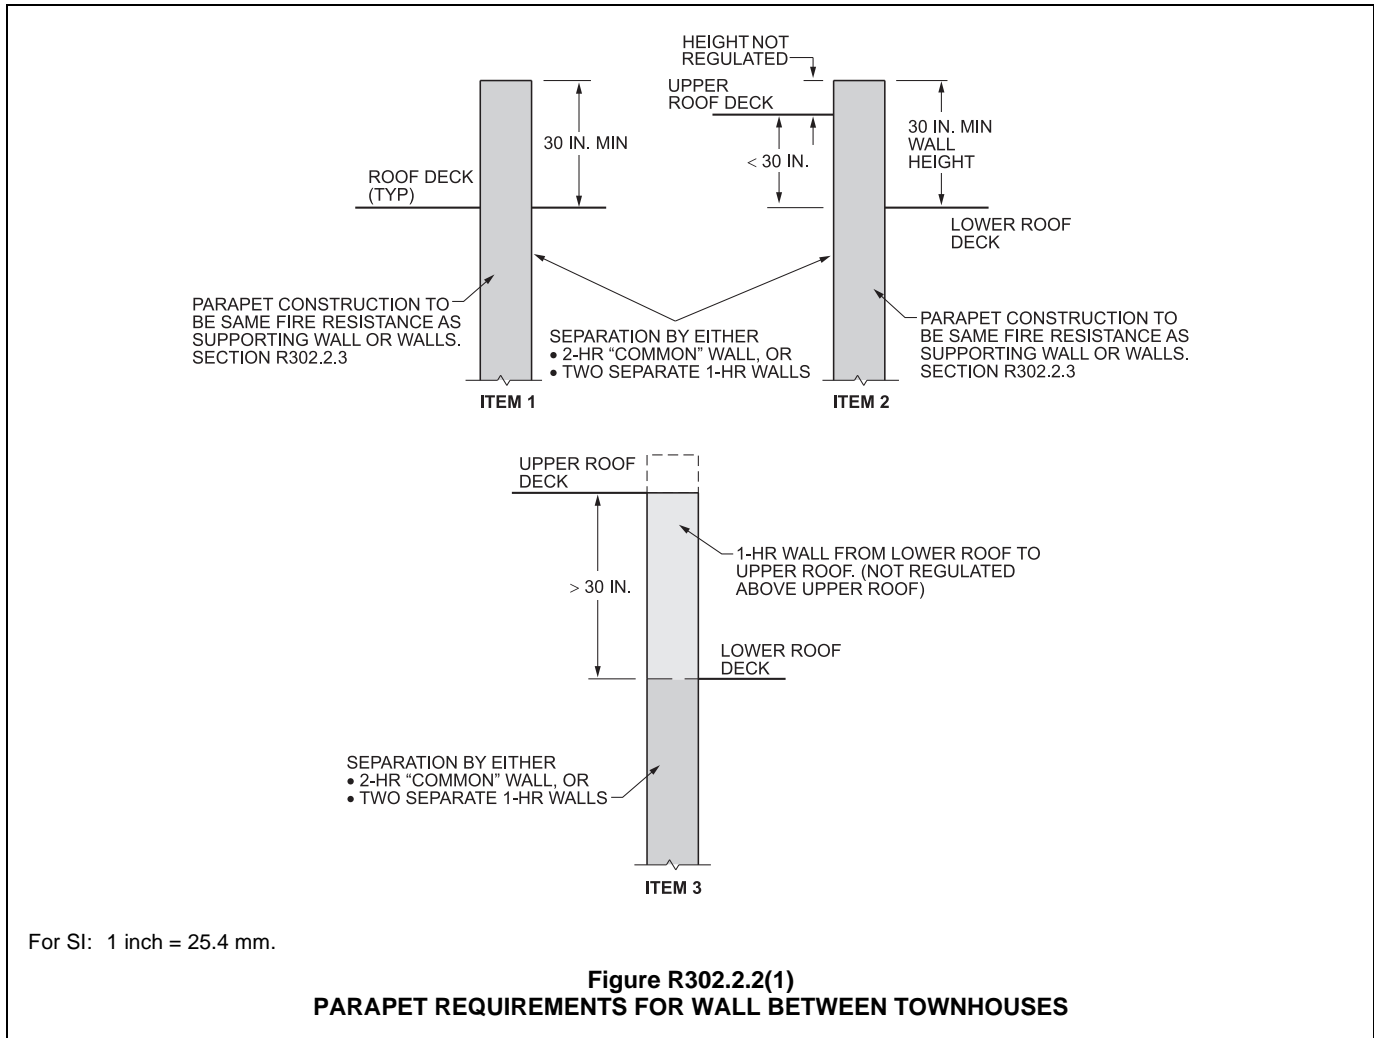

R302.2.3 Parapet construction. Parapets shall have the same fire-resistance rating as that required for the supporting wall or walls. On any side adjacent to a roof surface, the parapet shall have noncombustible faces for the uppermost 18 inches (457 mm), to include counterflashing and coping materials. Where the roof slopes toward a parapet at slopes greater than 2 units vertical in 12 units horizontal (16.7-percent slope), the parapet shall extend to the same height as any portion of the roof within a distance of 3 feet (914 mm), and the height shall be not less than 30 inches (762 mm).

- ❖ In addition to having the same degree of fire resistance as required for the wall or walls below, the surface of the parapet that faces the roof must be of noncombustible materials for the upper 18 inches (457 mm). Thus, a fire might travel along the roof and reach the parapet but would not be able to continue upward along the face of the parapet and over the top, exposing the adjacent building. The requirement applies to the upper 18 inches (457 mm) of the parapet to allow for extending the roof covering up the base of the parapet so that it can be effectively flashed. The 18-inch (457 mm) figure is based on a parapet height of at least 30 inches (762 mm) and would not be applicable to the face of the parapet that was toward the higher roof deck as constructed using Section R302.2.2, Item 2, nor would it be applicable where the parapet is not required based on the exception in Section R302.2.2 or on Item 3 of that section.

The 30-inch (762 mm) requirement is measured “above the roof surface” as stated in Section R302.2.2. When a cricket or other element is installed adjacent to the parapet, the 30-inch (762 mm) dimension must be taken from the top of the roof surface on the cricket so the parapet truly extends 30 inches (762 mm) above the roof.

In those cases where the roof slopes upward away from the parapet and the slope exceeds 2 units vertical in 12 units horizontal (16.7-percent slope), the parapet must be extended to the same height as any portion of

the roof that is within a distance of 3 feet (914 mm). However, in no case can the height of the parapet be less than 30 inches (762 mm). See Commentary Figure R302.2.3 for an illustration of this requirement.

R302.2.4 Structural independence. Each individual *townhouse* shall be structurally independent.

Exceptions:

1. Foundations supporting *exterior walls* or common walls.
2. Structural roof and wall sheathing from each unit fastened to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. *Townhouses* separated by a common wall as provided in Section R302.2, Item 1 or 2.

❖ Each townhouse must be structurally independent and capable of being removed without affecting the adjacent dwelling unit. This provision is applicable only to townhouses, not two-family dwellings. This independence is useful not only in the event of a fire in one unit, but also during any remodeling or alteration. The objective of this structural independence is that a complete burnout could occur on one side of the wall without causing the collapse of the adjacent townhouse. This condition occurs rarely. The provision also helps if there is ever a fire or other problem by creating a clear separation between the units. With separate ownership and each owner having a different insurance company, the ability to gain access or get repairs made can be difficult and time consuming. By having clearly separated units, it is much easier to determine who is responsible and to make any needed repairs.

The code lists five exceptions that waive the structural independence requirement. A quick review of the exceptions shows that they generally deal with items that will not structurally affect townhouses should a problem develop in the adjacent dwelling unit. Exception 1 is based on the norm within the industry for foundation construction. In the code, Section R402 lists only wood and concrete within the foundation materials section, although Section R404 accepts masonry foundation walls. In general, concrete and masonry are the most common types of foundations; wood foundations are viewed as unique. Given the performance of both masonry and concrete, and the fact that these foundation systems must sustain loads from both the structure and the adjacent soils, it is reasonable to assume that the foundation will not be the item that fails in most situations. Permitting a common foundation also helps solve other problems that would arise if the structural independence issue were taken as an absolute. An example where requiring separate foundations would probably create more problems or difficulty is in the dampproofing or waterproofing of below-grade foundation walls.

If a wood foundation is used between adjacent units, what is the level of fire protection that may be needed? Because concrete and masonry foundations are the norm, it would be easy to forget or overlook protecting the foundation when it is constructed of wood. In these cases, it would seem appropriate to deal with the foundation as any other wall, and protect it on any exposed side. The level of fire resistance should be equal to that of the wall or walls that the foundation supports.

R302.3 Two-family dwellings. *Dwelling units* in two-family dwellings shall be separated from each other by wall and floor assemblies having not less than a 1-hour fire-resistance rating where tested in accordance with ASTM E119 or UL 263. Fire-resistance-rated floor/ceiling and wall assemblies shall extend to and be tight against the *exterior wall*, and wall assemblies shall extend from the foundation to the underside of the roof sheathing.

Exceptions:

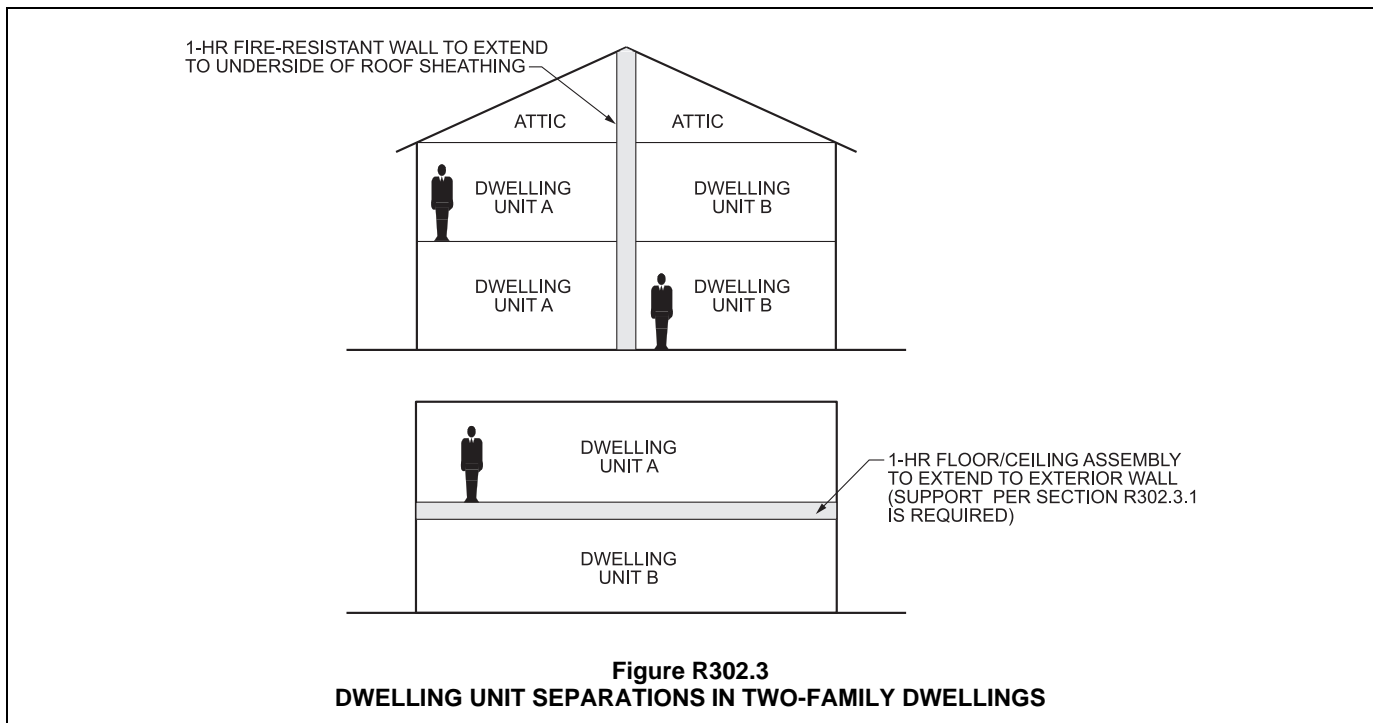

1. A fire-resistance rating of $1/2$ hour shall be permitted in buildings equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13.
 2. Wall assemblies need not extend through *attic* spaces where the ceiling is protected by not less than $5/8$ -inch (15.9 mm) Type X gypsum board, an *attic* draft stop constructed as specified in Section R302.12.1 is provided above and along the wall assembly separating the *dwellings* and the structural framing supporting the ceiling is protected by not less than $1/2$ -inch (12.7 mm) gypsum board or equivalent.
- ❖ Most of the nation's fires occur in residential buildings, particularly one- and two-family dwellings. These fires account for more than 80 percent of all deaths from fire in residential uses (including hotels, apartments, dormitories, etc.) and about two-thirds of all fire fatalities in any type of building. One- and two-family dwellings also account for more than 80 percent of residential property losses and more than one-half of all property losses from fire. Despite this poor fire record, there is widespread resistance to mandating much in the way of fire protection systems or methods because of our society's belief that people's homes are their castles. This viewpoint has limited the types of protection that

are imposed on these private homes to the installation of smoke alarms and the more recent requirement of dwelling unit separation. Section R302.3 provides a separation for protection of the occupants of one dwelling unit in a two-family dwelling from the actions of their neighbor in the adjacent dwelling unit. To accomplish this protection, the code addresses separation between the units, structural support and any openings or penetrations of the separation.

Depending on the layout of the various dwelling units, Section R302.3 requires that the walls and/or floor assemblies that divide one dwelling unit from the adjacent unit be at least 1-hour fire-resistance rated. See Commentary Figure R302.3 for examples of the separation. The separation rating is to be determined by either ASTM E119 or UL 263, which is the normal test used for determining fire resistance. Many tested assemblies are available for use in these locations.

The provisions of the section also address the continuity of the separation, so that one dwelling unit is completely divided from the other. The horizontal aspect of the separation, which requires that the assemblies extend to and be tight against the exterior wall, is not difficult to comply with. It is most likely the vertical aspect (continuing a wall assembly to the underside of the roof sheathing) that will require some detailed planning, careful construction and careful inspection for the units to be separated.

Exception 1 grants a reduction in the required separation for those cases in which the building is equipped with an automatic sprinkler system. In these cases, a rating of $1/2$ hour is permitted versus a 1-hour fire-resistance rating. The sprinkler system must be "installed in accordance with NFPA 13," and is to be installed "throughout" the building. The type of sprinkler system

used must meet NFPA 13 and may not be installed to either NFPA 13D or 13R, even though those two standards do address certain types of residential uses. The word “throughout” requires that the sprinkler system be installed in all portions of both dwelling units and any common spaces. The provisions of NFPA 13 that permit omitting sprinklers in certain areas, such as small concealed spaces, are applicable. Therefore, the provision requires a complying sprinkler system “throughout” the building (that is, in all areas of the building that must be protected according to the standard), and it does not accept any partial system, such as one installed in only one dwelling unit or only in the basement level of both units.

Exception 2 addresses separation in the area of the attic of two-family dwellings or duplexes. As long as an attic draft stop is present that meets the requirements in Section R302.12.1, the 1-hour fire separation is permitted to stop at a ceiling constructed of 5/8-inch (15.9 mm) Type X gypsum board. This may be beneficial as, in many cases, the type of truss or attic rafter and rafter tie/collar tie configuration will prohibit continuing construction of the 1-hour separation wall all the way up to the roof sheathing.

R302.3.1 Supporting construction. Where floor assemblies are required to be fire-resistance rated by Section R302.3, the supporting construction of such assemblies shall have an equal or greater fire-resistance rating.

- ❖ This provision applies only to walls that support the fire-resistance-rated floor assemblies that form the separation between dwelling units in a two-family dwelling where the dwelling units are stacked vertically. When either all or portions of a dwelling unit separation are provided by a floor assembly, the code requires that the structural supports for the separation have a rating equal to or higher than the floor. This is conceptually similar to the garage separation of Section R302.6. Without the supporting construction being protected, a fire on the lower level could lead to an early failure of the dwelling unit separation (see Commentary Figure R302.3.1).

R302.4 Dwelling unit rated penetrations. Penetrations of wall or floor-ceiling assemblies required to be fire-resistance rated in accordance with Section R302.2 or R302.3 shall be protected in accordance with this section.

- ❖ This section addresses the specific requirements for maintaining the integrity of fire-resistance-rated assemblies at penetrations. If the penetration of a rated assembly is not properly constructed, the assembly itself is jeopardized and may not perform as intended. The provisions of this section apply to penetrations of fire-resistance-rated walls and floor/ceiling assemblies that are a part of the dwelling unit separation in either two-family dwellings or townhouses. Penetrations of the rated assemblies range from combustible pipe and tubing to noncombustible wiring with combustible covering to noncombustible items, such as pipe, tube, conduit and ductwork.

Each type of penetration requires a specific method of protection, which is based on the type of fire-resistance-rated assembly penetrated and the size and type of the penetrating item. The first step in determining the type of penetration protection required is to identify whether a wall or floor/ceiling assembly is being penetrated. The next step is to determine the type of penetrating item and whether it is a membrane or through penetration. Once these factors are known, then the applicable section must be applied and the applicable method of protection must be decided upon.

R302.4.1 Through penetrations. Through penetrations of fire-resistance-rated wall or floor assemblies shall comply with Section R302.4.1.1 or R302.4.1.2.

Exception: Where the penetrating items are steel, ferrous or copper pipes, tubes or conduits, the annular space shall be protected as follows:

1. In concrete or masonry wall or floor assemblies, concrete, grout or mortar shall be permitted where installed to the full thickness of the wall or floor assembly or the thickness required to maintain the fire-resistance rating, provided that both of the following are complied with:
 - 1.1. The nominal diameter of the penetrating item is not more than 6 inches (152 mm).
 - 1.2. The area of the opening through the wall does not exceed 144 square inches (92 900 mm²).
2. The material used to fill the annular space shall prevent the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E119 or UL 263 time temperature fire conditions under a positive pressure differential of not less than 0.01 inch of water (3 Pa) at the location of the penetration for the time period equivalent to the fire-resistance rating of the construction penetrated.

- ❖ This section contains the general requirements for through penetrations, which are penetrations that pass through an entire assembly. A through penetration is in contrast to a membrane penetration, which creates a penetration through only one side of an assembly.

Membrane penetrations are addressed later in Section R302.4.2. See Commentary Figure R302.4.1 for an illustration of these two types of penetrations.

Through penetrations must be protected to maintain the fire resistance of the penetrated assembly. The code states two methods, found in Sections R302.4.1.1 and R302.4.1.2, which can be used to assure the adequacy of the penetration protection. The difference between these two is the test methodology used, but they both provide essentially the same results. The commentary for those sections is additional discussion of the differences.

Based on the history of these provisions and on the wealth of fire test data that exists concerning items such as conduit, water piping and other similar penetrations, the code provides two exceptions that permit protection by methods other than those generally required. The first permits the use of concrete, grout or mortar to protect certain penetrations of concrete and masonry wall or floor assemblies. The concrete, grout or mortar must be applied for the full thickness of the assembly unless evidence can be produced demonstrating that the required fire-resistance rating can be achieved with a lesser depth. Concrete, grout and mortar have traditionally been used as protection for the annular space in penetrations of concrete and masonry assemblies. Experience has shown this form of protection to be viable. However, caution must be used any time something, such as a water pipe or conduit, is placed in concrete or masonry. Sections P2603.3 and P2603.5 contain examples of protection of plumbing systems.

Exception 2 addresses the space between the penetrating item and the original assembly construction. This gap is called the annular space, and this exception provides a method to simply evaluate the performance of the material used to fill that space. It is often mistakenly believed that this exception permits a variety of untested items, but as can be seen from the provision itself, the materials need to meet a specific performance level. This exception requires that the ability of the material to prevent the passage of flame and hot gases sufficient to ignite cotton when subjected to the time-temperature criteria of the ASTM E119 test standard be prequalified. This requirement is similar to provisions found in both ASTM E119 and ASTM E814, the standards used to evaluate fire-resistant assemblies and penetration protection. Because it is very likely that the penetration in the actual fire will be exposed to a positive pressure, this section specifies that the test-fire exposure include a positive pressure of 0.01 inch (0.25 mm) of water column as a further means to verify the performance of this protection method. Thus the protection will not be blown out or moved from its place during a fire.

R302.4.1.1 Fire-resistance-rated assembly. Penetrations shall be installed as tested in the *approved* fire-resistance-rated assembly.

- ❖ This section addresses situations in which the penetration is tested as a part of the regular full-scale test for

the wall or floor/ceiling assembly. The penetration and proposed type of protection are evaluated as a part of the regular ASTM E119 test, which evaluates the wall or floor/ceiling rating. This section and the option it provides are not used frequently because of the cost of conducting such full-scale tests and the limitations placed on the application of the tested assembly. Because of these issues, penetrations are most often protected in accordance with one of the exceptions in Section R302.4.1 or the provisions of Section R302.4.1.2.

R302.4.1.2 Penetration firestop system. Penetrations shall be protected by an *approved* penetration firestop system installed as tested in accordance with ASTM E814 or UL 1479, with a positive pressure differential of not less than 0.01 inch of water (3 Pa) and shall have an F rating of not less than the required fire-resistance rating of the wall or floor-ceiling assembly penetrated.

- ❖ Through-penetration firestop systems consist of specific materials or an assembly of materials that are designed to restrict the passage of fire and hot gases for a prescribed period of time through openings made in fire-resistance-rated assemblies. To determine the effectiveness of a through-penetration firestop system in restricting the passage of fire, and to determine that the penetration has not jeopardized the original fire-resistant assembly, firestop systems must be subjected to fire testing using the ASTM E814 or UL 1479 test standard. This is a small-scale test method developed specifically for the evaluation of a firestop system's ability to resist the passage of flame and hot gases, withstand thermal stresses and restrict the transfer of heat through the penetrated assembly. There are hundreds if not thousands of tested through-penetration firestop systems available today. The actual type of system used will depend on the type and construction of the assembly being penetrated, the material makeup and size of the penetrating item, and the size of the annular

space that exists between the penetrating item and the assembly being penetrated. Because there are a multitude of products available, and there is no “one size fits all” system available, it is helpful if the methods of protection are included on the construction documents as covered by Section R106.1.1.

The actual rating of the through-penetration firestop system is generated from the results of the testing and is reported as an “F” (flame) rating and a “T” (temperature) rating. The code requires only an F rating. The F rating indicates the period of time, in hours, that the through-penetration firestop system remained in place without allowing the passage of fire during the fire exposure test, or the passage of water during the hose stream portion of the test. The required F rating must be equal to the fire-resistance rating of the wall or floor/ceiling assembly that is being penetrated. This means either a 1- or 2-hour rating, depending on the dwelling unit separation.

Two of the most common materials used in through-penetration firestop systems are intumescent and endothermic materials. Intumescent materials expand approximately 8 to 10 times their original volume when exposed to temperatures exceeding 250°F (121°C). The expansion of the material fills the voids or openings within the penetration to resist the passage of flame, while the outer layer of the expanded intumescent material forms an insulating charred layer that assists in limiting the transfer of heat. The expansion properties of intumescent materials allow them to seal openings left by combustible penetrating items that burn away during a fire, but they do not retard heat as well as endothermic materials. Intumescent materials are typically used with combustible penetrating items or where a higher T rating is not required.

Endothermic materials provide protection through chemically bound water released in the form of steam when exposed to temperatures exceeding 600°F (316°C). This released water cools the penetration and retards heat transfer through the penetration. Endothermic materials tend to be superior in heat-transfer resistance and have higher T ratings, but they do not expand to fill voids left by combustible penetrating items that burn away during a fire. Therefore, endothermic materials are typically used with noncombustible penetrating items and where a higher T rating is required.

R302.4.2 Membrane penetrations. Membrane penetrations shall comply with Section R302.4.1. Where walls are required to have a fire-resistance rating, recessed fixtures shall be installed so that the required fire-resistance rating will not be reduced.

Exceptions:

1. Membrane penetrations of not more than 2-hour fire-resistance-rated walls and partitions by steel electrical boxes that do not exceed 16 square inches (0.0103 m²) in area provided that the aggregate area of the openings through the membrane does not exceed 100 square inches (0.0645 m²) in any 100 square feet (9.29 m²) of wall area. The annular space between the

wall membrane and the box shall not exceed 1/8 inch (3.1 mm). Such boxes on opposite sides of the wall shall be separated by one of the following:

- 1.1. By a horizontal distance of not less than 24 inches (610 mm) where the wall or partition is constructed with individual noncommunicating stud cavities.
 - 1.2. By a horizontal distance of not less than the depth of the wall cavity where the wall cavity is filled with cellulose loose-fill, rock-wool or slag mineral wool insulation.
 - 1.3. By solid fireblocking in accordance with Section R302.11.
 - 1.4. By protecting both boxes with *listed* putty pads.
 - 1.5. By other *listed* materials and methods.
2. Membrane penetrations by *listed* electrical boxes of any materials provided that the boxes have been tested for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the *listing*. The annular space between the wall membrane and the box shall not exceed 1/8 inch (3.1 mm) unless *listed* otherwise. Such boxes on opposite sides of the wall shall be separated by one of the following:
 - 2.1. By the horizontal distance specified in the *listing* of the electrical boxes.
 - 2.2. By solid fireblocking in accordance with Section R302.11.
 - 2.3. By protecting both boxes with *listed* putty pads.
 - 2.4. By other *listed* materials and methods.
 3. The annular space created by the penetration of a fire sprinkler provided that it is covered by a metal escutcheon plate.

❖ This section deals with instances where only a single side of the fire-resistance-rated assembly is penetrated. This would be the situation for items such as electrical outlet boxes or plumbing fixtures located on one side of the wall only. Commentary Figure R302.4.1 shows this type of penetration. For the most part, a membrane penetration is to be protected by one of the previously described methods established for through penetrations. However, there are some penetrations that are allowed without a specific firestopping material in the annular space around them. These are addressed by the exceptions. This section also deals with the installation of recessed luminaires in fire-resistance-rated assemblies and states that their installation may not reduce the assembly's protection. Although these fixtures are common, they do represent a penetration of the assembly's protection and must be installed so that the assembly is not compromised.

Exception 1 allows penetrations of steel electrical outlet boxes under certain conditions. The criteria of this section limit the size of the box to 16 square inches

(0.0103 m²) or less in area and to an aggregate area not to exceed 100 square inches (64 500 mm²) in each 100 square foot (9.3 m²) area. Commentary Figure R302.4.2(1) shows some of the requirements of this section. The area limitations are consistent with the criteria from fire tests, which have shown that within these limitations, these penetrations will not adversely affect the fire-resistance rating of the assembly. However, the boxes are assumed to be installed as they were during the fire tests. In general, the test requirements match the limitations shown by the code regarding their size and the need to be offset. An additional requirement, one that does not appear in the code, regulates the size of the annular space created around the outlet boxes. Both the Underwriters Laboratory's (UL) *Fire-Resistance Directory* and the Gypsum Association's *Fire-resistance Design Manual* specify a maximum over-cut of 1/8 inch (3 mm) for the annular space around the outlet boxes. Additionally, Article 314 of the *National Electrical Code (NEC)* (also known as NFPA 70) includes the size limitation of the over-cut. Therefore, the exception applies only when the boxes are installed as they were during the original fire tests, including the limited annular space. Because outlet boxes on both sides of a wall create penetrations of both layers of a wall assembly's protection, the code provides five methods to address this problem. This gives code users several options and does not limit them to the usual 24-inch (610 mm) offset.

Exception 2 permits using outlet boxes of nonmetallic materials if they have been specifically tested. Because many different types of nonmetallic boxes are available, it is important to determine that the boxes being used in the rated dwelling unit separation have been tested. Although the exception applies to nonmetallic electrical outlet boxes, the same concept would apply to steel boxes that exceed the sizes specified in Exception 1.

Exception 3 provides an alternative to the annular space protection provisions for a fire sprinkler that penetrates a single membrane. This exception is available if the annular space around the sprinkler is completely

covered by an escutcheon plate of noncombustible material. The nature of the hazard posed by single-membrane penetrations of the sprinkler is limited by the size of the opening, the potential number of openings present and the presence of a sprinkler system. The installation of a noncombustible escutcheon provides protection against the free passage of fire through the annular space and allows for the movement of the sprinkler piping without breaking during a seismic event [see Commentary Figure R302.4.2(2)].

R302.5 Dwelling-garage opening and penetration protection. Openings and penetrations through the walls or ceilings separating the *dwelling* from the garage shall be in accordance with Sections R302.5.1 through R302.5.3.

- ❖ Openings to sleeping rooms from garages are not allowed because a person might not wake up in time if there was a hazard from CO fumes or smoke from the garage. The three subsections address doors, ducts and pipes. For wall and ceiling separation requirements, see Section R302.6 and Table R302.6.

R302.5.1 Opening protection. Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence shall be equipped with solid wood doors not less than 1 3/8 inches (35 mm) in thickness, solid or honeycomb-core steel doors not less than 1 3/8 inches (35 mm) thick, or 20-minute fire-rated doors, equipped with a self-closing device.

- ❖ Openings from the garage are permitted only into rooms that are not used for sleeping. These openings must be protected by the installation of a door complying with the provisions of this section. The most common situation is the door between the garage and the inside of the home. Solid wood doors 1 3/8-inches (35 mm) thick, solid or honeycomb steel doors and 20-minute fire-rated doors are required for use in the opening between the garage and dwelling unit. A self-closing device must be installed on these doors as a safeguard to limit free flow of carbon monoxide or other products of combustion into the living area.

R302.5.2 Duct penetration. Ducts in the garage and ducts penetrating the walls or ceilings separating the *dwelling* from the garage shall be constructed of a minimum No. 26 gage (0.48 mm) sheet steel or other *approved* material and shall not have openings into the garage.

- ❖ Ducts are permitted to penetrate the required separation (see Section R302.6) between the garage and dwelling unit when the ducts within the garage and the portion of the duct penetrating the wall are of No. 26 gage (0.48 mm) sheet steel or other materials acceptable to the building official. Steel ducts are required to help prevent the passage of an undetected fire within the garage to the dwelling unit (see Commentary Figure R302.5.2). The opening limitation in the garage is to limit the path for smoke to enter the dwelling unit.

R302.5.3 Other penetrations. Penetrations through the separation required in Section R302.6 shall be protected as required by Section R302.11, Item 4.

- ❖ This section addresses the annular space that results from a penetration of the common wall by pipes, conduits or ductwork. It is important that the building official verify that these spaces are properly filled and do not compromise the protection offered by the common wall between the residence and garage against the free passage of smoke, fire, noxious gases and odors.

R302.6 Dwelling-garage fire separation. The garage shall be separated as required by Table R302.6. Openings in garage walls shall comply with Section R302.5. Attachment of gypsum board shall comply with Table R702.3.5. The wall separation provisions of Table R302.6 shall not apply to garage walls that are perpendicular to the adjacent *dwelling unit* wall.

- ❖ Numerous potential hazards exist within garages because occupants of dwelling units tend to store a variety of hazardous materials there. Along with this and the potential for CO build-up within the garage, the code requires that the garage be separated from the

dwelling unit and attic as indicated in Table R302.6. Garage walls and ceilings that do not form a separation from the dwelling unit are not required to be rated unless they are an extension of a rated assembly.

TABLE R302.6. See page 3-57.

- ❖ This table specifies when and how the garage must be separated from the dwelling unit and any attic space. Walls between the residence and the attached garage, or ceilings between the garage and an attic space, must have at least 1/2-inch (12.7 mm) gypsum board on the garage side. If a habitable room is above the garage, the ceiling must be at least 5/8-inch (15.9 mm) Type X gypsum board on the garage side. Additionally, the exterior walls of the garage are required to have 1/2-inch (12.7 mm) gypsum board on the interior face where they support floors separating all or part of a dwelling unit above the garage.

Detached garages located less than 3 feet (305 mm) from an adjacent dwelling unit must be protected with at least 1/2-inch (12.7 mm) gypsum board applied to the interior side of the garage. The close proximity to adjacent dwellings requires the additional protection. This 1/2-inch (12.7 mm) gypsum board is required even when the exterior walls are exempted by Section R302.1.

The term “or equivalent” under each option allows for alternative means consistent with Section R104.11.

There are two primary reasons for the enhanced fire endurance of a garage ceiling located beneath a habitable room. First, a fire occurring in a garage may well go undetected for an extended period prior to activation of a detector or other visual alerting.

Second, the inherent fire load and hazardous household activities associated with a garage necessitate this additional level of protection if fire suppression forces are to have a reasonable opportunity to contain a garage fire to the area of origin.

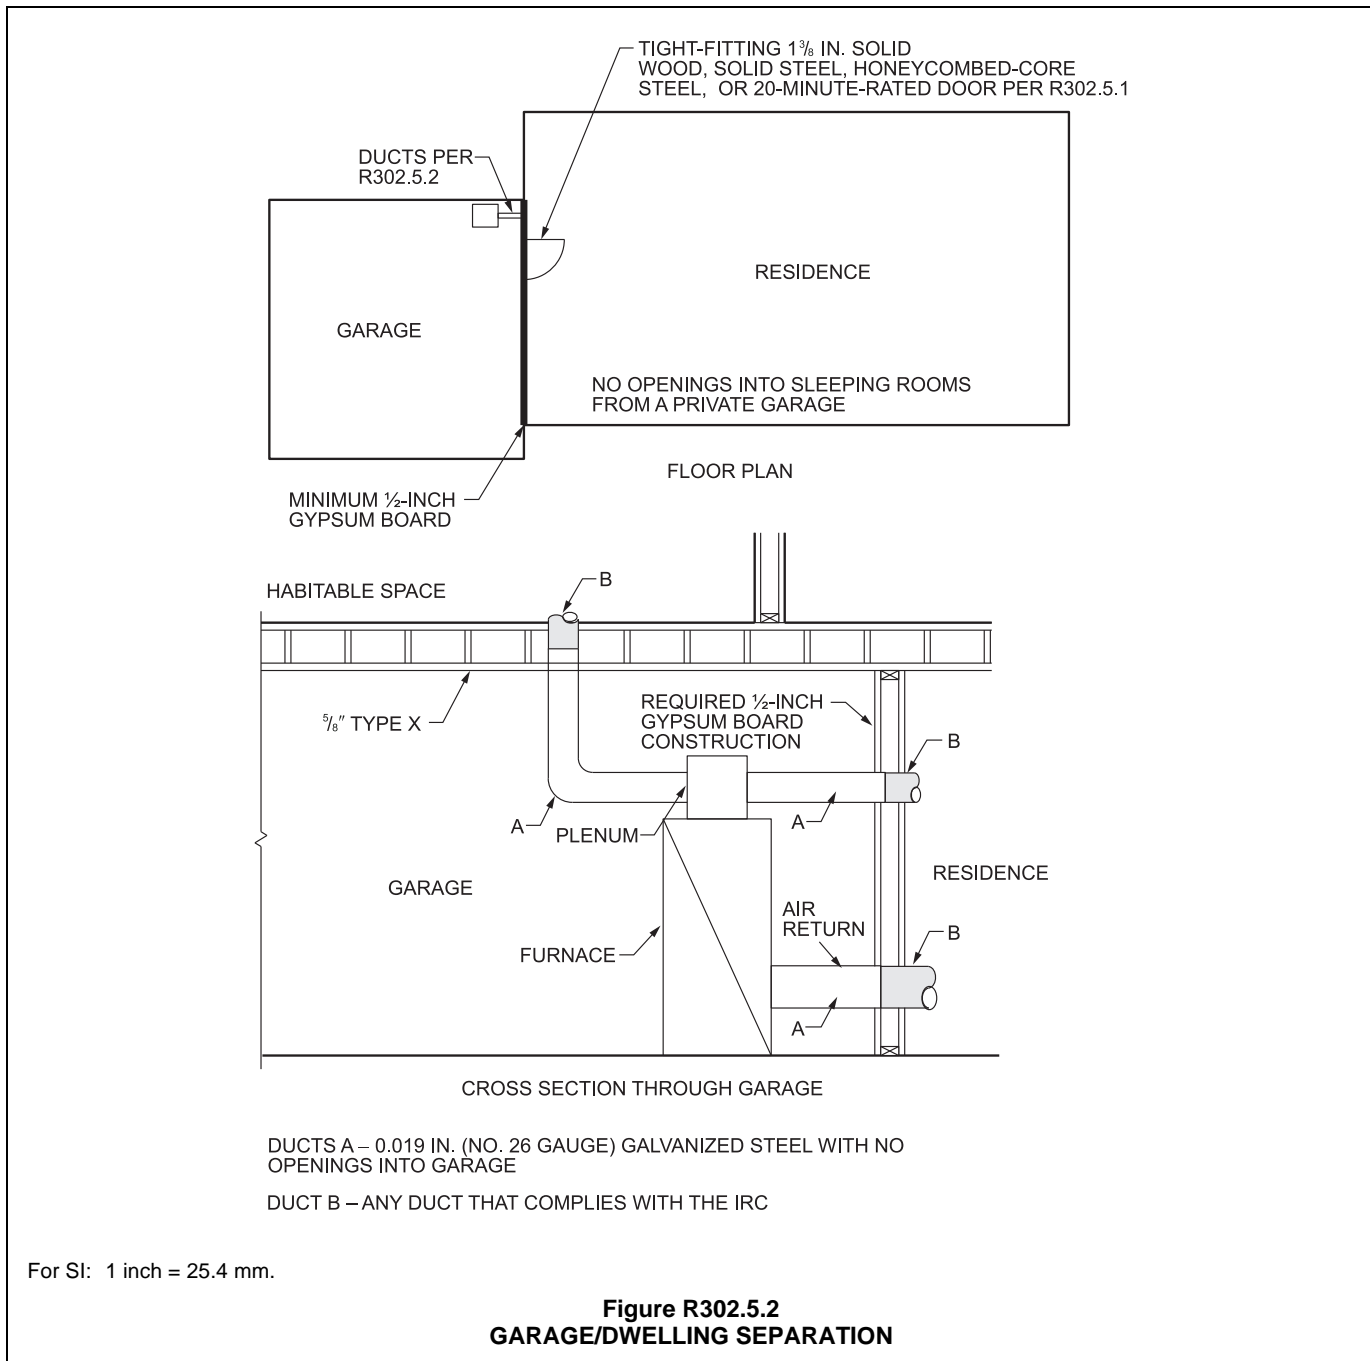

The single layer of 5/8-inch (15.9 mm) Type X gypsum board at the garage ceiling increases the fire endurance of the assembly considerably, from 15 minutes for a 1/2-inch (12.7 mm) layer, to at least 40 minutes, or a 167-percent increase in endurance. When added to the rating for floor joists and certain subflooring combinations, the final endurance is close to 1 hour.

Commentary Figure R302.6 shows two locations of gypsum wallboard; each achieves the protection required by the code.

R302.7 Under-stair protection. Enclosed accessible space under stairs shall have walls, under-stair surface and any soffit

fits protected on the enclosed side with 1/2-inch (12.7 mm) gypsum board.

❖ Often times the space under a stairway is used for storage because this space is often of little use for other purposes. The code permits the use of an open space beneath a stair without the need for any additional protection. Additionally, if the space is walled off and there is no access to the area, the code is also not concerned. If, however, the area beneath the stairway is enclosed and any type of access is provided into the space, the walls, soffits and ceilings of the enclosed space must be protected on the enclosed side with at least 1/2-inch (12.7 mm) gypsum board.

R302.8 Foam plastics. For requirements for foam plastics, see Section R316.

❖ This section provides a cross reference to the foam plastic fire-resistant requirements for when this product is used within a home. Foam plastics are most commonly used in applications where their thermal qualities can be a cost savings for the home owner over time.

R302.9 Flame spread index and smoke-developed index for wall and ceiling finishes. Flame spread and smoke developed indexes for wall and ceiling finishes shall be in accordance with Sections R302.9.1 through R302.9.4.

❖ Wall and ceiling finishes have requirements for flame spread and smoke-developed indexes, and testing, which are addressed in the following subsections.

**TABLE R302.6
DWELLING-GARAGE SEPARATION**

SEPARATION	MATERIAL
From the residence and attics	Not less than 1/2-inch gypsum board or equivalent applied to the garage side
From habitable rooms above the garage	Not less than 5/8-inch Type X gypsum board or equivalent
Structure(s) supporting floor/ceiling assemblies used for separation required by this section	Not less than 1/2-inch gypsum board or equivalent
Garages located less than 3 feet from a dwelling unit on the same lot	Not less than 1/2-inch gypsum board or equivalent applied to the interior side of exterior walls that are within this area

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

For SI: 1 inch = 25.4 mm.

R302.9.1 Flame spread index. Wall and ceiling finishes shall have a flame spread index of not greater than 200.

Exception: Flame spread index requirements for finishes shall not apply to trim defined as picture molds, chair rails, baseboards and handrails; to doors and windows or their frames; or to materials that are less than $\frac{1}{28}$ inch (0.91 mm) in thickness cemented to the surface of walls or ceilings if these materials exhibit flame spread index values not greater than those of paper of this thickness cemented to a noncombustible backing.

- ❖ The control of interior finishes is an important aspect of fire protection. Section R315.9 contains the requirements for controlling fire growth within buildings by restricting interior finish materials. The dangers of unregulated interior finish include both the rapid spread of fire and the contribution of additional fuel to the fire. The rapid spread of fire presents a threat to the occupants of a building by limiting or denying their use of exitways within and outside the building. This can be caused by the rapid spread of the fire itself or by the production of large quantities of dense, black smoke, which obscures the exit path or makes movement difficult. Unregulated finish materials also have the potential for adding fuel to the fire, thus increasing its intensity and shortening the time available for the occupants to exit safely. However, based on the test standard that is used, the code does not regulate the fuel contribution of interior finish materials.

The code regulates interior finish materials on both walls and ceilings. These provisions do not address the floor or any coverings applied to the floor. The level of performance the code establishes for finish materials is a flame spread index of 200 or less. The flame spread index for a material is based on reviewing its performance under the test standard specified in Section R302.9.3. The limitation of 200 for the flame spread index matches a “Class C” material in the IBC. Therefore, any material that has a flame spread index of less than 200 may be used as a finish material on both walls and ceilings. When foam plastics are used for interior wall and ceiling finishes, they must comply with Section R316.5.10.

The exception will permit the installation of materials that will not significantly contribute to a fire. This includes various types of trim, such as chair rails, door and window frames, and baseboards, which because of their quantities and locations, do not cause great concern. The actual size and quantity of such trim is not specified in the code because it has not been a concern. However, if some type of foam plastic is being used instead of other types of combustible trim, Section R316.5.9 does limit those situations. The exception also does not regulate thin materials, such as wallpaper, which are less than $\frac{1}{28}$ -inch (0.907 mm) thick when they are properly installed. These thin materials, when cemented to the surface of the wall or ceiling, behave essentially as the backing to which they are applied and, as a result, are not regulated.

R302.9.2 Smoke-developed index. Wall and ceiling finishes shall have a smoke-developed index of not greater than 450.

- ❖ The development of smoke affects the occupants’ safety. This section places a limitation of 450 on the density of smoke that is allowed from the wall and ceiling finishes. A product’s smoke-developed index is established for the finish materials when they are tested under the standard specified in Section R302.9.3. The test measures only the obscuration caused by the smoke and does not consider the toxic content within the smoke.

R302.9.3 Testing. Tests shall be made in accordance with ASTM E84 or UL 723.

- ❖ This section establishes that the standard test for flame spread and smoke-development characteristics is either ASTM E84 or UL 723, commonly known as the Steiner Tunnel Test. ASTM E84 and UL 723 determine the relative burning behavior of materials on exposed surfaces, such as ceilings and walls, by visually observing the flame spread along the test specimen. Flame spread and smoke density are reported. The test method renders measurements of surface flame spread and smoke density in comparison with test results obtained by using select red oak and asbestos-cement board as control materials. Red oak is used for the furnace calibration because it is a fairly uniform grade of lumber that is readily available nationally, is uniform in thickness and moisture content, and generally gives consistent and reproducible results. Asbestos-cement board has a flame spread index of zero, while the red oak is assigned a flame spread index of 100. All other materials are then given an index based on a comparison with these two materials. Therefore, the flame spread index of 200 that is permitted by Section R302.9.1 essentially means that the maximum flame spread index for any finish material is twice that of the sample specimen of red oak.

R302.9.4 Alternative test method. As an alternative to having a flame spread index of not greater than 200 and a smoke-developed index of not greater than 450 where tested in accordance with ASTM E84 or UL 723, wall and ceiling finishes shall be permitted to be tested in accordance with NFPA 286. Materials tested in accordance with NFPA 286 shall meet the following criteria:

The interior finish shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
 2. The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
 3. Flashover, as defined in NFPA 286, shall not occur.
 4. The peak heat release rate throughout the test shall not exceed 800 kW.
 5. The total smoke released throughout the test shall not exceed 1,000 m².
- ❖ This section allows the use of NFPA 286 instead of ASTM E84 or UL 723 for testing of wall and ceiling fin-

ishes other than textiles. NFPA 286 is known as a “room corner” fire test. In this test, a fire source consisting of a wood crib is placed in the corner of a compartment. The materials tested are then placed on the walls of the compartment (see Commentary Figure R302.9.4). This generally provides a more realistic understanding of the hazards involved with the materials.

Two levels of exposures are used during an NFPA 286 fire test to better represent a growing fire. The first is a 40-kW fire size for 5 minutes and then a 160-kW exposure for 10 minutes. The 40-kW exposure represents the beginning of a fire where the initial spread is critical. Therefore, the stated criterion is that the fire cannot spread to the ceiling. The 160-kW exposure is obviously a more intense fire and the criterion relates to preventing flashover (as defined by NFPA 286) and the extent of flame spread throughout the entire test assembly. There is also a peak heat release limit of 800 kW and a total smoke production limit of 1,000 square feet (92.9 m²) for both levels of exposure.

It should be noted that the flashover criteria for NFPA 286 are as follows:

- Heat release exceeds 1 MW,
- Heat flux at the floor exceeds 20 kW/m²,
- Average upper layer temperature exceeds 600°C (1112°F),
- Flames exit the doorway, and
- Autoignition of paper target on the floor occurs.

R302.10 Flame spread index and smoke-developed index for insulation. Flame spread and smoke-developed index for insulation shall be in accordance with Sections R302.10.1 through R302.10.5.

❖ Section R302.10 addresses insulating materials installed in building spaces. Insulating materials can affect fire development and fire spread and, therefore, are regulated. Insulation has requirements for flame spread, smoke development, critical radiant flux and testing, which are addressed in the following subsections. There are unique testing requirements for loose-fill insulations.

R302.10.1 Insulation. Insulation materials, including facings, such as vapor retarders and vapor-permeable membranes installed within floor-ceiling assemblies, roof-ceiling assemblies, wall assemblies, crawl spaces and *attics* shall have a flame spread index not to exceed 25 with an accompanying smoke-developed index not to exceed 450 where tested in accordance with ASTM E84 or UL 723.

Exceptions:

1. Where such materials are installed in concealed spaces, the flame spread index and smoke-developed index limitations do not apply to the facings, provided that the facing is installed in substantial contact with the unexposed surface of the ceiling, floor or wall finish.
2. Cellulose fiber loose-fill insulation, that is not spray applied, complying with the requirements of Section R302.10.3, shall not be required to meet the smoke-developed index of not more than 450 and shall be required to meet a smoke-developed index of not more than 450 where tested in accordance with CAN/ULC S102.2.
3. Foam plastic insulation shall comply with Section R316.

❖ Section R302.10.1 addresses the various insulating materials that may be installed in building spaces, including insulating batts, blankets, fills (including vapor barriers and vapor-permeable membranes) and other coverings. Exposed insulating materials represent the same fire exposure hazard as any other exposed material, such as an interior finish. The provisions of Sections R302.10.2, R302.10.3 and R302.10.4, as well as the foam plastic provisions of Section R316, should also be reviewed based on the actual type of insulation and how it is installed. As a general requirement, insulation, including facings used as vapor retarders or as breather papers, must have a flame spread index not in excess of 25 and a smoke-developed index not in excess of 450. These values limit the contribution of the insulation to a fire. The flame spread requirement of 25 for the insulation will be more limiting than the 200, which is accepted for interior finishes by Section R302.9. The test method used to establish these limits is either ASTM E84 or UL 723. See the commentary to Section R302.9.3 for additional information.

Exceptions 1 and 2 address situations where, because of the way the material is installed or because of other imposed regulations, the material does not make any significant contribution to a fire.

The first exception eliminates the flame spread and smoke-developed indexes for the facing portion of the insulation if it is installed “in substantial contact” with the unexposed surface of the ceiling, floor or wall finish. For example, when paper-backed insulation is placed directly on top of a ceiling, the paper facing is not required to meet the smoke and flame spread limits. If the same material is applied to the underside of a roof deck and the paper facing is exposed to the attic space, the paper facing must then meet the general criteria. The potential for flame spread is greatly diminished when the facings are installed in direct contact with the finish material because of the lack of airspace to support a fire if the facing were to be exposed to a source of ignition. See Commentary Figure R302.10.1 for an example of the various facing provisions.

The second exception addresses the fact that cellulosic fiber loose-fill insulation is federally regulated by the Consumer Product Safety Commission (CPSC). Parts 1209 and 1404 of CPSC 16 CFR contain various requirements that regulate the product to avoid excessive flammability or significant fire hazards. The smoke-developed index for cellulosic fiber loose-fill insulation that is spray applied must be 450 or less, as tested in accordance with CAN/ULC S102.2.

Exception 3 points the user to Section R316 for foam plastic insulation. Foam plastic materials pose some different problems that are addressed in Section R316.

R302.10.2 Loose-fill insulation. Loose-fill insulation materials that cannot be mounted in the ASTM E84 or UL 723 apparatus without a screen or artificial supports shall comply with the flame spread and smoke-developed limits of Section

R302.10.1 where tested in accordance with CAN/ULC S102.2.

Exception: Cellulosic fiber loose-fill insulation shall not be required to be tested in accordance with CAN/ULC S102.2, provided such insulation complies with the requirements of Sections R302.10.1 and R302.10.3.

- ❖ The main provision establishes that CAN/ULC S102.2 is used as the test standard to determine the flame spread and smoke-developed indexes for cellulosic fiber loose-fill insulation materials that cannot be tested using the normal ASTM E84 or UL 723 test method. The exception makes a distinction between cellulosic fiber insulation that is spray applied using a water-mist spray applicator and cellulose loose-fill insulation that is poured or blown into place. Spray-applied cellulosic fiber insulation can be exposed on vertical and horizontal ceiling-type surfaces, so it is tested like any other insulating material. Cellulosic fiber loose-fill insulation that is poured (see commentary to Section R302.10.1, Exception 2) is exempt from the test procedure described in this section.

R302.10.3 Cellulosic fiber loose-fill insulation. Cellulosic fiber loose-fill insulation shall comply with CPSC 16 CFR, Parts 1209 and 1404. Each package of such insulating material shall be clearly *labeled* in accordance with CPSC 16 CFR, Parts 1209 and 1404.

- ❖ Because cellulosic fiber loose-fill insulation is federally regulated, this section provides the reference to the various federal regulations that are to be used. Because the federal regulations have precedence, the code cannot impose other requirements on this product. Therefore, this section and the reference to it from Section R302.10.1, Exception 2, establish the requirements for this product and provide the exemption from the normal ASTM E84 or UL 723 test standards.

R302.10.4 Exposed attic insulation. Exposed insulation materials installed on *attic* floors shall have a critical radiant flux not less than 0.12 watt per square centimeter.

❖ This section provides the performance requirements for the test exposure that insulation must meet when it is exposed on the floor of an attic. It is tied to the testing provisions found in Section R302.10.5, which specifies that the ASTM E970 test is to be used for determining the critical radiant flux. See the commentary to Section R302.10.5 regarding the application of this requirement to cellulosic fiber loose-fill insulation.

R302.10.5 Testing. Tests for critical radiant flux shall be made in accordance with ASTM E970.

❖ ASTM E970 is a test method developed by the insulation industry to evaluate the fire hazard of exposed attic insulation and is referenced in the material standards for insulation. Cellulosic fiber loose-fill insulation must comply with CPSC 16 CFR, Part 1209 (see Sec-

tion R302.10.3), which requires testing by this standard. Spray-applied cellulose insulation that is not subject to the CPSC standard (see Section R302.10.1 and Exception 2 in that section) is also subject to the ASTM E970 testing by Section R302.10.4.

R302.11 Fireblocking. In combustible construction, fireblocking shall be provided to cut off both vertical and horizontal concealed draft openings and to form an effective fire barrier between stories, and between a top *story* and the roof space.

Fireblocking shall be provided in wood-framed construction in the following locations:

1. In concealed spaces of stud walls and partitions, including furred spaces and parallel rows of studs or staggered studs, as follows:
 - 1.1. Vertically at the ceiling and floor levels.
 - 1.2. Horizontally at intervals not exceeding 10 feet (3048 mm).

**Figure R302.11(9)
FIRESTOPPING—AROUND MASONRY CHIMNEYS AND FIREPLACES**

2. At interconnections between concealed vertical and horizontal spaces such as occur at soffits, drop ceilings and cove ceilings.
 3. In concealed spaces between stair stringers at the top and bottom of the run. Enclosed spaces under stairs shall comply with Section R302.7.
 4. At openings around vents, pipes, ducts, cables and wires at ceiling and floor level, with an *approved* material to resist the free passage of flame and products of combustion. The material filling this annular space shall not be required to meet the ASTM E136 requirements.
 5. For the fireblocking of chimneys and fireplaces, see Section R1003.19.
 6. Fireblocking of cornices of a two-family *dwelling* is required at the line of *dwelling unit* separation.
- ❖ To restrict the movement of flame and gasses to other areas of a building through concealed passages in building components, such as floors, walls and stairs, fireblocking of these concealed combustible spaces is required to form a barrier between stories, and between a top story and the roof space. For example, the following locations must be firestopped in wood frame construction:

- Concealed spaces of stud walls and partitions, including spaces at the ceiling and floor levels [see Commentary Figures R302.11(1) and R302.11(2)].
- Interconnections between concealed vertical and horizontal spaces such as soffits [see Commentary Figure R302.11(3)], dropped ceilings [see Commentary Figure R302.11(4)] and cove ceilings [see Commentary Figure R302.11(5)]. Interconnections shown in Commentary Figure R302.11(6) for a bathtub installation must also be firestopped.
- Concealed spaces between stair stringers at the top and bottom of the run [see Commentary Figure R302.11(7)].
- Openings around vent pipes, ducts, chimneys and fireplaces at ceiling and floor levels [see Commentary Figures R302.11(8) and R302.11(9)]. By not requiring compliance with ASTM E136, Item 4 indicates that the fireblocking material can be of combustible materials. Commentary Figure R302.11(9) illustrates non-combustible fireblocking at masonry chimneys and fireplaces as required in accordance with Section R1003.19. The fireblocking at the ductwork would be similar, but is not required to be noncombustible.

R302.11.1 Fireblocking materials. Except as provided in Section R302.11, Item 4, fireblocking shall consist of the following materials.

1. Two-inch (51 mm) nominal lumber.

2. Two thicknesses of 1-inch (25.4 mm) nominal lumber with broken lap joints.
3. One thickness of $2\frac{3}{32}$ -inch (18.3 mm) wood structural panels with joints backed by $2\frac{3}{32}$ -inch (18.3 mm) wood structural panels.
4. One thickness of $\frac{3}{4}$ -inch (19.1 mm) particleboard with joints backed by $\frac{3}{4}$ -inch (19.1 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-quarter-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool or glass fiber or other *approved* materials installed in such a manner as to be securely retained in place.
8. Cellulose insulation installed as tested in accordance with ASTM E119 or UL 263, for the specific application.

- ❖ This section specifies the material required for fireblocking. Fireblocking around chimneys and fireplaces must be noncombustible according to Section R1003.19 as specified in Item 5 of Section R302.11. The fireblocking at openings around vents, pipes, ducts and wires at the ceiling and floor level is required only to be adequate to resist the free passage of flames and smoke according to Item 4 of Section R302.11; however, this fireblocking can be constructed from combustible materials. So that it is not accidentally displaced, all fireblocking material must be securely fastened in place.

R302.11.1.1 Batts or blankets of mineral or glass fiber. Batts or blankets of mineral or glass fiber or other *approved* nonrigid materials shall be permitted for compliance with the 10-foot (3048 mm) horizontal fireblocking in walls constructed using parallel rows of studs or staggered studs.

- ❖ Batts or blankets may serve as horizontal fireblocking in walls where they are installed in accordance with Sections R302.11.1.2 through R302.11.1.3.

R302.11.1.2 Unfaced fiberglass. Unfaced fiberglass batt insulation used as fireblocking shall fill the entire cross section of the wall cavity to a height of not less than 16 inches (406 mm) measured vertically. Where piping, conduit or similar obstructions are encountered, the insulation shall be packed tightly around the obstruction.

- ❖ When batts or blankets are used for fireblocking they must fill the wall cavity from stud to stud and be at least 16 inches (406 mm) as measured from the bottom to the top of the fill.

R302.11.1.3 Loose-fill insulation material. Loose-fill insulation material shall not be used as a fireblock unless specifically tested in the form and manner intended for use to demonstrate its ability to remain in place and to retard the spread of fire and hot gases.

- ❖ Not every type of batt or blanket insulation is acceptable as a fireblocking material. Testing must show that the type utilized will provide the intended protection.

R302.11.2 Fireblocking integrity. The integrity of fire-blocks shall be maintained.

- ❖ Piping, ducts or other similar items that pass through firestops must be installed so that the integrity of the firestop is maintained. This may be accomplished by packing an oversized hole with an acceptable fire-blocking material.

R302.12 Draftstopping. In combustible construction where there is usable space both above and below the concealed space of a floor-ceiling assembly, draftstops shall be installed so that the area of the concealed space does not exceed 1,000 square feet (92.9 m²). Draftstopping shall divide the concealed space into approximately equal areas. Where the assembly is enclosed by a floor membrane above and a ceiling membrane below, draftstopping shall be provided in floor-ceiling assemblies under the following circumstances:

1. Ceiling is suspended under the floor framing.
2. Floor framing is constructed of truss-type open-web or perforated members.

- ❖ Draftstopping is required to limit the spread of fire through combustible spaces in floor/ceiling assemblies when such spaces create a connected area beyond the normal joist cavity. For example, draftstopping is required when the ceiling is suspended under the floor framing, as illustrated in Commentary Figure R302.12(1), or when the floor framing is constructed of truss-type or open-web perforated members, as illustrated in Commentary Figure R302.12(2). When such space exceeds 1,000 square feet (92.9 m²) in area, the code requires the space between the ceiling membrane and the floor to be divided into two approximately equal areas with no area larger than 1,000

square feet (92.9 m²). A floor/ceiling assembly having a space exceeding 2,000 square feet (185.8 m²), but not exceeding 3,000 square feet (278.7 m²), would have to be divided into a minimum of three approximately equal areas.

R302.12.1 Materials. Draftstopping materials shall be not less than 1/2-inch (12.7 mm) gypsum board, 3/8-inch (9.5 mm) wood structural panels or other *approved* materials adequately supported. Draftstopping shall be installed parallel to the floor framing members unless otherwise *approved* by the *building official*. The integrity of the draftstops shall be maintained.

- ❖ Materials used to meet draftstopping requirements are typically 1/2-inch (12.7 mm) gypsum board or 3/8-inch (9.5 mm) plywood adequately attached to the supporting members. Other materials may be used for draftstopping, if those materials produce an equivalent barrier.

The code places an additional restriction on the specific location of the draftstopping, mandating that the draftstopping be placed parallel to the main floor framing members. Commentary Figures R302.12(1) and R302.12(2) illustrate two examples of draftstopping orientation placed as required.

When a penetration through the draftstopping is necessary, the integrity of the draftstop must be maintained in a manner similar to firestopping penetrations.

R302.13 Fire protection of floors. Floor assemblies that are not required elsewhere in this code to be fire-resistance rated, shall be provided with a 1/2-inch (12.7 mm) gypsum wall-board membrane, 5/8-inch (16 mm) wood structural panel membrane, or equivalent on the underside of the floor framing member. Penetrations or openings for ducts, vents, elec-

Figure 302.12(1)
DRAFTSTOPPING OF CEILING SUSPENDED UNDER FLOOR FRAMING

tral outlets, lighting, devices, luminaires, wires, speakers, drainage, piping and similar openings or penetrations shall be permitted.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, or other approved equivalent sprinkler system.
 2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
 3. Portions of floor assemblies shall be permitted to be unprotected where complying with the following:
 - 3.1. The aggregate area of the unprotected portions does not exceed 80 square feet (7.4 m²) per story.
 - 3.2. Fireblocking in accordance with Section R302.11.1 is installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.
 4. Wood floor assemblies using dimension lumber or structural composite lumber equal to or greater than 2-inch by 10-inch (50.8 mm by 254 mm) nominal dimension, or other approved floor assemblies demonstrating equivalent fire performance.
- ❖ During a fire unprotected floor assemblies of light-weight construction have a short time gap between untenable conditions and the structural collapse of the floor assembly. Section R302.1.3 requires protection to floors of light-weight construction that will provide the occupants additional time for self-evacuation and safety for fire fighters performing search and rescue. This section requires all floor assemblies, not fire

rated, to be protected on the underside with 1/2-inch gypsum board, 5/8-inch wood structural panels or equivalent. This will apply mainly to floor assemblies located over nonsprinklered areas such as unfinished basements and crawl spaces for storage or containing fuel-fired appliances. There are four exceptions provided that specify where the protection is not required.

Exception 1 permits floor assemblies above any space protected by an automatic sprinkler system to be exempt from the application of the protective membrane to the underside of the floor-framing members. Section R313 requires an automatic residential fire sprinkler system (ARFSS) for new construction and the floor assemblies at each story will have the space below protected; therefore, Section R302.1.3 is not required. For crawl spaces used for storage or containing fuel-fired appliances and alterations or additions to existing buildings that are not provided with an ARFSS, existing buildings that are not provided with an AFRSS, this exception will permit deletion of the protective membrane if the space is protected by an AFRSS in accordance with Section P2904, NFPA 13 D or other approved methods.

Exception 2 exempts floor assemblies over crawl spaces, unless the crawl space contains fuel-fired appliances or is intended for storage. However, Exception 1 may be used for crawl spaces intended for storage or containing fuel-fired appliances.

Exception 3 prescribes an allowable area where the protective membrane may be omitted.

Exception 4 permits floor framing of sawn lumber or structural composite lumber equal to or greater than 2 × 10 nominal dimension to be exempt from the application of the protective membrane to the underside of the floor-framing members. The basis for this excep-

Figure 302.12(2)
DRAFTSTOPPING OF TRUSS-TYPE FLOOR FRAMING

tion is that tests conducted of floor framing constructed of 2 × 10 lumber and loaded to 50 percent of full design load showed that the assemblies provided adequate time for occupants to self-evacuate and safety for fire fighters performing search and reuse.

R302.14 Combustible insulation clearance. Combustible insulation shall be separated not less than 3 inches (76 mm) from recessed luminaires, fan motors and other heat-producing devices.

Exception: Where heat-producing devices are *listed* for lesser clearances, combustible insulation complying with the listing requirements shall be separated in accordance with the conditions stipulated in the listing.

Recessed luminaires installed in the *building thermal envelope* shall meet the requirements of Section N1102.4.5 of this code.

- ❖ The minimum clearance required between combustible insulation and light fixtures, fan motors, etc., minimizes the chance of accidental ignition of the insulation. If a heat-producing device is listed for less than the minimum clearance specified in this section and all conditions of the listing are satisfied, the reduced clearance would apply.

SECTION R303 LIGHT, VENTILATION AND HEATING

R303.1 Habitable rooms. Habitable rooms shall have an aggregate glazing area of not less than 8 percent of the floor area of such rooms. Natural *ventilation* shall be through windows, skylights, doors, louvers or other *approved* openings to the outdoor air. Such openings shall be provided with ready access or shall otherwise be readily controllable by the building occupants. The openable area to the outdoors shall be not less than 4 percent of the floor area being ventilated.

Exceptions:

1. The glazed areas need not be openable where the opening is not required by Section R310 and a whole-house mechanical *ventilation* system is installed in accordance with Section M1507.
 2. The glazed areas need not be installed in rooms where Exception 1 is satisfied and artificial light is provided that is capable of producing an average illumination of 6 footcandles (65 lux) over the area of the room at a height of 30 inches (762 mm) above the floor level.
 3. Use of sunroom and patio covers, as defined in Section R202, shall be permitted for natural *ventilation* if in excess of 40 percent of the exterior sunroom walls are open, or are enclosed only by insect screening.
- ❖ All habitable rooms are to be constructed with an aggregate glazing area of not less than 8 percent of the floor area. The code does not require the glazed area to be openable. This section also provides the standard of natural ventilation for all habitable rooms. Openings to the outdoor air, such as doors, windows and louvers, provide natural ventilation. The openable

area must be not less than 4 percent of the floor area being ventilated. This section does not, however, state or intend that the doors, windows or openings actually be constantly open. The intent is that they be maintained in an operable condition so that they are available for use at the discretion of the occupant. In addition to the natural ventilation provisions of this section, a whole-house mechanical ventilation system may be required in accordance with the provisions of Section R303.4.

Although the glazed area may be operable, Exception 1 permits the glazed area for all openings, except the ones required for emergency escape and rescue, to be fixed or “not openable” when a whole-house mechanical ventilation system is installed in accordance with Section M1507.

Exception 2 to Section R303.1 allows glazing to be completely deleted from habitable rooms where artificial light is available that is capable of producing an average illumination of 6 footcandles (65 lux) over the room at a height of 30 inches (762 mm) above the floor level and where a whole-house mechanical ventilation system complying with Exception 1 to Section R303.1 is installed.

Exception 3 allows for the openings in a sunroom (those in which more than 40 percent of the exterior sunroom walls is open) to provide natural ventilation when the exterior walls of the sunroom are open. Insect screening for these seasonal rooms is also acceptable to make use of this exception.

Various handbooks are available from lighting manufacturers for calculating the required illumination.

R303.2 Adjoining rooms. For the purpose of determining light and *ventilation* requirements, any room shall be considered to be a portion of an adjoining room where not less than one-half of the area of the common wall is open and unobstructed and provides an opening of not less than one-tenth of the floor area of the interior room and not less than 25 square feet (2.3 m²).

Exception: Openings required for light or *ventilation* shall be permitted to open into a sunroom with thermal isolation or a patio cover, provided that there is an openable area between the adjoining room and the sunroom or patio cover of not less than one-tenth of the floor area of the interior room and not less than 20 square feet (2 m²). The minimum openable area to the outdoors shall be based upon the total floor area being ventilated.

- ❖ Where rooms do not have access to an exterior wall to satisfy light and ventilation requirements, they may be considered as part of an adjoining room if they are open to that room as shown in Commentary Figure R303.2.

The exception deals with a very common circumstance, especially in residential construction. As long as the sunroom addition is large enough and is thermally isolated, the building owner need not move openings for lighting and/or ventilation when installing an addition that meets the definition of “Sunroom addition.”

R303.3 Bathrooms. Bathrooms, water closet compartments and other similar rooms shall be provided with aggregate glazing area in windows of not less than 3 square feet (0.3 m²), one-half of which must be operable.

Exception: The glazed areas shall not be required where artificial light and a local exhaust system are provided. The minimum local exhaust rates shall be determined in accordance with Section M1507. Exhaust air from the space shall be exhausted directly to the outdoors.

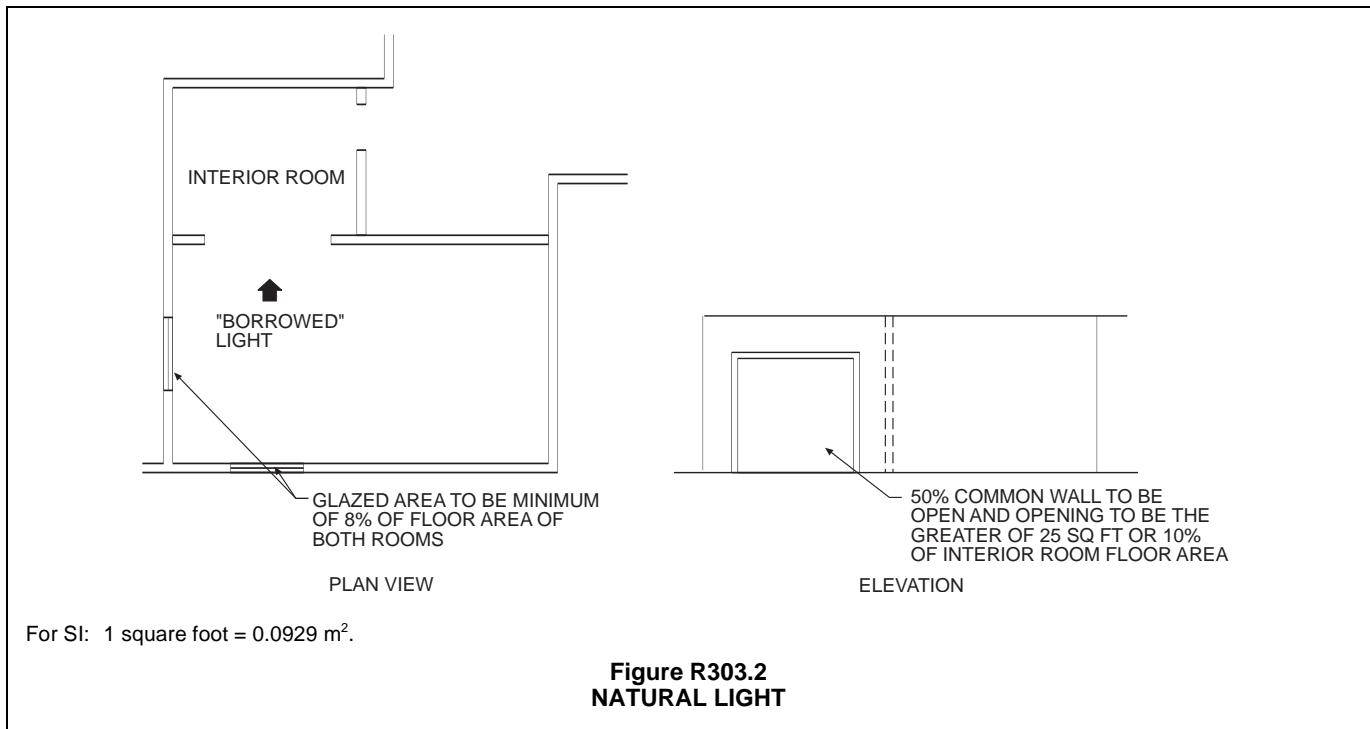

- ❖ Like habitable rooms, bathrooms must be provided with natural light and ventilation or adequate artificial light and mechanical ventilation. For natural light, exterior glazing of at least 3 square feet (0.3 m²) must be provided. To meet the natural ventilation requirement, at least 1.5 square feet (0.140 m²) must be operable.

For local exhaust the exhaust rates must be determined in accordance with Section M1507.4. The exhaust must be directly to the outdoors.

R303.4 Mechanical ventilation. Where the air infiltration rate of a *dwelling unit* is 5 air changes per hour or less where tested with a blower door at a pressure of 0.2 inch w.c (50 Pa) in accordance with Section N1102.4.1.2, the *dwelling unit* shall be provided with whole-house mechanical ventilation in accordance with Section M1507.3.

- ❖ Section R303.1 requires natural ventilation through windows, doors or other approved openings, with an option for mechanical ventilation. Multiple studies have shown that natural ventilation alone is not sufficient for dwellings that are tightly sealed such that their infiltration rate is below 5 air changes per hour (ACH). Section R303.4 sets the threshold for tightly sealed at 5 ACH at a 50 Pascal pressure differential between the indoors and outdoors (5 ACH50). For perspective, 50

Pa = 0.2 inch water column; 1 inch water column = 250 Pa. Traditionally, 0.35 ACH or 15 cfm per occupant has been the required mechanical ventilation rate allowed as an alternative to natural ventilation. An ACH of 0.35 at typical ambient pressure differentials is roughly equivalent to 7 to 10 ACH at a 50 Pa differential, thus the threshold of 5 ACH50 is comparable to the traditional ventilation rate. If the blower door test required by Section N1102.4.1.2 of the code indicates that the infiltration rate is less than 5 ACH50, the dwelling must be provided with whole-house mechanical ventilation. Note that Section N1102.4.1.2 intends for the infiltration rate to be 5 ACH50 or less, consistent with the trend for tighter building envelopes. Where a whole-house mechanical ventilation system is provided in accordance with Section R303.1, Exception 1, the intent of this section is satisfied and the ACH rate need not be known because Exception 1 short-cuts directly to Section M1507. As dwelling envelopes become more air tight, there is evidence that indoor contaminant levels are rising. Poor indoor air quality, the inability to predict ventilation rates from natural ventilation and the decreasing rates of infiltration have all led to this requirement for mechanical ventilation in dwellings. The model for the requirements of this section is ASHRAE 62.2, the standard for ventilation and indoor air quality in residential buildings, which is similar to that in Appendix B of ICC 700, *National Green Building Standard*. Also, several state codes now mandate mechanical ventilation in dwellings. This section applies whether or not the natural ventilation provisions of Section R303.1 are applied. In other words, the requirement of this section is in addition to the provisions of Section R303.1 (see commentary, Section M1507).

R303.5 Opening location. Outdoor intake and exhaust openings shall be located in accordance with Sections R303.5.1 and R303.5.2.

❖ This section regulates the locations of outdoor air intake and exhaust air openings. These provisions are intended to prevent the introduction of contaminants into the ventilation air of a building or to avoid the exhausting of contaminants into areas that may be occupied by people or into other buildings.

R303.5.1 Intake openings. Mechanical and gravity outdoor air intake openings shall be located not less than 10 feet (3048 mm) from any hazardous or noxious contaminant, such as vents, chimneys, plumbing vents, streets, alleys, parking lots and loading docks.

For the purpose of this section, the exhaust from *dwelling* unit toilet rooms, bathrooms and kitchens shall not be considered as hazardous or noxious.

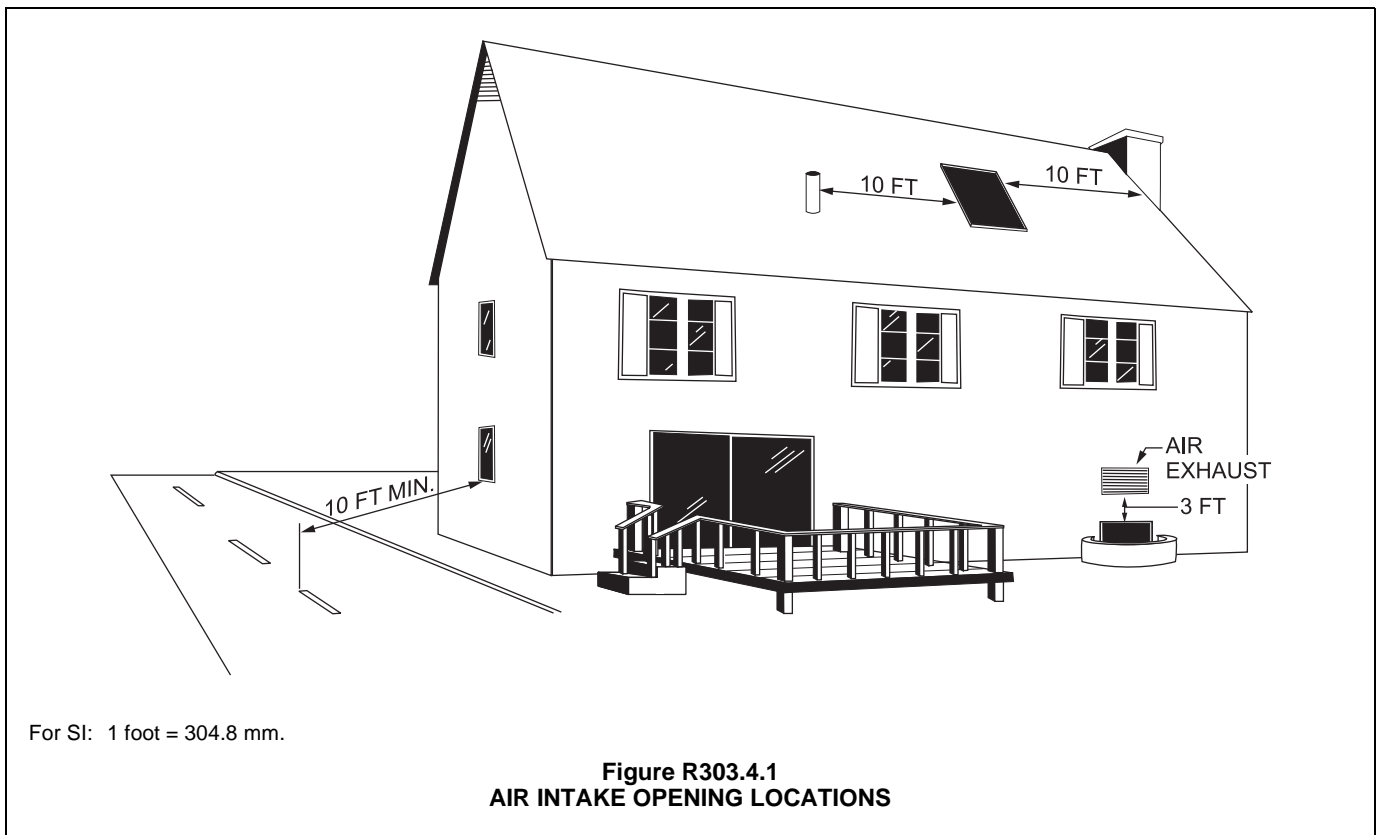

Exceptions:

1. The 10-foot (3048 mm) separation is not required where the intake opening is located 3 feet (914 mm) or greater below the contaminant source.
2. Vents and chimneys serving fuel-burning appliances shall be terminated in accordance with the applicable provisions of Chapters 18 and 24.
3. Clothes dryer exhaust ducts shall be terminated in accordance with Section M1502.3.

❖ In the context of this section, intake openings include windows, doors, gravity air intakes, soffit vents, com-

bustion air intake openings, outside air intakes for air handlers, makeup air intakes and similar openings that naturally or mechanically draw in air from the building exterior. This section identifies specific locations that are known to generate or emit noxious contaminants, and requires that both mechanical and gravity air intake openings be located a minimum of 10 feet (3048 mm) from such hazards to avoid introducing contaminants into the building. As an alternative, Exception 1 allows mechanical and gravity air intakes to be located within 10 feet (3048 mm) of such sources of contamination if the intakes are located at least 3 feet (914 mm) below the contaminant source. A 3-foot (914 mm) vertical separation distance will allow the noxious gases and contaminants to disperse into the atmosphere before they can be drawn into an air intake opening. Placing the source of contamination above an air intake takes advantage of the fact that normally encountered sources of contamination are lighter (less dense) than the surrounding air and, therefore, will rise above the vicinity of an air intake located below. Commentary Figure R303.4.1 shows an example of the relative locations for intake air openings for a building where sources of contaminants are present.

Particular types of exhausts may have more specific restrictions on their location that would supersede this section. Therefore, Exception 2 references Chapters 18 and 24 for the termination of vents and chimneys serving fuel-burning appliances and Exception 3 references Section M1502.3 for the termination of clothes dryer exhaust ducts.

R303.5.2 Exhaust openings. Exhaust air shall not be directed onto walkways.

- ❖ For obvious health reasons, exhaust air cannot be directed onto walkways in a manner that subjects the users of the walkway to the exhaust airstream.

Ideally, mechanical exhaust air openings should not be located in any position where they may create a nuisance. A “Nuisance” is defined in Chapter 2 of the *International Plumbing Code*® (IPC®) as “whatever is dangerous to human life or detrimental to health; whatever structure or premises is not sufficiently ventilated, sewerred, drained, cleaned or lighted, with respect to its intended occupancy; and whatever renders the air, or human food, drink or water supply unwholesome.” A nuisance is defined as much more than or much worse than simply “bothersome.” Unfortunately, it is not an easy task to determine whether or not a nuisance will be present because the conditions under which an exhaust system performs vary considerably with the change of seasons, the ambient temperatures and the prevailing winds. As much information as possible should be gathered regarding the installation in order to evaluate the hypothetical worst-case scenario. This would include the characteristics and geometry of the installation, as well as the local ambient conditions, so that an educated guess may be made to determine the “nuisance effect” of the exhaust outlet.

R303.6 Outside opening protection. Air exhaust and intake openings that terminate outdoors shall be protected with corrosion-resistant screens, louvers or grilles having an opening size of not less than $\frac{1}{4}$ inch (6 mm) and a maximum opening size of $\frac{1}{2}$ inch (13 mm), in any dimension. Openings shall be protected against local weather conditions. Outdoor air exhaust and intake openings shall meet the provisions for *exterior wall* opening protectives in accordance with this code.

- ❖ Outside air exhaust and intake openings must have corrosion-resistant screens, grilles or louvers to prevent foreign objects (such as insects or debris) from entering the system or building. Also, such openings must be protected against the entry of falling or wind-driven water, snow and ice. Exhaust systems sometimes incorporate rotating hoods over the opening to prevent high winds from restricting the flow of exhaust gases out of the system. The hoods align themselves with the direction of the wind to allow the unimpeded, and actually induced, discharge from the exhaust outlet. Rotating turbines are also used as both weather protection and a means of inducing airflow.

The opening sizes for louvers and grilles and the mesh sizes for screens must be within the specified range as indicated. The opening size must be large enough to inhibit blockage by debris, to prevent significant resistance to airflow, and still be small enough to keep out what must be kept out. A screen of such mesh size would restrict the passage of rodents and large insects and would be resistant to blockage by lint, debris and plant fibers.

R303.7 Interior stairway illumination. Interior stairways shall be provided with an artificial light source to illuminate the landings and treads. The light source shall be capable of illuminating treads and landings to levels of not less than 1 foot-candle (11 lux) as measured at the center of treads and landings. There shall be a wall switch at each floor level to control the light source where the stairway has six or more risers.

Exception: A switch is not required where remote, central or automatic control of lighting is provided.

- ❖ Interior stairways may be illuminated in two ways. The first option is to install artificial lighting in the vicinity of each landing and the treads. This would include top, intermediate and bottom landings and each tread run. However, this does not mean that a separate artificial light source must be installed in each of these locations. The artificial light must be capable of illuminating treads and landings to not less than 1 footcandle (11 lux). The measurement of 1 footcandle (11 lux) is to be taken at the center of landings and treads. Where a stair has six or more risers, a wall switch to control the artificial light source is required at each floor level, except where remote, central or automatic control is provided (see Commentary Figure R303.7).

R303.8 Exterior stairway illumination. Exterior stairways shall be provided with an artificial light source located at the top landing of the stairway. Exterior stairways providing access to a *basement* from the outdoor *grade* level shall be provided with an artificial light source located at the bottom landing of the stairway.

- ❖ Exterior stairways require illumination only at the top landing (see Commentary Figure R303.7).

Exterior stairways to a basement must have artificial illumination near the bottom landing.

The exception allows the light source to be installed over each individual stairway section, thus eliminating the lighting over the landings.

R303.9 Required glazed openings. Required glazed openings shall open directly onto a street or public alley, or a *yard* or court located on the same *lot* as the building.

Exceptions:

1. Required glazed openings that face into a roofed porch where the porch abuts a street, *yard* or court and the longer side of the porch is not less than 65 percent unobstructed and the ceiling height is not less than 7 feet (2134 mm).
 2. Eave projections shall not be considered as obstructing the clear open space of a *yard* or court.
 3. Required glazed openings that face into the area under a deck, balcony, bay or floor cantilever where a clear vertical space not less than 36 inches (914 mm) in height is provided.
- ❖ Glazed openings must be placed so that natural light will be available even after future adjacent construction occurs. Where glazing is required by the code, it must

face onto a street, public alley, yard or court of the lot on which the building is located. Glazed openings are not permitted in walls that must be of 1-hour fire-resistant construction in accordance with Section R302.1.

Exception 1 allows for an open porch where natural light will be available. Glazed openings required by the code are permitted to open onto a porch if it abuts a yard, street or court and the longer side is open at least 65 percent. The porch ceiling height must be at least 7 feet (2134 mm).

Yards and courts are defined as being open and unobstructed from the ground to the sky. Interpreted literally, this would prevent any projection above a required window. Yet, eaves are commonly placed above windows and in apartment buildings it is common to have decks over required windows. Exception 2 removes that problem. Concern that an eave could project to a lot line and, thus, block all natural light is unfounded as eave projections are limited from extending to a lot line so there will always be some open space above them.

Exception 3 addresses windows that open under balconies, decks, bays, etc. Section R310.5 permits emergency escape openings to open "under decks and porches provided the location of the deck allows the emergency escape window to be fully opened and provides a path not less than 36 inches (914 mm) in height to a yard or court." This allowance will make the two types of windows consistent.

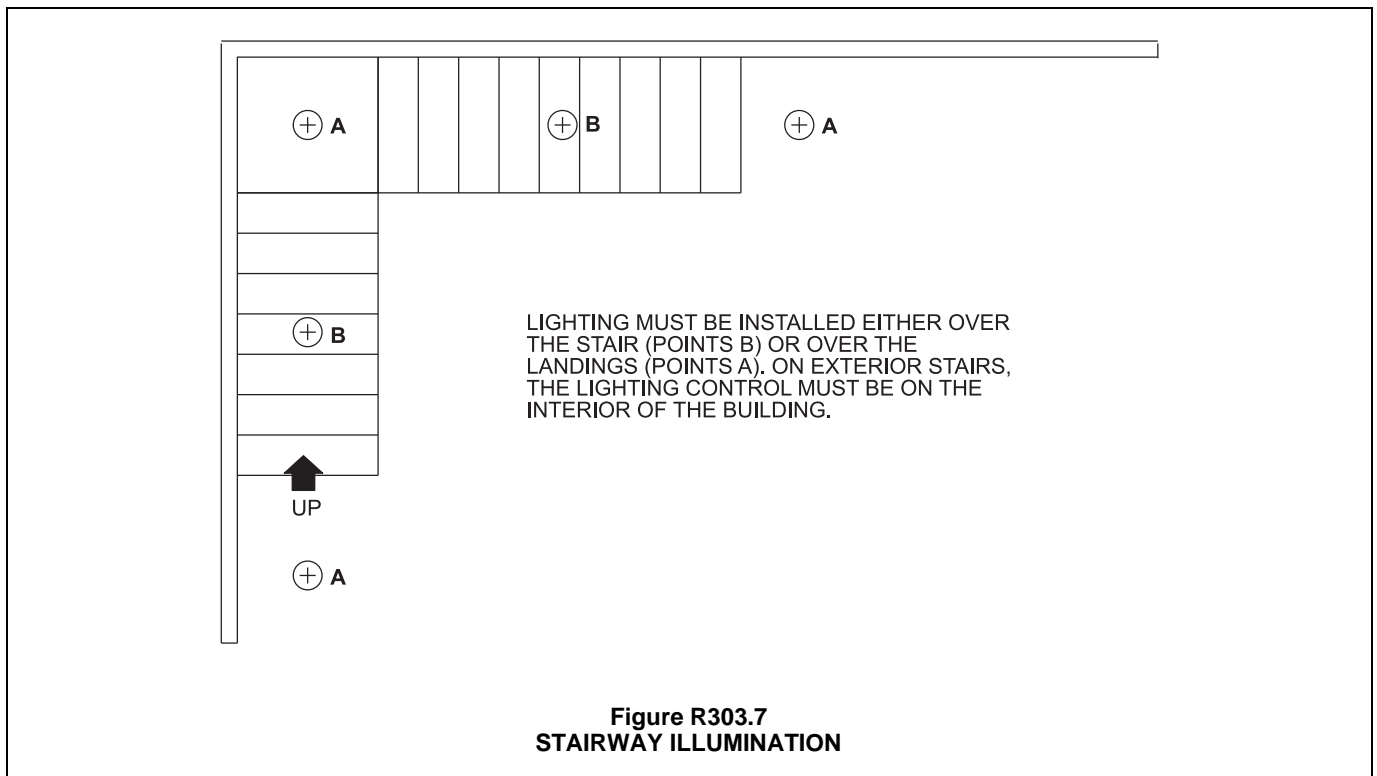

R303.9.1 Sunroom additions. Required glazed openings shall be permitted to open into sunroom *additions* or patio covers that abut a street, *yard* or court if in excess of 40 percent of the exterior sunroom walls are open, or are enclosed

only by insect screening, and the ceiling height of the sunroom is not less than 7 feet (2134 mm).

- ❖ This section permits openings for lighting to open into a sunroom that meets the criterion of being more than 40 percent open. Both enclosed porches and sunrooms must be a minimum of 7 feet (2134 mm) high and abut a court, yard or public space. Open areas near the sunroom enable the sunlight to effectively reach the structure. Sunrooms are those which are not conditioned and are either open or enclosed by screening or plastic.

R303.10 Required heating. Where the winter design temperature in Table R301.2(1) is below 60°F (16°C), every *dwelling unit* shall be provided with heating facilities capable of maintaining a room temperature of not less than 68°F (20°C) at a point 3 feet (914 mm) above the floor and 2 feet (610 mm) from exterior walls in habitable rooms at the design temperature. The installation of one or more portable space heaters shall not be used to achieve compliance with this section.

- ❖ Minimum heating requirements are for health reasons. In areas where the design temperature is based on Table R301.2(1) and is below 60°F (16°C), dwelling units must be provided with heating facilities capable of maintaining a minimum room temperature of 68°F (20°C). The primary need here is that of human comfort. The minimum temperature is measured at 3 feet (914 mm) above the floor and 2 feet (610 mm) from the exterior walls of all habitable rooms (see Commentary Figure R303.10). Portable space heaters cannot be used to achieve compliance with this section.

**SECTION R304
MINIMUM ROOM AREAS**

R304.1 Minimum area. Habitable rooms shall have a floor area of not less than 70 square feet (6.5 m²).

Exception: Kitchens.

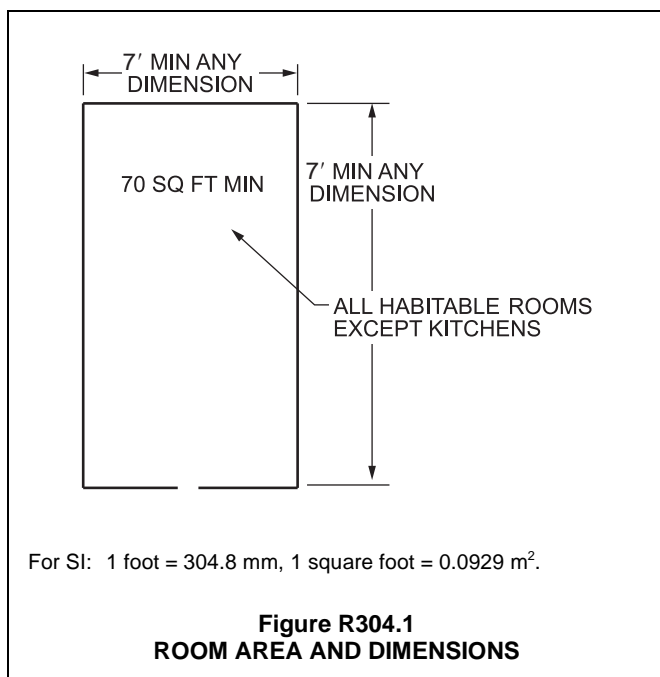

❖ The interior living environment is affected by a number of issues. Among these are the size of the room, tightness of construction, ceiling height, number of occupants and ventilation. These all interact and impact the interior living conditions including odors, moisture and disease transmission. The code regulates room sizes to assist in maintaining a safe and comfortable interior environment (see Commentary Figure R304.1). All

habitable rooms and spaces, other than kitchens, are required to have a minimum area of 70 square feet. The definition of “Habitable space” in Section R202 includes rooms used for living, sleeping, eating or cooking (see commentary for Section 305.1).

R304.2 Minimum dimensions. Habitable rooms shall be not less than 7 feet (2134 mm) in any horizontal dimension.

Exception: Kitchens.

❖ Except for kitchens, all habitable rooms must have a minimum horizontal dimension in any direction of at least 7 feet (2134 mm) (see Commentary Figure R304.1).

R304.3 Height effect on room area. Portions of a room with a sloping ceiling measuring less than 5 feet (1524 mm) or a furred ceiling measuring less than 7 feet (2134 mm) from the finished floor to the finished ceiling shall not be considered as contributing to the minimum required habitable area for that room.

- ❖ In a room with a sloping ceiling, any portion of the room with a vertical ceiling height of less than 5 feet (1524 mm), as measured from the finished floor, must not be included in the calculation of the minimum required floor area for habitation. Likewise, the area under a furred ceiling with a vertical height less than 7 feet (2134 mm) from the finished floor is not part of the habitable area. An example of the first case would be an A-frame structure, which consists of a sloping roof and no or minimal exterior walls. This condition could also exist in any room that has a sloping ceiling. The low height makes those portions of the room generally unusable for adults (see Commentary Figure R304.3 and commentary to Section 305.1).

SECTION R305 CEILING HEIGHT

R305.1 Minimum height. *Habitable space*, hallways and portions of *basements* containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). Bathrooms, toilet rooms and laundry rooms shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exceptions:

1. For rooms with sloped ceilings, the required floor area of the room shall have a ceiling height of not less than 5 feet (1524 mm) and not less than 50 percent of the required floor area shall have a ceiling height of not less than 7 feet (2134 mm).
 2. The ceiling height above bathroom and toilet room fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a ceiling height of not less than 6 feet 8 inches (2032 mm) above an area of not less than 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.
 3. Beams, girders, ducts or other obstructions in *basements* containing *habitable space* shall be permitted to project to within 6 feet 4 inches (1931 mm) of the finished floor.
- ❖ Minimum ceiling heights are required for habitable spaces (see the definition in Chapter 2), including kitchens, hallways, bathrooms, toilet rooms and laundry rooms, as well as those portions of basements that contain habitable space.
For habitable spaces and hallways, as well as portions of basements that contain such spaces, the minimum required ceiling height is 7 feet (2134 mm). This is intended to help maintain a healthy interior environment. The minimum required ceiling height for bathrooms, toilet rooms and laundry rooms is 6 feet 8 inches (2032 mm).

Exception 1 is applicable to habitable spaces that have sloped ceilings. It requires that not less than one half of the required room area (or 70 feet in accordance with Section R304.1, divided by 2, for a result of 35 square feet of room area) must have a ceiling height of not less than 7 feet, and the remaining portion of the required room area (70 square feet minus the area of the room with a ceiling height of not less than 7 feet) must have a ceiling height of not less than 5 feet. Sloped ceiling heights in the remainder of such rooms are not regulated. Note that, similar to Exception 1, Section R304.3 requires that portions of a room with sloped ceilings less than 5 feet in height, as well as furred ceilings with a height of less than 7 feet (2134 mm), as measured from finished floor to finished ceiling, are not allowed to be considered as part of the minimum required area of habitable rooms. Section R304.3 also requires that ceiling heights be measured from the top of finished floors to the underside of finished ceilings.

Exception 2 requires that showers and tubs equipped with a shower head have a ceiling height at the shower head of not less than 6 feet 8 inches for an area of not less than 30 inches (763 mm) by 30 inches (762 mm) at the shower head, but allows other areas over showers and tubs to have lesser ceiling heights, as long as the fixture is capable of being used for its intended purpose. Similarly, the required minimum ceiling height over other bathroom and toilet room fixtures is allowed to be less than 6 feet 8 inches (2032 mm), as long as the fixtures are capable of being used for their intended purpose. This exception would allow a sloping ceiling over toilet, bath or shower fixtures if the minimum ceiling height of 6 feet, 8 inches (2036 mm) is maintained over the front clearance area (see Figure R307.1). If the fixture can still be used effectively, the ceiling height can be lower over the fixture itself. For example, the ceiling height over the tank and bowl of the toilet can be below 6 feet, 8 inches (2033 mm), provided that the clearance was high enough to allow someone to sit on the toilet.

Exception 3 allows a ceiling height of 6 feet 4 inches (1931 mm), as measured from the top of the finished floor, under beams, girders, ducts and other obstructions in those portions of basements that contain habitable spaces (see commentary for Section R305.1.1).

R305.1.1 Basements. Portions of *basements* that do not contain *habitable space* or hallways shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exception: At beams, girders, ducts or other obstructions, the ceiling height shall be not less than 6 feet 4 inches (1931 mm) from the finished floor.

- ❖ Portions of basements that are not addressed in Section R305.1 need to have a ceiling height of only 6 feet, 8 inches (2033 mm) or more, with at least 6 feet, 4 inches (1932 mm) of clear height under beams, girders, ducts and similar obstructions (see commentary to Section R305.1).

SECTION R306 SANITATION

R306.1 Toilet facilities. Every *dwelling* unit shall be provided with a water closet, lavatory, and a bathtub or shower.

❖ Dwelling units must have at least one of each of the fixtures indicated in the code, and the fixtures must be connected to an approved sanitary sewer or private sewage disposal system. A water closet, lavatory and either a bathtub or shower are the minimum fixtures needed to maintain the occupant's health and cleanliness. For additional information on plumbing requirements, see Chapters 25 through 33.

R306.2 Kitchen. Each *dwelling* unit shall be provided with a kitchen area and every kitchen area shall be provided with a sink.

❖ Dwelling units must have a kitchen area with a sink for the basic preparation of food.

R306.3 Sewage disposal. Plumbing fixtures shall be connected to a sanitary sewer or to an *approved* private sewage disposal system.

❖ To maintain sanitary conditions in the dwelling, plumbing fixtures must be attached to either a sanitary sewer or approved private sewage disposal system.

R306.4 Water supply to fixtures. Plumbing fixtures shall be connected to an *approved* water supply. Kitchen sinks, lavatories, bathtubs, showers, bidets, laundry tubs and washing machine outlets shall be provided with hot and cold water.

❖ To provide proper sanitation for occupants of dwelling units, each plumbing fixture must be connected to an approved water supply. Additionally, specific fixtures must have both a hot and cold water supply.

SECTION R307 TOILET, BATH AND SHOWER SPACES

R307.1 Space required. Fixtures shall be spaced in accordance with Figure R307.1, and in accordance with the requirements of Section P2705.1.

❖ Fixtures require certain clearances to be accessible and usable. Figure R307.1 shows the minimum fixture clearances. The diagram is consistent with the requirements in Section P2705.1, Item 5. In addition, Item 5 also specifies that adjacent fixtures must be at least 30 inches (762 mm) center-to-center. A common fixture configuration in a bathroom that could be affected by this would be two adjacent lavatories in one vanity or a lavatory adjacent to a water closet.

FIGURE R307.1. See page 3-75.

❖ See the commentary to Section R301.1.

R307.2 Bathtub and shower spaces. Bathtub and shower floors and walls above bathtubs with installed shower heads and in shower compartments shall be finished with a nonab-

sorbent surface. Such wall surfaces shall extend to a height of not less than 6 feet (1829 mm) above the floor.

❖ Wall surfaces subject to water spray by showerheads must be protected with a nonabsorbent surface to a height of at least 6 feet (1829 mm) above the floor of a bathtub or shower.

SECTION R308 GLAZING

R308.1 Identification. Except as indicated in Section R308.1.1 each pane of glazing installed in hazardous locations as defined in Section R308.4 shall be provided with a manufacturer's designation specifying who applied the designation, designating the type of glass and the safety glazing standard with which it complies, which is visible in the final installation. The designation shall be acid etched, sandblasted, ceramic-fired, laser etched, embossed, or be of a type that once applied cannot be removed without being destroyed. A *label* shall be permitted in lieu of the manufacturer's designation.

Exceptions:

1. For other than tempered glass, manufacturer's designations are not required provided that the *building official* approves the use of a certificate, affidavit or other evidence confirming compliance with this code.
2. Tempered spandrel glass is permitted to be identified by the manufacturer with a removable paper designation.

❖ Once glass is installed in a window frame by a manufacturer, whether that glass is safety glazing or not is not easily determined. In theory, this can be established only by breaking the particular piece of glass, in which case the glass is no longer useable. Thus, the code requires that safety glazing be marked with a manufacturer's designation that is visible during the final building inspection. Except for tempered glass labels, labels may be omitted where approved by the building official and an affidavit, certificate or other evidence is submitted indicating compliance with the code. A manufacturer can identify safety glazing with a removable paper designation, provided removal would destroy the designation. This ensures that the designation will not be applied to a noncomplying piece of glass.

R308.1.1 Identification of multiple assemblies. Multipane assemblies having individual panes not exceeding 1 square foot (0.09 m²) in exposed area shall have not less than one pane in the assembly identified in accordance with Section R308.1. Other panes in the assembly shall be *labeled* "CPSC 16 CFR 1201" or "ANSI Z97.1" as appropriate.

❖ Multipane assemblies of glass need identification for the same reasons noted in Section R308.1. This provision allows labeling of only one pane of glass in

accordance with Section R308.1.1 when the exposed area of each pane is 1 square foot (0.09 m²) or less. All other panes must be labeled either “16 CFR 1201” or “ANSI Z97.1.”

R308.2 Louvered windows or jalousies. Regular, float, wired or patterned glass in jalousies and louvered windows shall be not less than nominal 3/16 inch (5 mm) thick and not more than 48 inches (1219 mm) in length. Exposed glass edges shall be smooth.

❖ The requirements for louvered windows exist because there is no edge support on the longitudinal edges of

these panes. The code requires that the exposed edges be smooth for safety. The minimum thickness and maximum span are specified so that the glass has sufficient resistance to human impact loads.

R308.2.1 Wired glass prohibited. Wired glass with wire exposed on longitudinal edges shall not be used in jalousies or louvered windows.

❖ Wired glass is not permitted in jalousies or louvered windows if the wire is exposed on the longitudinal edge because it would be a hazard.

For SI: 1 inch = 25.4 mm.

FIGURE R307.1
MINIMUM FIXTURE CLEARANCES

R308.3 Human impact loads. Individual glazed areas, including glass mirrors in hazardous locations such as those indicated as defined in Section R308.4, shall pass the test requirements of Section R308.3.1.

Exceptions:

1. Louvered windows and jalousies shall comply with Section R308.2.
 2. Mirrors and other glass panels mounted or hung on a surface that provides a continuous backing support.
 3. Glass unit masonry complying with Section R607.
- ❖ The code requires that glazing in hazardous locations subject to human impact pass impact tests. Criteria is based on size and location [see Section R308.3.1, and Tables R308.3.1(1) and R308.3.1(2)]. The exceptions provide for three types of glazing that have alternative means of offering protection when used in hazardous locations: louvered windows and jalousies meeting the thickness and length limitations in Section R308.2; mirrors or glass hung on a wall or fitted with a backing; and glass block constructed in accordance with Section R610. Glass block is becoming more prevalent in the design of homes. One of the more common uses is enclosures for walk-in showers.

R308.3.1 Impact test. Where required by other sections of the code, glazing shall be tested in accordance with CPSC 16 CFR 1201. Glazing shall comply with the test criteria for Category II unless otherwise indicated in Table R308.3.1(1).

Exception: Glazing not in doors or enclosures for hot tubs, whirlpools, saunas, steam rooms, bathtubs and showers shall be permitted to be tested in accordance with ANSI Z97.1. Glazing shall comply with the test criteria for Class A unless indicated in Table R308.3.1(2).

- ❖ Section R308.4 lists seven different situations where there is a chance of someone falling or reaching into a piece of glass and possibly injuring themselves; therefore, testing is required to resist these human impact loads. Glazing in hazardous locations must pass the test requirements of CPSC 16 CFR, Part 1201 and meet the test criteria of Category Class II. Table R308.3.1(1) permits some glazing in hazardous locations to be less than Category Class II. The exception allows for another standard, ANSI Z97.1, as an alternative test for glazing that is in a location other than in a door or serving as part of a bathing enclosure. This limitation in the exception is due to the mandatory location requirements in CPSC 16 CFR, Part 1201. The exception requires the glazing to pass ANSI Z97.1 and meet the test criteria of Category A. Table R308.3.1(2) then permits some glazing in hazardous locations to be less than Category A.

Following are the more significant differences between these two standards, both of which are applicable to safety glazing materials used in architectural applications. This overview makes no attempt to summarize all pertinent provisions of the two standards, only their significant differences.

The principal differences between CPSCs 16 CFR,

Part 1201 and ANSI Z97.1 relate to their scope and function. The CPSC standard is not only a test method and a procedure for determining the safety performance of architectural glazing, but also a federal standard that mandates where and when safety glazing materials must be used in architectural applications and preempts any nonidentical state or local standard. In contrast, ANSI Z97.1 is only a voluntary safety performance specification and test method. It does not purport to indicate where and when safety glazing materials must be used, leaving those determinations up to the building codes and to glass and fenestration specifiers. In this instance, the code provides the requirements regarding the safety performance of architectural glazing beyond that which is covered by the federal standard.

The CPSC standard requires the installation of safety glazing materials meeting 16 CFR, Part 1201 only in storm doors, combination doors, entrance-exit doors, sliding patio doors, closet doors, and shower and tub doors and enclosures. See Section 308.4 of the IBC for additional locations where the code requires safety glazing in commercial applications.

Test Specimens: For impact testing, the CPSC standard requires only one specimen of each nominal thickness be submitted for testing and specifies it must be the largest size the manufacturer produces up to a maximum size of 34 inches by 76 inches (864 mm by 1830 mm). ANSI Z97.1 requires that four specimens of each nominal thickness and size must be impact tested. The manufacturer has the option of testing either 34-inch by 76-inch (864 mm by 1830 mm) specimens or the largest size it commercially produces less than 34 inches by 76 inches (864 mm by 1830 mm), but with a minimum size of 24 inches by 30 inches (610 mm by 762 mm).

Types of Glass: The CPSC standard has no performance tests for plastics or for bent glass. ANSI Z97.1 has specific tests for both.

The CPSC standard does not prohibit the use of ordinary annealed glass in hazardous locations as long as it passes the appropriate impact tests, consistent with the concept of a performance-based impact test. [Thick, heavy annealed glass is likely to pass the CPSC 18-inch (457 mm) drop-height and 48-inch (1219 mm) drop-height impact tests for Category I and II locations.] ANSI Z97.1 contains an express limitation on annealed glass: "Monolithic annealed in any thickness is not considered safety glazing material under this standard."

Asymmetrical Glazing Material: The CPSC standard requires all asymmetrical glazing materials to be impacted on both sides of each specimen and then evaluated under the pass-fail criteria. There is no exception. ANSI Z97.1 requires that, with the exception of mirror glazing, all asymmetrical glass specimens must be impacted on both sides, two on one side and two on the other. With respect to mirror glazing products using reinforced or nonreinforced organic adhesive backing, all four specimens must be

impacted only on the nonreinforced side “and with no other material applied.”

Impact Categories or Levels: See the commentary to Tables R308.3.1(1) and R308.3.1(2).

Pass-fail Impact Criteria: The CPSC standard, like the ANSI standard, offers alternative criteria for evaluating whether a test specimen passes the impact test. The CPSC standard considers the specimen a pass if a 3-inch-diameter (76 mm) solid steel ball, weighing 4 pounds (18 N), will not pass through the opening when placed on the specimen for 1 second. ANSI uses the 3-inch (76 mm) sphere measure, but does not require the sphere to be a steel ball and does not specify its weight. It does require that the sphere not pass freely through the opening when a force of 4 pounds (18 N) is applied to the sphere. There is no time element associated with this alternative.

A second alternative pass-fail criterion under the CPSC standard involves weighing the 10 largest particles selected within 5 minutes after the impact test; they must weigh no more than the equivalent weight of 10 square inches (6452 m²) of the original specimen. The ANSI standard has an almost identical criterion, except the 10 largest particles must be “crack free.” It also includes additional product-specific qualifications applicable solely to selecting the 10 largest particles of tempered glass and offers a formula for determining the weight of 10 square inches (6452 m²) of the original specimen.

The CPSC standard has no separate pass-fail impact criteria for the scenario in which the glass specimen separates from the frame after impact and breaks or produces a hole in the glass. The ANSI standard has a special criterion for that scenario: to pass, the glass is subjected to the same 3-inch (76 mm) sphere measure or to the weight criterion for the 10 largest crack-free particles.

The CPSC standard involves impact testing of only a single specimen of each nominal glass thickness. Accordingly, if that specimen passes, all glass of that type and thickness is deemed to pass. Under the ANSI standard, four specimens of each type, size and thickness must be impact tested, and if any one of the four specimens fails, there is a failure of that specific type, thickness and size.

Impact Testing Apparatus: Relatively minor technical differences exist between the test frames and impactors specified in the CPSC standard and those in ANSI Z97.1. The ANSI standard prescribes special test frame and subframe configurations for impact testing bent glass; the CPSC standard has no provisions for testing bent glass. The ANSI standard includes detailed specifications for the impactor suspension device and traction and release system, and for their operation; the CPSC standard does not.

Weathering Tests: The CPSC standard requires a weathering test only for organic-coated glass. ANSI requires a weathering test for laminated glass and plastics, as well as for organic-coated glass.

The CPSC accelerated weathering test (only for

organic-coated glass) uses the xenon arc Weatherometer. The ANSI standard gives the manufacturer the choice of one of three weathering exposure alternatives: the xenon arc exposure, the enclosed twin carbon arc exposure or the 1-year outdoor exposure in South Florida. The ANSI prescribed xenon arc apparatus and procedure are the more current versions of the pertinent ASTM standards, ASTM D2565 and ASTM G155, than the versions referenced in the CPSC standard. The CPSC’s xenon arc procedure for interpreting results of the adhesion test requires an average adhesion value or pull force of no less than 90 percent of the average of the unexposed organic-coated glass specimens in order to “pass,” whereas the ANSI standard requires no less than 75 percent of the average of the unexposed specimens.

Indoor Aging Tests: The CPSC standard does not prescribe any indoor aging test; the ANSI standard requires specified indoor aging tests for plastics and organic-coated glass intended for indoor-use only, followed by impact tests.

TABLE R308.3.1(1). See page 3-78.

❖ In 1977, the CPSC adopted as a mandatory federal safety regulation *Safety Standard for Architectural Glazing Materials*, codified as 16 CFR, Part 1201. The CPSC amended the regulation on several occasions subsequent to its initial adoption, the last time on June 28, 1982. For additional information, see the commentary to Section R308.3.1.

Impact Categories or Levels: The CPSC standard has two distinct impact levels or categories, Category I and Category II, and specifies which defined hazardous location must contain Category II safety glazing materials and which may use Category I glazing materials. Glazing material successfully passing the impact test of a 48-inch (1219 mm) drop height at 400 foot-pound (940 J) impact is classified as Category II glass. Glazing material passing the 18-inch (457 mm) drop height, at 150 foot-pounds (203.4 J) impact, is classified as Category I glass.

TABLE R308.3.1(2). See page 3-78.

❖ ANSI Z97.1 was revised in 2004. Utilization of this testing for glazing in hazardous locations is limited by the exception in Section R308.3.1. For additional information, see the commentary to Section R308.3.1.

Impact Categories or Levels: ANSI Z97.1 has adopted three separate impact categories or classes, based on impact performance. ANSI Z97.1’s Class A glazing materials are comparable to the CPSC’s Category II glazing materials, passing a 48-inch (1219 mm) drop-height test, and its Class B glazing materials are comparable to the CPSC’s Category I glazing materials, passing the 18-inch (457 mm) drop-height test. ANSI Z97.1 also has a product-specific Class C impact test, a 12-inch (305 mm) drop-height test, applicable only for fire-resistant glazing materials. However, Table R308.3.1(2) does not identify Class C as an acceptable product for use in hazardous locations.

R308.4 Hazardous locations. The locations specified in Sections R308.4.1 through R308.4.7 shall be considered to be specific hazardous locations for the purposes of glazing.

❖ Section R308.4 lists seven specific hazardous locations (Sections R308.4.1 through R308.4.7) where safety glazing is required. Listed under each location are the exceptions specific to that location. Some of these locations are shown in Commentary Figures R308.4(1) through R308.4(11). In addition to the hazardous locations shown in the 11 drawings, safety glazing is also required in a number of other locations,

including fixed and sliding panels of sliding door assemblies, storm doors and glass railings.

Commentary Figure R308.4(1) illustrates several locations where safety glazing may or may not be required. To facilitate discussion, each glazed panel has been numbered. Panel 1 is not required to have safety glazing because a protective bar has been installed in compliance with Exception 2 to Section R308.4.3, the details of which are illustrated in Commentary Figure R308.4(2). Panels 4 and 7 require safety glazing because they are door sidelights.

TABLE R308.3.1(1)
MINIMUM CATEGORY CLASSIFICATION OF GLAZING USING CPSC 16 CFR 1201

EXPOSED SURFACE AREA OF ONE SIDE OF ONE LITE	GLAZING IN STORM OR COMBINATION DOORS (Category Class)	GLAZING IN DOORS (Category Class)	GLAZED PANELS REGULATED BY SECTION R308.4.3 (Category Class)	GLAZED PANELS REGULATED BY SECTION R308.4.2 (Category Class)	GLAZING IN DOORS AND ENCLOSURES REGULATED BY SECTION 308.4.5 (Category Class)	SLIDING GLASS DOORS PATIO TYPE (Category Class)
9 square feet or less	I	I	NR	I	II	II
More than 9 square feet	II	II	II	II	II	II

For SI: 1 square foot = 0.0929 m².
NR = "No Requirement."

TABLE R308.3.1(2)
MINIMUM CATEGORY CLASSIFICATION OF GLAZING USING ANSI Z97.1

EXPOSED SURFACE AREA OF ONE SIDE OF ONE LITE	GLAZED PANELS REGULATED BY SECTION R308.4.3 (Category Class)	GLAZED PANELS REGULATED BY SECTION R308.4.2 (Category Class)	DOORS AND ENCLOSURES REGULATED BY SECTION R308.4.5 ^a (Category Class)
9 square feet or less	No requirement	B	A
More than 9 square feet	A	A	A

For SI: 1 square foot = 0.0929 m².
a. Use is permitted only by the exception to Section R308.3.1.

Exception 2 to Section R308.4.3 does not apply to panels adjacent to a door, so even though Panel 7 has a protective bar, safety glazing is still required (see Section R308.4.2).

Commentary Figures R308.4(3) and R308.4(4) illustrate where safety glazing is required for panels adjacent to a door (see Section R308.4.2). This requirement applies to both fixed and operable panels. Where there is an intervening wall or permanent barrier, as shown in Commentary Figure R308.4(5), safety glazing would not be required (see Section R308.4.2, Exception 2). Commentary Figure R308.4(6) illustrates Exception 3 to Section R308.4.2, which applies to glazing positioned perpendicular to the plane of the door when it is in the closed position

and the perpendicular glazing is on the latch side. Only one side is considered to be the hazardous location, the side that the door swings toward. The other side need not have safety glazing. This wall has a much lower risk of problems. When a door swings open to a perpendicular wall with glazing within 24 inches (610 mm), it is possible that if the door were caught by a strong wind it could slam into the wall and break the glass, or the doorknob could hit the glass and break it. There is also the possibility that someone could be caught behind the door when it is opened and they could be pushed into/through the glass. Thus, this would be an appropriate area to have the required safety glazing to protect the occupants.

Panels 8 and 9, as well as Panels 2 and 3, fall under

Section R308.4.3. Under this section, all four stated conditions must occur before safety glazing is required. These conditions are as follows:

1. The area of an individual pane must be more than 9 square feet (0.84 m²);
2. The bottom edge must be less than 18 inches (457 mm) above the floor;
3. The top edge must be more than 36 inches (914 mm) above the floor; and
4. One or more walking surfaces must be within 36 inches (914 mm), measured horizontally from the glazed panel.

However, Panels 2 and 3 do not require safety glazing because their bottom edges are not less than 18 inches (457 mm) from the floor.

If Panels 8 and 9 have a walking surface within 36 inches (914 mm) horizontally of the interior, safety glazing would be required. From the exterior side, as

shown in Commentary Figure R308.4(1), the bottom of the panel appears to be more than 18 inches (457 mm) above the exterior walking surface, so the exterior condition would have no bearing on the determination. Panels 5 and 6 are glass doors, which require safety glazing based on the provisions of Section R308.4.1. Glazing in doors (except louvered or jalousies in accordance with Exception 1 to Section R308.3) requires safety glazing, but there are two exceptions. If openings in a door will not pass a 3-inch-diameter (76 mm) sphere, the glazing is exempt (see Section R308.4.1, Exception 1), as are assemblies of decorative glass which is defined in Chapter 2 (see Section R308.4.1, Exception 2). The latter exception applies not only to doors but also to sidelights and other glazed panels (see Section R308.4.2, Exception 1). Glazing in railings, balusters, panels and nonstructural in-fill panels, regardless of their height above a walking surface, requires safety glazing (see Section R308.4.4). Because of the high prob-

ability that people will strike guards, it is critical that an increased level of protection be provided.

Section R308.4.5 addresses glazing near water or wet areas. Safety glazing is required adjacent to hot tubs, spas, whirlpools, saunas, steam rooms, bathtubs, showers and swimming pools. Because of the presence of water, all of these locations represent slip hazards and need safety glazing to prevent injury in case of a fall. Glazing adjacent to these areas must be

safety glazed if the glazing is less than 60 inches above any standing or walking surface. Commentary Figure R308.4(7) illustrates the condition where a window occurs within a shower enclosure. Commentary Figure R308.4(8) illustrates the requirements of Section R308.4.5. Glazing that is more than 60 inches (1524 mm) from the water's edge of a bathtub, hot tub, spa, whirlpool, swimming pool, shower, sauna or steam room is not a hazardous location in accordance

with the exception to Section R308.4.5. Commentary Figure R308.4(9) illustrates the exception to Section R308.4.5.

Sections R308.4.6 and R308.4.7 address the hazardous locations to be considered for stairways, landings and ramps. Stairways and ramps present users with a greater risk for injury caused by falling than a flat surface. Not only is the risk of falling greater when using a stair, but the injuries are generally more severe. Unlike falling on a flat surface where the floor will, for the most part, break a person's fall, there is nothing to stop someone from continuing to fall until he or she reaches the bottom of the stair. The increased risks inherent in stairways, as well as

attempting to be consistent with other chapters in the code that mandate more restrictive requirements when addressing safety issues involving stairways and ramps, account for the more restrictive requirements for glazing in and around stairways and ramps.

Section R308.4.6 includes any glazing when the exposed surface of that glazing is within 36 inches (914 mm) above the plane of the adjacent walking surface. The walking surface in question would be part of a stair or ramp itself, including intermediate landings [see Commentary Figure R308.4(10)]. Safety glazing is not required for Exception 1 of Section R308.4.6 where the side of the stairway, landing or ramp has a rail, which can be part of the guard or handrail, which

has a load resistance of 50 pounds per linear foot (730 N/m) (for additional loading criteria for handrails and guards, see Table R301.5).

In Section R308.4.7, the concern is glazing that may be located within 60 inches (1524 mm) horizontally of the bottom tread of the stairway and within 36 inches (914 mm) vertically above the bottom landing of a stairway. The 60-inch (1524 mm) dimension is from any point along the nosing of the bottom tread, as measured horizontally in any direction to any surface of any glazing within that range [see Commentary Figure R308.4(11) and Figure R308.4.7]. The exception to Section R308.4.7 will permit nonsafety

glazing where a guard is installed and the actual plane of the glazing is located at least 18 inches (457 mm) from the guard.

R308.4.1 Glazing in doors. Glazing in fixed and operable panels of swinging, sliding and bifold doors shall be considered to be a hazardous location.

Exceptions:

1. Glazed openings of a size through which a 3-inch-diameter (76 mm) sphere is unable to pass.
2. Decorative glazing.

❖ See the commentary to Section R308.4.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure R308.4(10)
GLAZING ADJACENT TO STAIRWAYS
(Section to R308.4.6)

For SI: 1 inch = 25.4 mm.

Figure R308.4(11)
GLAZING ADJACENT TO THE BOTTOM STAIR LANDING
(Section R308.4.7)

R308.4.2 Glazing adjacent to doors. Glazing in an individual fixed or operable panel adjacent to a door shall be considered to be a hazardous location where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) above the floor or walking surface and it meets either of the following conditions:

1. Where the glazing is within 24 inches (610 mm) of either side of the door in the plane of the door in a closed position.
2. Where the glazing is on a wall perpendicular to the plane of the door in a closed position and within 24 inches (610 mm) of the hinge side of an in-swinging door.

Exceptions:

1. Decorative glazing.
2. Where there is an intervening wall or other permanent barrier between the door and the glazing.
3. Where access through the door is to a closet or storage area 3 feet (914 mm) or less in depth. Glazing in this application shall comply with Section R308.4.3.
4. Glazing that is adjacent to the fixed panel of patio doors.

❖ See the commentary to Section R308.4.

R308.4.3 Glazing in windows. Glazing in an individual fixed or operable panel that meets all of the following conditions shall be considered to be a hazardous location:

1. The exposed area of an individual pane is larger than 9 square feet (0.836 m²),
2. The bottom edge of the glazing is less than 18 inches (457 mm) above the floor,
3. The top edge of the glazing is more than 36 inches (914 mm) above the floor; and
4. One or more walking surfaces are within 36 inches (914 mm), measured horizontally and in a straight line, of the glazing.

Exceptions:

1. Decorative glazing.
2. Where a horizontal rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and have a cross-sectional height of not less than 1½ inches (38 mm).
3. Outboard panes in insulating glass units and other multiple glazed panels where the bottom edge of the glass is 25 feet (7620 mm) or more above *grade*, a roof, walking surfaces or other horizontal [within 45 degrees (0.79 rad) of horizontal] surface adjacent to the glass exterior.

❖ See the commentary to Section R308.4.

R308.4.4 Glazing in guards and railings. Glazing in *guards* and railings, including structural baluster panels and nonstruc-

tural in-fill panels, regardless of area or height above a walking surface shall be considered to be a hazardous location.

❖ See the commentary to Section R308.4.

R308.4.5 Glazing and wet surfaces. Glazing in walls, enclosures or fences containing or facing hot tubs, spas, whirlpools, saunas, steam rooms, bathtubs, showers and indoor or outdoor swimming pools where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) measured vertically above any standing or walking surface shall be considered to be a hazardous location. This shall apply to single glazing and each pane in multiple glazing.

Exception: Glazing that is more than 60 inches (1524 mm), measured horizontally and in a straight line, from the water's edge of a bathtub, hot tub, spa, whirlpool or swimming pool or from the edge of a shower, sauna or steam room.

❖ See the commentary to Section R308.4.

R308.4.6 Glazing adjacent to stairs and ramps. Glazing where the bottom exposed edge of the glazing is less than 36 inches (914 mm) above the plane of the adjacent walking surface of stairways, landings between flights of stairs and ramps shall be considered to be a hazardous location.

Exceptions:

1. Where a rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and have a cross-sectional height of not less than 1½ inches (38 mm).
2. Glazing 36 inches (914 mm) or more measured horizontally from the walking surface.

❖ See the commentary to Section R308.4.

R308.4.7 Glazing adjacent to the bottom stair landing. Glazing adjacent to the landing at the bottom of a stairway where the glazing is less than 36 inches (914 mm) above the landing and within a 60-inch (1524 mm) horizontal arc less than 180 degrees from the bottom tread nosing shall be considered to be a hazardous location.

Exception: The glazing is protected by a *guard* complying with Section R312 and the plane of the glass is more than 18 inches (457 mm) from the *guard*.

❖ See the commentary to Section R308.4.

FIGURE R308.4.7. See page 3-85.

❖ This figure depicts glazing locations that are to be considered hazardous in accordance with Sections R308.4 and R308.4.7, unless the exception to Section R308.4.7 is satisfied (see the commentary to Section R308.4).

R308.5 Site-built windows. Site-built windows shall comply with Section 2404 of the *International Building Code*.

❖ Because site-built windows are not constructed in a manufacturing facility that follows industry standards, they must be constructed in accordance with Section

2404 of the IBC, which sets forth the wind, snow, seismic and dead loads on glass.

R308.6 Skylights and sloped glazing. Skylights and sloped glazing shall comply with the following sections.

- ❖ Sloped glazing and skylights consist of glazing installed in roofs or walls that are on a slope 15 degrees (0.26 rad) or more from the vertical. The provisions of the code address loads normally attributed to roofs. The provisions also enhance the protection of the occupants of a building from the possibility of falling glazing materials.

R308.6.1 Definitions. The following terms are defined in Chapter 2:

SKYLIGHT, UNIT.

- ❖ Unit skylights are a specific type of sloped glazing assembly which is factory assembled. The IBC and the code contain specific provisions that are appropriate for this type of building component. Factory-assembled units, as opposed to site-built skylights, can be designed, tested and rated as one component, which incorporates both glazing and framing, if applicable. The individual components of site-built glazing must be designed to resist the design loads of the codes individually, and are not usually rated as an assembly.

SKYLIGHTS AND SLOPED GLAZING.

- ❖ The failure of skylights and sloped glazing could result in injury and building damage. This definition establishes the criteria to which the code requirements of Section R308.6 are to apply.

TUBULAR DAYLIGHTING DEVICE (TDD).

- ❖ This definition provides the distinction from a unit skylight. Although tubular daylighting devices (TDDs) and unit skylights are similar and subjected to the same testing and labeling requirements, there are some dif-

ferences. A TDD is typically field assembled from a manufactured kit, unlike a unit skylight which is typically shipped as a factory-assembled unit. If the unit skylight definition is applied to TDDs, it would imply that TDDs be entirely assembled in the factory. Also, the dome of a TDD is not necessarily constructed out of a single panel of glazing material. As such, a separate definition from that of a unit skylight is needed. The definition is adapted from the definition in AAMA/WDMA A440.

R308.6.2 Materials. The following types of glazing shall be permitted to be used:

1. Laminated glass with not less than a 0.015-inch (0.38 mm) polyvinyl butyral interlayer for glass panes 16 square feet (1.5 m²) or less in area located such that the highest point of the glass is not more than 12 feet (3658 mm) above a walking surface or other accessible area; for higher or larger sizes, the interlayer thickness shall be not less than 0.030 inch (0.76 mm).
2. Fully tempered glass.
3. Heat-strengthened glass.
4. Wired glass.
5. *Approved rigid plastics.*

- ❖ The provisions of this section limit glazing materials in skylights and sloped glazing to those specified, and they outline glazing materials and protective measures for sloped glazing and skylights. The materials and their characteristics and limitations are as follows:

Laminated glass. Laminated glass is usually constructed with an inner layer of polyvinyl butyral, which has a minimum thickness of 0.030 inch (0.76 mm). Such glass is highly resistant to impact and, as a result, requires no further protection below. When used within dwelling units, laminated glass is permit-

FIGURE R308.4.7
PROHIBITED GLAZING LOCATIONS AT BOTTOM STAIR LANDINGS

ted to have a 0.015-inch (0.38 mm) polyvinyl butyral inner layer if each pane of glass is 16 square feet (1.5 m²) or less in area, and the highest point of the glass is no more than 12 feet (3658 mm) above a walking surface or other accessible area.

Fully tempered glass. Tempered glass has been specifically heat-treated or chemically treated to obtain high strength. When broken, the entire piece of glass immediately breaks into numerous small granular pieces. Because of its high strength and manner of breakage, tempered glass has been considered in the past to be a desirable glazing material for skylights that have no protective screens. However, as a result of studies by the industry that show that tempered glass is subject to spontaneous breakage that can result in large chunks of glass falling, the code requires screen protection below tempered glass.

Heat-strengthened glass. Heat-strengthened glass that has been reheated to just below its melting point and then cooled. This process forms a compression on the outer surface and increases the strength of the glass. However, heat-strengthened glass requires screen protection below the skylight to protect the occupants from falling shards.

Wired glass. Wired glass is resistant to impact and, when used as a single-layer glazing, requires no additional protection below.

Approved rigid plastics. Rigid plastics are fairly durable as a glazing material.

Annealed glass. Annealed glass is not allowed because it is subject to breakage by impact and has very low strength. Annealed glass is also unsatisfactory for use as a skylight because it breaks up under impact into large sharp shards, which, when they fall, are hazardous to occupants of a building.

R308.6.3 Screens, general. For fully tempered or heat-strengthened glass, a retaining screen meeting the requirements of Section R308.6.7 shall be installed below the glass, except for fully tempered glass that meets either condition listed in Section R308.6.5.

❖ As a general rule, single-layer glazing of heat-strengthened glass and fully tempered glass must be fitted with screens below the glazing material.

R308.6.4 Screens with multiple glazing. Where the inboard pane is fully tempered, heat-strengthened or wired glass, a retaining screen meeting the requirements of Section R308.6.7 shall be installed below the glass, except for either condition listed in Section R308.6.5. Other panes in the multiple glazing shall be of any type listed in Section R308.6.2.

❖ As does Section R308.6.3, this section states that screens are required for the inbound plane of glazing when it is fully tempered, heat-strengthened or wired glass. The screen must comply with Section R308.6.7. Screens are not required for either approved laminated glass or approved rigid plastics.

R308.6.5 Screens not required. Screens shall not be required where fully tempered glass is used as single glazing or the inboard pane in multiple glazing and either of the following conditions are met:

1. Glass area 16 square feet (1.49 m²) or less. Highest point of glass not more than 12 feet (3658 mm) above a walking surface or other accessible area, nominal glass thickness not more than $\frac{3}{16}$ inch (4.8 mm), and (for multiple glazing only) the other pane or panes fully tempered, laminated or wired glass.
2. Glass area greater than 16 square feet (1.49 m²). Glass sloped 30 degrees (0.52 rad) or less from vertical, and highest point of glass not more than 10 feet (3048 mm) above a walking surface or other accessible area.

❖ Section R308.6.5 states two exceptions to the provisions of Sections R308.6.3 and R308.6.4. The first exception applies to a glazing area that is no larger than 16 square feet (1.49 m²) and no more than 12 feet (3658 mm) above a walking surface or other accessible area. The second exception applies to sloped glazing with a maximum slope of 30 degrees (0.52 rad) from vertical that is not larger than 16 square feet (1.49 m²) in area and is no greater than 10 feet (3048 mm) above a walking surface or other accessible area. Generally, installed skylights and sloped glazing will meet one of these exceptions, so screens are not required.

R308.6.6 Glass in greenhouses. Any glazing material is permitted to be installed without screening in the sloped areas of greenhouses, provided that the greenhouse height at the ridge does not exceed 20 feet (6096 mm) above *grade*.

❖ The glazing regulations for greenhouses are less stringent because greenhouses are seldom occupied during storms that might break the glass. These provisions also explain an exception to the screening provisions of Sections R308.6 and R308.6.4, specifically for the sloped glazing areas within greenhouses. Screens are not required for sloped areas of greenhouses if the ridge of the greenhouse is not more than 20 feet (6096 mm) above *grade*.

R308.6.7 Screen characteristics. The screen and its fastenings shall be capable of supporting twice the weight of the glazing, be firmly and substantially fastened to the framing members, and have a mesh opening of not more than 1 inch by 1 inch (25 mm by 25 mm).

❖ It is critical that screens be installed in a manner that will adequately support the weight of the glass. In using a safety factor of 2, the screen and its fastenings must be capable of supporting twice the weight of the glazing. To accomplish this, the screen is to be fastened firmly to the framing members.

R308.6.8 Curbs for skylights. Unit skylights installed in a roof with a pitch flatter than three units vertical in 12 units horizontal (25-percent slope) shall be mounted on a curb extending not less than 4 inches (102 mm) above the plane of

the roof unless otherwise specified in the manufacturer's installation instructions.

- ❖ Skylights installed on low-sloped roofs are more susceptible to leaking than those on higher pitched roofs because water does not drain as quickly on low-sloped roofs. For these skylights to be properly flashed to prevent leakage, they must be placed on a 4-inch-high (102 mm) curb unless the manufacturer's installation instructions indicate otherwise.

R308.6.9 Testing and labeling. Unit skylights and tubular daylighting devices shall be tested by an *approved* independent laboratory, and bear a *label* identifying manufacturer, performance grade rating and *approved* inspection agency to indicate compliance with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440.

- ❖ The referenced standard, ANSI/AAMA/WDMA 101/I.S.2/NAFS: *Voluntary Performance Specification for Windows, Skylights and Glass Doors*, includes a separate rating system for positive and negative pressure on skylights and TDDs which allows the manufacturer to design and fabricate products that are best suited for the climate in which they will be used. The standard establishes the performance requirements for skylights and TDDs based on the desired performance grade rating which includes minimum requirements for resistance to air leakage, water infiltration and the design load pressures. The resulting performance grade rating states the design load pressure used to rate the product, but it also includes consideration of these additional performance characteristics. For skylights and TDDs certified for only one performance grade, the rating is based on the minimum requirements met for both positive and negative design pressure. Skylights and TDDs certified for two performance grades are rated separately for positive and negative design pressure.

Skylights and TDDs must be capable of withstanding the component and cladding wind pressures of Table R301.2(2) adjusted by the height and exposure coefficients given in Table R301.2(3).

The most critical load on a skylight or TDD is determined by the climate in which it is installed. In a colder climate with heavier snow loads and moderate design wind speeds, the positive load on a skylight or TDD from the combined snow and dead load will be more critical than the negative load from wind uplift. The opposite will be the case in warmer, coastal climates with higher design wind speeds and little or no snow load.

R308.6.9.1 Comparative analysis for glass-glazed unit skylights. Structural wind load design pressures for glass-glazed unit skylights different than the size tested in accordance with Section R308.6.9 shall be permitted to be different than the design value of the tested unit where determined

in accordance with one of the following comparative analysis methods:

1. Structural wind load design pressures for glass-glazed unit skylights smaller than the size tested in accordance with Section R308.6.9 shall be permitted to be higher than the design value of the tested unit provided that such higher pressures are determined by accepted engineering analysis. Components of the smaller unit shall be the same as those of the tested unit. Such calculated design pressures shall be validated by an additional test of the glass-glazed unit skylight having the highest allowable design pressure.
 2. In accordance with WDMA I.S. 11.
- ❖ Comparative analysis based on accepted engineering methods provides a proven, accurate and reliable means for determining design pressures of different sized products within a fenestration product line based on testing of specimen units from the respective line. This alleviates the need for design pressure (DP) testing of all sizes within the line, saving considerable construction costs and providing greater design flexibility without incurring additional time and costs, especially for specialty/custom products.

Previously the code only allowed comparative analysis for windows and doors in Section R609.3.1, which has been and continues to be widely utilized for those products for the reasons stated above. Since comparative analysis as noted above is equally applicable to glass-glazed unit skylights, it is also permitted by the code for them.

Method 1 is taken verbatim from the existing comparative analysis provision in Section R609.3.1, except for the substitution of "glass-glazed unit skylights" for "windows and door units." However, Section R609.3.1 is limited only to allowing comparative analysis for units smaller than the unit tested, not larger. Because comparative analysis can also be effectively used to accurately determine DP ratings for fenestration products that are larger in width and/or height than the actual tested specimens, provided proper analytical methods are followed, it is also permitted by the code for glass-glazed unit skylights for that purpose as long as proper engineering analysis is provided.

Method 2 requires compliance with WDMA I.S. 11. WDMA I.S. 11—*Industry Standard for Voluntary Analytical Method for Design Pressure (DP) Ratings of Fenestration Products*. This standard provides more comprehensive alternative methods appropriate for using comparative analysis to determine DP of units different in size, both smaller and larger, than that of the tested units within a product line. The comparative analysis methods included in WDMA I.S. 11 are based on accepted engineering analysis which must also be sealed by a licensed Professional Engineer (PE), making it technically sound for use in the code for this purpose.

SECTION R309 GARAGES AND CARPORTS

R309.1 Floor surface. Garage floor surfaces shall be of *approved* noncombustible material.

The area of floor used for parking of automobiles or other vehicles shall be sloped to facilitate the movement of liquids to a drain or toward the main vehicle entry doorway.

- ❖ Garage floor surfaces must be of an approved noncombustible material such as concrete. Additionally, the floor surface must either slope toward the garage door opening or slope to an approved drain. This allows grease, flammable liquids or other hazardous materials that might drain from an automobile to drain from the garage.

R309.2 Carports. Carports shall be open on not less than two sides. Carport floor surfaces shall be of *approved* noncombustible material. Carports not open on two or more sides shall be considered to be a garage and shall comply with the provisions of this section for garages.

Exception: Asphalt surfaces shall be permitted at ground level in carports.

The area of floor used for parking of automobiles or other vehicles shall be sloped to facilitate the movement of liquids to a drain or toward the main vehicle entry doorway.

- ❖ The area of floor used for the parking of automobiles or other vehicles must be sloped to facilitate the movement of liquids associated with motor vehicles such as oil, gasoline or antifreeze. These are toxic or flammable materials that should not be allowed to collect in the building.

Carports must have at least two sides open to outside air. If two sides are not open, the structure is a garage and comes under the provisions of Sections R302.5, R302.6, R309.1 and R309.3.

R309.3 Flood hazard areas. For buildings located in flood hazard areas as established by Table R301.2(1), garage floors shall be:

1. Elevated to or above the design flood elevation as determined in accordance with Section R322; or
 2. Located below the design flood elevation provided that the floors are at or above *grade* on not less than one side, are used solely for parking, building access or storage, meet the requirements of Section R322 and are otherwise constructed in accordance with this code.
- ❖ Floors of garages in flood hazard areas must meet one of two requirements. The first option is to construct the garage floor elevated to or above the design flood elevation. The second option allows the floor of the garage to be below the design flood elevation if construction is compliant with the applicable provisions of Section R322 for enclosures, including: 1. The floor is at or above finished exterior grade on at least one side (not a basement); 2. It complies with provisions for enclosed areas below the design flood elevation (see Section R322.2.2 in A Zones and Section R322.3.5 in V Zones and Coastal A Zones); 3. Materials and fin-

ishes below the design flood elevation are flood resistant (see Section R322.1.8); and 4. Service equipment and systems comply with Section R322.1.6. Because of these limitations, garages must not be designed or converted to accommodate other uses.

R309.4 Automatic garage door openers. Automatic garage door openers, if provided, shall be *listed* and *labeled* in accordance with UL 325.

- ❖ The code does not require an automatic garage door opener. However, if one is installed, it must be listed and labeled in accordance with UL 325. Federal law requires automatic residential garage door openers to conform to the entrapment protection requirements of UL 325.

R309.5 Fire sprinklers. Private garages shall be protected by fire sprinklers where the garage wall has been designed based on Table R302.1(2), Footnote a. Sprinklers in garages shall be connected to an automatic sprinkler system that complies with Section P2904. Garage sprinklers shall be residential sprinklers or quick-response sprinklers, designed to provide a density of 0.05 gpm/ft². Garage doors shall not be considered obstructions with respect to sprinkler placement.

- ❖ Section R309.5 provides a limitation on the application of Table R302.1(2) by only allowing use of sprinkler incentives in areas where sprinklers are provided. Normally, garages aren't required to have sprinklers; however, where a designer chooses to take advantage of reduced separation requirements for a garage wall, it is appropriate for the garage to be provided with sprinklers as a means of property protection. Proposed design criteria for sprinklers were derived from NFPA 13R Section 6.8.3.3, which addresses sprinkler protection for garages in buildings protected by NFPA 13R sprinkler systems. Often, garage protection is provided by dry pendant or dry sidewall sprinklers connected to a wet pipe sprinkler system.

SECTION R310 EMERGENCY ESCAPE AND RESCUE OPENINGS

R310.1 Emergency escape and rescue opening required. *Basements, habitable attics* and every sleeping room shall have not less than one operable emergency escape and rescue opening. Where *basements* contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a *yard* or court that opens to a public way.

Exception: Storm shelters and *basements* used only to house mechanical *equipment* not exceeding a total floor area of 200 square feet (18.58 m²).

- ❖ Because so many fire deaths occur as a result of occupants being asleep in a residential building during a fire, the code requires that all basements, habitable attics and sleeping rooms have windows or doors that may be used for emergency escape or rescue. The requirement for emergency escape and rescue openings in sleeping rooms exists because a fire will usually

have spread before the occupants are aware of the problem, and the normal exit channels may be blocked. The requirement for basements and habitable attics exists because they are so often used as sleeping rooms. A fire in a mechanical room adjacent to a stairway could engulf the only means of egress for the basement without the egress window or door.

Openings required for emergency escape or rescue must be located on the exterior of the building so that rescue can be performed from the exterior and so that occupants may escape through that opening to the exterior of the building without having to travel through the building itself. Therefore, where openings are required, they should open directly into a public street, public alley, yard or court. After the occupants pass through the emergency escape and rescue opening, their continued egress is essential. Where a basement contains sleeping rooms and a habitable space, an emergency escape and rescue opening is required in each sleeping room, but is not required in adjoining areas of the basement.

There is an exception for storm shelters and basements used only to house mechanical equipment with a total floor area not exceeding 200 square feet (18.58 m²).

The dimensions prescribed in the code for emergency escape and rescue openings in Sections R310.2 through R310.2.2, and as illustrated in Commentary Figure R310.2.1, are based, in part, on extensive testing by the San Diego Building and Fire Departments to determine the proper relationships of the height and width of window openings to adequately serve for both rescue and escape. The minimum of 20 inches (508 mm) for the width is based on two criteria: the width necessary to place a ladder within the window opening and the width necessary to admit a fire fighter with full rescue equipment, including a breathing apparatus. The minimum 24-inch (610 mm) height is based on the minimum size necessary to admit a fire fighter with full rescue equipment. By requiring a minimum net clear opening size of at least 5.7 square feet (0.53 m²), the code provides for an opening of adequate dimensions. To be accessible from the interior of the sleeping room, attic or basement, Section R310.2.2 requires that the emergency escape and rescue opening be located not more than 44 inches (1118 mm) above the floor. The measurement is to be taken from the floor to the bottom of the clear opening.

Section R310.1.1 requires that the required opening dimensions be achieved by the normal operation of the window, door or hatch from the inside without the use of keys, tools or special knowledge. Section R310.1.1 also allows window opening control devices to be used on windows that serve as required emergency escape and rescue openings, provided that such devices comply with ASTM F2090. The window industry is a highly competitive market. Manufacturers are constantly developing new products that are easier to clean and possess higher thermal protection properties. It is important to keep in mind that no special knowledge for

operation of the egress window is a key operational constraint. It is impractical to assume that all occupants can operate a window that requires a special sequence of operations to achieve the required opening size. Although most occupants are familiar with the normal operation to open the window, children and guests are frequently unfamiliar with special procedures necessary to remove the sashes. The time spent comprehending special operations unnecessarily delays egress from the bedroom and could lead to panic and further confusion. Thus, windows that achieve the required opening dimensions only by performing a special sequence of operations, such as the removal of sashes or mullions, are not permitted. For example, if a specific area of the window has to be depressed or manipulated to allow the sash to be removed or released to achieve the open area requirement of 5.7 square feet (0.53 m²), the window does not qualify as an egress window.

R310.1.1 Operational constraints and opening control devices. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge. Window opening control devices complying with ASTM F2090 shall be permitted for use on windows serving as a required emergency escape and rescue opening.

- ❖ Openings for emergency escape and rescue must be operational from the inside. Keys, tools or special knowledge must not be needed to operate these openings. If keys or tools were necessary, they might not be readily available in an emergency or panic situation, and an individual might not be able to operate them, rendering the opening unusable. Section R310.1 also requires the opening size to be obtained by the normal operation of the window (see commentary to Section R310.1).

R310.2 Emergency escape and rescue openings. Emergency escape and rescue openings shall have minimum dimensions as specified in this section.

- ❖ See the commentary to Section R310.1.

R310.2.1 Minimum opening area. Emergency and escape rescue openings shall have a net clear opening of not less than 5.7 square feet (0.530 m²). The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. The net clear height opening shall be not less than 24 inches (610 mm) and the net clear width shall be not less than 20 inches (508 mm).

Exception: *Grade* floor or below *grade* openings shall have a net clear opening of not less than 5 square feet (0.465 m²).

- ❖ The minimum opening dimensions for emergency space and rescue openings are 24 inches (610 mm) in height and 20 inches (508 mm) in width. These dimensions are based on the minimum dimensions for a fire fighter with full rescue equipment to navigate through the opening (see commentary to Section R310.1 and Commentary Figure R310.2.1). Note that this section

requires a minimum opening area of 5.7 square feet, which cannot be achieved if both the minimum height and the minimum width dimensions are used.

The exception allows the opening size requirement to be reduced to 5 square feet (0.46 m²) where the emergency escape and rescue window is located at grade level. This results from the increased ease of access from the exterior and the probability that a ladder will not be needed (see Commentary Figure R310.2.1).

R310.2.2 Window sill height. Where a window is provided as the emergency escape and rescue opening, it shall have a sill height of not more than 44 inches (1118 mm) above the floor; where the sill height is below *grade*, it shall be provided with a window well in accordance with Section R310.2.3.

❖ See the commentary to Section R310.1.

R310.2.3 Window wells. The horizontal area of the window well shall be not less than 9 square feet (0.9 m²), with a horizontal projection and width of not less than 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened.

Exception: The ladder or steps required by Section R310.2.3.1 shall be permitted to encroach not more than 6 inches (152 mm) into the required dimensions of the window well.

❖ Window wells in front of emergency escape and rescue openings also have minimum size requirements. These provisions address those emergency escape windows that occur below grade. Just applying the standard emergency escape window criteria to these

windows will result in an opening that occupants can get through, but the window well may actually trap the occupants against the building without providing for their escape from the window well or providing for a fire fighter to enter the residence.

The minimum size requirements in cross section are similar to the emergency escape and opening criteria; that is, they are sufficient to provide a nominal size to allow for the escape of occupants or the entry of fire fighters (see Commentary Figure R310.2.3). The ladder or steps requirement is the main difference.

R310.2.3.1 Ladder and steps. Window wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the window in the fully open position. Ladders or steps required by this section shall not be required to comply with Sections R311.7 and R311.8. Ladders or rungs shall have an inside width of not less than 12 inches (305 mm), shall project not less than 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center vertically for the full height of the window well.

❖ When the depth of a window well exceeds 44 inches (1118 mm), a ladder or steps from the window is required. The details for construction of steps are not identified in the provisions; however, the design of the ladder is specifically addressed. Because ladders and steps in window wells are provided for emergency use only, they are not required to comply with the provisions for stairways found in Section R311.7.

R310.2.3.2 Drainage. Window wells shall be designed for proper drainage by connecting to the building's foundation

drainage system required by Section R405.1 or by an approved alternative method.

Exception: A drainage system for window wells is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

❖ This section requires the window well to be properly drained. Improper window well drainage could create a water accumulation level that could cause the window to become inoperable, or even break due to the pressure and blow out into the occupied room causing serious injury. Improper window well drainage may cause an emergency escape window to become a hazard to the occupants. If the foundation is on well-drained soil, the exception permits deletion of the drainage system.

R310.2.4 Emergency escape and rescue openings under decks and porches. Emergency escape and rescue openings shall be permitted to be installed under decks and porches provided that the location of the deck allows the emergency escape and rescue openings to be fully opened and provides a path not less than 36 inches (914 mm) in height to a yard or court.

❖ The design of some homes makes the underside of decks the only location where an emergency escape and rescue window can be located. The 36-inch (914 mm) minimum height requirement allows a usable means of egress pathway. The 36-inch (914 mm) minimum height was based on the minimum window well size of 3 feet by 3 feet (914 mm by 914 mm).

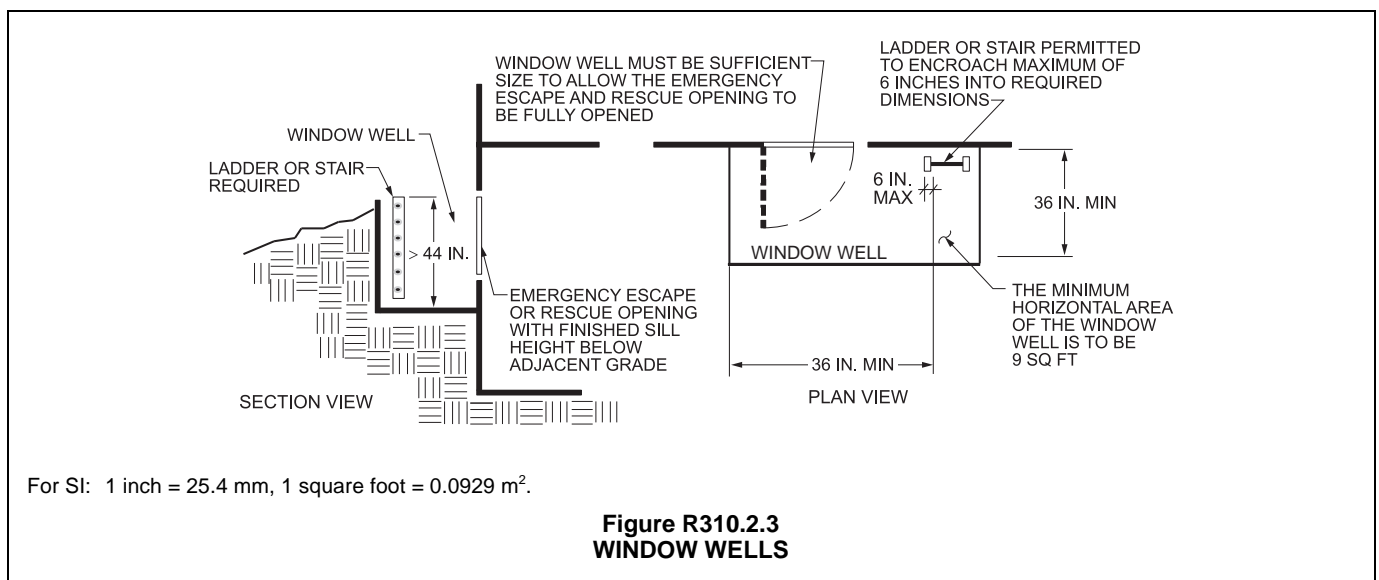

R310.2.5 Replacement windows. Replacement windows installed in buildings meeting the scope of this code shall be exempt from the maximum sill height requirements of Sections R310.1 and Sections R310.2.1 and R310.2.2, provided the replacement window meets the following conditions:

1. The replacement window is the manufacturer's largest standard size window that will fit within the existing frame or existing rough opening. The replacement window is of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

2. The replacement window is not part of a change of occupancy.
- ❖ Window replacements are one of the most common alterations to existing one- and two-family dwellings and townhomes. These provisions are based on requirements in the State of Minnesota's residential code and are consistent with similar provisions in the *International Existing Building Code*® (IEBC®).

Requiring replacement windows to meet the strict requirements for emergency escape and rescue openings, such as is required by Sections R310.2.1 and R310.2.2 for basements, habitable attics and sleeping rooms in new buildings, can be prohibitive and can discourage alterations that might otherwise improve building safety. These requirements are intended to ensure that the IRC does not discourage or prevent improvements in emergency escape and rescue openings, especially improvements related to fire safety, in older residential occupancies.

Many older dwellings have been constructed under codes that did not include the same emergency escape and rescue opening provisions that the IRC now requires for new construction. As such, window replacements often could only be accomplished by increasing the size of the rough opening, altering the interior and/or exterior walls and/or lowering the window sill height. This often led to significant costs and design challenges. This could discourage or prevent window replacement and, at worst, could discourage or prevent the replacement of older windows that may be (a) harder to operate, (b) inoperable due to their age or to poor maintenance, or (c) significantly less energy efficient. When that happens, improvements to safety as well as energy efficiency may be needlessly compromised. For these reasons, the provisions of this section relax the opening size and sill height requirements for replacement windows in existing buildings, as com-

pared to the emergency escape and rescue opening requirements for new construction contained in Sections R310.2.1 and R310.2.2. For example, while some windows in sleeping rooms of older homes may not provide the full clear opening that is required for new construction or may have a sill height above 44 inches, they nonetheless may still provide a viable emergency and escape rescue opening, which is the primary intent of the code. Replacement of these windows with the same type of operating window or other type that can provide an equal or greater clear opening than the existing window—even if they do not fully meet the clear opening or sill height requirements of Section 310—is always an improvement in safety, especially when a replacement opening can provide a larger clear opening than the existing window. Such improvements in safety should not be discouraged or prevented by overly onerous requirements for replacement windows.

These requirements ensure that does not happen by essentially providing limited exceptions to the requirements of Section 310 that can only be applied when certain conditions are met and an acceptable level of safety is provided. The requirements for new construction stating that emergency escape and rescue openings be provided as well as the operational requirements of Section 310.1.1 are retained and are still applicable to replacement windows.

R310.3 Emergency escape and rescue doors. Where a door is provided as the required emergency escape and rescue opening, it shall be permitted to be a side-hinged door or a slider. Where the opening is below the adjacent ground elevation, it shall be provided with a bulkhead enclosure.

- ❖ This section is intended to provide minimum requirements for doors that are intended to serve as emergency escape and rescue openings. Such doors must be either side hinged or sliders and, where such doors are located below the adjacent grade, a bulkhead enclosure must be provided.

R310.3.1 Minimum door opening size. The minimum net clear height opening for any door that serves as an emergency and escape rescue opening shall be in accordance with Section R310.2.1.

- ❖ This section requires that doors that are intended to serve as emergency escape and rescue openings must comply with the opening area and size requirements of Section R310.2.1, which are the same provisions that regulate the area and size of windows that serve as emergency escape and rescue openings.

R310.3.2 Bulkhead enclosures. Bulkhead enclosures shall provide direct access from the *basement*. The bulkhead enclosure shall provide the minimum net clear opening equal to the door in the fully open position.

- ❖ Bulkhead enclosures required by Section R310.3 must meet the net openable area provisions of Section R310.2.1.

R310.3.2.1 Drainage. Bulkhead enclosures shall be designed for proper drainage by connecting to the building's foundation drainage system required by Section R405.1 or by an *approved* alternative method.

Exception: A drainage system for bulkhead enclosures is not required where the foundation is on well-drained soil or sand-gravel mixture soils in accordance with the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

- ❖ Similar to Section R310.2.2, which applies to window well drainage, this section requires that bulkhead enclosures that serve emergency escape and rescue openings be properly drained. Improper bulkhead drainage could create a water accumulation level that could cause the bulkhead enclosure to become inoperable, or even cause serious injury. Improper window well drainage may cause a bulkhead enclosure to become a hazard to the occupants. If the foundation is on well-drained soil, the exception permits deletion of the drainage system.

R310.4 Bars, grilles, covers and screens. Bars, grilles, covers, screens or similar devices are permitted to be placed over emergency escape and rescue openings, bulkhead enclosures, or window wells that serve such openings, provided that the minimum net clear opening size complies with Sections R310.1.1 to R310.2.3, and such devices shall be releasable or removable from the inside without the use of a key, tool, special knowledge or force greater than that required for the normal operation of the escape and rescue opening.

- ❖ The ever-increasing concern for security, particularly in residential buildings, has created a fairly large demand for security devices, such as grilles, bars and steel shutters. Unless properly designed and constructed, the security devices over bedroom windows can completely defeat the purpose of the emergency escape and rescue opening. Therefore, the code makes provisions for security devices if the release mechanism has been approved and is operable from the inside without the use of a key, tool or force greater than that required for the normal operation of the escape and rescue opening.

The essence of the requirement for emergency escape openings is that a person must be able to effect escape or be rescued in a short period of time because the fire might have spread to a point where all other exit routes are blocked. Thus, time cannot be wasted in figuring out means of opening rescue windows or obtaining egress through them. Any impediment to escape or rescue caused by security devices, inadequate window size or difficult operating mechanisms is not permitted by the code.

R310.5 Dwelling additions. Where *dwelling additions* occur that contain sleeping rooms, an emergency escape and rescue opening shall be provided in each new sleeping room. Where *dwelling additions* occur that have *basements*, an emergency

escape and rescue opening shall be provided in the new *basement*.

Exceptions:

1. An emergency escape and rescue opening is not required in a new *basement* that contains a sleeping room with an emergency escape and rescue opening.
 2. An emergency escape and rescue opening is not required in a new *basement* where there is an emergency escape and rescue opening in an existing *basement* that is accessible from the new *basement*.
- ❖ This section reaffirms that the requirements for emergency escape and rescue openings in sleeping rooms and basements that are applicable to new construction are also applicable to sleeping rooms in additions. Note that the new and added portions of a basement are evaluated as one common basement for the purposes of this section.

R310.6 Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing *basements* undergo alterations or repairs.

Exception: New sleeping rooms created in an existing *basement* shall be provided with emergency escape and rescue openings in accordance with Section R310.1.

- ❖ Where alterations are made to an existing basement, emergency escape and rescue openings are required only where new sleeping rooms are created.

SECTION R311 MEANS OF EGRESS

R311.1 Means of egress. *Dwellings* shall be provided with a means of egress in accordance with this section. The means of egress shall provide a continuous and unobstructed path of vertical and horizontal egress travel from all portions of the *dwelling* to the required egress door without requiring travel through a garage. The required egress door shall open directly into a public way or to a *yard* or court that opens to a public way.

- ❖ Sections R311.2 through R311.8 contain the requirements for the exit and the means of egress components. All dwelling units must have at least one egress door that opens directly to a public way or a yard or court that opens to a public way and complies with the provisions of Sections R311.2 and R311.3. This door must also access the exterior without the dwelling's occupants traveling through a garage where hazards could prevent a suitable means of egress. A ramp or stairway is required for access to habitable areas not having an exit on that level (see Section R311.4). The emergency escape and rescue openings in Section 310 are not considered an exit.

R311.2 Egress door. Not less than one egress door shall be provided for each *dwelling* unit. The egress door shall be side-hinged, and shall provide a clear width of not less than 32 inches (813 mm) where measured between the face of the door and the stop, with the door open 90 degrees (1.57 rad). The clear height of the door opening shall be not less than 78 inches (1981 mm) in height measured from the top of the

threshold to the bottom of the stop. Other doors shall not be required to comply with these minimum dimensions. Egress doors shall be readily openable from inside the *dwelling* without the use of a key or special knowledge or effort.

- ❖ All dwelling units must have at least one exit door that complies with the provisions of Sections R311.2 through R311.3.3. Other exterior doors need not comply with the provisions of this section.

The required egress door must be side hinged. A sliding patio door would not count as the required egress door.

Typically, a 36-inch-wide (914 mm) door slab would be required to achieve a minimum 32-inch-wide (813 mm) width opening. Door slabs are manufactured in width increments of 2 inches (51 mm) [32 inches (813 mm), 34 inches (864 mm), 36 inches (914 mm), etc.]. Once the thickness of the door slab [usually $1\frac{3}{4}$ inches (44 mm) for exterior doors], thickness of the door stop and allowance for hinges or other hardware are combined, the difference between the width of the door slab and the resultant opening size is greater than 2 inches (51 mm). Therefore, a 34-inch-wide (864 mm) door slab would not provide the 32-inch-wide (813 mm) door opening required, and a 36-inch-wide (914 mm) slab would need to be used.

In a similar fashion, the 80-inch (2032 mm) door height requirement is replaced with a 78-inch (1981 mm) height of opening requirement, with the height of the opening measured from the bottom of the doorstop to the top of the threshold. Since door slabs are also manufactured in height increments of 2 inches (51 mm), it is not anticipated that this proposal would result in a reduction in the actual door size.

So that egress is always available, any locks provided on the egress door must be openable from the inside without the use of a key or special knowledge. While this would not limit the number of locks someone could install on the egress door, this will prohibit the type of dead bolt lock that is key operated from both the inside and outside. These lock provisions are not applicable to other exterior doors, however, just in case the way to the required egress door was blocked, following these provisions for other exterior doors may provide an extra level of safety.

R311.3 Floors and landings at exterior doors. There shall be a landing or floor on each side of each exterior door. The width of each landing shall be not less than the door served. Every landing shall have a dimension of not less than 36 inches (914 mm) measured in the direction of travel. The slope at exterior landings shall not exceed $\frac{1}{4}$ unit vertical in 12 units horizontal (2 percent).

Exception: Exterior balconies less than 60 square feet (5.6 m²) and only accessible from a door are permitted to have a landing less than 36 inches (914 mm) measured in the direction of travel.

- ❖ Landings are required for exterior doors and must be constructed on both the exterior and interior side of the door. Landings must be the same width as the door they serve and must be at least 36 inches (914 mm) in

length. The length of a landing is measured in the direction of travel. The exterior landing must be reasonably level (a slope not exceeding 25:12) while still allowing enough of a slope for proper drainage.

The exception allows for smaller landings when an exterior door only leads out onto a small balcony. An example of this would be the french balconies commonly found in New Orleans' style architecture.

R311.3.1 Floor elevations at the required egress doors. Landings or finished floors at the required egress door shall be not more than 1½ inches (38 mm) lower than the top of the threshold.

Exception: The landing or floor on the exterior side shall be not more than 7¾ inches (196 mm) below the top of the threshold provided the door does not swing over the landing or floor.

Where exterior landings or floors serving the required egress door are not at *grade*, they shall be provided with access to *grade* by means of a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

❖ Thresholds should not be higher than 1½ inches (38 mm) above interior floor level (see Commentary Figure R311.3.1). The exception permits the exterior landing of an exterior egress door, to be a maximum of 7¾ inches (196 mm) below the top of the threshold. The threshold height represents an important element in building construction. It has to be high enough to keep out snow accumulation and driving rain, yet low enough not to represent a tripping hazard or become a barrier to entry. The exception is limited to locations where the door swings in. Since this is the typical design for single-family homes and townhouses, the step down for the exterior landing will typically be permitted. A screen door that swung out in front of an egress door that swung in would not violate this exception (see Section R311.3.2).

If the door landing is not at grade level, any stairway or ramp leading from the door landing to grade must comply with the stairway and ramp provisions in Sections R311.7 and R311.8.

R311.3.2 Floor elevations for other exterior doors. Doors other than the required egress door shall be provided with landings or floors not more than 7¾ inches (196 mm) below the top of the threshold.

Exception: A top landing is not required where a stairway of not more than two risers is located on the exterior side of the door, provided that the door does not swing over the stairway.

❖ For exterior doors other than the required egress door, the top of the threshold can be up to 7¾ inches (196 mm) above both the inside and outside floor surface. Note that, in typical applications, the landing at the exterior side of an exterior door is lower than the interior landing or floor surface, and this “threshold” dimension is intended to include the riser that is inherently created by the difference in elevation between the exterior and interior landings.

The exception would not require a top landing when two or fewer stair risers are on the exterior side of exterior doors other than required egress door (for the required egress exit door, see Section R311.3.1). However, the door, other than a storm or screen door, is not allowed to swing over the steps to take advantage of this exception (see Section R311.3.3).

R311.3.3 Storm and screen doors. Storm and screen doors shall be permitted to swing over exterior stairs and landings.

❖ Sections R311.3.1 and R311.3.2 both have allowances for landing elevations when the door does not swing out over the landing. A common scenario is to have both a screen door and a wood/metal door at the front and/or rear entrance to the home. The screen door swinging out over the landing would not violate these exceptions.

R311.4 Vertical egress. Egress from habitable levels including habitable attics and *basements* not provided with an egress door in accordance with Section R311.2 shall be by a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

❖ All dwelling units must have at least one egress door that complies with the provisions of Sections R311.2 and R311.3. In a multiple-level home, a ramp or stairway is required for access from basements, upper floors, mezzanines, split levels or habitable attics that do not have an exit on that level. The emergency escape and rescue openings in Section 310 are not considered an exit.

R311.5 Construction.

R311.5.1 Attachment. Exterior landings, decks, balconies, stairs and similar facilities shall be positively anchored to the primary structure to resist both vertical and lateral forces or shall be designed to be self-supporting. Attachment shall not be accomplished by use of toenails or nails subject to withdrawal.

❖ Exterior exit balconies, stairs and similar exit facilities must be properly attached to the primary structure so that their reaction to vertical and lateral forces will not cause separation from the structure. This is reiterating the requirement for a complete load path in Section R301.1. The reason for doing so is the need to main-

tain key elements of the egress system that are needed for emergency evacuations and the increased possibility of overlooking such connection. The requirement for positive anchor to the primary structure applies to all exterior means of egress components used as part of an egress system whether part of the required exit or not.

R311.6 Hallways. The width of a hallway shall be not less than 3 feet (914 mm).

- ❖ Hallways must be a minimum of 3 feet (914 mm) wide to accommodate moving furniture into rooms off the hallway and for safe egress from the structure. The code uses the term “hallway” instead of corridors to avoid confusion with the IBC. In the IBC, “corridor” is a defined term, and corridors may have a required fire-resistance rating.

R311.7 Stairways.

- ❖ The requirements for stairways are contained in Sections R311.7.1 through R311.7.9. The provisions address a wide variety of issues that must be considered when designing a stairway that is both safe and usable.

R311.7.1 Width. Stairways shall be not less than 36 inches (914 mm) in clear width at all points above the permitted handrail height and below the required headroom height. Handrails shall not project more than 4½ inches (114 mm) on either side of the stairway and the clear width of the stairway at and below the handrail height, including treads and landings, shall be not less than 31½ inches (787 mm) where a handrail is installed on one side and 27 inches (698 mm) where handrails are provided on both sides.

Exception: The width of spiral stairways shall be in accordance with Section R311.7.10.1.

- ❖ Section R311.7.1 requires a minimum stairway width of 36 inches (914 mm). Generally, when the code specifies a required width of a component in the egress

system, the width will be the clear, net, usable, unobstructed width. In this case, however, the width is specified as applying only to the area “above the permitted handrail height and below the required headroom height.”

At and below the handrail height, the required width for the stairway, including treads and landings, is 27 inches (686 mm) if handrails are provided on each side, and 31½ inches (800 mm) if there is a handrail installed on only one side. In essence, the code is not concerned about elements such as trim, stringers or other items that may be found below the level of the handrail, as long as they do not exceed the handrail’s projection. This reduced width below the handrail is based on a body’s movements as a person walks on a stair or other surface (see Commentary Figure R311.7.1). The exception and the provisions of Section R311.7.10.1 will permit a minimum width of 26 inches (660 mm) for spiral stairways.

It is important to note that each of the three key elements in the means of egress, hallways, stairways and the egress door, have a required minimum width.

R311.7.2 Headroom. The headroom in stairways shall be not less than 6 feet 8 inches (2032 mm) measured vertically from the sloped line adjoining the tread nosing or from the floor surface of the landing or platform on that portion of the stairway.

Exceptions:

1. Where the nosings of treads at the side of a flight extend under the edge of a floor opening through which the stair passes, the floor opening shall be allowed to project horizontally into the required headroom not more than 4¾ inches (121 mm).
2. The headroom for spiral stairways shall be in accordance with Section R311.7.10.1.

- ❖ A minimum headroom clearance of 6 feet, 8 inches (2032 mm) is required in connection with every stair-

Figure R311.7.1
STAIRWAY CLEARANCES

way. This includes not only the above-the-tread portion, but also above any landings serving the stairway. The clearance is to be measured vertically above a plane that connects the stair nosings and also vertically above any landing or floor surface that is a part of the stairway [see Commentary Figure R311.7.2(1)]. This specific height requirement overrides the general ceiling height limitations of Section R305 and is modified for spiral stairways by Section R311.7.10.1.

The exception clarifies interpretation and practice by recognizing the common method of stairwell construction in which the open side of a stair is supported by the same structure as the side of the opening through which the stairway passes. The exception allows for common stairways that are slightly wider at the bottom and narrow in width as they ascend through a smaller width opening in the floor above. In this case, the plane of the nosings, from which headroom is determined, at the side of the stairs, extends under the ceiling or joist above at the edge of the floor opening. The exception allows this offset to be a maximum of $4\frac{3}{4}$ inches (121 mm) without being considered a projection into the required headroom. It is important to note that this exception only applies at the side of stairs [see Commentary Figure R311.7.2(2)].

R311.7.3 Vertical rise. A flight of stairs shall not have a vertical rise larger than 147 inches (3734 mm) between floor levels or landings.

❖ Between landings and platforms, the vertical rise is to be measured from one landing walking surface to another. The limited height provides a reasonable interval for users with physical limitations to rest on a level surface and also serves to alleviate potential negative psychological effects of long and uninterrupted stairway flights.

R311.7.4 Walkline. The walkline across winder treads shall be concentric to the curved direction of travel through the turn and located 12 inches (305 mm) from the side where the winders are narrower. The 12-inch (305 mm) dimension shall be measured from the widest point of the clear stair width at the walking surface of the winder. If winders are adjacent within the flight, the point of the widest clear stair width of the adjacent winders shall be used.

❖ This requirement is essential for smooth, consistent travel on stairs that turn with winder treads. It provides a standard location for the regulation of the uniform tread depth of winders. Due to the wide range of anthropometrics of stairway users, there is no one line that all persons will travel on stairs. However, the code recognizes that a standard location of a walkline is essential to design and enforcement. Each footfall of the user through the turn can be connected in an arc to describe the path traveled. As a user ascends or descends the flight, the turning at each step should be consistent through the turn. The walkline is established concentric, having the same center, or approximately parallel to the arc of travel of the user. The tread depth dimension at the walkline is one of two tread depths across the width of the stair at which winder tread depth is regulated. The second is the minimum tread depth. Regulation at these two points controls the angularity of the turn and the configuration of the flight. In order to establish consistently shaped winders, tread depths must always be measured concentric to the arc of travel. The walkline is unique as the only line or path of travel where winder tread depth is controlled by the same minimum tread depth as rectangular treads. However, Section R311.7.5.2 recognizes winder tread depth need not be compared to rectangular tread depths for dimensional uniformity in the same

flight because the location of the walkline is chosen for the purpose of providing a standard and cannot be specific to the variety of actual paths followed by all users. This specific line location is determined by measuring along each nosing edge 12 inches (305 mm) from the extreme of the clear width of the stair at the surface of the winder tread or the limit of where the foot might be placed in use of the stair [see Commentary Figures R311.7.5.2.1(1) and R311.7.5.2.1(2)]. If adjacent winders are present the point of the widest clear stair width at the surface of the tread in the group of adjacent consecutive winders is used to provide the reference from which the 12-inch (305 mm) dimension will be measured along each nosing. The tread depth may be determined by measuring between adjacent nosings at these determined intersections of the nosings with the walkline. It is important to note that the clear stair width is only that portion of the stair width that is clear for passage. Portions of the stair beyond the clear width are not consequential to use of the stair, consistent travel or location of the walkline.

R311.7.5 Stair treads and risers. Stair treads and risers shall meet the requirements of this section. For the purposes of this section, dimensions and dimensioned surfaces shall be exclusive of carpets, rugs or runners.

❖ The riser height, tread depth and profile requirements for stairways are specified in Sections R311.7.5.1 through R311.7.5.3. These provisions facilitate smooth and consistent travel. This section provides dimensional ranges and tolerances for the component elements to allow the flexibility required to design and

construct a stair or a flight of stairs, which are elements of a stairway. The allowed proportion of maximum riser height and minimum tread depth provides for a maximum angle of ascent, but there is no maximum tread depth or minimum riser height that would define a minimum angle for a stairway. Nor is the proportion of riser height to tread depth compared with the limitations of the length of the users stride on stairways that is significantly foreshortened from the users stride on the level. For this reason, care should be taken when incorporating large tread depths or short risers to proportion the riser height and tread depth to avoid a step that is wide enough to require more than one step to cross or a short narrow step, which can be easily stepped over. With these same limitations for proportion in mind, by controlling the minimum depth of rectangular treads and the minimum depth and angularity of winder treads, these components can control the configuration of the plan of a flight of stairs to provide for smooth and consistent travel. Carpets, rugs and runners, like furniture, are frequently changed by the occupants and are not regulated by the code. For this reason, it is essential that the riser height and tread depth be regulated exclusive of these transitory surfaces to provide an enforceable standard. This practice minimizes the possible variation due to the removal of nonpermanent carpeting throughout the life of a structure and provides a standard enforcement methodology that will provide consistency across the built environment for all users. When owners or occupants add carpeting, rugs or runners they need to be able to add it to all tread and landing surfaces in the

Figure R311.7.2(2)
EXAMPLE OF EXCEPTION TO SECTION R311.7.2

stairway. It is important that the tread and landing surfaces are consistent and comply with the code prior to the addition of carpet. This methodology of enforcement makes it unnecessary to reconstruct floor and stair elevations in the stairway when nonpermanent carpet surfaces are changed that do not require a building permit and eliminates the resulting variations in the built environment that will not comply with the tolerance in Sections R311.7.5.1 and R311.7.5.2.

R311.7.5.1 Risers. The riser height shall be not more than $7\frac{3}{4}$ inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than $\frac{3}{8}$ inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that the openings located more than 30 inches (762 mm), as measured vertically, to the floor or grade below do not permit the passage of a 4-inch-diameter (102 mm) sphere.

Exceptions:

1. The opening between adjacent treads is not limited on spiral stairways.
 2. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1.
- ❖ The code establishes that the maximum riser height is $7\frac{3}{4}$ inches (197 mm). The provisions specify how the riser height is to be measured [see Commentary Figure R311.7.5.1(1)]. The uniformity of risers and treads is a safety factor in any flight of stairs. The section of a stairway leading from one landing to the next is defined as a flight of stairs. This is important because variations in excess of the $\frac{3}{8}$ -inch (9.5 mm) tolerance could interfere with the rhythm of the stair user. It is true that adequate attention to the use of the stair can compensate for substantial variations in risers and treads; however, the stair user does not always give the necessary attention.

To obtain the best uniformity possible in a flight of stairs, the maximum variation between the highest and lowest risers is limited to $\frac{3}{8}$ inch (9.5 mm). This tolerance is not to be used as a design variation, but its inclusion is in recognition that normal construction practices give rise to variables that make it impossible to get exactly identical riser heights and tread dimensions in constructing a stairway. Therefore, the code allows the variation indicated in Commentary Figure R311.7.5.1(2).

The risers must be vertical or slope back, effectively providing a wider overall tread depth. The code does not require solid risers, but riser openings that are located more than 30 inches above the floor or grade below must not allow the passage of a 4-inch-diameter sphere. This is consistent with the guard provisions of Section R312, where a 4-inch (102 mm) sphere is used to determine compliance.

For spiral stairways, the openings between adjacent treads are not limited and riser heights are regulated by Section R311.7.10.1.

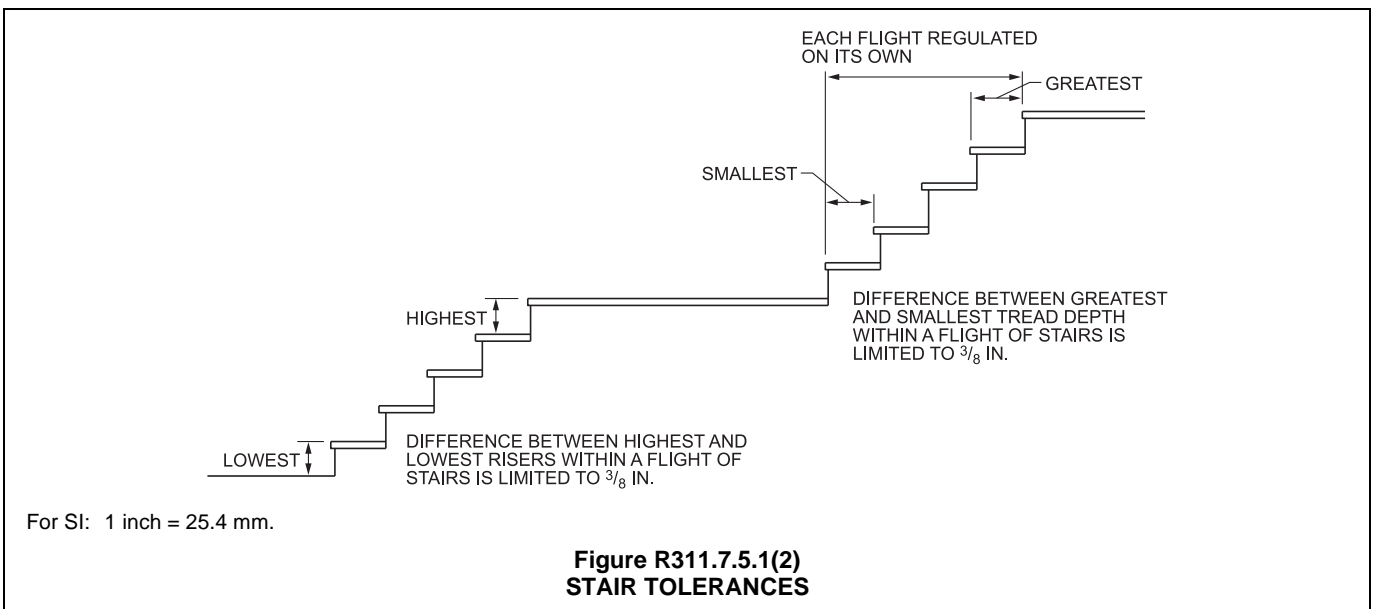

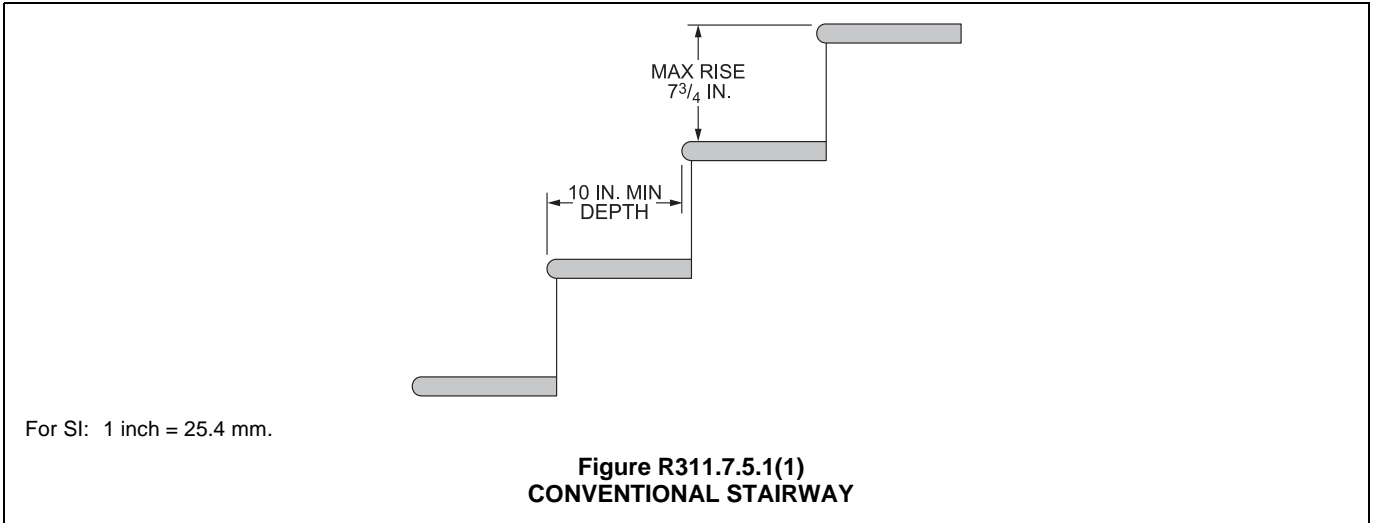

R311.7.5.2 Treads. The tread depth shall be not less than 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than $\frac{3}{8}$ inch (9.5 mm).

- ❖ The code establishes that the minimum tread depth is 10 inches (254 mm). The provisions specify how the tread depth is to be measured [see Commentary Figure R311.7.5.1(1)]. To obtain the best uniformity possible in a flight of stairs, the maximum variation between the greatest and smallest tread depth is limited to $\frac{3}{8}$ inch (9.5 mm). See the commentary to Section R311.7.5.1 for the discussion on uniformity.

R311.7.5.2.1 Winder treads. Winder treads shall have a tread depth of not less than 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a tread depth of not less than 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than $\frac{3}{8}$ inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within $\frac{3}{8}$ inch (9.5 mm) of the rectangular tread depth.

Exception: The tread depth at spiral stairways shall be in accordance with Section R311.7.10.1.

- ❖ The same criterion for rectangular treads applies to winder treads. However, the depth is to be measured as the horizontal distance between the points where the nosing of the adjacent treads intersects with the "walkline." The location of the "walkline" is defined in Section R311.7.4. Winder treads must have a minimum depth of 6 inches (152 mm) at any point. A stairway may have straight treads and winder treads within the same flight. If winders are used, they can either be used for an entire flight of a stairway, as a portion of a flight to provide a change of direction or to form a curved stairway. Because winder treads are used to change the direction of the stair it is important that winders comply with the specified dimensional criteria. See Commentary Figure R311.7.5.2.1(1) for examples of winders used as a portion of a stairway at a change of direction. See Commentary Figure R311.7.5.2.1(2) for an example of winders used to form a circular stairway. Rectangular treads can be used in combination with winder treads. The goal is to allow the foot placement along the walkline to be consistent along the length of the flight. For spiral stairs, tread depth is regulated by Section R311.7.10.1.

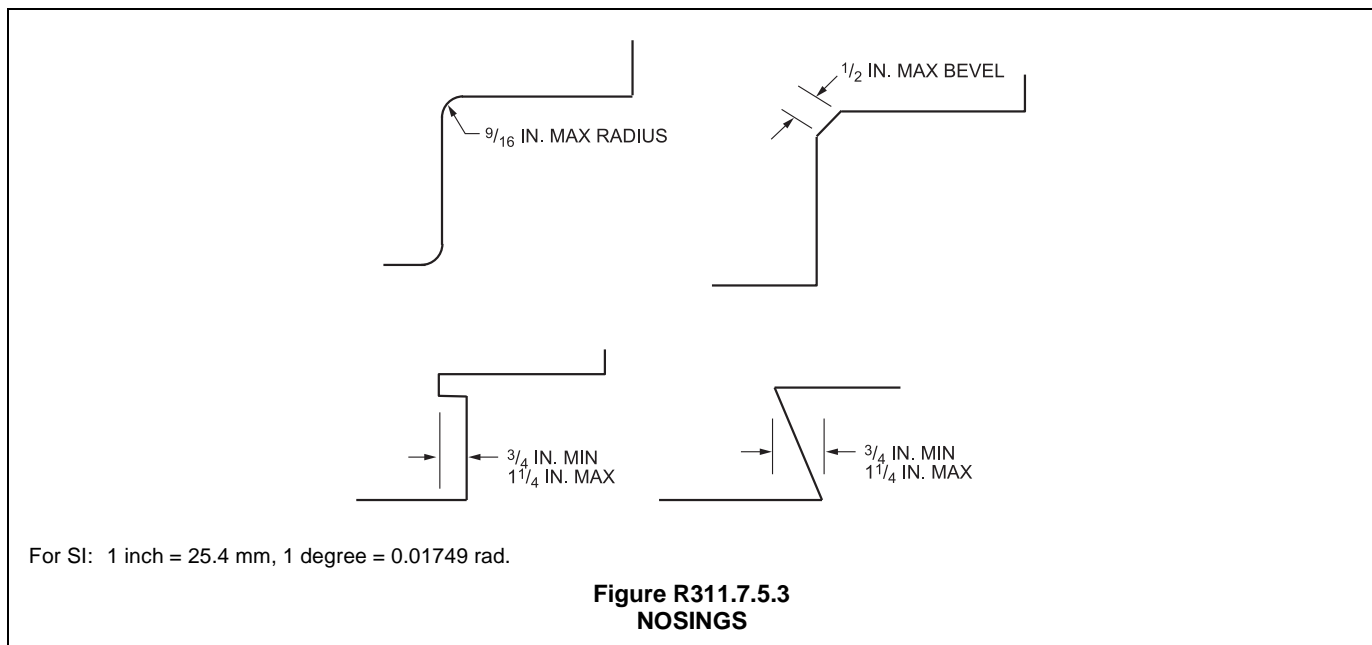

R311.7.5.3 Nosings. The radius of curvature at the nosing shall be not greater than $\frac{9}{16}$ inch (14 mm). A nosing projection not less than $\frac{3}{4}$ inch (19 mm) and not more than $1\frac{1}{4}$ inches (32 mm) shall be provided on stairways with solid risers. The greatest nosing projection shall not exceed the smallest nosing projection by more than $\frac{3}{8}$ inch (9.5 mm) between two stories, including the nosing at the level of floors and landings. Beveling of nosings shall not exceed $\frac{1}{2}$ inch (12.7 mm).

Exception: A nosing projection is not required where the tread depth is not less than 11 inches (279 mm).

- ❖ The sectional parameters of the components of a step or stair contribute to stairway safety. The radius or bevel of the nosing eases the otherwise square edge of the tread and prevents irregular chipping that can become a maintenance issue seriously affecting the

safe use of the stair; and eliminates a sharp square edge that will cause greater injury in falls. A radius or bevel allows light modeling, reflecting light at various angles, providing a certain contrast from the other surfaces of the stair allowing easier visual location of the start of the tread surface. The maximum radius of curvature at the leading edge of the tread is intended to allow descending foot placement on a surface that does not pitch the foot forward or allow the ball of the foot to slide off the treads and ascending foot placement to slide on to the tread without catching on a square edge. If a stairway design uses a beveled nosing configuration, the bevel is limited to a depth of $\frac{1}{2}$ inch (12.7 mm). A nosing projection allows the descending foot to be placed further forward on the tread and the heel to then clear the nosing of the tread above as it swings down in an arc landing further away from the riser on the tread that is effectively deeper than if no nosing projection is used. Nosing projections are so common in stair design that they are noticed by users when absent as affecting their gait and anticipated clearance for their heels from the riser in descent. A nosing projection may also be accommodated by slanting the riser under the tread above. The nosing projection is between $\frac{3}{4}$ inch minimum (19 mm) and $1\frac{1}{4}$ inches (32 mm) maximum (see Commentary Figure R311.7.5.3). It is critical that all tread and landing nosings associated with each step in the stairway be uniform to ensure that the user does not experience an effective change in tread depth outside the $\frac{3}{8}$ inch (9.5 mm) between stories. Critical to this understanding is that tread depth is regulated by measuring between the nosing edges of treads or a tread and a landing. The lack of a uniform nosing at the top landing of a flight is a serious safety problem that may not be apparent in initial rough inspections. Treads with a tread depth of at least 11 inches (279 mm) are allowed with or without a nosing projection.

R311.7.5.4 Exterior plastic composite stair treads. Plastic composite exterior stair treads shall comply with the provisions of this section and Section R507.3.

- ❖ Stair treads made of wood/plastic composite materials must meet the requirements for installation, labeling and compliance with ASTM D7032 in accordance with Section R507.3, in addition to the requirements of Section R311.7.5.

R311.7.6 Landings for stairways. There shall be a floor or landing at the top and bottom of each stairway. The width perpendicular to the direction of travel shall be not less than the width of the flight served. Landings of shapes other than square or rectangular shall be permitted provided that the depth at the walk line and the total area is not less than that of a quarter circle with a radius equal to the required landing width. Where the stairway has a straight run, the depth in the direction of travel shall be not less than 36 inches (914 mm).

Exception: A floor or landing is not required at the top of an interior flight of stairs, including stairs in an enclosed garage, provided that a door does not swing over the stairs.

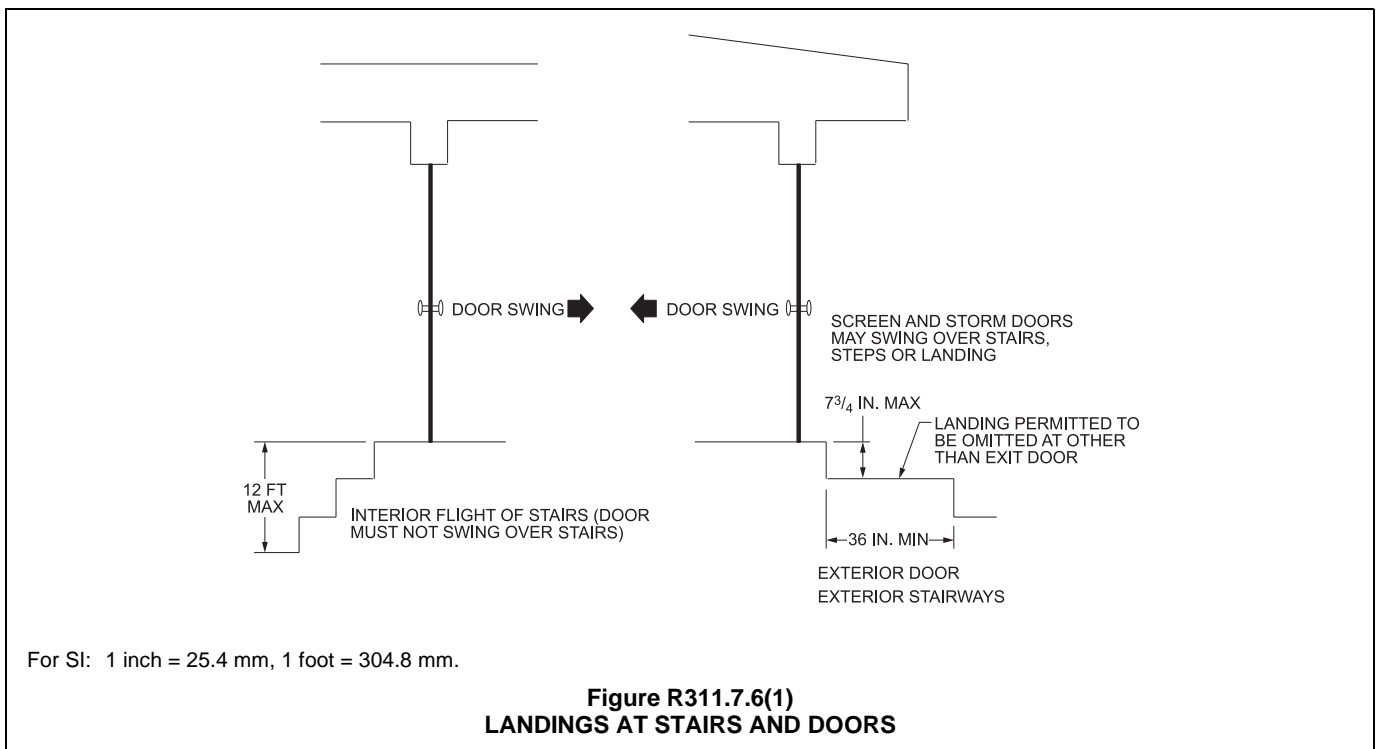

- ❖ A landing is required at the top and bottom of each stairway; however, a landing is not required at the top of interior stairways, including an enclosed garage, if a door does not swing over the stairway [see Commentary Figure R311.7.6(1)]. Section R311.7.3 states that flights must be interrupted by a landing or floor such that they do not have a total rise of more than 12 feet (3658 mm).

The width of landings for stairways is measured perpendicular to the direction of travel. It is not the intent to require specifically shaped landings. Landings may have curved or segmented periphery edges provided the width perpendicular to the direction of travel is not

less than the width of the stairway served. For a straight stairway run, the minimum dimension of 36 inches (914 mm) in the direction of travel is intended to provide a minimum depth at the landing that cannot be overstepped in descent of a straight run stairway. Landings that are square or rectangular serve to limit the minimum angle of turn of a landing to 90 degrees (1.57 rad) for at least 36 inches (914 mm). Landings for turns of 90 degrees (1.57 rad) or less or of any shape are permitted provided the depth of the tread at the walkline and the total area of the landing are the same as a quarter circle with a radius the same as the stairway width. See Commentary Figure R311.7.6(2) for an example.

R311.7.7 Stairway walking surface. The walking surface of treads and landings of stairways shall be sloped not steeper than one unit vertical in 48 inches horizontal (2-percent slope).

- ❖ The slope of the walking surfaces must provide drainage to stairs and landings that may be subjected to accumulation of liquids, such as water, rain or melting snow. The use of such a slope, called a “wash,” is a common technique used on all stairs to allow the nosing to be at a lower elevation than the remainder of the tread surface. This technique of building the flight to a slightly shorter total rise than the actual condition slopes the entire flight forward and better accommodates the placement of the user’s foot as it slides onto the tread. It also serves to prevent long-term wear and tear at the nosing limiting problematic maintenance and safety issues. This section provides a limit of the slope to maintain a safe walking surface. This requirement applies to all stairs and landings, both exterior and interior.

R311.7.8 Handrails. Handrails shall be provided on not less than one side of each continuous run of treads or flight with four or more risers.

❖ The provision of handrails increases the level of safety when used by the occupants while ascending and descending stairs. Handrails are used for guidance, stabilization, pulling and to assist in arresting a fall. This section states that a handrail must be provided on at least one side of flights of four or more risers. Handrails may be provided on both sides and this eliminates choosing the best side to securely attach the handrail. Otherwise, the generally preferred location is for use by the right hand in descent when feasible. Sections R311.7.8.1 through R311.7.8.3 contain provisions essential to the height, continuity and grip size of the handrail provided.

R311.7.8.1 Height. Handrail height, measured vertically from the sloped plane adjoining the tread nosing, or finish surface of ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

Exceptions:

1. The use of a volute, turnout or starting easing shall be allowed over the lowest tread.
 2. Where handrail fittings or bendings are used to provide continuous transition between flights, transitions at winder treads, the transition from handrail to *guard*, or used at the start of a flight, the handrail height at the fittings or bendings shall be permitted to exceed 38 inches (956 mm).
- ❖ Where handrails are required, they must be installed at a height of not less than 34 inches (864 mm) and not more than 38 inches (965 mm). This height is to be measured vertically to the top of the handrail from the plane adjoining the tread nosings of the flight or the surface of the ramp slope. Exception 1 allows common starting fittings used as terminals over the lowest tread to fall outside the required height range. Exception 2 allows transition fittings to exceed the required height when used to provide a continuous rail at changes in the pitch of the rail within the stairway.

R311.7.8.2 Continuity. Handrails for stairways shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals. Handrails adjacent to a wall shall have a space of not less than 1½ inches (38 mm) between the wall and the handrails.

Exceptions:

1. Handrails shall be permitted to be interrupted by a newel post at the turn.
 2. The use of a volute, turnout, starting easing or starting newel shall be allowed over the lowest tread.
- ❖ The required handrail is to be continuous for the length of the flight. Where stairway flights are separated by landings or floor levels, handrails are not required (see Commentary Figure R311.7.8.2). The term “continuous” means not only that a single handrail must run from the top riser to the bottom riser, but it also indicates that users should be able to grasp the handrail and maintain their grasp without having to release the rail where it is supported. There is no requirement within the code for installation of a second handrail, but depending on the design and the placement of the required handrail, the requirement for a guard should be reviewed. The two exceptions to this section create situations where the graspable portion of the handrail may not be completely continuous from the top riser to the bottom riser. These traditional situations are well known to the occupants and have not been shown to represent a safety hazard requiring their restriction.

The ends of handrails are to be returned to the wall or floor, or to end in some type of terminal that will not catch clothing or limbs. A clear space of at least 1½ inches (38 mm) is necessary between the handrail and any abutting wall. This distance will permit the fingers to slide past any adjacent rough surface that may cause injury, and it will provide an adequate distance so that the handrail may be quickly grabbed as an assist in the arrest of a fall.

R311.7.8.3 Grip-size. Required handrails shall be of one of the following types or provide equivalent graspability.

1. Type I. Handrails with a circular cross section shall have an outside diameter of not less than 1¹/₄ inches (32 mm) and not greater than 2 inches (51 mm). If the handrail is not circular, it shall have a perimeter dimension of not less than 4 inches (102 mm) and not greater than 6¹/₄ inches (160 mm) with a cross section of dimension of not more than 2¹/₄ inches (57 mm). Edges shall have a radius of not less than 0.01 inch (0.25 mm).
 2. Type II. Handrails with a perimeter greater than 6¹/₄ inches (160 mm) shall have a graspable finger recess area on both sides of the profile. The finger recess shall begin within a distance of 3³/₄ inch (95 mm) measured vertically from the tallest portion of the profile and achieve a depth of not less than 5⁵/₁₆ inch (8 mm) within 7⁷/₈ inch (22 mm) below the widest portion of the profile. This required depth shall continue for not less than 3³/₈ inch (10 mm) to a level that is not less than 1³/₄ inches (45 mm) below the tallest portion of the profile. The width of the handrail above the recess shall be not less than 1¹/₄ inches (32 mm) and not more than 2³/₄ inches (70 mm). Edges shall have a radius of not less than 0.01 inch (0.25 mm).
- ❖ To be effective, a handrail must be easily grasped by the vast majority of users. If it is too large, it is difficult for a user to get a strong enough grip to provide the needed support. If it is too small the fingers wrap and interfere with the thumb and palm and cannot close in a sufficient grip. For this reason Type I rails have minimum and maximum perimeters to restrict their use to the effective size range. Tests have proven that it is beneficial to have graspable recesses for the fingers and opposing thumb such that wider and taller shapes can provide graspability comparable to rails within the Type I size range limitations. The Type II handrail requirements provide details for the location and depth of the recess as it relates to the variables of crown height and width to ensure that the design is of a graspable shape. The mountings of smaller profiles can cause interference, as well. Care should be taken to minimize the interference caused by brackets and bal-

usters supporting profiles that require the bottom mounting surface to be grasped.

The code specifies that the handrail be either Type I or Type II, or be equivalently graspable. A Type I handrail can be either circular or noncircular in shape. See Commentary Figure R311.7.8.3(1) for examples of Type I handrails.

A Type II handrail has a perimeter larger than 6¹/₄ inches (160 mm) with graspable finger recess area on both sides of the profile. See Commentary Figure R311.7.8.3(2) for the limitations of a Type II handrail.

R311.7.8.4 Exterior plastic composite handrails. Plastic composite exterior handrails shall comply with the requirements of Section R507.3.

❖ Handrails made of wood/plastic composite materials must meet the requirements for installation and labeling, and comply with ASTM D7032 in accordance with Section R507.3, in addition to the general requirements for handrails in this section.

R311.7.9 Illumination. Stairways shall be provided with illumination in accordance with Section R303.7.

❖ This section contains a reference to the illumination provisions of Section R303.7. The proper illumination of stairways is an important part of stairway safety. This lighting can assist users by making sure the level changes do not occur in areas with shadows or in contrasting light, which would therefore make them difficult to see. See the commentary to Section R303.7 for additional information.

R311.7.10 Special stairways. Spiral stairways and bulkhead enclosure stairways shall comply with the requirements of Section R311.7 except as specified in Sections R311.7.10.1 and R311.7.10.2.

❖ Sections R311.7.10.1 and R311.7.10.2 are exceptions to the general requirements for stairways as prescribed in Section R311.7.

R311.7.10.1 Spiral stairways. Spiral stairways are permitted, provided that the clear width at and below the handrail is not less than 26 inches (660 mm) and the walkline radius is not greater than 24¹/₂ inches (622 mm). Each tread shall have

a depth of not less than $6\frac{3}{4}$ inches (171 mm) at the walkline. All treads shall be identical, and the rise shall be not more than $9\frac{1}{2}$ inches (241 mm). Headroom shall be not less than 6 feet 6 inches (1982 mm).

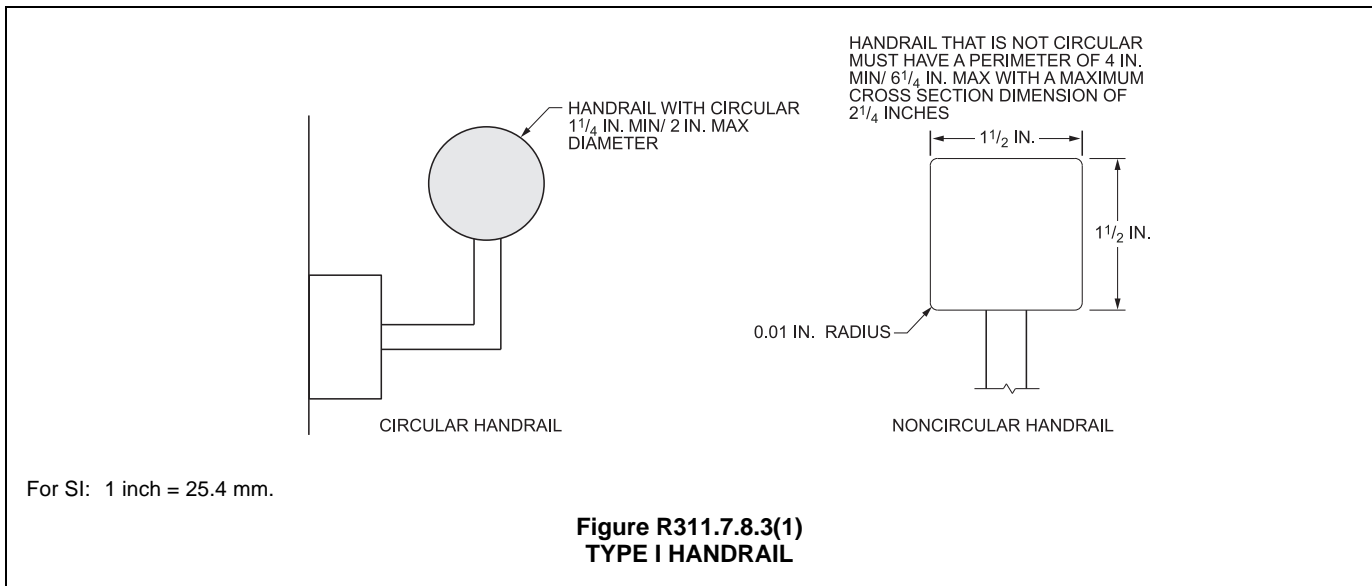

❖ A spiral stairway is one of two types of special stairs that the code permits. Although a spiral stair may be difficult to use to move furniture from one level to another, the code places no limitations on its use within the egress system if it meets the size requirements of this section. A spiral stairway that meets these requirements may provide the only means of egress from a level within an individual dwelling regardless of the occupant load or size of area served.

A spiral stairway is one in which the treads radiate from a central pole. Such a stair must provide a clear width of at least 26 inches (660 mm) at and below the handrail. Each tread must be identical and have a minimum dimension of $7\frac{1}{2}$ inches (191 mm) at a point 12

inches (305 mm) from its narrow end. The stair must have at least 6 feet, 6 inches (1981 mm) of headroom as measured vertically from the leading edge of the tread. The rise between treads can be as much as, but not more than, $9\frac{1}{2}$ inches (241 mm). Commentary Figure R311.7.10.1 shows the required dimensions of a spiral stairway.

R311.7.10.2 Bulkhead enclosure stairways. Stairways serving bulkhead enclosures, not part of the required building egress, providing access from the outside *grade* level to the *basement* shall be exempt from the requirements of Sections R311.3 and R311.7 where the height from the *basement* finished floor level to *grade* adjacent to the stairway is not more than 8 feet (2438 mm) and the *grade* level opening to the stairway is covered by a bulkhead enclosure with hinged doors or other *approved* means.

❖ This section exempts exterior “bulkhead enclosure stairways” from the landing stairway and handrail

requirements found in Chapter 3, and it therefore permits a situation that has been fairly common in some areas.

See Commentary Figure R311.7.10.2 for an illustration of the requirements. Because these stairways are not a part of the building's egress system and serve only as a convenient way to access the basement from the exterior, the code exemption will not greatly affect the occupants' safety. Through this exemption, the size of the enclosure that is needed to provide weather protection for the stairway is greatly reduced.

R311.7.11 Alternating tread devices. Alternating tread devices shall not be used as an element of a means of egress. Alternating tread devices shall be permitted provided that the required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches (508 mm).

❖ Prior to the 2015 edition of the code, alternating tread devices were occasionally used in residential applications, but were not regulated. This language adopts the specifications from the IBC providing the needed guidance when they are used. These provisions further clarify that an alternating tread device cannot be used as an element of a means of egress, and can only be used to access a space that does not require a means of egress, or where a required means of egress stairway or ramp is also provided to serve the same spaces that the alternating tread devices serve at each level.

Alternating tread devices are constructed in such a way that each tread alternates with each adjacent tread so that the device consists of a system of right-footed and left-footed treads (see Commentary Figure R311.7.11) and the definition of "Alternating tread

device" in Section R202). The use of center stringer construction, half-treads and an incline that is considerably steeper than allowed for ordinary stairway construction makes the alternating tread device unique. However, because of its structural features, only single-file use of the device (between handrails) is possible, thus preventing occupants from passing one another. The pace of occupant travel is set by the slowest user, a condition that could become critical in an emergency situation. Furthermore, it is impossible for fire service personnel to use an alternating tread device at the same time and in a direction opposite that being used by occupants to exit the premises, possibly causing a serious delay in fire-fighting operations.

This section specifies the minimum width between handrails for alternating tread devices as 20 inches. Sections R311.7.11.1 and R311.7.11.2 contain tread and handrail details, respectively, for alternating tread devices.

R311.7.11.1 Treads of alternating tread devices. Alternating tread devices shall have a tread depth of not less than 5 inches (127 mm), a projected tread depth of not less than 8½ inches (216 mm), a tread width of not less than 7 inches (178 mm) and a riser height of not more than 9½ inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial tread of the device shall begin at the same elevation as the platform, landing or floor surface.

❖ Alternating tread stairways (see Section R311.7.1) are required to have tread depths of at least 5 inches (127

Figure R311.7.10.2
BULKHEAD ENCLOSURE STAIRWAY

mm). Tread projections when measured from tread nosing to tread nosing of next tread above or below must provide a minimum projected tread depth of 8½ inches (216 mm) (see Commentary Figure R311.7.11).

The riser height, or the vertical distance between alternating risers (next adjacent tread to the left or right), must be not more than 9½ inches (241 mm). The rise between treads on the same side would be 19 inches (482 mm) maximum. Applying the limiting dimensions stated above results in a device with a very steep incline that is common to ladders; however, because the device may be walked facing down in descent, it is considered a type of stairway in the code.

Tread widths are required to be a minimum of 7 inches (178 mm). With a center support, the total width will be more than 15 inches (381 mm). Although no maximum width of the tread is stated, the device must be of a width to provide for functional use of both handrails at the same time in ascent and descent. For this reason, handrail heights for alternating tread devices are modified from those stairways in Section R311.7.

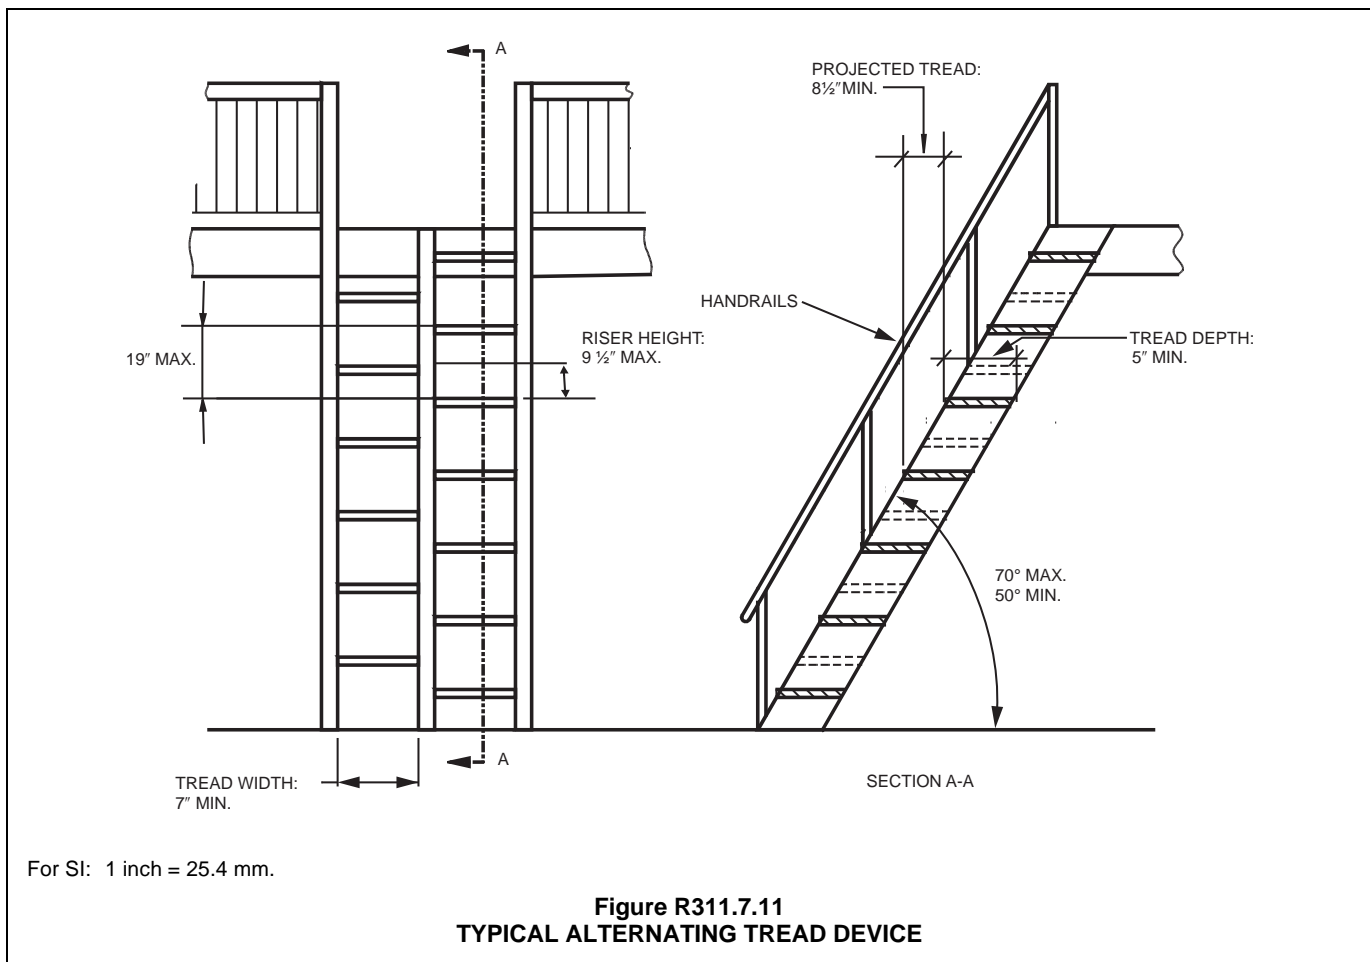

Just using the dimensions could result in an alternating tread device with an angle of over 75 degrees (1.3 rad) from horizontal. However, the code requires the overall angle of the device to be between 50 and 70 degrees (0.87 and 1.22 rad).

R311.7.11.2 Handrails of alternating tread devices. Handrails shall be provided on both sides of alternating tread devices and shall comply with Sections R311.7.8.2 to R311.7.8.4. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

❖ For the safety of occupants, this section references the dimensional requirements for handrails of Sections R311.7.8.2 through R311.7.8.4, which are also applicable to means of egress stairs. Because of the steepness of these devices, handrails on both sides are essential for safe functional use and additional clearances are required so that hand movement will not be encumbered by obstructions. The top of handrails for alternating tread devices must be uniform and be located not less than 30 inches and not more than 34 inches, as measured vertically, above an imaginary line connecting the leading edge of the treads (see Commentary Figure R311.7.11).

R311.7.12 Ship's ladders. Ship's ladders shall not be used as an element of a means of egress. Ship's ladders shall be permitted provided that a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches.

❖ Prior to the 2015 edition of the code, ship's ladders were occasionally used in residential applications, but

were not regulated. This language adopts the specifications from the IBC providing the needed guidance where they are used. These provisions further clarify that a ship's ladder cannot be used as an element of a means of egress, and can only be used to access a space that does not require a means of egress, or where a required means of egress stairway or ramp is also provided to serve the same spaces that the ship's ladders serve at each level.

Ship's ladders must be at least 20 inches wide, as measured at and below handrails. Sections R311.7.12.1 and R311.7.12.2 contain tread and handrail details, respectively, for ship's ladders (see Commentary Figure R311.7.12).

R311.7.12.1 Treads of ship's ladders. Treads shall have a depth of not less than 5 inches (127 mm). The tread shall be projected such that the total of the tread depth plus the nosing projection is not less than 8½ inches (216 mm). The riser height shall be not more than 9½ inches (241 mm).

❖ See Commentary Figure R311.7.12 for an example of this configuration.

R311.7.12.2 Handrails of ship's ladders. Handrails shall be provided on both sides of ship's ladders and shall comply with Sections R311.7.8.2 to R311.7.8.4. Handrail height shall

be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

❖ For the safety of occupants, this section references the dimensional requirements for handrails of Sections R311.7.8.2 through R311.7.8.4, which are also applicable to means of egress stairs. Because of the steepness of ship's ladders, handrails on both sides are essential for safe functional use and additional clearances are required so that hand movement will not be encumbered by obstructions. The height at the top of handrails for ship's ladders must be uniform and be located not less than 30 inches and not more than 34 inches, as measured vertically, above an imaginary line connecting the leading edge of the treads. See Commentary Figure R311.7.12 for an example of this configuration.

R311.8 Ramps.

❖ Section R311.8 states the code requirements for ramps when they are used to access, or are located within, a dwelling.

"Ramps" are defined in Section R202 as being a walking surface that has a running slope steeper than one unit vertical in 20 units horizontal (5-percent slope).

R311.8.1 Maximum slope. Ramps serving the egress door required by Section R311.2 shall have a slope of not more than 1 unit vertical in 12 units horizontal (8.3-percent slope). All other ramps shall have a maximum slope of 1 unit vertical in 8 units horizontal (12.5 percent).

Exception: Where it is technically infeasible to comply because of site constraints, ramps shall have a slope of not more than 1 unit vertical in 8 units horizontal (12.5 percent).

❖ Section R311.8.1 requires ramps that serve the egress door required by Section R311.2 to have a maximum slope of 1 unit vertical in 12 units horizontal (8.3-percent), unless it is technically infeasible to do so. For ramps serving other exterior doors or located within the dwelling unit, or where it is technically infeasible for a ramp serving the egress door to have a slope of 1:12, the code requires maximum slope of 1 unit vertical in 8 units horizontal (12.5 percent). A 1:12 slope can sometimes be difficult to achieve and absorbs much more space than may be necessary. For example, additions to older homes sometimes have new basements at a deeper level and the owner may wish to make the transition by ramp. Media rooms are often designed to have sloping floors with ramps serving the seating, and again the 1:12 slope is problematic. This proposal gives some relief for those situations where accessibility may not be an issue. This also is consistent with Section 1012.2 of the IBC which allows a 1:8 slope for pedestrian ramps not used as a means of egress.

R311.8.2 Landings required. There shall be a floor or landing at the top and bottom of each ramp, where doors open onto ramps, and where ramps change directions. The width of the landing perpendicular to the ramp slope shall be not less than 36 inches (914 mm).

❖ The code requires a floor or landing that measures not less than 36 inches both in the direction of travel, and perpendicular to the direction of travel at three specific locations for ramps. Landings should be provided at the top and bottom of each ramp run. When a ramp leaves or approaches a door, there needs to be a level landing to allow someone to open the door from a level surface. A change in direction could be any angle; however, these provisions are not intended to prohibit curved ramps. These dimensions are not tied to the actual width of the ramp. For doors that open onto ramps, the code calls for a larger size landing if it is also required by Section R311.3. The specified landing dimensions coordinate with the requirements for non-accessible dwelling units, which are found in exceptions in the IBC. While not a requirement, if the ramp is intended to serve as part of an accessible route, the landing should be sized as indicated in ICC A117.1 in order to allow full wheelchair access.

R311.8.3 Handrails required. Handrails shall be provided on not less than one side of ramps exceeding a slope of one unit vertical in 12 units horizontal (8.33-percent slope).

❖ Where a ramp exceeds a slope of one unit vertical in 12 units horizontal (8.3-percent slope) the code

requires that a handrail be installed on at least one side to assist ramp users. Therefore, ramps would require handrails when the exception to Section R311.8.1 was utilized. This provision differs from that of the IBC, where a slope of one unit vertical in 20 units horizontal (5-percent slope) and a ramp rise of 6 inches (152 mm) establishes the limits. A designer might choose to provide handrails, edge protection and/or guards on a ramp as a safety concern, even if it is not literally a requirement. If the purpose of the ramp is for wheelchair access, ICC A117.1 would be a good resource for information.

R311.8.3.1 Height. Handrail height, measured above the finished surface of the ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

❖ Where handrails are required, they must be installed at a height within a range of at least 34 inches (864 mm) and not more than 38 inches (965 mm), measured vertically from the finished surface of the ramp slope. This height should be measured to the top of the handrail.

R311.8.3.2 Grip size. Handrails on ramps shall comply with Section R311.7.8.3.

❖ The grip size for handrails along ramps is the same as that required for stairways (see commentary, Section R311.7.8.3).

R311.8.3.3 Continuity. Handrails where required on ramps shall be continuous for the full length of the ramp. Handrail ends shall be returned or shall terminate in newel posts or safety terminals. Handrails adjacent to a wall shall have a space of not less than 1½ inches (38 mm) between the wall and the handrails.

❖ The continuity requirement for the ramp handrail is similar to the continuity requirement for the stair handrail (see commentary, Section R311.7.8.2).

SECTION R312 GUARDS AND WINDOW FALL PROTECTION

R312.1 Guards. *Guards* shall be provided in accordance with Sections R312.1.1 through R312.1.4.

❖ The guard provisions of the code address the issue of protecting occupants from falling from any type of elevated walking surface. The provisions in Section R312 provide the scoping requirements, as well as the general construction requirements for the guards. Besides this section, code users should be aware that Section R301.5 contains the design load criteria for guards.

R312.1.1 Where required. *Guards* shall be located along open-sided walking surfaces, including stairs, ramps and landings, that are located more than 30 inches (762 mm) measured vertically to the floor or *grade* below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a *guard*.

❖ Section R312.1.1 establishes stairs, ramps and landings as examples of open-sided walking surfaces, but this is not an all-inclusive list of locations where guards are required. This section gives further specifics, to

define the minimum elevation of the walking surface as greater than 30 inches (762 mm) that requires a guard. It also recognizes that a guard is needed to minimize falls if the elevation exceeds the 30-inch (762 mm) height at any point within 36 inches (914 mm) of the edge of the walking surface in consideration of such conditions as a sloping site or sudden drop. The scoping requirement for guards along open sides of stairs only applies to that portion of the stairway that is more than 30 inches (762 mm) above the determined point on the grade or floor below (see Commentary Figure R312.1.1).

Insect screening lacks sufficient strength to prevent someone from falling under a top rail. For this reason a guard is required for porches and decks enclosed with insect screening where the walking surface is located more than 30 inches (762 mm) above a floor or grade below.

R312.1.2 Height. Required *guards* at open-sided walking surfaces, including stairs, porches, balconies or landings, shall be not less than 36 inches (914 mm) in height as measured vertically above the adjacent walking surface or the line connecting the leading edges of the treads.

Exceptions:

1. *Guards* on the open sides of stairs shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.
2. Where the top of the *guard* serves as a handrail on the open sides of stairs, the top of the *guard* shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm) as measured vertically from a line connecting the leading edges of the treads.

❖ Where guards are required by Section R312.1.1, Section 312.1.2 specifies a minimum height for those

guards. The code requires guards at open sides along walking surfaces and gives examples, but this list is not to be considered all inclusive. Required guards must be of an adequate height to minimize the chances of someone from falling off the edge of the walking surface. Therefore, the code establishes 36 inches (914 mm) as the minimum acceptable height for most guards at walking surfaces. However, Exceptions 1 and 2 recognize that the minimum height for handrails along stairways is 34 inches (864 mm), therefore, there is a special allowance at the top of the guard along stairways that is consistent with the height of such handrails.

Guard heights are determined by measuring vertically from the walking surface or the line connecting the nosings of the treads on stairways; however, when fixed seating is adjacent to a guard the height of the guard is to be measured from the seat where children might be inclined to stand or walk. See Commentary Figures R312.1.1 and R312.1.2 for examples of how this provision is applied.

R312.1.3 Opening limitations. Required *guards* shall not have openings from the walking surface to the required *guard* height that allow passage of a sphere 4 inches (102 mm) in diameter.

Exceptions:

1. The triangular openings at the open side of stair, formed by the riser, tread and bottom rail of a *guard*, shall not allow passage of a sphere 6 inches (153 mm) in diameter.
2. *Guards* on the open side of stairs shall not have openings that allow passage of a sphere $4\frac{3}{8}$ inches (111 mm) in diameter.

❖ Guards must be constructed so that they prohibit smaller occupants, such as children, from falling

through them. To prohibit people from slipping through a guard, any required guard would need to have supports, spindles, intermediate rails or some type of ornamental pattern so that a 4-inch (102 mm) sphere cannot pass through it. This spacing was chosen based on the head size and the chest depth of a child who had not yet developed an ability to crawl. The code does allow two exceptions for this spacing requirement. A $4\frac{3}{8}$ -inch (111 mm) sphere rule is used for the guard on the open side of stair treads. This minor difference of just $\frac{3}{8}$ inch (9.5 mm) allows the use of just two balusters at each tread greatly reducing costs with no limitation of safety. A 6-inch (152 mm)

sphere rule is used for the triangular area formed by the riser, tread and bottom rail of a guard along the open side of a stair because the triangular shape is more restrictive (see Commentary Figure R312.1.3).

R312.1.4 Exterior plastic composite guards. Plastic composite exterior *guards* shall comply with the requirements of Section R317.4.

❖ Guards made of wood or plastic composite materials must meet the requirements for installation and labeling, and must comply with ASTM D7032, as stated in Section R317.4, in addition to the general requirements for guards in this section.

R312.2 Window fall protection. Window fall protection shall be provided in accordance with Sections R312.2.1 and R312.2.2.

❖ Section R312.2 requires compliance with Sections R312.2.1 and R312.2.2 for window fall protection.

Section R312.2.1 indicates that the window fall protection is only required for windows that meet all of the following conditions:

1. Are operable,
2. Are located more than 72 inches (1829 mm) above finished grade or other exterior surface below, and
3. Have a sill height of less than 24 inches, as measured vertically from the floor surface of the room in which they are located.

Where a window meets all of these conditions, Section R312.2.1 requires that they comply with at least one of the following:

1. Have openings which will not allow passage of a 4-inch-diameter (102 mm) sphere,
2. Be equipped with a window fall prevention device in accordance with ASTM F2090, or
3. Be equipped with opening control devices in accordance with Section R312.2.2 (see Commentary Figure R312.2.1).

Where a window opening device in accordance with ASTM F2090 is used, Section R312.2.2 requires that the device must not reduce the net clear opening area of the window in its fully open position to less than that

required for required emergency escape and rescue openings (Section R310.2.1).

The intent of these provisions is to prevent small children from falling out of open windows. An opening control device installed on any window must have an emergency release device that is clearly identified and that operates without the need for a key, tool or special knowledge. These operation criteria match the language in the provisions for emergency escape and rescue openings.

The code references ASTM F2090, *Window Fall Prevention Devices with Emergency Escape (Egress) Release Mechanisms* for the device requirements. The standard requires window fall prevention devices to be constructed such that a 4-inch-diameter (102 mm) sphere cannot pass through. Window fall prevention devices installed on any window must conform to ASTM F2090, thereby complying with the operation provisions for emergency escape and rescue openings in Section R310.

R312.2.1 Window sills. In dwelling units, where the top of the sill of an operable window opening is located less than 24 inches (610 mm) above the finished floor and greater than 72 inches (1829 mm) above the finished *grade* or other surface below on the exterior of the building, the operable window shall comply with one of the following:

1. Operable windows with openings that will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening where the opening is in its largest opened position.
2. Operable windows that are provided with window fall prevention devices that comply with ASTM F2090.

3. Operable windows that are provided with window opening control devices that comply with Section R312.2.2.

❖ See the commentary to Section R312.2.

R312.2.2 Window opening control devices. Window opening control devices shall comply with ASTM F2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the net clear opening area of the window unit to less than the area required by Section R310.2.1.

❖ See the commentary to Section R312.2.

SECTION R313 AUTOMATIC FIRE SPRINKLER SYSTEMS

R313.1 Townhouse automatic fire sprinkler systems. An automatic residential fire sprinkler system shall be installed in *townhouses*.

Exception: An automatic residential fire sprinkler system shall not be required where *additions* or *alterations* are made to existing *townhouses* that do not have an automatic residential fire sprinkler system installed.

❖ Residential occupancies are the number one group of occupancies that suffer loss of life during fire events. A published study by the National Institute of Standards and Technology (NIST) entitled *Benefit-cost Analysis of Residential Fire Sprinkler Systems*, reports that, out of almost 2,000 fire incidents in homes equipped with fire sprinklers during the 4-year period 2002 to 2005, there were no fire-related fatalities. This statistic demonstrates the potential for sprinklers to save lives that would otherwise be lost in residential fires.

Since installation of a sprinkler system could be extensive in an existing dwelling unit, sprinkler systems are not required when an existing dwelling unit is being altered or has an addition. If the dwelling unit already has a sprinkler system, that system must be altered or added to as appropriate.

R313.1.1 Design and installation. Automatic residential fire sprinkler systems for *townhouses* shall be designed and installed in accordance with Section P2904 or NFPA 13D.

❖ This section requires compliance with either Section P2904 or NFPA 13D for the design of a sprinkler system in a townhouse. Section P2904 includes requirements considered to provide an equivalent level of protection as an NFPA 13D sprinkler system. Section P2904 provides criteria for sprinklers, sprinkler piping, water supply, pipe sizing, instructions and inspection.

R313.2 One- and two-family dwellings automatic fire systems. An automatic residential fire sprinkler system shall be installed in one- and two-family *dwellings*.

Exception: An automatic residential fire sprinkler system shall not be required for *additions* or *alterations* to exist-

ing buildings that are not already provided with an automatic residential sprinkler system.

❖ See the commentary to Section R313.1.

R313.2.1 Design and installation. Automatic residential fire sprinkler systems shall be designed and installed in accordance with Section P2904 or NFPA 13D.

❖ This section and Section P2904.1 allows for a designer to use either Section P2904 or NFPA 13D requirements for the design of a sprinkler system in a single-family home or duplex. Section P2904 includes requirements considered to provide an equivalent level of protection as an NFPA 13D sprinkler system. Section P2904 provides criteria for sprinklers, sprinkler piping, water supply, pipe sizing, instructions and inspection.

SECTION R314 SMOKE ALARMS

R314.1 General. Smoke alarms shall comply with NFPA 72 and Section R314.

❖ Section R314 provides the details of smoke detection and notification to alert occupants of potential problems. When asleep, the occupants of residential buildings will usually be unaware of a fire, and the fire will have an opportunity to spread before being detected. A majority of fire deaths occurring in residential buildings have occurred because of this delay in detection. It is for this reason that the code requires smoke alarms that comply with NFPA 72 and Section R314.

R314.1.1 Listings. Smoke alarms shall be *listed* in accordance with UL 217. Combination smoke and carbon monoxide alarms shall be *listed* in accordance with UL 217 and UL 2034.

❖ Smoke alarms must be listed to UL 217. Combination smoke and carbon monoxide alarms, if they are provided, must be listed in accordance with UL 217 and UL 2034.

R314.2 Where required. Smoke alarms shall be provided in accordance with this section.

❖ See commentary to Section R314.1.

R314.2.1 New construction. Smoke alarms shall be provided in *dwelling units*.

❖ See commentary to Section R314.1.

R314.2.2 Alterations, repairs and additions. Where *alterations*, *repairs* or *additions* requiring a permit occur, or where one or more sleeping rooms are added or created in existing *dwellings*, the individual *dwelling unit* shall be equipped with smoke alarms located as required for new *dwellings*.

Exceptions:

1. Work involving the exterior surfaces of *dwellings*, such as the replacement of roofing or siding, the

addition or replacement of windows or doors, or the addition of a porch or deck, are exempt from the requirements of this section.

2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

❖ This section contains a unique provision in the code, applying the smoke alarm provisions to existing buildings when an addition, alteration or repair is made that will require a permit, or if any sleeping rooms are added or created. See the commentary to Section R105.2 regarding what types of repairs or alterations require a permit. The smoke alarms in these existing buildings are to be installed in the same manner as required for new dwellings. This would not only require their installation in the same locations within the dwelling, but also that they be interconnected and receive their power from the building wiring. The commentary to Section R314.4 contains more discussion of the power source.

Two exceptions provide relief from the normal smoke alarm requirements in existing buildings that undergo some types of alteration, repair or addition.

The first exception exempts “exterior surface” repairs from initiating the requirement for smoke alarms being placed in an existing dwelling. This exception exempts work that is done on the exterior only. The final determination of what type of work is included is left to the building official, but this would generally be viewed as covering reroofing, siding repairs or siding replacement and could possibly include some window replacements.

The second exception exempts alterations that involve the replacement or repair of plumbing or mechanical equipment, fixtures or systems. This exception would allow replacement of items such as a furnace without expanding the project to include smoke alarms.

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
 2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
 3. On each additional *story* of the *dwelling*, including *basements* and *habitable attics* and not including crawl spaces and uninhabitable *attics*. In *dwellings* or *dwell-ing units* with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full *story* below the upper level.
 4. Smoke alarms shall be installed not less than 3 feet (914 mm) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by Section R314.3.
- ❖ So that all areas have at least some level of protection, and so that sleeping areas are adequately protected,

Section R314.3 specifies where smoke alarms are to be installed. The code requires that alarms be located within each sleeping room, as well as outside each separate sleeping area in the immediate vicinity of the bedrooms. The device within the bedroom will provide protection should the fire begin within that sleeping room, while the device outside of the room will provide early notification and protection should a problem develop in the area that generally will serve as the egress path for the bedroom. In addition, Item 3 will require installation of at least one smoke alarm on each story of the dwelling, including basements and habitable attics. The code does not require the installation of alarms within crawl spaces or within attics that are not habitable. This provides detection and notification within the areas of general occupancy, but ignores spaces that are not occupied. See Commentary Figure R314.3(1) for an illustration of the required alarm locations.

Where split levels occur in a dwelling and the adjacent levels openly communicate with each other, the alarm may be placed on the upper portion of the split level if it is not more than one full story different in elevation. Commentary Figure R314.3(2) is an example of this provision. This requirement is based on the fact that any fire initiating on the lower portion of the level will send products of combustion up to the upper portion and that a detector there will provide a quick response and early warning.

Item 4 prohibits smoke alarms within 3 feet, as measured horizontally, from doors or openings to spaces that contain a tub or shower, except where it would interfere with the location of another smoke alarm required by this section.

R314.3.1 Installation near cooking appliances. Smoke alarms shall not be installed in the following locations unless this would prevent placement of a smoke alarm in a location required by Section R314.3.

1. Ionization smoke alarms shall not be installed less than 20 feet (6096 mm) horizontally from a permanently installed cooking *appliance*.
 2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3048 mm) horizontally from a permanently installed cooking *appliance*.
 3. Photoelectric smoke alarms shall not be installed less than 6 feet (1828 mm) horizontally from a permanently installed cooking *appliance*.
- ❖ Ionization smoke alarms must not be installed within 20 feet, as measured horizontally, of a permanently installed cooking appliance except that, where the alarms are equipped with an alarm-silencing switch, they are permitted to be installed within 10 feet. Photoelectric smoke alarms must not be installed within 6 feet (1828 mm) of a permanently installed cooking appliance. These restrictions do not apply if they would prevent smoke alarm placement in accordance with Section R314.3.

R314.4 Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling unit in accordance with Section R314.3, the alarm devices shall be interconnected in such a manner that the actuation of one alarm will activate all of the alarms in the individual *dwelling unit*. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm.

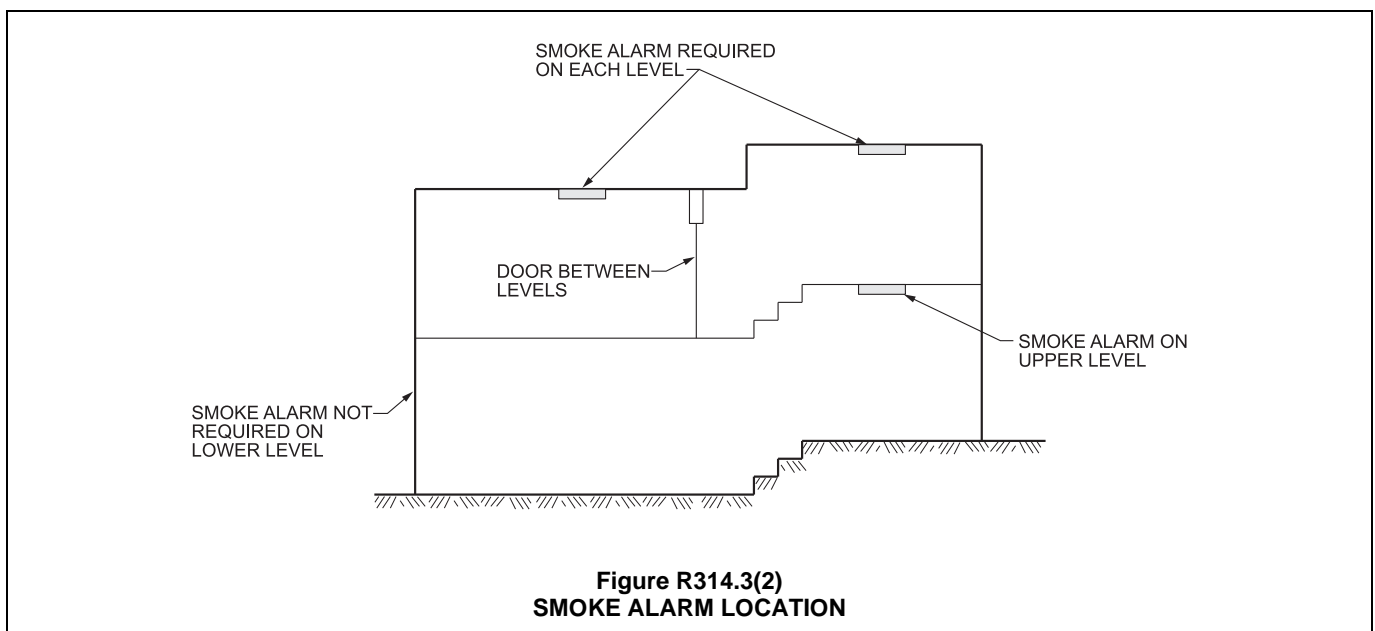

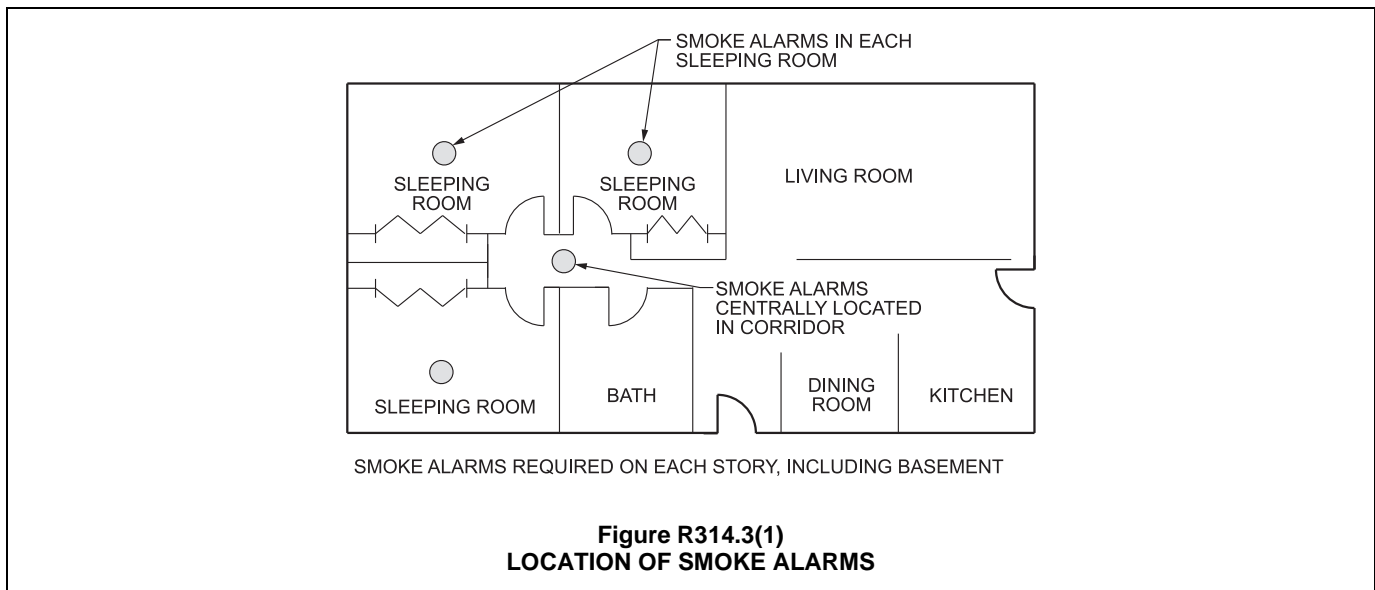

Exception: Interconnection of smoke alarms in existing areas shall not be required where *alterations* or repairs do not result in removal of interior wall or ceiling finishes exposing the structure, unless there is an *attic*, crawl space or *basement* available that could provide access for interconnection without the removal of interior finishes.

- ❖ Smoke detectors within a dwelling are required to be interconnected so that activation of any of the smoke

detectors on any level will activate all detectors in the building and ensure that occupants are alarmed. Section R314.4 will allow listed wireless interconnected alarms to substitute for wired interconnection of the smoke alarms in both new and existing construction.

One of the main concerns of the code is occupants who may be asleep and unaware of any developing fire. The code requires that the alarm signal be “clearly audible” in the bedroom area. If smoke alarms are being installed in an existing building, see the commentary to Section R314.2.2, which contains an exception to the requirement for interconnection.

The exception lifts the requirement for interconnection in alterations and repairs where ceiling and wall finishes are not removed to reveal the structural members, unless an attic, crawl space or basement provides access that facilitates the interconnection.

R314.5 Combination alarms. Combination smoke and carbon monoxide alarms shall be permitted to be used in lieu of smoke alarms.

- ❖ This section allows listed combination smoke and carbon monoxide alarms to be used in lieu of smoke alarms.

R314.6 Power source. Smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and, where primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. Smoke alarms shall be permitted to be battery operated where installed in buildings without commercial power.
 2. Smoke alarms installed in accordance with Section R314.2.2 shall be permitted to be battery powered.
- ❖ Smoke alarms must use AC power as their primary source and battery power as a secondary source to enhance their reliability. For example, during a power outage, the probability of fire is increased because of the use of candles or lanterns for temporary light. Required backup battery power provides for continued performance of the smoke alarms. Smoke alarms are commonly designed to emit a recurring signal when batteries are low and need to be replaced. It is also for the reliability issue that the code does not permit the alarms to be on any type of circuit that could be disconnected or turned off, such as a lighting circuit with a switch. The only way to disconnect power to the smoke alarms should be through the electrical panel box by either flipping a circuit breaker or removing the circuit's fuse.

The exceptions acknowledge that the code does not require that smoke alarms in all existing buildings be served from a commercial power source. Battery-operated smoke alarms may be the only power source when a commercial power source is not available or when extensive alterations or repairs (see Section R314.2.2) are not being made. Where permanent building wiring can be installed without the removal of interior finishes, this section recognizes the increased reliability that the "hardwired" commercial power source with battery back-up can provide. Therefore, where feasible, permanent wiring is to be installed.

R314.7 Fire alarm systems. Fire alarm systems shall be permitted to be used in lieu of smoke alarms and shall comply with Sections R314.7.1 through R314.7.4.

- ❖ The detection and notification system requirements of Sections R314.7 through R314.7.4 provide early warning to occupants of the building in the event of a fire, thereby providing a greater opportunity for everyone in the building to evacuate or relocate to a safe area. Installation of a fire alarm system in accordance with this section is considered a viable alternative to the installation of required smoke alarms. Of all of the pro-

visions for safety features that have been placed within the code over the past few decades other than fire sprinkler system requirements, the provisions for these detection and alarm devices have probably offered the greatest benefit in increasing safety and reducing the loss of life, and these benefits come at a comparatively minor expense.

Requiring the system to become a permanent fixture (see Section R314.7.3) of the occupancy and not be leased will prevent the system from being removed due to nonpayment. "Owned by the homeowner" is a good beginning and adds additional language that will ensure system reliability by requiring the owner to have the system electronically monitored and maintained in accordance with the referenced standard.

For larger homes, the only possible way to provide detection is through the use of a household fire warning system (see Section R314.7.1). NFPA 72, *National Fire Alarm Code*, has limits as to the number of smoke alarms that may be interconnected. Section 11.8.2.2 of the 2006 edition of the NFPA 72 allows only 12 smoke alarms to be interconnected if the interconnecting means is not supervised. Up to 42 smoke alarms may be interconnected if they are supervised. A number of homeowners prefer that their household fire warning systems be monitored by a supervising station. The requirement in Section R314.1.1 for listing of smoke alarms with UL 217, however, prohibits them from being monitored.

R314.7.1 General. Fire alarm systems shall comply with the provisions of this code and the household fire warning *equipment* provisions of NFPA 72. Smoke detectors shall be *listed* in accordance with UL 268.

- ❖ See the commentary to Section R314.7.

R314.7.2 Location. Smoke detectors shall be installed in the locations specified in Section R314.3.

- ❖ See the commentary to Section R314.7.

R314.7.3 Permanent fixture. Where a household fire alarm system is installed, it shall become a permanent fixture of the occupancy, owned by the homeowner.

- ❖ See the commentary to Section R314.7.

R314.7.4 Combination detectors. Combination smoke and carbon monoxide detectors shall be permitted to be installed in fire alarm systems in lieu of smoke detectors, provided that they are *listed* in accordance with UL 268 and UL 2075.

- ❖ See the commentary to Section R314.7.

SECTION R315 CARBON MONOXIDE ALARMS

R315.1 General. Carbon monoxide alarms shall comply with Section R315.

- ❖ Carbon monoxide (CO) is an odorless, colorless and toxic gas. Because it is impossible to see, taste or smell the toxic fumes, CO can kill occupants before they are aware it is in their home. At lower levels of

exposure, CO causes mild effects that are often mistaken for the flu. These symptoms include headaches, dizziness, disorientation, nausea and fatigue. The effects of CO exposure can vary greatly from person to person depending on age, overall health, and the concentration and length of exposure. According to the *Journal of the American Medical Association (JAMA)*, CO is the leading cause of accidental poisoning deaths in America.

Sources of CO include unvented kerosene and gas space heaters; leaking chimneys and furnaces; back-drafting from furnaces, gas water heaters, wood stoves and fireplaces; gas stoves; generators and other gasoline-powered equipment; and automobile exhaust from attached garages. Incomplete oxidation during combustion in gas ranges and unvented gas or kerosene heaters may cause high concentrations of CO in indoor air. Worn or poorly adjusted and maintained combustion devices (e.g., boilers, furnaces) can be significant sources, especially if the flue is improperly sized, blocked, disconnected or is leaking. Auto, truck or bus exhaust from attached garages, nearby roads or parking areas can also be a source.

Average levels of CO in homes without gas stoves vary from 0.5 to 5 parts per million (ppm). Levels near properly adjusted gas stoves are often 5 to 15 ppm and those near poorly adjusted stoves may be 30 ppm or higher.

CO alarms and detectors must not be considered a replacement for the proper use and maintenance of fuel-burning appliances. The industry has addressed the issue of reliability by updating the requirements of UL 2034. All CO detectors available today meet the updated requirements, which eliminated the false positive indications that occurred when CO detectors were first brought to market in the 1990s.

For new construction, Section R315.2.1 requires carbon monoxide alarms where dwelling units contain a fuel-fired appliance or have an attached garage with a door at the common wall between the dwelling unit and the garage.

For alterations, repairs and additions that require a permit, or where one or more sleeping rooms are added or created, Section R315.2.2 indicates that the requirements are the same as for new construction. However, Section R315.2.2 exempts carbon monoxide alarms for work related to plumbing and mechanical systems, as well as work related to exterior surfaces, such as the replacement of siding or roofing or the addition of windows, doors, porches and decks.

Section R315.3 requires that CO alarms be located outside each separate sleeping area in the immediate vicinity of the bedrooms. The carbon monoxide alarm can be located near the smoke alarm required in the immediate area of the bedrooms by Section R314.3. Section R315.1.1 requires that the alarms be listed in accordance with UL 2034. Alternatively, Sections R315.1.1 and R315.4 allow combination carbon monoxide alarms and smoke alarms where they are listed in accordance with both UL 2034 and UL 217.

For new construction, Section R315.5 requires that carbon monoxide alarms be “hard wired” to the building wiring where the building wiring is from a commercial source, such as a utility company. A battery back-up is required so that power is also available when the commercial source is interrupted. For alterations, repairs and additions, the system is permitted to be either battery powered or hard wired.

Section R315.1 does not require CO detectors to be hard wired or interconnected like smoke alarms (see Commentary Figure R315.3).

R315.1.1 Listings. Carbon monoxide alarms shall be *listed* in accordance with UL 2034. Combination carbon monoxide and smoke alarms shall be *listed* in accordance with UL 2034 and UL 217.

❖ See the commentary to Section R315.1.

R315.2 Where required. Carbon monoxide alarms shall be provided in accordance with Sections R315.2.1 and R315.2.2.

❖ See the commentary to Section R315.1.

R315.2.1 New construction. For new construction, carbon monoxide alarms shall be provided in dwelling units where either or both of the following conditions exist.

1. The *dwelling unit* contains a fuel-fired *appliance*.
2. The *dwelling unit* has an attached garage with an opening that communicates with the dwelling unit.

❖ See the commentary to Section R315.1.

R315.2.2 Alterations, repairs and additions. Where *alterations*, repairs or *additions* requiring a permit occur, or where one or more sleeping rooms are added or created in existing *dwelling*s, the individual *dwelling unit* shall be equipped with carbon monoxide alarms located as required for new *dwelling*s.

Exceptions:

1. Work involving the exterior surfaces of *dwelling*s, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck, is exempt from the requirements of this section.
2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

❖ See the commentary to Section R315.1.

R315.3 Location. Carbon monoxide alarms in *dwelling units* shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms. Where a fuel-burning *appliance* is located within a bedroom or its attached bathroom, a carbon monoxide alarm shall be installed within the bedroom.

❖ See the commentary to Section R315.1.

R315.4 Combination alarms. Combination carbon monoxide and smoke alarms shall be permitted to be used in lieu of carbon monoxide alarms.

❖ See the commentary to Section R315.1.

R315.5 Power source. Carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and, where primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. Carbon monoxide alarms shall be permitted to be battery operated where installed in buildings without commercial power.
2. Carbon monoxide alarms installed in accordance with Section R315.2.2 shall be permitted to be battery powered.

❖ See the commentary to Section R315.1.

R315.6 Carbon monoxide detection systems. Carbon monoxide detection systems shall be permitted to be used in lieu of carbon monoxide alarms and shall comply with Sections R315.6.1 through R315.6.4.

❖ Section 9.6.5 of NFPA 720 requires that when two or more carbon monoxide alarms are to be installed that they be interconnected. The rationale for this requirement is that if a CO device is activated in the basement, the occupants on the second floor on the opposite end of the home may be unable to hear the audible alarm if the devices are not interconnected. NFPA 720 requires CO devices to be installed on every level of a dwelling unit, including basements as well as outside each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms.

Section R315.6.2 indicates that the location requirements for carbon monoxide detectors are the same as those for carbon monoxide alarms and these requirements supersede the locations indicated in NFPA 720.

The requirement of Section R315.6.3 for the household carbon monoxide detection system to be owned by the homeowner and to be monitored by an approved supervising station mirrors the household fire alarm system requirements in Section R314.7.3.

Section R315.6.4 requires combination carbon monoxide detectors and smoke detectors to be listed in accordance with UL2075 and UL268 where they are part of a carbon monoxide detection system.

R315.6.1 General. Household carbon monoxide detection systems shall comply with NFPA 720. Carbon monoxide detectors shall be *listed* in accordance with UL 2075.

❖ See the commentary to Section R315.6.

R315.6.2 Location. Carbon monoxide detectors shall be installed in the locations specified in Section R315.3. These locations supersede the locations specified in NFPA 720.

❖ See the commentary to Section R315.6.

R315.6.3 Permanent fixture. Where a household carbon monoxide detection system is installed, it shall become a permanent fixture of the occupancy and owned by the homeowner.

❖ See the commentary to Section R315.6.

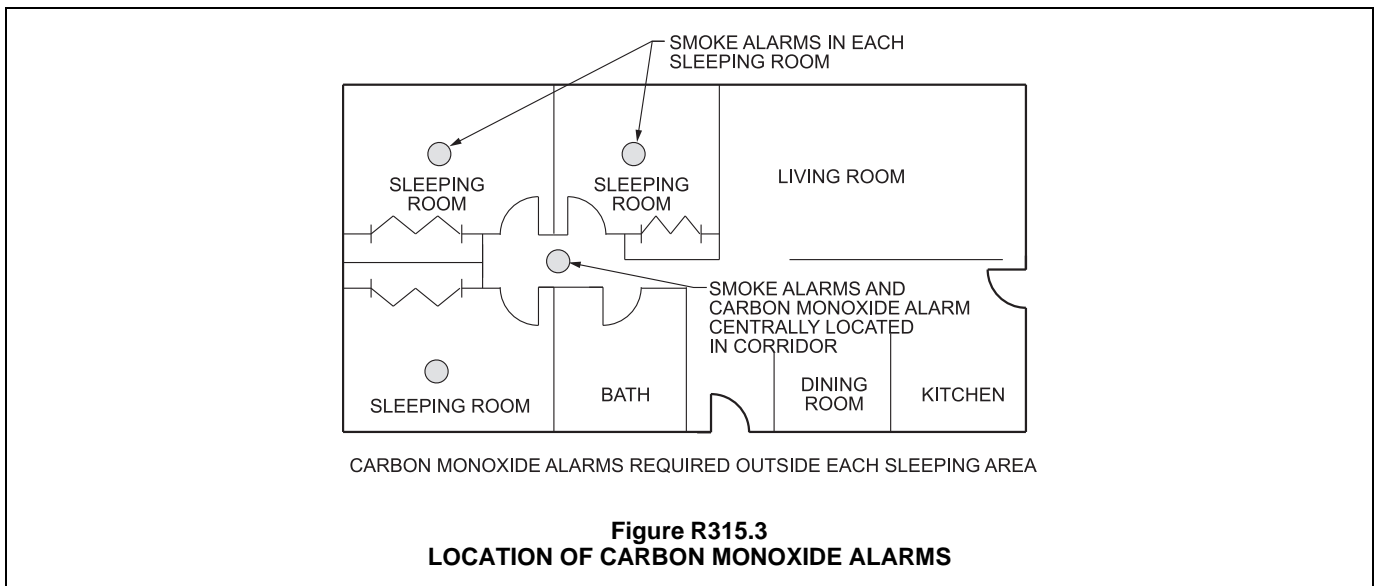

R315.6.4 Combination detectors. Combination carbon monoxide and smoke detectors shall be permitted to be installed in carbon monoxide detection systems in lieu of carbon monoxide detectors, provided that they are *listed* in accordance with UL 2075 and UL 268.

❖ See the commentary to Section R315.6.

**SECTION R316
FOAM PLASTIC**

R316.1 General. The provisions of this section shall govern the materials, design, application, construction and installation of foam plastic materials.

❖ Section R316 covers several topics related to the use and installation of various types of foam plastic materials used for insulation, trim and finishes. These requirements cover the acceptable uses of this combustible product and the associated protection needed to use it in building construction.

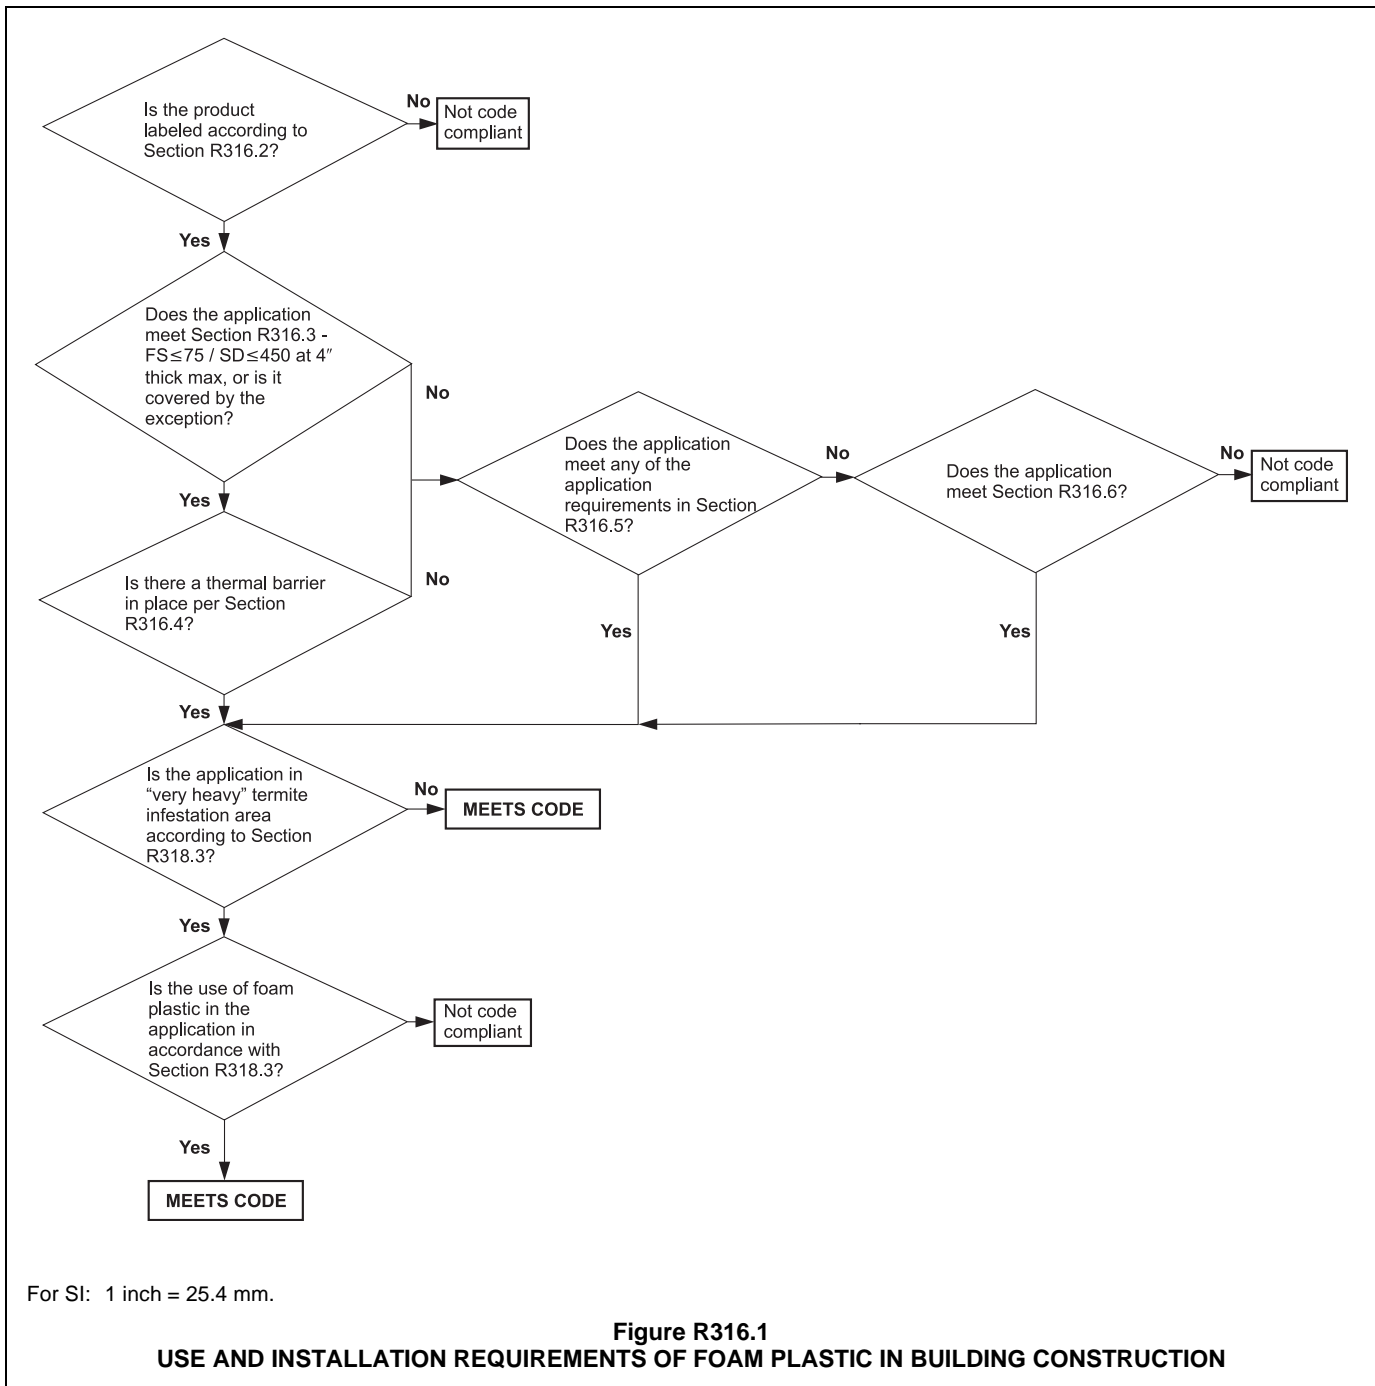

Section R316.1 lists the two basic issues that serve as the basis for foam plastic insulation requirements: the flame spread rating of the material and the separation of the foam plastic insulation from the interior of the building.

Commentary Figure R316.1 shows a simple flow-chart to help the code user more easily comply with the foam plastics sections of the code.

R316.2 Labeling and identification. Packages and containers of foam plastic insulation and foam plastic insulation components delivered to the job site shall bear the *label* of an *approved agency* showing the manufacturer’s name, the prod-

uct listing, product identification and information sufficient to determine that the end use will comply with the requirements.

- ❖ Foam plastics or packages of foam plastics delivered to the construction site must be labeled. Also, labels are required on containers [usually two components in 55-gallon (208 L) drums] of ingredients delivered for the production of foam plastic at the construction site. The label must include the name of the manufacturer or distributor, the type of foam plastic, the performance characteristics required to show code compliance and the name of the approved testing agency. The label may reference documents, such as ICC-ES reports,

approval agency certificates and other information, that can be used to determine code-required performance characteristics. [Note, although not required by the code, the Federal Trade Commission (FTC) also places specific labeling requirements regarding the insulation power or *R*-value on all insulations, including foam plastic insulation, used in residential applications.]

R316.3 Surface burning characteristics. Unless otherwise allowed in Section R316.5, foam plastic or foam plastic cores used as a component in manufactured assemblies used in building construction shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 when tested in the maximum thickness and density intended for use in accordance with ASTM E84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

Exception: Foam plastic insulation more than 4 inches (102 mm) thick shall have a flame spread index of not more than 75 and a smoke-developed index of not more than 450 where tested at a thickness of not more than 4 inches (102 mm), provided that the end use is *approved* in accordance with Section R316.6 using the thickness and density intended for use.

❖ Unless otherwise allowed in Section R316.5 or R316.6, foam plastic or foam plastic cores used as a component in manufactured assemblies used in building construction must have a flame spread index of not more than 75 and a smoke-developed index of not more than 450 when tested in the maximum thickness and density intended for use in accordance with ASTM E84 or UL 723. Loose-fill-type foam plastic insulation must be tested as board stock for the flame spread index and smoke-developed index.

Foam plastic insulation or foam plastic cores used as a component in a manufactured assembly are combustible and must be assessed for flame spread (FS) and smoke-developed indexes. Foam plastic materials must be tested in accordance with test method ASTM E84 or UL 723, unless they are:

1. Specifically exempted in accordance with Section R316.3;
2. One of several applications listed in Section R316.5 (i.e., roofing, foam-filled exterior doors, foam, filled garage doors, interior trim, interior finish); or
3. Tested in an application that has been approved through Section R316.6 (testing under actual end-use configurations).

When testing in accordance with ASTM E84 or UL 723 is required, the materials must be tested in the maximum thickness and density to be used [up to 4-inch (102 mm) thickness] with flame spread index results less than 75 and smoke-developed index results less than 450 SD, unless otherwise specified. If thicker foam is going to be used, it must still be

tested to ASTM E84 or UL 723 at 4-inch (102 mm) thickness with flame spread index results less than 75 and smoke-developed index results less than 450 results, as well as testing in accordance with Section R316.6 that is done at the actual foam thickness and density. If the material is loose-fill-type foam plastic, it must be tested as board stock for flame spread and smoke-development performances.

The maximum flame spread value of 75 was chosen on the basis that it was lower than untreated wood (which usually was 100 to 165). The maximum smoke-developed rating of 450 was selected because, at the time, the code permitted interior finish materials that gave off “smoke no more dense than that given off by untreated wood.” In selecting the maximum flame spread and smoke developed values, it was believed that a conservative approach was being taken by requiring an insulation material to meet the same requirements as interior finish, even though the insulation was intended to be covered with an interior finish material. The requirements for surface-burning characteristics of foam plastic apply to foam plastics used as cores of manufactured assemblies. The intent is that, even though the finished assemblies might or might not require testing for surface-burning characteristics, the foam plastic core is not exempt from the general requirement; therefore, foam plastic is regulated in factory-manufactured assemblies the same as it is in field-fabricated applications.

R316.4 Thermal barrier. Unless otherwise allowed in Section R316.5, foam plastic shall be separated from the interior of a building by an *approved* thermal barrier of not less than $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard, $\frac{23}{32}$ -inch (18.2 mm) wood structural panel or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

❖ The use of an approved thermal barrier to separate foam plastics from the interior of a building is a basic requirement for the use of foam plastic as shown in this section of the code. The job of a thermal barrier is to isolate the foam plastic. An approved thermal barrier is defined as minimum $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard, $\frac{23}{32}$ -inch (18.2 mm) wood structural panel or a material tested to NFPA 275. Before 1975, experience had shown that foam plastics covered with plaster or $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard had performed satisfactorily in building fires. For this reason, $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard was included in the code as a minimum requirement. It is recognized that specifying a single material is not desirable in a performance code; therefore, a material tested to NFPA 275 is permitted.

This section sets forth the test methods and performance criteria by which alternative thermal barriers are to be qualified. NFPA 275 *Standard Method of Fire Tests for the Evaluation of Thermal Barriers Used Over Foam Plastic Insulation* was developed to specifically address the testing of materials to qualify as a

thermal barrier. The test method provides specific sample construction, fire exposures and acceptance criteria to qualify a material to be a 15-minute thermal barrier. The test methods address both the capability of the material to retard heat transfer via a fire-resistance test and to remain in place via a full-scale fire test.

Sections R316.5 and R316.6 describe circumstances where the requirement for a thermal barrier is modified or eliminated.

R316.5 Specific requirements. The following requirements shall apply to these uses of foam plastic unless specifically *approved* in accordance with Section R316.6 or by other sections of the code or the requirements of Sections R316.2 through R316.4 have been met.

❖ This prescriptive section can be used as another path to code compliance for foam plastics. As the flowchart in the commentary to Section R316.1 points out, if an application, including any listed below, meets the requirements in Sections R316.2, R316.3, R316.4 and R316.7, or Sections R316.2, R316.6 and R316.7, that application is code compliant and the requirements spelled out below do not apply. It is only when the requirements of Section R316.3 or R316.4 are not met that the applications spelled out below can be used to show code compliance. Many of the applications below modify or remove the flame spread and smoke-developed requirements of Section R316.3 or modify or remove the need for the thermal barrier specified in Section R316.4.

Two applications that have caused confusion in the past are foam backer board and foam insulation used in residential applications. These two applications, by definition, are examples of foam plastic insulation used on the exterior of a wall assembly. If the foam plastic being used meets the requirements of Section R316.3 (requiring a flame spread index less than 75 and a smoke-developed index less than 450) and Section R316.4 [thermal barrier of 1/2-inch (12.7 mm) gypsum board or an equivalent on the interior of the wall], the foam plastic insulation can be used up to the allowed

thickness of 4 inches (102 mm), and Sections R316.5.7 and R316.5.8 do not apply.

R316.5.1 Masonry or concrete construction. The thermal barrier specified in Section R316.4 is not required in a masonry or concrete wall, floor or roof when the foam plastic insulation is separated from the interior of the building by not less than a 1-inch (25 mm) thickness of masonry or concrete.

❖ No thermal barrier is required when 1 inch (25 mm) or more of masonry or concrete is placed between the foam plastic and the interior of the building. The intent is to accept 1-inch (25 mm) of masonry or concrete as adequate protection against ignition, even though the concrete does not necessarily meet the performance criteria for thermal barriers. This condition can arise when foam plastics are installed either within a wall or on one side of a wall. Some common examples are when foam plastics are installed:

- In the cavity of a hollow masonry wall,
- As the core of a concrete-faced panel,
- On the exterior face of a masonry wall and covered with an exterior finish, or
- Within the cores of hollow masonry units.
- Encapsulated within a minimum of 1 inch (25 mm) concrete or masonry wall, floor or roof system, as in insulated tilt-up or pour-in-place concrete panels (see Commentary Figure R316.5.1).

R316.5.2 Roofing. The thermal barrier specified in Section R316.4 is not required where the foam plastic in a roof assembly or under a roof covering is installed in accordance with the code and the manufacturer’s instructions and is separated from the interior of the building by tongue-and-groove wood planks or wood structural panel sheathing, in accordance with Section R803, that is not less than 15/32 inch (11.9 mm) thick bonded with exterior glue, identified as Exposure 1 and with edges supported by blocking or tongue-and-groove joints or an equivalent material. The smoke-developed index for roof applications shall not be limited.

❖ No thermal barrier is required when a foam plastic is incorporated into a roof assembly on the exterior side,

Figure R316.5.1
ENCAPSULATED FOAM PLASTIC

over tongue-and-groove wood planks or wood structural panel sheathing, if the wood product meets all of the following:

- Used in accordance with Section R803,
- Identified as Exposure 1,
- Manufactured with exterior grade glue,
- Minimum $1\frac{5}{32}$ inch thick (12 mm),
- Installed according to manufacturer's instructions and
- Installed to provide adequate edge support (blocking when edges do not occur over framing members, tongue-and-groove joints or equivalent).

Also, the flame spread rating of the foam plastic used must comply with the requirements of Section R316.3, but the smoke-developed rating of the foam plastic is not limited.

R316.5.3 Attics. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. Attic access is required by Section R807.1.
2. The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation has been tested in accordance with Section R316.6 or the foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. $1\frac{1}{2}$ -inch-thick (38 mm) mineral fiber insulation.
 - 3.2. $\frac{1}{4}$ -inch-thick (6.4 mm) wood structural panels.
 - 3.3. $\frac{3}{8}$ -inch (9.5 mm) particleboard.
 - 3.4. $\frac{1}{4}$ -inch (6.4 mm) hardboard.

- 3.5. $\frac{3}{8}$ -inch (9.5 mm) gypsum board.
- 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm).
- 3.7. $1\frac{1}{2}$ -inch-thick (38 mm) cellulose insulation; or
- 3.8. $\frac{1}{4}$ -inch (6.4 mm) fiber-cement panel, soffit or backer board.

The ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

❖ In an attic where access is required by Section R807.1 [where attic areas exceed 30 square feet (2.8 m²) and have a vertical height of 30 inches (762 mm) or more], and entry is only for service of utilities, foam plastics are not required to be provided with the thermal barrier required by Section R316.4 where (a) the foam plastic has been tested in accordance with Section R316.6, or (b) where an ignition barrier is used in place of a thermal barrier to cover the foam plastic. Multiple materials are listed that can be used as the ignition barrier (see Commentary Figure R316.5.3). The foam plastic material, covered with the ignition barrier can be on the floor, wall (often called a knee wall or gable end) or the ceiling of the attic. The phrase "purposes of repairs and maintenance" applies to attics that contain only mechanical equipment, electrical wiring, fans, plumbing, gas or electric hot water heaters, gas or electric furnaces, etc. The attic space cannot be used for storage. The reduced provision (from a thermal barrier to an ignition barrier) provides a barrier whose only purpose is to prevent the direct impingement of flame on the foam plastic insulation.

R316.5.4 Crawl spaces. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. Crawl space access is required by Section R408.4.

2. Entry is made only for purposes of repairs or maintenance.
3. The foam plastic insulation has been tested in accordance with Section R316.6 or the foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1½-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. ¼-inch-thick (6.4 mm) wood structural panels;
 - 3.3. ⅜-inch (9.5 mm) particleboard;
 - 3.4. ¼-inch (6.4 mm) hardboard;
 - 3.5. ⅜-inch (9.5 mm) gypsum board; or
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm).

❖ In a crawl space where access is required by Section R408.4 (access must be provided to all under-floor spaces) and entry is only for service of utilities, foam plastics are not required to be provided with the thermal barrier required by Section R316.4 where (a) the foam plastic has been tested in accordance with Section R316.6, or (b) where an ignition barrier is used in place of a thermal barrier to cover the foam plastic. Multiple materials are listed that can be used as the ignition barrier (see Commentary Figure R316.5.3). The foam plastic material, covered with the ignition barrier can be on the floor, wall or ceiling of the crawl space. The phrase “purposes of repairs or maintenance” applies to crawl spaces that contain only mechanical equipment, electrical wiring, fans, plumbing, gas, or electric hot water heaters, gas or electric furnaces, etc. The crawl space cannot be used for storage. The reduced requirement (from a thermal barrier to an ignition barrier) provides a barrier whose only purpose is to prevent the direct impingement of flame on the foam plastic.

R316.5.5 Foam-filled exterior doors. Foam-filled exterior doors are exempt from the requirements of Sections R316.3 and R316.4.

❖ No thermal barrier (see Section R316.4) or surface-burning characteristics testing (see Section R316.3) is required for foam-filled exterior doors.

R316.5.6 Foam-filled garage doors. Foam-filled garage doors in attached or detached garages are exempt from the requirements of Sections R316.3 and R316.4.

❖ No thermal barrier (see Section R316.4) or surface-burning characteristics testing (see Section R316.3) is required for foam-filled garage doors in either an attached or detached garage.

R316.5.7 Foam backer board. The thermal barrier specified in Section R316.4 is not required where siding backer board foam plastic insulation has a thickness of not more than 0.5 inch (12.7 mm) and a potential heat of not more than 2000

Btu per square foot (22 720 kJ/m²) when tested in accordance with NFPA 259 provided that:

1. The foam plastic insulation is separated from the interior of the building by not less than 2 inches (51 mm) of mineral fiber insulation;
2. The foam plastic insulation is installed over existing *exterior wall* finish in conjunction with re-siding; or
3. The foam plastic insulation has been tested in accordance with Section R316.6.

❖ The code contains a definition for “Foam backer board” (see Section R202). If these siding products are used on the exterior of a wall and the requirements of Sections R316.3 and R316.4 are met, this section of the code does not apply. If a thermal barrier is not used on the interior of the building, limitations are placed on the product and its use. In addition to the flame spread limitations of Section R316.3, other properties of the foam plastic portion of the product include maximum thickness of ½ inch (12.7 mm) and potential heat of no more than 2000 British thermal units (Btu) per square foot (22 720 kJ/m²) when tested using NFPA 259. Limitation in siding/foam combination product use includes separation from the interior of the building by no less than 2 inches (51 mm) of mineral fiber insulation or installation over an existing wall finish as part of residing or the foam plastic insulation is tested in accordance with Section R316.6. The removal of the thermal barrier requirement in this section is reasonable considering the separation provided by the existing construction and the limitation of the potential heat of the foam plastic imposed by the code.

R316.5.8 Re-siding. The thermal barrier specified in Section R316.4 is not required where the foam plastic insulation is installed over existing *exterior wall* finish in conjunction with re-siding provided that the foam plastic has a thickness of not more than 0.5 inch (12.7 mm) and a potential heat of not more than 2000 Btu per square foot (22 720 kJ/m²) when tested in accordance with NFPA 259.

❖ Foam plastic is frequently used in residing applications to provide a leveling surface for new siding, while also bringing additional insulation value to the wall assembly. If these products are used in a wall assembly and the requirements of Sections R316.3 and R316.4 are met, this section of the code does not apply. If a thermal barrier is not used between the foam plastic and the interior of the building, the foam insulation must meet the flame spread requirements of Section R316.3, is limited to a maximum thickness of ½ inch (12.7 mm) and potential heat of not less than 2,000 Btu per square foot (22 720 kJ/m²) when tested using NFPA 259. The removal of the thermal barrier requirement in this section is reasonable considering the separation provided by the existing construction and the limitation of the potential heat of the foam plastic imposed by the code.

R316.5.9 Interior trim. The thermal barrier specified in Section R316.4 is not required for exposed foam plastic interior trim, provided that all of the following are met:

1. The density is not less than 20 pounds per cubic foot (320 kg/m³).
2. The thickness of the trim is not more than 0.5 inch (12.7 mm) and the width is not more than 8 inches (204 mm).
3. The interior trim shall not constitute more than 10 percent of the aggregate wall and ceiling area of any room or space.
4. The flame spread index does not exceed 75 when tested per ASTM E84 or UL 723. The smoke-developed index is not limited.

❖ Foam plastic interior trim is defined in Section R202 as exposed foam plastic used as picture molds, chair rails, crown moldings, baseboards, handrails, ceiling beams, door trim and window trim, and similar decorative or protective materials.

Foam plastic interior trim must be provided with a thermal barrier (which would effectively prevent its actual use as interior trim) unless it complies with all four items listed in this section.

Item 1: The density of materials must be at least 20 pounds per cubic foot (pcf) (320 kg/m³). The intent was to separate those materials used for trim from those intended for use as insulation. As a comparison, most foam plastic insulation is in the range of 1 to 2¹/₂ pounds per cubic foot (16.02 to 40 kg/m³) with very few materials over 5 pcf (81 kg/m³).

Item 2: Even though other nonfoam plastic trim materials are not limited in dimension, the maximum thickness and width of foam plastic trim is limited to 1/2 inch (12.7 mm) and 4 inches (12.7 mm and 102 mm), respectively.

Item 3: Foam plastic trim cannot constitute more than 10 percent of the aggregate area of the walls and ceiling of a room.

Item 4: The flame spread index must not be higher than 75 when tested in accordance with ASTM E84 or UL 723. The value of 75 was selected to be consistent with the requirement for foam plastic insulation, even though other materials used as trim are permitted to have flame spread indexes of up to 200 in many locations. The smoke-developed index is not regulated.

R316.5.10 Interior finish. Foam plastics shall be permitted as interior finish where *approved* in accordance with Section R316.6. Foam plastics that are used as an interior finish shall meet the flame spread index and smoke-developed index requirements of Sections R302.9.1 and R302.9.2.

❖ Foam plastic used as interior finish must be approved through Section R316.6. This means that the foam plastic material must be tested in order to eliminate the thermal barrier in accordance with NFPA 286 and the acceptance criteria of Section R302.9.4, FM 4880, UL 723, UL 1040 or UL 1715, or fire tests related to actual end-use configurations (including the foam plastic thickness). The foam plastic must also meet the flame

spread index requirements of Section R302.9 (flame spread index less than 200).

R316.5.11 Sill plates and headers. Foam plastic shall be permitted to be spray applied to sill plates and headers or installed in the perimeter joist space without the thermal barrier specified in Section R316.4 subject to all of the following:

1. The thickness of the foam plastic shall be not more than 3¹/₄ inches (83 mm).
2. The density of the foam plastic shall be in the range of 0.5 to 2.0 pounds per cubic foot (8 to 32 kg/m³).
3. The foam plastic shall have a flame spread index of 25 or less and an accompanying smoke-developed index of 450 or less when tested in accordance with ASTM E84 or UL 723.

❖ No thermal barrier is required when a foam plastic is spray applied to the sill plate and joist header where all of the conditions listed in Section R316.5.11 are met. Because foam plastic insulation in this application is left exposed, the three conditions listed [thickness less than 3¹/₄ inches (82.6 mm), density 0.5 to 2.0 pcf (24 to 32 kg/m³), flame spread index less than 25 and smoke-developed index less than 450] control the spray applied foam plastic used in this application (see Commentary Figure R316.5.11).

Figure R316.5.11
FOAM PLASTIC SPRAY APPLIED
TO SILL PLATE AND HEADER

R316.5.12 Sheathing. Foam plastic insulation used as sheathing shall comply with Section R316.3 and Section R316.4. Where the foam plastic sheathing is exposed to the *attic* space at a gable or kneewall, the provisions of Section R316.5.3 shall apply. Where foam plastic insulation is used as *exterior wall* sheathing on framed wall assemblies, it shall comply with Section R316.8.

❖ Foam plastic used as sheathing is a very common application, adding insulation to the framing of the building. Where used as a sheathing material, foam

plastic sheathing must meet the requirements of Sections R316.3 and R316.4. Often foam plastic sheathing is used on the outside of an exterior wall, continuously covering the wall. Where used on framed wall assemblies, exterior foam plastic sheathing must comply with the wind resistance requirements of Section R316.8.

Consider an example where the living area of the building has a thermal barrier, such as $\frac{1}{2}$ -inch (12.7 mm) gypsum board, in place. That thermal barrier, combined with foam plastic that meets the surface burning requirements of less than 75 for a flame spread index and less than 450 for a smoke developed index, results in a code compliant application.

Where foam plastic sheathing is exposed to the attic space at a gable or knee wall, the foam plastic insulation must meet the requirements of Section R316.5.3. For applications where foam plastic is used as sheathing, code approval follows the same paths outlined in Section R316.1.

If the foam plastic insulation has passed testing, in the thickness and density intended for use, in accordance with Section R316.6, no thermal barrier or ignition barrier is required over the foam plastic insulation and this section of the code does not apply. It is important to note that the actual configuration must be tested, including typical seams, joints and other details that will occur in the finished installation.

R316.5.13 Floors. The thermal barrier specified in Section R316.4 is not required to be installed on the walking surface of a structural floor system that contains foam plastic insulation when the foam plastic is covered by not more than a nominal $\frac{1}{2}$ -inch-thick (12.7 mm) wood structural panel or equivalent. The thermal barrier specified in Section R316.4 is required on the underside of the structural floor system that contains foam plastic insulation when the underside of the structural floor system is exposed to the interior of the building.

❖ In today's construction, new types of products are being used that incorporate foam plastic insulation for energy reasons. One example is structural insulated panels where foam plastic is laminated between two structural wood facings. This type of panel can be used as a wall, floor or roof. Foam plastic is required to be protected by a thermal barrier which typically is $\frac{1}{2}$ -inch (12.7 mm) gypsum wallboard. In the case of flooring, gypsum wallboard or other common thermal barrier materials cannot be used on the walking surfaces due to their friability, etc. Section R316.5.13 addresses this problem. The requirement for the $\frac{1}{2}$ -inch-thick (12.7 mm) plywood or equivalent will provide sufficient protection to the foam plastic insulation. While $\frac{1}{2}$ -inch (12.7 mm) plywood is not by itself a thermal barrier, in the case of a floor, it will provide sufficient protection since in the event of an interior fire, the floor is typically the last building element to be significantly exposed by the fire. If the foam plastic on the underside of the floor system is exposed to the interior of the building, then the foam plastic on the underside of the floor system must be covered by the required thermal barrier

R316.6 Specific approval. Foam plastic not meeting the requirements of Sections R316.3 through R316.5 shall be specifically *approved* on the basis of one of the following *approved* tests: NFPA 286 with the acceptance criteria of Section R302.9.4, FM 4880, UL 1040 or UL 1715, or fire tests related to actual end-use configurations. Approval shall be based on the actual end-use configuration and shall be performed on the finished foam plastic assembly in the maximum thickness intended for use. Assemblies tested shall include seams, joints and other typical details used in the installation of the assembly and shall be tested in the manner intended for use.

❖ Foam plastic does not have to comply with the installation and use requirements of Sections R316.3 through R316.5 where specific approval is obtained in accordance with this section. This section lists examples of specific large-scale tests, such as FM 4880, NFPA 286, UL 1040 or UL 1715. Also, other large-scale fire tests related to actual end-use configuration can be used. The intent is to require testing based on the proposed end-use configuration of the foam plastic assembly with a fire exposure that is appropriate in size and location for the proposed application. These tests must be performed on full-scale assemblies. The tested assemblies must include typical seams, joints and other details that will occur in the finished installation. The foam plastic must be tested in the maximum thickness and density intended for use. Thorough testing provides an accurate depiction of the in-place fire performance of assemblies and systems using foam plastics.

There are two ways to show code compliance under Section R316.6. One method is to provide the actual test report that contains a description of the assembly and test results showing that the foam plastic, in the end use application, has passed the test. The second method is to obtain, from the ICC-ES, an evaluation report that covers the end-use application.

R316.7 Termite damage. The use of foam plastics in areas of "very heavy" termite infestation probability shall be in accordance with Section R318.4.

❖ This section of the code refers to Section R318.4 that addresses the use of foam plastics in areas of "very heavy" termite infestation probability. When the structure is built in an area defined as "very heavy" termite infestation, Section R318.4 prohibits the use of foam plastics installed on the exterior face of below grade foundations walls or slab foundations, under exterior or interior foundation walls or slab foundations below-grade or where located within 6 inches (152 mm) of exposed earth. Section R318.4 states three exceptions where foam plastics are permitted:

1. Where the structural members of the building are either noncombustible or pressure-preservative-treated wood;
2. Where, in addition to the requirements of Section R318.1, the foam plastic is adequately protected from subterranean termite damage; or
3. On the interior side of basement walls.

R316.8 Wind resistance. Foam plastic insulation complying with ASTM C578 and ASTM C1289 and used as *exterior wall* sheathing on framed wall assemblies shall comply with SBCA FS 100 for wind pressure resistance unless installed directly over a sheathing material that is separately capable of resisting the wind load or otherwise exempted from the scope of SBCA FS 100.

- ❖ Foam plastic insulation sheathing that complies with ASTM C578 and C1289, is used as exterior wall sheathing on framed wall assemblies and is intended to resist wind pressure must comply with SBCA FS 100. This standard provides a methodology by which a manufacturer can qualify their product, through testing, to meet the requirements of the *International Codes*® (I-Codes®) in establishing the wind pressure resistance of the product. It also provides for on-going quality control procedures to ensure that the product continues to meet its qualified wind pressure resistance.

SECTION R317 PROTECTION OF WOOD AND WOOD-BASED PRODUCTS AGAINST DECAY

R317.1 Location required. Protection of wood and wood-based products from decay shall be provided in the following locations by the use of naturally durable wood or wood that is preservative-treated in accordance with AWP A U1 for the species, product, preservative and end use. Preservatives shall be listed in Section 4 of AWP A U1.

1. Wood joists or the bottom of a wood structural floor when closer than 18 inches (457 mm) or wood girders when closer than 12 inches (305 mm) to the exposed ground in crawl spaces or unexcavated area located within the periphery of the building foundation.
2. Wood framing members that rest on concrete or masonry exterior foundation walls and are less than 8 inches (203 mm) from the exposed ground.
3. Sills and sleepers on a concrete or masonry slab that is in direct contact with the ground unless separated from such slab by an impervious moisture barrier.
4. The ends of wood girders entering exterior masonry or concrete walls having clearances of less than $\frac{1}{2}$ inch (12.7 mm) on tops, sides and ends.
5. Wood siding, sheathing and wall framing on the exterior of a building having a clearance of less than 6 inches (152 mm) from the ground or less than 2 inches (51 mm) measured vertically from concrete steps, porch slabs, patio slabs and similar horizontal surfaces exposed to the weather.
6. Wood structural members supporting moisture-permeable floors or roofs that are exposed to the weather, such as concrete or masonry slabs, unless separated from such floors or roofs by an impervious moisture barrier.
7. Wood furring strips or other wood framing members attached directly to the interior of exterior masonry walls or concrete walls below *grade* except where an *approved* vapor retarder is applied between the wall and the furring strips or framing members.

- ❖ This section addresses the need for minimum protection against decay damage for wood members located in certain locations.

For those portions of a wood-framed structure that are subject to damage by decay, the code mandates that the lumber be pressure-preservative treated or be naturally durable wood, or be of a species of wood having a natural resistance to decay. Naturally durable wood by definition is the heartwood of decay-resistant redwood, cedars, black locust and black walnut.

Item 1: Crawl spaces and unexcavated areas under a building usually contain moisture-laden air. These spaces must be ventilated in accordance with Section R408 to remove as much moisture as possible before it causes decay. Wood placed a minimum specified distance above grade in unexcavated under-floor areas or crawl spaces, as shown in Commentary Figure R317.1(1), need not be either preservative-treated wood or wood that is naturally decay-resistant durable wood. These clearances below floor joists and beams are deemed to be the minimum necessary to allow adequate circulation and removal of moisture from the air and from the wood framing members. Such clearances apply within the exterior wall line of the building foundation.

Item 2: Foundation walls will absorb moisture from the ground and by capillary action move it to framing members that are in contact with the foundation. Unless a minimum clearance of 8 inches (203 mm) is maintained from the finished grade to wood sills resting on concrete or masonry exterior foundation walls, decay-resistant or preservative-treated wood, as shown in Commentary Figure R317.1(2), must be used. The 8-inch (203 mm) clearance specified in this section has been determined to be large enough to prevent wetting of wood framing members under most circumstances.

Item 3: Concrete and masonry slabs that are in direct contact with the earth are very susceptible to moisture because of absorption of ground water. This can occur on interior slabs, as well as at the perimeter. In the case of wood sills or sleepers placed on concrete or masonry slabs, decay-resistant wood or pressure-treated wood is required where the slabs are in direct contact with the ground, as illustrated in Commentary Figure R317.1(3). Concrete that is fully separated from the ground by a vapor barrier is not in direct contact with earth.

Item 4: A minimum $\frac{1}{2}$ -inch (12.7 mm) clearance along the top, sides and ends of wood members projecting into exterior masonry or concrete walls must be maintained, as illustrated in Commentary Figure R317.1(4), unless the wood is treated or is of a species that is naturally decay resistant.

Item 5: Experience has shown that wood siding may extend below the sill plate to within 6 inches (152 mm) of the earth without decaying. Commentary Figure R317.1(5) shows the required minimum 6-inch (152 mm) clearance from the ground for wood siding,

sheathing and wall framing on the exterior of a building. It should not be in direct contact with the foundation wall. If the sheathing is located over a concrete step or slab, the clearance may be reduced to 2 inches (51 mm) minimum.

Item 6: Concrete or masonry slabs that serve as roofs or floor systems that are exposed to the weather are very susceptible to moisture from rain or snow. If these slabs are supported by wood, the wood must be decay resistant or must be separated from the slabs by vapor barriers so there is not direct contact. This is similar to Item 3.

Item 7: When a basement area is finished, a common practice is to provide wood furring strips on top of the concrete or masonry walls for attachment of finishes. These furring strips must either be of decay-resistant material or must be separated from the wall by a vapor barrier. This will prevent the moisture from moving through the walls and rotting the furring strips, and even possibly transferring the moisture to the inside finish materials.

R317.1.1 Field treatment. Field-cut ends, notches and drilled holes of preservative-treated wood shall be treated in the field in accordance with AWPA M4.

❖ The requirement for field treatment of cuts and holes is duplicated from Section R318.1.2, which addresses the same type of situation in treated wood applications for termite protection. Where pressure-preservative-treated wood is used for protection against decay, any cuts, notches or bored holes done in the field must be retreated. The retreatment methods and materials are to be in accordance with AWPA M4, which regulates the care of preservative-treated wood products.

R317.1.2 Ground contact. All wood in contact with the ground, embedded in concrete in direct contact with the

ground or embedded in concrete exposed to the weather that supports permanent structures intended for human occupancy shall be *approved* pressure-preservative-treated wood suitable for ground contact use, except that untreated wood used entirely below groundwater level or continuously submerged in fresh water shall not be required to be pressure-preservative treated.

❖ Wood members that are designed to be in contact with the ground and wood that is embedded in concrete in direct contact with the ground, or embedded in concrete exposed to the weather must be suitable for ground contact use. This provision applies to all wood members that support permanent structures designed for human occupancy. Untreated wood is permitted only where the wood members will be located below

For SI: 1 inch = 25.4 mm.

Figure R317.1(2)
WOOD SILLS ON FOUNDATION WALLS

For SI: 1 inch = 25.4 mm.

Figure R317.1(1)
MINIMUM SEPARATION OF NONTREATED WOOD FROM GROUND

the ground water level or where the members are continuously submerged in fresh water because fungus that decays wood and termites cannot survive in a water-only environment with no oxygen (see Commentary Figure R317.1.2).

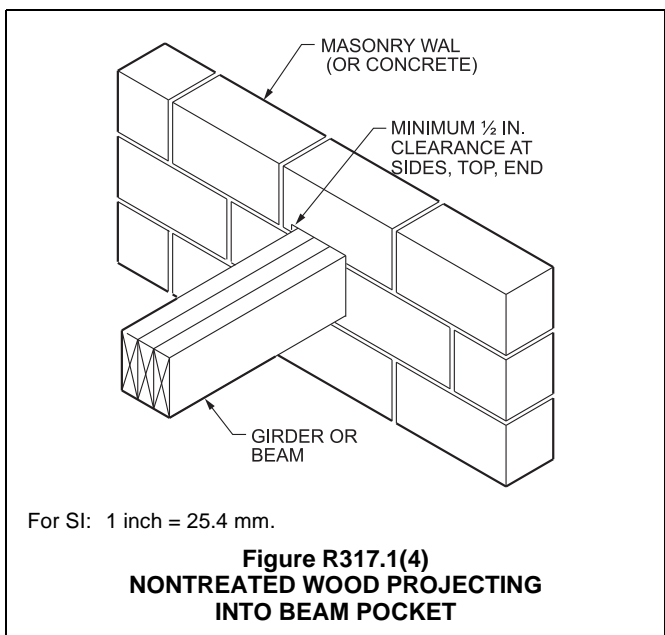

R317.1.3 Geographical areas. In geographical areas where experience has demonstrated a specific need, *approved* naturally durable or pressure-preservative-treated wood shall be used for those portions of wood members that form the structural supports of buildings, balconies, porches or similar permanent building appurtenances when those members are exposed to the weather without adequate protection from a roof, eave, overhang or other covering that would prevent moisture or water accumulation on the surface or at joints between members. Depending on local experience, such members may include:

1. Horizontal members such as girders, joists and decking.
2. Vertical members such as posts, poles and columns.
3. Both horizontal and vertical members.

❖ This section gives the local jurisdiction the authority to require additional protection where the need can be

documented by experience. Such experience may include high water tables, extended high-humidity conditions, etc.

Guidance is provided in this section for the protection of wood members other than those specifically identified elsewhere in this section that are exposed to

the weather without benefit of protective elements. Included in the list of possible wood members that must be pressure-preservative treated or naturally durable wood are girders, joists, decking, columns and similar structural members of porches, balconies and other exterior building elements.

R317.1.4 Wood columns. Wood columns shall be *approved* wood of natural decay resistance or *approved* pressure-preservative-treated wood.

Exceptions:

1. Columns exposed to the weather or in *basements* where supported by concrete piers or metal pedestals projecting 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth and the earth is covered by an *approved* impervious moisture barrier.
 2. Columns in enclosed crawl spaces or unexcavated areas located within the periphery of the building when supported by a concrete pier or metal pedestal at a height more than 8 inches (203 mm) from exposed earth and the earth is covered by an impervious moisture barrier.
 3. Deck posts supported by concrete piers or metal pedestals projecting not less than 1 inch (25 mm) above a concrete floor or 6 inches (152 mm) above exposed earth.
- ❖ Protection against decay is required for wood structural columns. The exceptions permit the use of common framing lumber where the column is isolated from the earth or concrete. Generally, structural elements in basements or cellars are easier to inspect, which explains the lower clearances. Columns in crawl spaces must have a larger separation distance to safeguard against termites between inspections. In Exceptions 1 and 2, an impervious moisture barrier must be installed to ensure the column does not absorb water from the earth or concrete pier. Exception 3 allows deck posts to be of nontreated wood if they are supported on concrete piers or metal pedestals at least 1 inch thick.

R317.1.5 Exposed glued-laminated timbers. The portions of glued-laminated timbers that form the structural supports of a building or other structure and are exposed to weather and not properly protected by a roof, eave or similar covering shall be pressure treated with preservative, or be manufactured from naturally durable or preservative-treated wood.

- ❖ It is common practice to design large glued-laminated arches that are connected to foundations near ground level. Exterior walls are built inside the span of these arches, leaving the initial few feet of the wood arches exposed to the weather. Experience has shown that covering the tops of these arches with metal or other water seals is not sufficient to prevent decay of the timber. Therefore, arches and other exposed wood members not protected by roofs or similar covers must be laminated of naturally durable or preservative-treated wood.

R317.2 Quality mark. Lumber and plywood required to be pressure-preservative treated in accordance with Section R318.1 shall bear the quality *mark* of an *approved* inspection agency that maintains continuing supervision, testing and inspection over the quality of the product and that has been *approved* by an accreditation body that complies with the requirements of the American Lumber Standard Committee treated wood program.

- ❖ The quality of lumber or plywood that has been pressure-preservative treated in accordance with the code is identifiable through a quality mark, such as shown in Commentary Figure R317.2.1. Without the proper identifying mark, it would be impossible to determine in the field that preservative-treated wood conforms to the applicable standards. The identifying mark must be from an approved inspection agency that has continuous follow-up services. Additionally, the inspection agency must be certified as being competent by an approved organization. The required identifying mark is in addition to the requirements for grade marks to identify the species and grade as specified elsewhere in the code.

R317.2.1 Required information. The required quality *mark* on each piece of pressure-preservative-treated lumber or plywood shall contain the following information:

1. Identification of the treating plant.
2. Type of preservative.
3. The minimum preservative retention.
4. End use for which the product was treated.
5. Standard to which the product was treated.
6. Identity of the *approved* inspection agency.
7. The designation “Dry,” if applicable.

Exception: Quality *marks* on lumber less than 1 inch (25 mm) nominal thickness, or lumber less than nominal 1 inch by 5 inches (25 mm by 127 mm) or 2 inches by 4 inches (51 mm by 102 mm) or lumber 36 inches (914 mm) or less in length shall be applied by stamping the faces of exterior pieces or by end labeling not less than 25 percent of the pieces of a bundled unit.

- ❖ This section provides the information that must be shown on a quality mark for pressure-preservative-treated lumber or plywood. Commentary Figure R317.2.1 illustrates how this information may be shown on a quality label.

R317.3 Fasteners and connectors in contact with preservative-treated and fire-retardant-treated wood. Fasteners, including nuts and washers, and connectors in contact with preservative-treated wood and fire-retardant-treated wood shall be in accordance with this section. The coating weights for zinc-coated fasteners shall be in accordance with ASTM A153. Stainless steel driven fasteners shall be in accordance with the material requirements of ASTM F1667.

- ❖ This section provides a charging statement for fasteners utilized in situations where the surroundings or the type of wood could corrode the fasteners over time.

ASTM A153 specifies criteria for hot-dipped zinc coating for iron and steel hardware. ASTM F1667 provides minimum specifications for driven nails, spikes and staples.

R317.3.1 Fasteners for preservative-treated wood. Fasteners, including nuts and washers, for preservative-treated wood shall be of hot-dipped, zinc-coated galvanized steel, stainless steel, silicon bronze or copper. Coating types and weights for connectors in contact with preservative-treated wood shall be in accordance with the connector manufacturer’s recommendations. In the absence of manufacturer’s recommendations, a minimum of ASTM A653 type G185 zinc-coated galvanized steel, or equivalent, shall be used.

Exceptions:

1. 1/2-inch-diameter (12.7 mm) or greater steel bolts.
2. Fasteners other than nails and timber rivets shall be permitted to be of mechanically deposited zinc-coated steel with coating weights in accordance with ASTM B695, Class 55 minimum.
3. Plain carbon steel fasteners in SBX/DOT and zinc borate preservative-treated wood in an interior, dry environment shall be permitted.

❖ Except for large steel bolts, all fasteners used in conjunction with pressure-preservative-treated wood must be corrosion resistant. Some chemicals used to preservative-treat or fire-retardant-treat wood may have a corrosive effect on fasteners installed in locations that are high in moisture. Acceptable materials include stainless steel, silicon bronze, copper or hot-dipped zinc-coated galvanized steel. Such fasteners are also mandated for use with fire-retardant-treated wood members. Use of durable fasteners is required to decrease the likelihood that the load-carrying capacity of fasteners will be reduced by corrosion.

The second exception allows the use of a mechanical galvanization process in which the coating weight is mandatory as outlined in ASTM B695.

The third exception permits the use of nonzinc-

coated galvanized steel where used in a dry environment and in contact with SBX/DOT and zinc borate-treated wood.

R317.3.2 Fastenings for wood foundations. Fastenings, including nuts and washers, for wood foundations shall be as required in AF&PA PWF.

❖ A permanent wood foundation (PWF) system is intended for light-frame construction including residential buildings. The AWC PWF—*Permanent Wood Foundation Design Specification*, primarily addresses the structural design requirements.

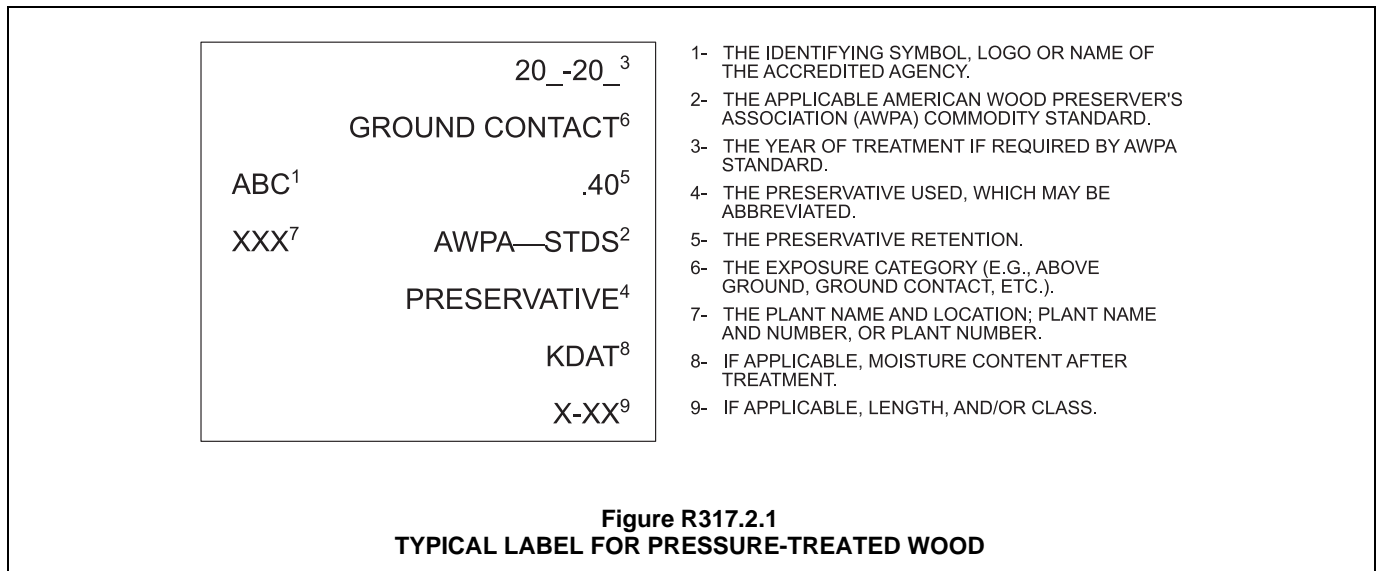

The PWF is a load-bearing wood frame wall and floor system designed for both above- and below-grade use as a foundation for light-frame construction. The PWF specifications are based on information developed cooperatively by the wood products industry and the U.S. Forest Service, with the advice and guidance of the Department of Housing and Urban Development’s (HUD) Federal Housing Administration, and utilizing research findings of the National Association of Home Builders Research Center.

The PWF standard is also referenced in Sections R401.1 and R404.2.3.

R317.3.3 Fasteners for fire-retardant-treated wood used in exterior applications or wet or damp locations.

Fasteners, including nuts and washers, for fire-retardant-treated wood used in exterior applications or wet or damp locations shall be of hot-dipped, zinc-coated galvanized steel, stainless steel, silicon bronze or copper. Fasteners other than nails and timber rivets shall be permitted to be of mechanically deposited zinc-coated steel with coating weights in accordance with ASTM B695, Class 55 minimum.

❖ Sections R317.3.3 and R317.3.4 are intended to recognize the different exposures for fire-retardant-treated wood and the fastener requirements for that exposure. For wet conditions where corrosion may be a concern, this section allows the use of a mechanical galvanization process in which the coating weight is mandatory as outlined in ASTM B695.

R317.3.4 Fasteners for fire-retardant-treated wood used in interior applications. Fasteners, including nuts and washers, for fire-retardant-treated wood used in interior locations shall be in accordance with the manufacturer's recommendations. In the absence of the manufacturer's recommendations, Section R317.3.3 shall apply.

❖ Sections R317.3.3 and R317.3.4 are intended to recognize the different exposures for fire-retardant-treated wood and the fastener requirements for that exposure. The interior exposure for fire-retardant-treated wood is far less severe than the exposure for fire-retardant treated wood in wet, damp or exterior locations. Manufacturers of fire-retardant-treated wood make their recommendations for the appropriate fastener for fire-retardant-treated wood based on testing. If the manufacturer has no recommendations, the more restrictive provisions in Section R317.3.3 are applicable.

R317.4 Plastic composites. Plastic composite exterior deck boards, stair treads, guards and handrails containing wood, cellulosic or other biodegradable materials shall comply with the requirements of Section R507.3.

❖ Plastic composite materials, commonly used in exterior deck boards, guards and handrails, must be rated for appropriate performance criteria. These materials have a widespread acceptance for residential construction, and requiring that wood, cellulosic and other biodegradable materials comply with Section R507.3 will ensure the safe application of these materials in exterior deck systems. The standard referenced in Section R507.3, ASTM D7032, includes performance evaluations, such as flexural tests, ultraviolet resistance tests, freeze-thaw resistance tests, biodeterioration tests, fire performance tests, creep recovery tests, mechanical fastener holding tests and slip resistance tests. The standard also includes considerations of the effects of temperature and moisture, concentrated loads and fire propagation tests.

SECTION R318 PROTECTION AGAINST SUBTERRANEAN TERMITES

R318.1 Subterranean termite control methods. In areas subject to damage from termites as indicated by Table R301.2(1), methods of protection shall be one, or a combination, of the following methods:

1. Chemical termiticide treatment in accordance with Section R318.2.
2. Termite baiting system installed and maintained in accordance with the *label*.
3. Pressure-preservative-treated wood in accordance with the provisions of Section R317.1.
4. Naturally durable termite-resistant wood.
5. Physical barriers in accordance with Section R318.3 and used in locations as specified in Section R317.1.

6. Cold-formed steel framing in accordance with Sections R505.2.1 and R603.2.1.

❖ This section establishes the rules for the protection of structures from damage caused by termites. The methods of protection address not only wood members, but also foam plastic and cold-formed steel materials.

Figure R301.2(6) illustrates those geographical areas where termite damage is probable. In those areas, the structure must be protected from termite damage in an appropriate manner. There are a number of methods permitted by the code to provide the necessary protection against termite damage. The most common method of termite control is soil poisoning. Alternatives include the use of pressure-preservative treated, naturally termite-resistant wood and barriers over perimeter walls. Often a combination of these methods is necessary to establish the required level of protection. The six acceptable methods of protection are broken out to make them easier to read.

R318.1.1 Quality mark. Lumber and plywood required to be pressure-preservative treated in accordance with Section R318.1 shall bear the quality *mark* of an *approved* inspection agency that maintains continuing supervision, testing and inspection over the quality of the product and that has been *approved* by an accreditation body that complies with the requirements of the American Lumber Standard Committee treated wood program.

❖ The required quality mark is similar to what is required for pressure-preservative-treated wood where decay is a concern (see commentary, Section R317.2 and Commentary Figure R317.2.1).

R318.1.2 Field treatment. Field-cut ends, notches and drilled holes of pressure-preservative-treated wood shall be retreated in the field in accordance with AWP A M4.

❖ Where pressure-preservative-treated wood is used for protection against termites, any cuts, notches or bored holes done in the field must be retreated. The retreatment methods and materials are to be in accordance with AWP A M4, which regulates the care of preservative-treated wood products. This same requirement is found in Section R317.1.1 for pressure-preservative-treated wood used to prevent decay.

R318.2 Chemical termiticide treatment. Chemical termiticide treatment shall include soil treatment or field-applied wood treatment. The concentration, rate of application and method of treatment of the chemical termiticide shall be in strict accordance with the termiticide *label*.

❖ This language accurately reflects the current industry terminology in reference to termiticides and it emphasizes the necessity of using chemicals as required by their labels.

Where using a chemical poisoning of the soil for termite control, the chemical's instructions must be followed in detail. Treatment must be consistent with the recommendations of the chemical manufacturer.

R318.3 Barriers. *Approved* physical barriers, such as metal or plastic sheeting or collars specifically designed for termite prevention, shall be installed in a manner to prevent termites from entering the structure. Shields placed on top of an exterior foundation wall are permitted to be used only if in combination with another method of protection.

❖ This section specifically lists several specific types of termite barriers. In addition, the proper use of a termite shield is addressed. Historically, termite shields were assumed to be effective in preventing termite penetration. However, the term “shield” is actually somewhat of a misnomer because they do not stop termites and were originally designed to make inspection and observation easier.

R318.4 Foam plastic protection. In areas where the probability of termite infestation is “very heavy” as indicated in Figure R301.2(6), extruded and expanded polystyrene, polyisocyanurate and other foam plastics shall not be installed on the exterior face or under interior or exterior foundation walls or slab foundations located below *grade*. The clearance between foam plastics installed above *grade* and exposed earth shall be not less than 6 inches (152 mm).

Exceptions:

1. Buildings where the structural members of walls, floors, ceilings and roofs are entirely of noncombustible materials or pressure-preservative-treated wood.
 2. Where in *addition* to the requirements of Section R318.1, an *approved* method of protecting the foam plastic and structure from subterranean termite damage is used.
 3. On the interior side of *basement walls*.
- ❖ In those geographical areas where there is a very high risk of termite infestation, the code prohibits the use of foam plastic materials below or adjacent to ground level. This prohibition includes foam plastics installed on the exterior face of foundation walls or slab foundations, under exterior or interior foundation walls or slab foundations below grade or where located within 6 inches (152 mm) of exposed earth. Foam plastics are permitted where they are adequately protected or where the structural members are either noncombustible or of pressure-preservative-treated wood.

**SECTION R319
SITE ADDRESS**

R319.1 Address identification. Buildings shall be provided with *approved* address identification. The address identification shall be legible and placed in a position that is visible from the street or road fronting the property. Address identification characters shall contrast with their background. Address numbers shall be Arabic numbers or alphabetical letters. Numbers shall not be spelled out. Each character shall be not less than 4 inches (102 mm) in height with a stroke width of not less than 0.5 inch (12.7 mm). Where required by the fire code official, address identification shall be provided in

additional *approved* locations to facilitate emergency response. Where access is by means of a private road and the building address cannot be viewed from the public way, a monument, pole or other sign or means shall be used to identify the structure. Address identification shall be maintained.

❖ The address requirements are consistent with the IBC, IFB and the code. The code requires buildings to have plainly visible and legible address numbers posted on the building or in such a place on the property that the building may be identified by emergency services, such as fire, medical and police. The primary concern is that emergency forces should be able to locate the building without going through a lengthy search procedure. In furthering the concept, the code states that the approved street numbers must be placed in a location readily visible from the street or roadway fronting the property if a sign on the building would not be visible from the street. Address posting on a mailbox is not adequate for emergency responders when they are grouped or placed across the street from the dwelling. This section also gives the fire code official the authority to require address identification in other locations to facilitate emergency response.

**SECTION R320
ACCESSIBILITY**

R320.1 Scope. Where there are four or more *dwelling units* or sleeping units in a single structure, the provisions of Chapter 11 of the *International Building Code* for Group R-3 shall apply.

❖ Several editions of the IBC have been certified by HUD as a safe harbor document for complying with the accessibility provisions in the Fair Housing Act (FHA). Safe harbor means that the requirements in the IBC and ICC A117.1 meet or exceed the accessibility construction requirements in the Fair Housing Accessibility Guidelines (FHAG). Since FHA requirements start when four units are constructed together, detached one-, two- and three-family homes are not required to comply with the IBC for accessibility requirements. However, town-houses and congregate residences are covered in Chapter 11 of the IBC. Such facilities should use the requirements in the IBC for Group R-3 occupancies to identify which units and facilities have accessibility requirements.

The scope of this code (see Section R101.2) includes some small group homes, live/work units and bed-and-breakfast hotels or lodging houses that are owner occupied and have not more than five guestrooms. IRC Section R320.1.1 requires dwelling units that contain guestrooms to comply with Chapter 11 of the IBC for Group R-3. For the purpose of applying the IBC provisions, guestrooms are to be considered as sleeping rooms. The exception to Section R320.1.1 exempts owner-occupied lodging houses from accessibility requirements where they have not more than five guestrooms and they are constructed in accordance with the IRC. Note that Exception 2 of Section

R101.2 requires that such lodging houses be sprinkled in accordance with Section P2904.

“Guestrooms” and “Lodging houses” are defined in Section R202. A guestroom is a room that is intended to be used for living or sleeping purposes by one or more guests. A lodging house is a one-family dwelling where at least one occupant is primarily permanent in nature, and rent is paid for.

Sleeping units are not defined in the IRC, except as they apply to energy provisions, but they are relevant to Fair Housing/Type B unit requirements. While some may not prefer to define sleeping rooms in group homes as guestrooms, with the current language, that is the best fit.

Section 1103.2.3 of the IBC reinforces the detached home exception by specifying that detached one- and two-family dwellings, their accessory structures and their associated sites and facilities need not be accessible.

Section 1007.6.3 of the IBC requires that, for Group R-3 with four or more dwelling or sleeping units in a single structure, every unit must meet Type B unit requirements. Notice the use of the term “structure” rather than “building.” To determine the number of units in a single structure, the FHA considers all the units built under the same roof. The FHA does not recognize separating units with fire walls to create separate buildings. Neither are legal property lines considered to create separate buildings. All dwelling units built in a single structure are counted together. Bedrooms in congregate living facilities must be considered and counted as sleeping units for the purpose of determining the number of units. If a structure or individual unit has elevator service (passenger elevators, limited use/limited access (LULA) elevators or private residence elevators), the units served by the elevator must comply with the Type B accessibility requirements in Section 1004 of ICC A117.1.

Sections 1107.7 through 1107.7.5 of the IBC provide for a series of exceptions for Type B units. Section 1107.7.2 is an exception for multiple-story units without elevator service which would basically exempt most multiple-story townhouses. Since “multiple-story” is defined in Section R202 as having living space on two or more levels, single-story townhouses with finished basements and two- and three-story townhouses would be exempted from complying with Type B unit requirements. In congregate residences without elevators, the grade level must contain at least one sleeping unit, and all shared spaces must meet Type B unit requirements. Section 1107.7.4 of the IBC exempts some structures in very hilly sites. Section 1107.7.5 of the IBC has allowances for homes constructed in areas with requirements for raised floor elevations due to flood concerns.

When there are units that must comply with Type B requirements, there are also provisions for the parking, building entrances and the site, including any recreational facilities. See the commentary to Chapter 11

and Section 1107 of the IBC for additional history and information on these requirements.

R320.1.1 Guestrooms. A *dwelling* with guestrooms shall comply with the provisions of Chapter 11 of the *International Building Code* for Group R-3. For the purpose of applying the requirements of Chapter 11 of the *International Building Code*, guestrooms shall be considered to be sleeping units.

Exception: Owner-occupied lodging houses with five or fewer guestrooms constructed in accordance with the *International Residential Code* are not required to be accessible.

❖ “Lodging house” and “Guestroom” are defined in Chapter 2. Lodging houses that are both owner occupied and have five or fewer rooms to rent are scoped to the IBC in Section 101.2 Exception 2. Consistent with Section 1103.2.11 of the IBC, these small bed-and-breakfast-type hotels are not required to be accessible.

SECTION R321 ELEVATORS AND PLATFORM LIFTS

R321.1 Elevators. Where provided, passenger elevators, limited-use and limited-application elevators or private residence elevators shall comply with ASME A17.1/CSA B44.

❖ ASME A17.1 is the safety code for elevators. All three types of elevators listed in this section are considered “passenger elevators.” The vertical travel of the elevator car and which types can be used for public or private use is part of the ASME A17.1 safety requirements. Part V applies to elevators installed in or at a private residence. This part also applies to similar elevators installed in buildings as a means of access to private residences within such buildings if the elevators are installed so that they are not available to the general public or to other occupants of the building. All three types of elevators can serve as part of a required accessible route as they also comply with ICC A117.1 (see Section R320).

R321.2 Platform lifts. Where provided, platform lifts shall comply with ASME A18.1.

❖ The previous technical standard (i.e., ASME A17.1) required key operation to platform lifts, which necessarily inhibits independent access by persons with physical disabilities. The requirements for platform lifts have been removed from the platform standard and now have their own standard, ASME 18.1, *Safety Standard for Platform Lifts and Stairway Chair Lifts*, which is referenced in this section.

A platform lift is an electrically operated mechanical device designed to transport a person who cannot use stairs over a short vertical distance. Platform lifts must be sized to accommodate a wheelchair user. Platform lifts can be used by wheelchair users and persons with limited mobility and are sometimes also equipped with folding seats. A fold-down seat that moves up the stairway is not a platform lift. While a stairway chair lift can

be installed within a dwelling unit, it cannot serve as part of a required accessible route (see Section R320). A platform lift is most suitable for changes of elevation of one story or less where the installation of a ramp or elevator is not feasible. The maximum rise for a platform lift is 14 feet.

There are two kinds of platform lifts: vertical lifts and inclined lifts. Vertical lifts are similar to elevators in that they travel only up and down in a fixed vertical space. Inclined platform lifts are usually installed in conjunction with a stairway and travel along the slope of the stairway. Inclined lifts are a design consideration for long flights of stairs where a vertical platform lift is not practical, where headroom is limited or where ceilings are low.

R321.3 Accessibility. Elevators or platform lifts that are part of an accessible route required by Chapter 11 of the *International Building Code*, shall comply with ICC A117.1.

- ❖ Section 1107 of the IBC includes scoping requirements for three levels of accessibility: Accessible units, Type A units and Type B units. The types of facilities can include dwelling units or congregate residences constructed under the code. Accessible routes may also be required to public or common areas on a site, including recreational facilities, such as a pool or community building in a townhouse complex. Also see Section R320.1. This section requires that all elevators or platform lifts on an accessible route be useable by a person in a wheelchair without assistance. ICC A117.1 provides technical data on elevator and platform lift size, operation and controls. LULA elevators and private residence elevators are considered a type of passenger elevator that can serve as part of an accessible route.

SECTION R322 FLOOD-RESISTANT CONSTRUCTION

R322.1 General. Buildings and structures constructed in whole or in part in flood hazard areas, including A or V Zones and Coastal A Zones, as established in Table R301.2(1), and substantial improvement and restoration of substantial damage of buildings and structures in flood hazard areas, shall be designed and constructed in accordance with the provisions contained in this section. Buildings and structures that are located in more than one flood hazard area shall comply with the provisions associated with the most restrictive flood hazard area. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

- ❖ This section addresses general requirements for all buildings and structures proposed to be located in whole or in part in areas designated as flood hazard areas. These areas are commonly referred to as “flood plains” and are shown on a community’s FIRM prepared by FEMA or other adopted flood hazard map. Flood hazard areas are determined using the base flood, which is defined as having a 1-percent chance (one chance in 100) of occurring in any given year. The

maps do not show the worst case flood, nor the “flood of record,” which usually refers to the most severe flood in the history of the community. Although a 1-percent chance seems fairly remote, larger floods occur regularly throughout the United States. Application of the flood-resistant provisions of the code cannot prevent or eliminate all future flood damage. These provisions represent a reasonable balance of the knowledge and awareness of flood hazards, methods to guide development to less hazard-prone locations, methods of design and construction intended to resist flood damage, and each community’s and landowner’s reasonable expectations to use the land.

FEMA uses multiple designations for the flood hazard areas shown on each FIRM, including A, AO, AH, A1-30, AE, A99, AR, AR/A1-30, AR/AE, AR/AO, AR/AH, AR/A, VO, V1 -30, VE and V. Along many open coasts and lake shores, where wind-driven waves are predicted, the flood hazard area is commonly referred to as the “V Zone.” Flood hazard areas that are inland of coastal high-hazard areas subject to high-velocity wave action, plus flood hazard areas along rivers and streams, are commonly referred to as “A Zones.” Because of waves, the flood loads in areas subject to high-velocity wave action differ from those in other flood hazard areas.

Some buildings are proposed to be located such that either they are in more than one flood zone or only a portion of the building is in a flood zone. Where this occurs, the entire building or structure is required to be designed and constructed according to the requirements of the more restrictive flood zone. For example, if a building is partially in a coastal high-hazard area (V Zone), then the entire building must meet the requirements for that area. Similarly, if a building is partially in a flood hazard area and partially out of the mapped flood hazard area, then the entire building must be designed and constructed in accordance with the flood-resistant provisions of the building code.

Some riverine floodplains are mapped to show floodways. Because floodways typically are characterized by deeper and faster moving water, it is appropriate that the design of buildings in these areas explicitly accounts for flood loads as called for in ASCE 24. Designs prepared in accordance with ASCE 24 should be prepared and sealed by registered design professionals.

Since 2009, some FIRMs prepared for coastal communities show the “Limit of Moderate Wave Action,” which is the inland extent of the 1½-foot (457 mm) wave height. Post-flood field investigations and laboratory testing have indicated that significant structural damage can occur in areas shown as A/AE Zones that are inland of V Zones and inland of some shorelines without V Zones, and where breaking wave heights are less than 3 feet (914 mm), but more than 1½ feet (457 mm) [areas with breaking waves 3 feet (914 mm) or higher are designated as V Zones]. In ASCE 7 and ASCE 24, as well as in common usage, the area between the V Zone and Limit of Moderate Wave

Action is called “Coastal A Zone” (see commentary, Section R322.2).

Some coastal communities have FIRMs that show areas that are designated as units of the Coastal Barrier Resource System (CBRS) established by the Coastal Barrier Resource Act (CoBRA) of 1982 and subsequent amendments. The NFIP is prohibited from offering flood insurance on new or substantially improved buildings in these areas. Jurisdictions are responsible for the application of the provisions of the code concerning flood resistance in all designated flood hazard areas, even if federal flood insurance is not available.

Communities that have AR Zones and A99 Zones shown on their FIRMs should consult with the appropriate state agency or FEMA regional office for guidance on requirements that must apply if the community participates in the NFIP. AR Zones are areas that result from the decertification of a previously accredited flood protection system (such as a levee) that is determined to be in the process of being restored to provide base flood protection. A99 Zones are areas subject to inundation by the 1-percent-annual-chance flood event, but which will ultimately be protected upon completion of an under-construction federal flood protection system.

Through the adoption of the code, communities meet some of the requirements necessary to participate in the NFIP. To learn more about how communities may meet the requirements by adoption of the code and the IBC (with IBC Appendix G or a comparable ordinance), see *Reducing Flood Losses Through the International Code Series: Coordinating Building Codes and Floodplain Management Regulations* (ICC and FEMA).

The NFIP was established to reduce flood losses, to better indemnify individuals from flood losses and to reduce federal expenditures for disaster assistance. A community that has flood hazard areas participates in the NFIP to protect health, safety and property, and so that its citizens can purchase federally-backed flood insurance. FEMA administers the NFIP and monitors community compliance with the flood plain management requirements of the NFIP.

Many states require that communities regulate flood plain development to a higher standard than the minimum standards established by the NFIP. Communities considering using the code and other I-Codes to meet the flood plain management requirements of the NFIP are advised to consult with their NFIP state coordinator or the appropriate FEMA regional office.

R322.1.1 Alternative provisions. As an alternative to the requirements in Section R322, ASCE 24 is permitted subject to the limitations of this code and the limitations therein.

- ❖ This section provides an engineering option to the requirements of Section R322 by allowing designs in accordance with ASCE 24. Designs prepared in accordance with ASCE 24 should be prepared and sealed by registered design professionals; Section R322.3.6

requires designs for dwellings in coastal high-hazard areas and Coastal A Zones to be prepared and sealed by registered design professionals.

R322.1.2 Structural systems. Structural systems of buildings and structures shall be designed, connected and anchored to resist flotation, collapse or permanent lateral movement due to structural loads and stresses from flooding equal to the design flood elevation.

- ❖ New buildings, new structures and substantial improvements to existing buildings and structures in flood hazard areas must be designed and constructed to resist flood forces to minimize damage. Buildings must be connected to structural foundation systems that are capable of resisting flood forces, including flotation, lateral (hydrostatic) pressures, moving water (hydrodynamic) pressures, wave impact and debris impact.

See commentary for Section R322.3.3 for reference to FEMA P-550, a publication that provides residential foundation designs for open foundations (pilings and piers) up to 15 feet (4572 mm) above ground level and for closed foundations (crawl spaces and stemwalls) up to 8 feet (2438 mm) above ground level, subject to certain limitations such as wind speed.

R322.1.3 Flood-resistant construction. Buildings and structures erected in areas prone to flooding shall be constructed by methods and practices that minimize flood damage.

- ❖ In addition to the structural requirement of Section R322.1.2, this section establishes a broad requirement that techniques used for construction in flood hazard areas must contribute to flood resistance by minimizing flood damage.

R322.1.4 Establishing the design flood elevation. The design flood elevation shall be used to define flood hazard areas. At a minimum, the design flood elevation shall be the higher of the following:

1. The base flood elevation at the depth of peak elevation of flooding, including wave height, that has a 1 percent (100-year flood) or greater chance of being equaled or exceeded in any given year; or
2. The elevation of the design flood associated with the area designated on a flood hazard map adopted by the community, or otherwise legally designated.

- ❖ This section defines the “design flood elevation (DFE)” that is used to delineate and define flood hazard areas. At a minimum, the flood plain is the Special Flood Hazard Area shown on the community’s FIRM. The term “design flood elevation” is used throughout the code. The design flood elevation is the greater of the base flood elevation shown on the FIRM or other flood hazard area map identified in Table R301.2(1). The majority of communities use the FIS and FIRM as the basis for regulations, and in those communities the design flood elevation is the base flood elevation.

R322.1.4.1 Determination of design flood elevations. If design flood elevations are not specified, the *building official*

is authorized to require the applicant to comply with either of the following:

1. Obtain and reasonably use data available from a federal, state or other source; or
 2. Determine the design flood elevation in accordance with accepted hydrologic and hydraulic engineering practices used to define special flood hazard areas. Determinations shall be undertaken by a registered *design professional* who shall document that the technical methods used reflect currently accepted engineering practice. Studies, analyses and computations shall be submitted in sufficient detail to allow thorough review and approval.
- ❖ Many FIRMs show flood hazard areas without specifying base flood elevations. These areas, often referred to as unnumbered A Zones or approximate A Zones, are subject to the flood resistant construction requirements of the code even though the minimum elevation to which buildings and structures must be elevated has not been determined by FEMA. An important step in regulating these flood hazard areas is determination of the design flood elevation. As defined in Section R322.1.4, at a minimum the DFE is the base flood elevation shown on a community's FIRM identified in Table R301.2(1). In some instances, flood elevation information may have been developed by sources other than FEMA, including other federal or state agencies or other sources, such as the U.S. Army Corps of Engineers, the Natural Resources Conservation Service, a state agency (transportation, water resources, environment), local planning or public works department, a flood control agency or district, or historical records. The building official is to obtain the information if it is available or the building official can require the permit applicant to determine the DFE in accordance with accepted engineering practices. Some communities develop flood hazard information and provide it to applicants so that all development in an area is based on the same level of risk. Local officials unfamiliar with establishing design flood elevations in unnumbered flood zones are encouraged to contact the NFIP state coordinator or the appropriate FEMA regional office. For additional guidance, refer to FEMA 265.

R322.1.4.2 Determination of impacts. In riverine flood hazard areas where design flood elevations are specified but floodways have not been designated, the applicant shall demonstrate that the effect of the proposed buildings and structures on design flood elevations, including fill, when combined with other existing and anticipated flood hazard area encroachments, will not increase the design flood elevation more than 1 foot (305 mm) at any point within the *jurisdiction*.

- ❖ Although FEMA has provided floodways along many rivers and streams shown on a community's FIRM, other riverine flood hazard areas have base flood elevation but do not have designated floodways. In these areas, the potential effects that flood plain activities

may have on flood elevations have not been evaluated. If FEMA has not designated a regulatory floodway, the community is responsible for regulating development so as not to increase flood elevations by more than 1 foot (305 mm) at any point in the community. In effect, this means a community must either prepare a hydraulic analysis for proposed activities or require permit applicants to do so. These analyses should be prepared in accordance with accepted engineering practices by a qualified professional (see commentary, Section R322.1.4.1). Several states have guidance for satisfying this requirement and some states have more restrictive requirements, which can be determined by contacting the NFIP state coordinator.

R322.1.5 Lowest floor. The lowest floor shall be the lowest floor of the lowest enclosed area, including *basement*, and excluding any unfinished flood-resistant enclosure that is useable solely for vehicle parking, building access or limited storage provided that such enclosure is not built so as to render the building or structure in violation of this section.

- ❖ The lowest floor is the most important reference point when designing and constructing a building or structure in a flood hazard area. The term is specifically defined to include basements, which are any areas that are below grade on all sides. (This definition differs from the one in Chapter 2, which includes areas that are partly below grade.) To avoid being considered basements, the interior grade or floor of crawl spaces or enclosures should be at or above the finished exterior grade along one entire side of the building.

It is important to understand the lowest floor of a building or structure and how it relates to enclosures. The NFIP recognizes that elevated buildings may have enclosures below the elevated building that will be subject to flooding. Enclosures that are built in accordance with the code are deemed not to be the lowest floor. Federal flood insurance premium rates take into account a number of factors, including the elevation of the lowest floor relative to the BFE. For flood hazard areas known as "A Zones," enclosure provisions are set forth in Section R322.2.2. For coastal high-hazard areas (identified as "V Zones,") and Coastal A Zones, provisions for enclosures are set forth in Sections R322.3.4 and R322.3.5. In Chapter 2, the definition of "Habitable space" notes that certain spaces and areas are not considered habitable spaces (bathrooms, closets, hallway, storage or utility spaces, and similar areas). However, to comply with the requirements of Section 322, only three nonhabitable uses are allowed as enclosures below elevated buildings: vehicle parking, building access and limited storage.

R322.1.6 Protection of mechanical, plumbing and electrical systems. Electrical systems, *equipment* and components; heating, ventilating, air conditioning; plumbing *appliances* and plumbing fixtures; *duct systems*; and other service *equipment* shall be located at or above the elevation required in Section R322.2 or R322.3. If replaced as part of a substantial improvement, electrical systems, *equipment* and components; heating, ventilating, air conditioning and plumbing *appli-*

ances and plumbing fixtures; *duct systems*; and other service *equipment* shall meet the requirements of this section. Systems, fixtures, and *equipment* and components shall not be mounted on or penetrate through walls intended to break away under flood loads.

Exception: Locating electrical systems, *equipment* and components; heating, ventilating, air conditioning; plumbing *appliances* and plumbing fixtures; *duct systems*; and other service *equipment* is permitted below the elevation required in Section R322.2 or R322.3 provided that they are designed and installed to prevent water from entering or accumulating within the components and to resist hydrostatic and hydrodynamic loads and stresses, including the effects of buoyancy, during the occurrence of flooding to the design flood elevation in accordance with ASCE 24. Electrical wiring systems are permitted to be located below the required elevation provided that they conform to the provisions of the electrical part of this code for wet locations.

- ❖ This section sets a broad requirement that electrical, plumbing and mechanical system elements, including electrical, heating, ventilating, air-conditioning, plumbing fixtures, duct systems and other service equipment, are to be located above the elevations specified depending on whether the location is in a flood hazard area (A Zone) or coastal high-hazard areas (V Zones) or Coastal A Zone. The same requirement applies to the replacement of electrical and mechanical system elements that are included as part of substantial improvements to existing buildings. Attention should be paid to ductwork. If ducts must be installed under a floor system or between floor joists and if the ducts are not water tight, then the lowest floor must be placed high enough so that the ducts are at or above the elevation specified by the code. If a building is elevated to satisfy the minimum requirement, anything installed below that elevation is automatically not in compliance with this section unless it explicitly complies with the exception. For additional guidance, refer to FEMA 348.

The exception to this section provides criteria for placing equipment below the required elevation. It is important to be clear that to do so the equipment must be designed to prevent the entry or accumulation of water. For example, typical dwellings have exterior air-conditioning units located on the ground adjacent to the structure. These types of units typically are not designed to withstand the entry of water and would not meet the requirements of this exception.

Personal elevators may be allowed even though they extend below the design flood elevation provided the control equipment is above that elevation. In coastal high-hazard areas (V Zones), and Coastal A Zones flood loads acting on the elevator components and any nonbreakaway shaft walls must be accounted for in the building design. For guidance, see FEMA TB #4.

R322.1.7 Protection of water supply and sanitary sewage systems. New and replacement water supply systems shall be designed to minimize or eliminate infiltration of flood waters into the systems in accordance with the plumbing provisions of this code. New and replacement sanitary sewage systems shall

be designed to minimize or eliminate infiltration of floodwaters into systems and discharges from systems into floodwaters in accordance with the plumbing provisions of this code and Chapter 3 of the *International Private Sewage Disposal Code*.

- ❖ Health concerns arise when water supply systems are exposed to flood waters, and contamination from flooded sewage systems can pose health and environmental risks. To reduce these risks, water supply systems and sanitary sewage systems must be designed to minimize or eliminate infiltration and discharges under flood conditions. For on-site sewage disposal systems, the effects of flooding may be reduced by locating the systems on the highest available ground. State health regulations may apply to on-site sewage disposal systems proposed in flood hazard areas.

R322.1.8 Flood-resistant materials. Building materials and installation methods used for flooring and interior and exterior walls and wall coverings below the elevation required in Section R322.2 or R322.3 shall be flood damage-resistant materials that conform to the provisions of FEMA TB-2.

- ❖ To minimize flood damage, materials used below the elevation required in this section must resist damage caused by flood waters. Even though certain enclosures may be allowed under otherwise elevated buildings, the materials used in those enclosures must be resistant to water damage to minimize flood losses. For general flood-resistance requirements, see FEMA TB #2, and for corrosion resistance, see FEMA TB #8.

R322.1.9 Manufactured homes. The bottom of the frame of new and replacement *manufactured homes* on foundations that conform to the requirements of Section R322.2 or R322.3, as applicable, shall be elevated to or above the elevations specified in Section R322.2 (flood hazard areas including A Zones) or R322.3 in coastal high-hazard areas (V Zones and Coastal A Zones). The anchor and tie-down requirements of the applicable state or federal requirements shall apply. The foundation and anchorage of *manufactured homes* to be located in identified floodways shall be designed and constructed in accordance with ASCE 24.

- ❖ The placement of new manufactured homes is subject to the same elevation requirements as other new construction. Replacement of existing manufactured homes is considered “new construction” and must comply with the provisions of this section. Manufactured homes are to be elevated so that the bottom of the frames is at or above the elevations specified based on flood zone. Because of anticipated flood forces, units must be anchored and tied down in accordance with applicable requirements. Within floodways, where water depths and velocities are anticipated to be greatest, foundation and anchorage must be designed in accordance with the ASCE 24. Some states and communities do not allow manufactured homes to be installed in coastal high-hazard areas (V Zones) or floodways. See FEMA P-85 for additional guidance and several pre-engineered foundation solutions.

HUD’s October 2007 final rule for Model Manufactured Home Installation Standard (24 CFR, Part 3285)

includes some provisions related to flood hazard areas. Manufacturers must clearly specify that their installation instructions and foundation specifications have either (a) been designed for flood-resistant considerations [in which case the conditions are to be listed (velocities, depths, or wave action) and the design must be certified by a registered professional engineer or architect], or (b) not been designed to address flood loads, in which case the instructions must direct the installer to “obtain an alternate design prepared and certified by a registered professional engineer or registered architect for the support and anchorage.” HUD places the burden on the installer to determine whether a home site is wholly or partly in a flood hazard area and to obtain additional designs, if needed.

R322.1.10 As-built elevation documentation. A registered *design professional* shall prepare and seal documentation of the elevations specified in Section R322.2 or R322.3.

❖ Documentation of the “as-built” elevations is to be submitted to verify compliance. Most communities require or request submission of FEMA’s Elevation Certificate (FEMA Form 086-0-33), which is designed to obtain the information necessary to show compliance. Building owners will need elevation information to obtain federal flood insurance, and insurance agents use the information to compute the applicable flood insurance premium rates. The elevation certificate is available on-line. For guidance on the elevation certificate, see FEMA P-467-1.

As called for in Section R109.1.3, as part of the flood plain inspection the elevation information is to be provided when the lowest floor elevation is set and before further vertical construction occurs. If an error is discovered at the time, it will be significantly easier and less expensive to correct at this stage. Section R109.1.6.1 requires submission of “as-built” elevation documentation prior to the final inspection and before the certificate of occupancy is issued to determine that the building is in compliance with the flood-resistant provisions of the code. The building official must maintain copies of the elevation information on file and make elevation and related building information available for insurance rating and other purposes. Elevation documentation may be reviewed as part of periodic community assistance visits conducted by FEMA or states; FEMA considers buildings without elevation documentation to be violations.

R322.2 Flood hazard areas (including A Zones). Areas that have been determined to be prone to flooding and that are not subject to high-velocity wave action shall be designated as flood hazard areas. Flood hazard areas that have been delineated as subject to wave heights between 1½ feet (457 mm) and 3 feet (914 mm) or otherwise designated by the jurisdiction shall be designated as Coastal A Zones and are subject to the requirements of Section R322.3. Buildings and structures constructed in whole or in part in flood hazard areas shall be

designed and constructed in accordance with Sections R322.2.1 through R322.2.3.

❖ Flood hazard areas, often referred to as “A Zones,” are found along nontidal waterways and lakes, and include the inland portions of coastal flood plains that are not subject to high velocity wave action [i.e., where waves are less than 3 feet (914 mm) in height]. The zone designation does not indicate anticipated velocities of river and stream flooding. Especially in areas where the slopes of streambeds are relatively steep, designers should check the Flood Insurance Study and local sources of information to see whether velocity information is available for use in considering the effects of hydrodynamic flood loads.

Some FIRMs in coastal communities show the “limit of moderate wave action,” which is the inland extent of the 1½-foot (457 mm) wave height. Post-flood field investigations and laboratory testing indicate that significant structural damage can occur in areas shown as A/AE Zones that are inland of V Zones and inland of some shorelines without V Zones, where wave heights are less than 3 feet (914 mm), but more than 1½ feet (457 mm). These areas are commonly called “Coastal A Zones.” Some communities designate Coastal A Zones even if a limit of moderate wave action is not shown on the FIRM, for example by specifying a certain distance inland of the Zone V boundary. A new requirement in the 2015 IRC is that if a Coastal A Zone is delineated or designated, the requirements of Section R322.3 apply so that Coastal A Zones are regulated like Zone V. Commentary Figure R322.2 shows how the limit of moderate wave action is delineated on FIRMs.

R322.2.1 Elevation requirements.

1. Buildings and structures in flood hazard areas, including flood hazard areas designated as Coastal A Zones, shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.
2. In areas of shallow flooding (AO Zones), buildings and structures shall have the lowest floor (including *basement*) elevated to a height above the highest adjacent *grade* of not less than the depth number specified in feet (mm) on the FIRM plus 1 foot (305 mm), or not less than 3 feet (915 mm) if a depth number is not specified.
3. Basement floors that are below *grade* on all sides shall be elevated to or above base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.

Exception: Enclosed areas below the design flood elevation, including *basements* with floors that are not below *grade* on all sides, shall meet the requirements of Section R322.2.2.

❖ The minimum requirement is that lowest floors must be elevated at least 1 foot above the base flood elevation

or the BFE. Earlier editions of the IRC permitted the lowest floor to be at or above the BFE. Note that Section R322.2 states that Coastal A Zones are subject to the requirement of Section R322.3; thus, in Coastal A Zones the elevation of the bottom of the lowest horizontal structural member of the lowest floor is specified in Section R322.2, superseding application of Item 1 in those areas. The benefits of elevating lowest floors higher than the minimum NFIP requirements have been documented in several sources, notably in an independent report prepared for FEMA, *Evaluation of the National Flood Insurance Program's Building Standards* (American Institutes for Research, 2006) that documented the benefits in terms of avoided flood damage over a building's life as well as lower cost federal flood insurance. The report concluded that, based on avoided damage alone, it is worth spending an additional amount over the cost of the at-BFE building cost to incorporate freeboard.

AO Zones are areas of shallow flooding where FEMA has specified a "depth number" rather than a flood elevation that is referenced to a datum. Buildings in AO Zones must be elevated so the lowest floor, including the basement, is at least as high above grade as the depth number plus 1 foot, or at least 3 feet (915 mm) if a depth number is not specified. The point where this depth is measured is at the highest natural grade adjacent to the proposed building. FEMA refers to some areas subject to shallow flooding as AH Zones. AH Zones have base flood elevations and they are treated the same as other A Zones with base flood elevations.

This section emphasizes that basements that are below grade on all sides must be elevated to at least 1 foot above the base flood elevation, or to design flood elevation, whichever is higher. The NFIP defines a basement not by its common use, but by whether it is below grade on all sides. Even if below grade on all sides by only 1 inch (25 mm), such an area is, technically, a basement.

In many flood hazard areas, it is common to place fill to elevate a building site above the design flood elevation. Fills that are exposed to flooding may become saturated and unstable and slopes may be exposed to erosive velocities and waves during a flood. For additional guidance for development activities involving the placement of fill in a flood hazard area, refer to FEMA TB #10. Building officials may require applicants to submit documentation regarding the use of fill and whether structures on fill are reasonably safe from flooding.

The specification in Item 3 means that basements must not be excavated below the design flood elevation. The exception to this section allows enclosures that, if designed and constructed to meet the use limitations and the flood opening specifications of Section R322.2.2, are not the lowest floor. Allowable uses of such enclosures include parking of vehicles, building access, limited storage and crawl spaces.

R322.2.2 Enclosed area below design flood elevation.

Enclosed areas, including crawl spaces, that are below the design flood elevation shall:

1. Be used solely for parking of vehicles, building access or storage.
 2. Be provided with flood openings that meet the following criteria and are installed in accordance with Section R322.2.2.1:
 - 2.1. The total net area of nonengineered openings shall be not less than 1 square inch (645 mm²) for each square foot (0.093 m²) of enclosed area where the enclosed area is measured on the exterior of the enclosure walls, or the openings shall be designed as engineered openings and the *construction documents* shall include a statement by a registered *design professional* that the design of the openings will provide for equalization of hydrostatic flood forces on *exterior walls* by allowing for the automatic entry and exit of floodwaters as specified in Section 2.7.2.2 of ASCE 24.
 - 2.2. Openings shall be not less than 3 inches (76 mm) in any direction in the plane of the wall.
 - 2.3. The presence of louvers, blades, screens and faceplates or other covers and devices shall allow the automatic flow of floodwater into and out of the enclosed areas and shall be accounted for the determination of the net open area.
- ❖ This section contains the use limitations and flood opening requirements that apply to enclosures below otherwise properly elevated buildings. If enclosures meet these requirements they are not considered the "lowest floor." The use limitation states that enclosures, including crawl spaces, must be used only for parking of vehicles, building access or storage (see commentary to Section R322.1.5 regarding use limitations and the terms habitable and nonhabitable spaces that are defined elsewhere in the code). Although the NFIP regulations do not define storage, most states interpret it to mean "limited" storage. Some states specify that hazardous materials must not be stored in enclosures. Experience has suggested that two design factors influence the use of enclosures and may discourage illegal conversions by owners: the size of the enclosed area and utility service. Some states and communities limit the size of enclosures. Plumbing service is not appropriate for the allowable uses, and only minimal electrical service should be provided (a light switch for a stairwell, for example, or electrical outlets wired from above).

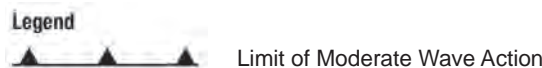

Enclosed areas below elevated buildings must have flood openings. The total net open area of the flood openings is determined prescriptively (called "nonengineered openings") by computing the total area enclosed by the walls that extend below the design flood elevation and providing 1 square inch of net open area for every square foot (6944 mm² per m²) of

enclosed area. Alternatively, flood openings may be designed to automatically equalize hydrostatic flood forces (called “engineered openings”), in which case the construction documents must include a statement from a registered design professional that the openings are designed to meet this requirement. Engineered openings may be site-built and individually certified, or they may be products manufactured to meet this requirement, in which case they must have been issued an evaluation report by the ICC-ES. Devices intended for under-floor ventilation openings may be used as nonengineered openings. Care should

be taken to determine the net open area provided by any devices, taking into account obstructions such as louvers, blades, screens, face plates, grilles, slats and other coverings. Airflow vent devices must be disabled in the “open” position to ensure automatic functioning in the event of a flood. For additional guidance on meeting the flood opening requirements of this section, see FEMA TB #1.

R322.2.2.1 Installation of openings. The walls of enclosed areas shall have openings installed such that:

1. There shall be not less than two openings on different sides of each enclosed area; if a building has more than

Notes to Users

The AE Zone category has been divided by a Limit of Moderate Wave Action (LiMWA). The LiMWA represents the approximate landward limit of the 1.5-foot breaking wave. The effects of wave hazards between the VE Zone and the LiMWA (or between the shoreline and the LiMWA for areas where VE Zones are not identified) will be similar to, but less severe than those in the VE Zone.

For Information on available products associated with the FIRM visit the Map Service Center (MSC) website at <http://msc.fema.gov>. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the MSC website.

If you have questions about this map, how to order products or the National Flood Insurance Program in general, please call the FEMA Map Information eXchange (FMIX) at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA website at <http://www.fema.gov/business/nfip>.

**Figure R322.2
SAMPLE FIRM WITH LiMWA**

one enclosed area below the design flood elevation, each area shall have openings.

2. The bottom of each opening shall be not more than 1 foot (305 mm) above the higher of the final interior grade or floor and the finished exterior grade immediately under each opening.
 3. Openings shall be permitted to be installed in doors and windows; doors and windows without installed openings do not meet the requirements of this section.
- ❖ Openings intended to relieve differential hydrostatic pressure during the rise and fall of floodwaters must be installed as specified. Information about the number, size and location of flood openings is collected when a FEMA Elevation Certificate is completed. The information is useful for compliance inspections and property owners are required to submit it to obtain federal flood insurance.

The requirements related to the location of flood openings are clear. Openings are to be in exterior walls on different sides of the enclosed area and they are to be no more than 1 foot above the higher of the interior grade/floor or the finished exterior grade under each opening. For additional guidance on meeting the flood opening requirements of this section, see FEMA TB #1.

R322.2.3 Foundation design and construction. Foundation walls for buildings and structures erected in flood hazard areas shall meet the requirements of Chapter 4.

Exception: Unless designed in accordance with Section R404:

1. The unsupported height of 6-inch (152 mm) plain masonry walls shall be not more than 3 feet (914 mm).
2. The unsupported height of 8-inch (203 mm) plain masonry walls shall be not more than 4 feet (1219 mm).
3. The unsupported height of 8-inch (203 mm) reinforced masonry walls shall be not more than 8 feet (2438 mm).

For the purpose of this exception, unsupported height is the distance from the finished *grade* of the under-floor space to the top of the wall.

- ❖ Flood conditions impose additional or different loads on foundation walls than those imposed solely by unbalanced fill conditions. Flood loads include hydrostatic and hydrodynamic loads. If foundation walls form enclosed areas, unequal hydrostatic loads are relieved by meeting the flood opening requirements of Section R322.2.2. FEMA analyzed hydrodynamic loads at varying depths and velocities to re-examine the structural adequacy of the masonry walls prescribed in Chapter 4 and referenced in this section.

The results indicate that unless the walls are designed in accordance with Section R404, in flood hazard areas it is appropriate to limit the unsupported height of masonry walls based on wall thickness and whether they are plain or reinforced.

R322.2.4 Tanks. Underground tanks shall be anchored to prevent flotation, collapse and lateral movement under conditions of the base flood. Above-ground tanks shall be installed at or above the elevation required in Section R322.2.1 or shall be anchored to prevent flotation, collapse and lateral movement under conditions of the base flood.

- ❖ Tanks dislodged during flooding not only can release contents into floodwater, but they can become battering debris that can contribute to damage of buildings and structures. Underground tanks need to be installed in ways that take into consideration the fact that soils may be saturated during flooding, creating conditions that can cause tanks to be dislodged. Above-ground tanks must be elevated otherwise buildings would not comply with the free of obstruction requirement in Section R322.3.3.

R322.3 Coastal high-hazard areas (including V Zones and Coastal A Zones, where designated). Areas that have been determined to be subject to wave heights in excess of 3 feet (914 mm) or subject to high-velocity wave action or wave-induced erosion shall be designated as coastal high-hazard areas. Flood hazard areas that have been designated as subject to wave heights between 1½ feet (457 mm) and 3 feet (914 mm) or otherwise designated by the jurisdiction shall be designated as Coastal A Zones. Buildings and structures constructed in whole or in part in coastal high-hazard areas and coastal A Zones, where designated, shall be designed and constructed in accordance with Sections R322.3.1 through R322.3.7.

- ❖ Buildings and structures located in flood hazard areas known as “V Zones,” or coastal high-hazard areas, are exposed to flooding and wind-driven waves 3 feet (914 mm) or higher and in Coastal A Zones they are exposed to flooding and waves between 1½ and 3 feet high. Waves impose additional loads on foundations and can cause erosion. A new requirement in the 2015 IRC is that Coastal A Zones are regulated like Zone V if they are delineated or designated by a community.

Note that Section R322.1.1 allows building officials to accept designs based on ASCE 24 or to specify that buildings in these areas must be designed according to ASCE 24. In addition, designers are referred to FEMA P-55, and builders are referred to FEMA P-499. Training on the design and construction of residential structures in coastal areas may be offered by the NFIP state coordinator or the appropriate FEMA regional office. Additional guidance about design and construction in coastal areas can be found in FEMA TB #5, FEMA TB #8, and FEMA TB #9.

R322.3.1 Location and site preparation.

1. New buildings and buildings that are determined to be substantially improved pursuant to Section R105.3.1.1 shall be located landward of the reach of mean high tide.
2. For any alteration of sand dunes and mangrove stands, the *building official* shall require submission of an engineering analysis that demonstrates that the pro-

posed *alteration* will not increase the potential for flood damage.

- ❖ Buildings, including existing buildings for which a determination has been made that proposed work constitutes substantial improvement (or repair of substantial damage) must be sited such that they are not regularly affected by normal (mean) high tides. Many coastal locations benefit from natural storm protection because of the presence of sand dunes and mangrove stands. Those natural features must remain intact. However, alterations may be considered if specific analyses indicate that the alterations will not increase the potential for flood damage, including increasing the exposure of the site to greater flood depths and higher wave heights.

R322.3.2 Elevation requirements.

1. Buildings and structures erected within coastal high-hazard areas and Coastal A Zones, shall be elevated so that the bottom of the lowest horizontal structural members supporting the lowest floor, with the exception of piling, pile caps, columns, grade beams and bracing, is elevated to or above the base flood elevation plus 1 foot (305 mm) or the design flood elevation, whichever is higher.
2. Basement floors that are below *grade* on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.
5. Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

- ❖ Buildings and structures to be located in coastal high-hazard areas (V Zones) and Coastal A Zones must be elevated so that the bottom of the lowest horizontal structural members is not subject to flood loads during conditions of the base flood. Elevation is one of the most important requirements to provide resistance to flood damage. It is also the main factor used in determining federal flood insurance premium rates for buildings and structures.

Prior to the 2015 edition, this code had different elevation requirements based on the orientation of the lowest horizontal structural member. The 2015 edition simplifies application of the elevation requirement by eliminating differences as a function of orientation of the lowest horizontal structural member. Instead, the minimum requirement for all dwellings is that the bottom of the lowest horizontal structural member must be at or above the base flood elevation plus 1 foot, or the DFE, whichever is higher. The benefits of additional elevation above the NFIP minimum, called “freeboard,” have been documented in several sources, notably in an independent report prepared for FEMA, *Evaluation of the National Flood Insurance Program’s Building*

Standards (American Institutes for Research, 2006) that documented the benefits in terms of avoided flood damage over a building’s life as well as lower cost federal flood insurance. The report concluded that, based on avoided damage alone, it is worth spending an additional percentage of the at-BFE building code to incorporate freeboard.

In coastal high-hazard areas and Coastal A Zones, the use of fill to provide structural support is prohibited because areas subject to wave action are more likely to experience flood-related erosion, which may lead to the failure of foundations on fill. Minor quantities of nonstructural fill may be allowed for the limited purposes of drainage and landscaping. For more guidance on acceptable uses of fill, see FEMA TB #5.

This section and the NFIP allow certain enclosures under buildings that otherwise meet the elevation requirements, and the exception notes that the requirements for such enclosures are found in Sections R322.3.4 and R322.3.5.

R322.3.3 Foundations. Buildings and structures erected in coastal high-hazard areas and Coastal A Zones shall be supported on pilings or columns and shall be adequately anchored to such pilings or columns. The space below the elevated building shall be either free of obstruction or, if enclosed with walls, the walls shall meet the requirements of Section R322.3.4. Pilings shall have adequate soil penetrations to resist the combined wave and wind loads (lateral and uplift). Water-loading values used shall be those associated with the design flood. Wind-loading values shall be those required by this code. Pile embedment shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the piling. Pile systems design and installation shall be certified in accordance with Section R322.3.6. Spread footing, mat, raft or other foundations that support columns shall not be permitted where soil investigations that are required in accordance with Section R401.4 indicate that soil material under the spread footing, mat, raft or other foundation is subject to scour or erosion from wave-velocity flow conditions. If permitted, spread footing, mat, raft or other foundations that support columns shall be designed in accordance with ASCE 24. Slabs, pools, pool decks and walkways shall be located and constructed to be structurally independent of buildings and structures and their foundations to prevent transfer of flood loads to the buildings and structures during conditions of flooding, scour or erosion from wave-velocity flow conditions, unless the buildings and structures and their foundations are designed to resist the additional flood load.

Exception: In Coastal A Zones, stem wall foundations supporting a floor system above and backfilled with soil or gravel to the underside of the floor system shall be permitted provided the foundations are designed to account for wave action, debris impact, erosion and local scour. Where soils are susceptible to erosion and local scour, stem wall foundations shall have deep footings to account for the loss of soil.

- ❖ Several provisions applicable to foundations for buildings and structures in coastal high-hazard areas (V Zones) and Coastal A Zones are in this section. During coastal storms, both wind and water loads are signifi-

cant, and buildings must be designed and constructed to withstand both loads. Buildings must be anchored to their foundations, and the foundations must withstand the anticipated forces. The requirement that the area under elevated buildings be free of obstructions is intended to minimize flood loads on foundations. Building elements that may be obstructions unless properly designed and constructed include stairs and ramps, decks and patios, elevators, equipment and cabinets mounted on foundation elements, foundation bracing (especially if perpendicular to the anticipate direction of wave approach), grade beams, shear walls, and slabs, including slabs used for parking (see FEMA TB #5).

Where soils are subject to scour and erosion from wave action, spread footing, mat, raft or other foundation elements cannot be used to support columns; if those foundation elements are used elsewhere, the requirements of ASCE 24 apply. It is common to have structures, such as pools, pool decks and slabs, built immediately adjacent to buildings in coastal communities. Such structures should be located and built so they do not obstruct waves and the flow of water or adversely impact buildings during a flood, including wave-induced scour and erosion. Additional guidance on these elements is found in FEMA TB #5.

After Hurricane Katrina, FEMA produced FEMA P-550. The designs account for wind loads and flood loads and are applicable throughout the United States, with certain limitations. Selection of applicable designs depends on several factors, including flood depths, wind loads and soils. Designs applicable in coastal high-hazard areas and Coastal A Zones are provided for open foundations (pilings and columns) up to 15 feet (4572 mm) above ground level.

The exception to allow stem wall foundations in Coastal A Zones was added in the 2015 edition of the code. FEMA P-550 notes that stem wall foundations have been observed to perform well in Coastal A Zones where erosion and local scour effects are minor, but this foundation type should not be used without a deep footing. The stem wall foundation design included in FEMA P-550 does not account for potential, site-specific erosion and local scour.

R322.3.4 Walls below design flood elevation. Walls and partitions are permitted below the elevated floor, provided that such walls and partitions are not part of the structural support of the building or structure and:

1. Electrical, mechanical and plumbing system components are not to be mounted on or penetrate through walls that are designed to break away under flood loads; and
 2. Are constructed with insect screening or open lattice; or
 3. Are designed to break away or collapse without causing collapse, displacement or other structural damage to the elevated portion of the building or supporting foundation system. Such walls, framing and connections shall have a resistance of not less than 10 (479 Pa) and not more than 20 pounds per square foot (958 Pa) as determined using allowable stress design; or
4. Where wind loading values of this code exceed 20 pounds per square foot (958 Pa), as determined using allowable stress design, the *construction documents* shall include documentation prepared and sealed by a registered *design professional* that:
 - 4.1. The walls and partitions below the design flood elevation have been designed to collapse from a water load less than that which would occur during the base flood.
 - 4.2. The elevated portion of the building and supporting foundation system have been designed to withstand the effects of wind and flood loads acting simultaneously on structural and non-structural building components. Water-loading values used shall be those associated with the design flood. Wind-loading values shall be those required by this code.
 5. Walls intended to break away under flood loads as specified in Item 3 or 4 have flood openings that meet the criteria in Section R322.2.2, Item 2.
- ❖ Buildings and structures in coastal high-hazard areas and Coastal A Zones must be elevated to or above the elevations specified in Section R322.3. However, certain enclosures are allowed below elevated buildings if the walls surrounding the enclosures (and partition walls) are designed to fail or break away under certain loads without causing damage to the foundation. Post-flood investigations indicate that breakaway walls do not perform as intended if wires, pipes and other utility components are mounted on or penetrate through the walls. Walls other than lattice, slats, shutters or insect screening must meet specific loading resistance; they are to be designed to fail under certain specified loads. If anticipated allowable loads exceed 20 pounds per square foot (958 Pa) as determined using allowable stress design, the wall design is to be certified as meeting certain specifications. Wood or plastic lattice, slats or shutters installed between the foundation elements are not considered walls, provided at least 40 percent of the area is open to the passage of floodwaters and the material used is thin enough to break away, considered to be no thicker than $\frac{1}{2}$ inch (12.7 mm) for lattice and no thicker than 1 inch (25 mm) for slats and shutters. For additional guidance, refer to FEMA TB #5, FEMA P-499 and FEMA P-55. FEMA TB #9 is particularly useful because it includes three methods to design breakaway walls: a prescriptive design approach, a simplified design approach and a performance-based design approach.
- A new requirement in the 2015 IRC is for flood opening walls in all flood zones. Experience shows that walls designed to break away are breaking away under water depths and wave conditions that are less than the conditions of the base flood. Having openings will permit the water level inside to match the water level outside, limiting failure under “shallow” flooding that occurs more frequently than the base (100-year) flood. These same requirements are included in ASCE 24. Homes that are built with enclosures surrounded by

breakaway walls that have flood openings will sustain damage less frequently, not only to the walls themselves, but the interior of the enclosures will not be exposed to wind-driven rain and sand. In addition, with fewer wall failures there will be less debris added to floodwater which will reduce damage by battering.

R322.3.5 Enclosed areas below design flood elevation.

Enclosed areas below the design flood elevation shall be used solely for parking of vehicles, building access or storage.

- ❖ The limitations that are outlined in Section R322.2.2 on how enclosures below elevated buildings are used are repeated here. Enclosures are to be used only for parking, building access and storage. Although the NFIP regulations do not define storage, most states interpret it to mean “limited” storage. Some states specify that hazardous materials must not be stored in enclosures. Experience has suggested that two design factors influence the use of enclosures and may discourage illegal conversions by owners: the size of the enclosed area and utility service. Some communities limit the size of enclosures [federal flood insurance costs more if buildings in coastal high-hazard areas have enclosures, especially enclosures larger than 300 square feet (28 m²)]. Another factor that influences enclosure use is the availability of utility services. Plumbing service is not associated with the allowable uses and in accordance with Section R322.1.6 must not be located below the design flood elevation. Only minimal electrical service should be provided (a light switch for a stairwell, for example, or electrical outlets that are wired from above).

R322.3.5.1 Protection of building envelope. An exterior door that meets the requirements of Section R609 shall be installed at the top of stairs that provide access to the building and that are enclosed with walls designed to break away in accordance with Section R322.3.4.

- ❖ Post-disaster investigations have identified increased damage to elevated buildings if breakaway walls fail as designed, exposing building interiors to wave splash, wave run-up, and wind-driven rain that enters through unprotected doors at the top of stairs.

R322.3.6 Construction documents. The *construction documents* shall include documentation that is prepared and sealed by a registered *design professional* that the design and methods of construction to be used meet the applicable criteria of this section.

- ❖ Documentation must be submitted to demonstrate that the design and proposed construction methods address the provisions of the code. This requirement recognizes that coastal high-hazard areas and Coastal A Zones subject to waves and erosion are dynamic environments that impose significant loads on buildings. This documentation is different than the documentation of the elevation of the bottom of the lowest horizontal structural member that is required in Section 109.1.3 (flood plain inspections), Section 109.1.6.1

(prior to final inspection), and Section R322.1.10 (as-built).

R322.3.7 Tanks. Underground tanks shall be anchored to prevent flotation, collapse and lateral movement under conditions of the base flood. Above-ground tanks shall be installed at or above the elevation required in Section R322.3.2. Where elevated on platforms, the platforms shall be cantilevered from or knee braced to the building or shall be supported on foundations that conform to the requirements of Section R322.3.

- ❖ Tanks dislodged during flooding not only can release contents into floodwater, but they become battering debris that can contribute to damage of buildings and structures. Underground tanks need to be installed in ways that take into consideration the fact that soils may be saturated during flooding, creating conditions that can cause tanks to be dislodged. Above-ground tanks must be elevated otherwise buildings would not comply with the free of obstruction requirement in Section R322.3.3.

SECTION R323 STORM SHELTERS

R323.1 General. This section applies to storm shelters where constructed as separate detached buildings or where constructed as safe rooms within buildings for the purpose of providing refuge from storms that produce high winds, such as tornados and hurricanes. In addition to other applicable requirements in this code, storm shelters shall be constructed in accordance with ICC/NSSA-500.

- ❖ ICC 500 provides requirements for the design and construction of shelters to protect people from the violent winds of hurricanes and tornadoes. The standard includes special requirements for structural design, including wind loads that are considerably higher than the wind loads required by Section 301.2.1 for all structures.

Wind loads for storm shelters will be based upon wind speed contour maps developed specially for this standard. The wind load design requirements are relatively severe when compared to the wind speed maps in Chapter 3. Contour maps for wind speeds in hurricane-prone regions were determined based upon a 10,000-year mean return period. The map shows 200 mph (88 m/s) wind speeds on the coast of Florida and the Carolinas, and wind speeds higher than 200 mph (88 m/s) in some locations. These are wind speeds associated with a Category 5 hurricane. Shelter design wind speeds in the central part of the United States (a region called “tornado alley”) are as high as 250 mph (110 m/s).

Such high wind speeds, of course, produce flying debris, turning construction materials into deadly missiles. The standard contains specific test methods and pass-fail criteria for window and door protection from flying debris.

SECTION 324 SOLAR ENERGY SYSTEMS

R324.1 General. Solar energy systems shall comply with the provisions of this section.

❖ Solar thermal energy systems are water- and/or air-based systems, while solar photovoltaic energy systems are electrical-based systems. As the provisions related to solar photovoltaic energy systems were not related to plumbing and are actually of a structural and installation or general nature, they have been moved from Chapter 23 to Chapter 3 for the 2015 edition of the IRC, along with further enhancements. The solar thermal requirements of the code remain in Chapter 23 and Section R324.2 provides a pointer to reinforce that fact.

Although Section R324.2 requires that solar thermal systems also comply with the IFC, the solar-related provisions of the IFC (Section 605.11) pertain to rooftop-mounted solar photovoltaic arrays, not solar thermal systems.

R324.2 Solar thermal systems. Solar thermal systems shall be designed and installed in accordance with Chapter 23 and the *International Fire Code*.

❖ See the commentary to Section R324.1.

R324.3 Photovoltaic systems. Photovoltaic systems shall be designed and installed in accordance with Sections R324.3.1 through R324.6.1 and NFPA 70. Inverters shall be *listed* and *labeled* in accordance with UL 1741. Systems connected to the utility grid shall use inverters listed for utility interaction.

❖ Section R324.3 requires that solar photovoltaic energy systems comply with Sections R324.3.1 through R324.6.1 and NFPA 70. NFPA 70 is the *National Electrical Code*®.

Section R324.3 also requires that inverters for photovoltaic solar energy systems be listed and labeled in accordance with UL 1741 and that, where systems are connected to the utility grid, the inverters be listed for that purpose.

The ever-increasing demand for alternative power sources brings with it new hazards to confront emergency responders. Among the most popular of these alternative energy sources are solar photovoltaic (PV) power systems. A number of United States electric utility power suppliers offer incentives for the installation of PV systems on buildings because such systems offer the property owners the ability to generate their own electricity and, in many cases, sell excess electricity back to the utility provider. Such an arrangement is a benefit to the utility provider because it reduces their power generation demand, which in turn can control the rates that commercial and residential customers pay. Demand for PV power systems has increased by several orders of magnitude in the past decade. According to the U.S. Energy Information Administration, approximately 21,200 PV cells and modules were shipped domestically in 1999; by 2008, the number shipped was over 524,200. As the number of PV power systems increases, economy of scale will continue to reduce the system's costs, making them more common on com-

mercial and residential buildings.

PV systems are designed to convert light energy into direct current (DC) electricity. They have no moving parts and do not contain fluids. The light-to-electricity conversion begins at the PV cell, which is commonly a semiconductor device that generates electricity when exposed to light. To be effective, PV cells are assembled into PV modules, which are then assembled into PV panels. The panels are assembled onto a frame or a flexible substrate, which then can be affixed to the roof of buildings to create a PV array. The PV arrays and its modules are wired together and generally operate as a series electrical circuit. PV arrays are required by NFPA 70 to have a fuse or other means of branch-circuit protection to prevent them from being overloaded. While not required, a PV array is commonly equipped with a blocking diode. A blocking diode is analogous to a check valve in a piping system because it limits the direction the electrons can travel. The blocking diode prevents electrical current from one power supply from finding entry into another. In PV systems, the blocking diode protects each individual PV panel if other panels fail and prevents the withdrawal of electricity from the system during the nighttime.

The greatest danger facing emergency responders operating in proximity to solar energy collection systems is the lack of knowledge needed to operate safely around these systems. Some of the potential hazards associated with PV systems are tripping hazards and/or falls for fire fighters operating on the roof and the potential for earlier roof collapse due to the added dead load and electric shock. The provisions of Sections R324.3 through R324.6.1 were based on similar provisions in the IFC and were developed to provide for the proper installation of PV systems and to address the potential hazards to fire fighters.

R324.3.1 Equipment listings. Photovoltaic panels and modules shall be listed and labeled in accordance with UL 1703.

❖ Photovoltaic panels and modules must be listed and labeled by an approved agency to show that they comply with applicable national standards. The label is the primary, if not the only, assurance to the installer, the inspector and the end user that a similar appliance has been tested and evaluated by an approved agency and performed safely and efficiently when installed and operated in accordance with its listing. Photovoltaic panels and modules must be listed and labeled to UL 1703, which is a referenced standard for flat plate photovoltaic modules and panels with a system voltage of 1,000 or less.

R324.4 Rooftop-mounted photovoltaic systems. Rooftop-mounted photovoltaic panel systems installed on or above the roof covering shall be designed and installed in accordance with Section R909.

❖ For photovoltaic panel systems that are mounted directly to rooftops, Section R324.3.1 requires compliance with the structural and installation requirements of Section 909. Section 909 applies specifically to roof-

top-mounted photovoltaic panel systems. Photovoltaic panel systems are defined in Section R202.

R324.4.1 Roof live load. Roof structures that provide support for photovoltaic panel systems shall be designed for applicable roof live load. The design of roof structures need not include roof live load in the areas covered by photovoltaic panel systems. Portions of roof structures not covered by photovoltaic panels shall be designed for roof live load. Roof structures that provide support for photovoltaic panel systems shall be designed for live load, L_R , for the load case where the photovoltaic panel system is not present.

❖ This section addresses live loads for photovoltaic (PV) panel systems (see the definition of “Photovoltaic panel system”) and indicates where and how such loads must be considered. Note that the loads imposed by PV panel systems are dead loads, not live loads. This section does not address dead loads. This section addresses roof live loads in two cases as follows:

Case 1, areas of roofs that are covered by PV panels: Roof live load is not required to be considered or modeled in these areas because the assumption is that no one will be walking on top of the panels or on the roof area covered by the panels.

Case 2, areas of roofs that are not covered by PV panels: The code-prescribed roof live load is required to be considered in the same manner that they typically would in conditions where photovoltaic panels are not present.

R324.5 Building-integrated photovoltaic systems. Building-integrated photovoltaic systems that serve as roof coverings shall be designed and installed in accordance with Section R905.

❖ Building-integrated photovoltaic product is defined in Section R202 as a building product that is part of the building envelope and incorporates photovoltaic modules. Building integrated photovoltaic systems must be designed and installed in accordance with Section 905. Section R202 also defines “Photovoltaic module.”

R324.5.1 Photovoltaic shingles. Photovoltaic shingles shall comply with Section R905.16.

❖ Where photovoltaic collectors also function as shingle roof coverings, they must comply with Section R905.16, which specifically addresses photovoltaic shingles, and its subsections. Section R202 defines “Photovoltaic shingles” and “Photovoltaic module.” Photovoltaic shingles are roof coverings that include photovoltaic modules and resemble conventional shingles. Photovoltaic modules are environmentally protected units that include solar cells, optics and components, other than a tracker, that generate electrical power from sunlight.

R324.6 Ground-mounted photovoltaic systems. Ground-mounted photovoltaic systems shall be designed and installed in accordance with Section R301.

❖ Photovoltaic systems that are mounted on the ground must meet the structural design provisions of Section R301.

R324.6.1 Fire separation distances. Ground-mounted photovoltaic systems shall be subject to the *fire separation distance* requirements determined by the local *jurisdiction*.

❖ The code does not contain specific requirements for ground-mounted photovoltaic systems based on fire separation distance. Instead, the code defaults to the local jurisdiction for guidance on this subject.

SECTION R325 MEZZANINES

R325.1 General. Mezzanines shall comply with Section R325.

❖ Mezzanines are defined in Section R202 as intermediate levels between the floor and ceiling of a story. The provisions for mezzanines in the IRC were adapted from relevant portions of the mezzanine provisions in the IBC.

The provisions for mezzanines are not intended to prevent portions of one story from being open to another story. They are intended to set a threshold over which intermediate levels must be considered as stories.

Mezzanines are not required to be considered as stories because they are limited in size and because they are subject to provisions that provide protection from fire hazards.

Section R301.2.2.3.1 indicates that mezzanines are not to be considered stories in the context of height limitations for buildings in higher seismic design categories. Mezzanines that are large in relation to the size of the story will act more like a story in response to seismic forces and, therefore, should be treated as stories. Otherwise, unsafe conditions could be created.

Section R325.2 requires a clear height of at least 7 feet above and below mezzanines.

Section R325.3 includes specific provisions for determining the portion of a room that can be included in the allowable area of a mezzanine. The area of the mezzanine, or multiple mezzanines relative to any individual story, must not be greater than one-third of the area of the space in which they are located.

Section R325.4 requires compliance with the means of egress requirements of Section R311.

Section R325.5 specifies the minimum degree of openness that must be provided between a mezzanine and the room or story in which it is located. This provides early warning to occupants should a fire occur in either the mezzanine or in the room. The exceptions to Section R325.5 specify the conditions under which openness is not required.

R325.2 Mezzanines. The clear height above and below mezzanine floor construction shall be not less than 7 feet (2134 mm).

❖ See the commentary to Section R325.1.

R325.3 Area limitation. The aggregate area of a mezzanine or mezzanines shall be not greater than one-third of the floor area of the room or space in which they are located. The enclosed

portion of a room shall not be included in a determination of the floor area of the room in which the *mezzanine* is located.

❖ See the commentary to Section R325.1.

R325.4 Means of egress. The means of egress for mezzanines shall comply with the applicable provisions of Section R311.

❖ See the commentary to Section R325.1.

R325.5 Openness. Mezzanines shall be open and unobstructed to the room in which they are located except for walls not more than 36 inches (914 mm) in height, columns and posts.

Exceptions:

1. Mezzanines or portions thereof are not required to be open to the room in which they are located, provided that the aggregate floor area of the enclosed space is not greater than 10 percent of the mezzanine area.
2. In buildings that are not more than two stories above *grade plane* and equipped throughout with an automatic sprinkler system in accordance with Section R313, a mezzanine shall not be required to be open to the room in which the mezzanine is located.

❖ See the commentary to Section R325.1.

**SECTION R326
SWIMMING POOLS, SPAS AND HOT TUBS**

R326.1 General. The design and construction of pools and spas shall comply with the *International Swimming Pool and Spa Code*.

❖ This section references the *International Swimming Pool and Spa Code*® (ISPSC®) for the design of aquatic vessels.

The ISPSC uses the term “aquatic vessels” to cover all types of vessels including pools, water parks, spas and hot tubs. The ISPSC provisions comprehensively address all aspects of such vessels including:

- Administration and definitions.
- Construction features for pools including size and depth, wall and floor construction, and calculation of bather occupant load.
- Safety features such as barriers to pool entry and deep areas.
- Equipment such as suction entrapment avoidance, circulation, filters, pumps and motors, skimmers, heaters, return and suction fittings.
- Appurtenances such as ladders and diving equipment.

The ISPSC is a comprehensive set of regulations for swimming pools and spas that is consistent and coordinated with the I-Codes. Technical content was developed from provisions of the I-Codes and applicable standards from the Association of Pool & Spa Professionals (APSP). The APSP standards considered were:

- ANSI-1 2003 Public Swimming Pools

- ANSI-2 1999 Public Spas
- ANSI-3 1999 Permanent Residential Spas
- ANSI-4 2007 Aboveground/On-ground Residential Swimming Pools
- ANSI-5 2003 Residential In-ground Swimming Pools
- ANSI-6 1999 Portal Spas
- ANSI-7 2006 Suction Entrapment Avoidance
- ANSI-8 2005 Model Barrier Code
- ANSI-9 2005 Aquatic Recreational Facilities
- ANSI-11 2009 Standard for water quality in public swimming pools and spas

Chapter 4: Foundations

General Comments

Section R401 establishes the scope and applicability of the chapter. The criteria provide the details necessary for designing, building and inspecting most common foundation systems for homes. The selection of a particular type of foundation is based on many variables and it should result in the system that best suits the needs of a particular project. Also, the lot itself must be evaluated to determine the type of soil and the drainage pattern.

Section R402 specifies material requirements for wood, concrete and precast concrete foundations. Section R403 provides minimum requirements for concrete and masonry footings as well as footing for wood foundations and precast concrete foundations. Section R404 regulates foundation walls of concrete, masonry and wood as well as insulating concrete form foundation walls and precast concrete foundation walls. Section R405 has important criteria for maintaining the drainage of water away from foundations. The requirements for waterproofing and dampproofing in Section R406 protect below-grade habitable spaces from moisture. Section R407 provides requirements for underfloor areas and for protecting columns. Section R408 includes provisions

for proper ventilation, adequate access, the removal of debris and flood resistance.

Purpose

Chapter 4 provides the requirements for the design and construction of foundation systems for buildings regulated by the code. Provisions for seismic load, flood load and frost protection are contained in this chapter. A foundation system consists of two interdependent components: the foundation structure itself and the supporting soil.

This chapter provides prescriptive requirements for constructing footings and walls for foundations of wood, masonry, concrete, and precast concrete. In addition to a foundation's ability to support the required design loads, this chapter addresses several other factors that can affect foundation performance. These include controlling surface water and subsurface drainage, requiring soil tests where conditions warrant, and evaluating proximity to slopes and minimum depth requirements. The chapter also provides requirements to minimize adverse effects of moisture, decay and pests in basements and crawl spaces.

SECTION R401 GENERAL

R401.1 Application. The provisions of this chapter shall control the design and construction of the foundation and foundation spaces for buildings. In addition to the provisions of this chapter, the design and construction of foundations in flood hazard areas as established by Table R301.2(1) shall meet the provisions of Section R322. Wood foundations shall be designed and installed in accordance with AWC PWF.

Exception: The provisions of this chapter shall be permitted to be used for wood foundations only in the following situations:

1. In buildings that have no more than two floors and a roof.
2. Where interior *basement* and foundation walls are constructed at intervals not exceeding 50 feet (15 240 mm).

Wood foundations in Seismic Design Category D_0 , D_1 or D_2 shall be designed in accordance with accepted engineering practice.

❖ This chapter contains all requirements relating to the design and construction of foundations and underfloor spaces. Also, an explicit link is provided to the flood-resistant construction provisions of Section R322.

Thus, foundations for buildings to be located in flood hazard areas are to meet the provisions of Section R322 as well.

This section also specifically allows a wood foundation system designed and installed according to the American Wood Council (PWF) *Permanent Wood Foundation Design Specification*. When this system is installed under the prescriptive code requirements of this chapter, the code limits its use to structures where the loads exerted on the foundation are relatively light and to areas of low or moderate seismic hazard. This type of foundation construction is essentially a below-grade, load-bearing, wood-frame system capable of providing support for light frame structures. It generally would consist of the following components:

1. Walls consisting of plywood fastened to wood studs (see Section R404.2).
2. A composite footing made up of a continuous wood plate set on a bed of granular materials, such as sand, gravel, or crushed stone, which in turn supports the foundation walls and transmits their loads to the bearing soil below (see Section R403.2).
3. Polyethylene film that serves as a vapor barrier and covers the exterior side of the plywood

FOUNDATIONS

foundation walls from grade level down to the footing plate (see Section R406.3).

4. Caulking compounds used for sealing the joints in the plywood walls, bonding agents for attaching the polyethylene film to the plywood, and for the film joints (see Section R406.3).
5. Metal fasteners made of silicon bronze, copper, or stainless steel or hot-dipped zinc-coated steel nails or staples (see Section R402.1).
6. Pressure-treated plywood and lumber to protect the foundation material against decay, termites, and other insects (see Section R402.1).

R401.2 Requirements. Foundation construction shall be capable of accommodating all loads in accordance with Section R301 and of transmitting the resulting loads to the supporting soil. Fill soils that support footings and foundations shall be designed, installed and tested in accordance with accepted engineering practice. Gravel fill used as footings for wood and precast concrete foundations shall comply with Section R403.

❖ In order to fulfill its role in the complete load path, the foundation must support the required design loads and transmit these to the soil. The phrase “accepted engineering practice” in this section means common practice that is acceptable to the code official of the jurisdiction.

R401.3 Drainage. Surface drainage shall be diverted to a storm sewer conveyance or other *approved* point of collection that does not create a hazard. *Lots* shall be graded to drain surface water away from foundation walls. The *grade* shall fall a minimum of 6 inches (152 mm) within the first 10 feet (3048 mm).

Exception: Where *lot lines*, walls, slopes or other physical barriers prohibit 6 inches (152 mm) of fall within 10 feet (3048 mm), drains or swales shall be constructed to ensure drainage away from the structure. Impervious surfaces

within 10 feet (3048 mm) of the building foundation shall be sloped a minimum of 2 percent away from the building.

❖ Along with the proper support for a structure through the foundation system, adequate preparation of the building site is necessary to keep water drainage away from the supporting foundations. Proper site drainage is an important element in preventing wet basements, damp crawl spaces, eroded banks, and possible failure of a foundation system.

One of the most important considerations is the arrangement of structures on a building site in a manner that retains natural drainage patterns and minimizes the alteration or disturbance to existing grades. If the designer keeps such factors in mind, the result will be a reduction of ground surface stabilization problems and opportunities for differential settlement through the reduction in the use of fills. A detailed treatment of drainage design is beyond the scope of this document; therefore, only rough guidelines can be provided for areas where a more comprehensive set of grading regulations does not exist.

As illustrated in Commentary Figures R401.3(1) and R401.3(2), drainage patterns should result in adequate slopes to approved drainage devices that are capable of carrying concentrated runoff. In some cases, control of concentrated roof runoff by gutters and downspouts may be needed, and if gutters and downspouts are used, provisions should be made to discharge runoff in order to prevent soil erosion. Refer also to Section R801.3.

Cross-lot drainage and drainage over graded slopes should generally be avoided. Slopes should be designed with as moderate a grade as possible to minimize instability and erosion. The minimum slope gradients which should be used are a function of the combined ground frost and moisture conditions, soil type, geological features, and geographic conditions. The slope away from the building is required to be 6 inches (152 mm) within the first 10 feet (3048 mm). The

Figure R401.3(1)
LOT GRADING EXAMPLE

GRADING METHOD FOR LOT WHERE DWELLING IS LOCATED ON A RIDGE. DRAINAGE SWALES ARE LOCATED AT SIDE YARDS IN AREA OF POSITIVE SLOPES.

Figure R401.3(2)
LOT GRADING EXAMPLE

exception in this section allows for use of drains and swales if lot lines or physical barriers, such as a steeply sloping lot, do not allow for a 6-inch (152 mm) slope.

R401.4 Soil tests. Where quantifiable data created by accepted soil science methodologies indicate expansive, compressible, shifting or other questionable soil characteristics are likely to be present, the *building official* shall determine whether to require a soil test to determine the soil’s characteristics at a particular location. This test shall be done by an *approved agency* using an *approved method*.

❖ Loading conditions beyond the normal live, dead, and wind or earthquake loading generally include the types of loading attributable to special regional conditions. Such conditions might include soil instability, forces generated on foundations by expansive soils, and increased lateral pressures due to a high water table or surcharge loads from adjacent structures. Accounting for such conditions in the structure is generally considered to be beyond the scope of the conventional methods of foundation construction specified within this chapter. In some cases, a soil test may be required to evaluate the existing conditions.

Where the bearing capacity of the soil has not been determined by geotechnical evaluation such as borings, field load tests, laboratory tests, and engineering analysis, it is a common practice to use presumptive bearing values for the design of the foundation system. Section R401.4.1 requires that the presumptive bearing values in Table R401.4.1 be used if a geotechnical evaluation has not been performed.

R401.4.1 Geotechnical evaluation. In lieu of a complete geotechnical evaluation, the load-bearing values in Table R401.4.1 shall be assumed.

❖ See the commentary to Section R401.4.

TABLE R401.4.1
PRESUMPTIVE LOAD-BEARING VALUES OF
FOUNDATION MATERIALS^a

CLASS OF MATERIAL	LOAD-BEARING PRESSURE (pounds per square foot)
Crystalline bedrock	12,000
Sedimentary and foliated rock	4,000
Sandy gravel and/or gravel (GW and GP)	3,000
Sand, silty sand, clayey sand, silty gravel and clayey gravel (SW, SP, SM, SC, GM and GC)	2,000
Clay, sandy, silty clay, clayey silt, silt and sandy siltclay (CL, ML, MH and CH)	1,500 ^b

For SI: 1 pound per square foot = 0.0479 kPa.

- a. Where soil tests are required by Section R401.4, the allowable bearing capacities of the soil shall be part of the recommendations.
- b. Where the building official determines that in-place soils with an allowable bearing capacity of less than 1,500 psf are likely to be present at the site, the allowable bearing capacity shall be determined by a soils investigation.

❖ As explained in the commentary to Section R401.4, where a soils investigation is not required by the code, load-bearing values of Table R401.4.1 are to be used. The values vary by soil classifications, which are based on the Unified Soil Classification System. Table R405.1 also gives these soil descriptions in more detail. The allowable soil bearing values listed in the table are based on lengthy experience with the behavior of these materials in supporting loads from all types of structures.

R401.4.2 Compressible or shifting soil. Instead of a complete geotechnical evaluation, where top or subsoils are compressible or shifting, they shall be removed to a depth and width sufficient to ensure stable moisture content in each

active zone and shall not be used as fill or stabilized within each active zone by chemical, dewatering or presaturation.

- ❖ A geotechnical engineer should be consulted by the owner or the owner's builder if there is a concern that a compressible or shifting soil condition exists. Where these conditions are present, one of two methods must be used. The first of these deals with removal and replacement of the soil, thus reducing the forces associated with soil movement. The second approach is soil stabilization by chemical means, dewatering or presaturation.

SECTION R402 MATERIALS

R402.1 Wood foundations. Wood foundation systems shall be designed and installed in accordance with the provisions of this code.

- ❖ The wood foundation system requirements are from the American Wood Council (PWF) *Permanent Wood Foundation Design Specification*. Figures R403.1(2) and R403.1(3) of the code illustrate some typical details of this system. Also refer to the commentary to Section R401.1.

R402.1.1 Fasteners. Fasteners used below *grade* to attach plywood to the exterior side of exterior *basement* or crawl-space wall studs, or fasteners used in knee wall construction, shall be of Type 304 or 316 stainless steel. Fasteners used above *grade* to attach plywood and all lumber-to-lumber fasteners except those used in knee wall construction shall be of Type 304 or 316 stainless steel, silicon bronze, copper, hot-dipped galvanized (zinc coated) steel nails, or hot-tumbled galvanized (zinc coated) steel nails. Electro-galvanized steel nails and galvanized (zinc coated) steel staples shall not be permitted.

- ❖ Appropriate fasteners must be used in wood foundation construction because the presence of any moisture in combination with the preservative treatment can corrode incompatible fasteners.

R402.1.2 Wood treatment. All lumber and plywood shall be pressure-preservative treated and dried after treatment in accordance with AWWPA U1 (Commodity Specification A, Use Category 4B and Section 5.2), and shall bear the *label* of an accredited agency. Where lumber and/or plywood is cut or drilled after treatment, the treated surface shall be field treated with copper naphthenate, the concentration of which shall contain a minimum of 2-percent copper metal, by repeated brushing, dipping or soaking until the wood absorbs no more preservative.

- ❖ Performance of the wood foundation system is dependent on the use of properly treated materials; thus, the code provision emphasizes the use of properly treated lumber and plywood. Verification of the proper materials is provided by identification showing the approval of an accredited inspection agency. An example of such identification is shown in Commentary Figure R402.1.2. Where treated lumber or plywood is field cut

(exposing wood that is untreated), the code specifies the method of treating the cut surface.

R402.2 Concrete. Concrete shall have a minimum specified compressive strength of f'_c as shown in Table R402.2. Concrete subject to moderate or severe weathering as indicated in Table R301.2(1) shall be air entrained as specified in Table R402.2. The maximum weight of fly ash, other pozzolans, silica fume, slag or blended cements that is included in concrete mixtures for garage floor slabs and for exterior porches, carport slabs and steps that will be exposed to deicing chemicals shall not exceed the percentages of the total weight of cementitious materials specified in Section 19.3.3.4 of ACI 318. Materials used to produce concrete and testing thereof shall comply with the applicable standards listed in Chapters 19 and 20 of ACI 318 or ACI 332.

- ❖ The code specifies minimum concrete compressive strengths ranging from 2,500 to 3,000 psi (17.2 to 24.1 Mpa). Table R402.2 specifies the required compressive strength of concrete based on a locale's weathering potential and a building element's exposure. Section R301 uses the Weathering Probability Map for Concrete to classify an area's weathering potential as negligible, moderate or severe. For concrete that will be subject to freezing and thawing in a moist condition (i.e., weathering) or subject to direct or indirect application of deicing chemicals, Table R402.2 requires the use of higher-strength, air-entrained concrete. Freezing and thawing cycles can be the most destructive weathering factors for concrete when it is wet. Water freezing in the cement matrix, in the aggregate, or both causes deterioration of concrete that is not air-entrained. Studies have documented that concrete with proper air entrainment is highly resistant to this deterioration.

All materials and testing must be in accordance with the American Concrete Institute's ACI 318, *Building Code Requirements for Structural Concrete*. Cementitious materials include portland cement (ASTM C150), blended hydraulic cements (ASTM C595 and ASTM C1157), and expansive cement (ASTM C845). They can also include pozzolanic materials such as fly ash and other raw or calcined natural pozzolan (ASTM C618), ground granulated blast-furnace slag (ASTM C989), and/or silica fume (ASTM C1240) when used in combination with the cements. Most concrete contains admixtures such as fly ash or other pozzolans that are added as a replacement for a portion of the cement. Although such substitutions can be for economic reasons, in some cases they can also be used to improve certain concrete properties.

TABLE R402.2. See page 4-5.

- ❖ The code requires the use of higher-strength, air-entrained concrete for enclosed garage floor slabs in moderate and severe weathering regions. Even though these slabs may be enclosed and not subject to freezing and thawing conditions, they are likely to be subject to the deteriorating effects of deicing chemicals that drip from vehicles. The replacement of portland

cement with other cementitious materials can be detrimental to the durability of the concrete if the concrete will be exposed to deicing chemicals. Thus, the code limits the total amount of these replacement materials to 50 percent of the total weight of all cementitious materials.

Note c to Table R402.2 requires air-entrained concrete for concrete elements not exposed to freezing and thawing conditions when the building is completed if it is likely that these elements will be subject to freezing and thawing during construction (also see commentary, Section R404.2).

Note f permits the air entrainment to be reduced to not less than 3 percent where the garage floor will have

steel trowel finish. Field experience has shown that durable concrete may be obtained with a lesser amount of air-entrainment if the specified compressive strength of the concrete is increased to 4,000 psi (27.6 MPa). The higher concrete strength is accompanied by a denser cement-paste matrix, which results in the concrete being less permeable. This option has been successfully used on garage slabs with a steel trowel finish in areas of moderate and severe exposures.

R402.2.1 Materials for concrete. Materials for concrete shall comply with the requirements of Section R608.5.1.

❖ See the commentary to Section R608.5.1.

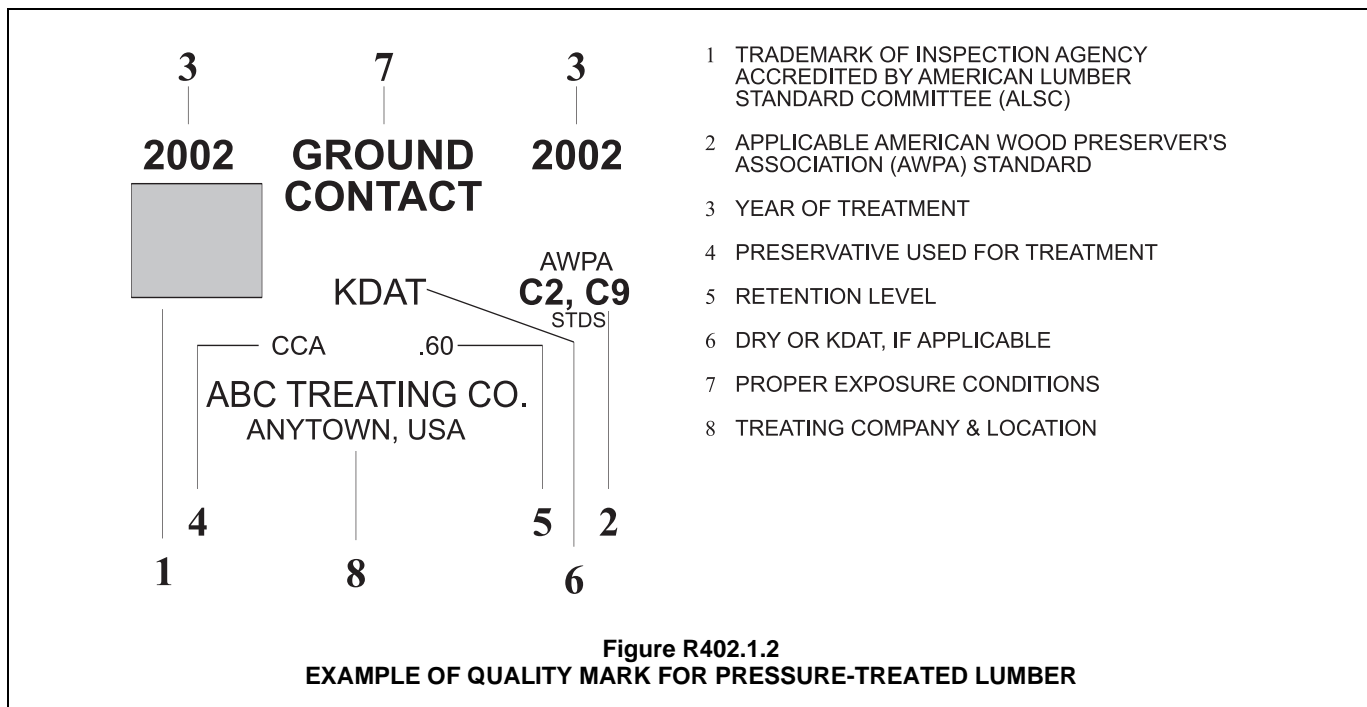

TABLE R402.2
MINIMUM SPECIFIED COMPRESSIVE STRENGTH OF CONCRETE

TYPE OR LOCATION OF CONCRETE CONSTRUCTION	MINIMUM SPECIFIED COMPRESSIVE STRENGTH ^a (f' _c)		
	Weathering Potential ^b		
	Negligible	Moderate	Severe
Basement walls, foundations and other concrete not exposed to the weather	2,500	2,500	2,500 ^c
Basement slabs and interior slabs on grade, except garage floor slabs	2,500	2,500	2,500 ^c
Basement walls, foundation walls, exterior walls and other vertical concrete work exposed to the weather	2,500	3,000 ^d	3,000 ^d
Porches, carport slabs and steps exposed to the weather, and garage floor slabs	2,500	3,000 ^{d, e, f}	3,500 ^{d, e, f}

For SI: 1 pound per square inch = 6.895 kPa.

a. Strength at 28 days psi.

b. See Table R301.2(1) for weathering potential.

c. Concrete in these locations that is subject to freezing and thawing during construction shall be air-entrained concrete in accordance with Footnote d.

d. Concrete shall be air-entrained. Total air content (percent by volume of concrete) shall be not less than 5 percent or more than 7 percent.

e. See Section R402.2 for maximum cementitious materials content.

f. For garage floors with a steel-troweled finish, reduction of the total air content (percent by volume of concrete) to not less than 3 percent is permitted if the specified compressive strength of the concrete is increased to not less than 4,000 psi.

R402.3 Precast concrete. Precast concrete foundations shall be designed in accordance with Section R404.5 and shall be installed in accordance with the provisions of this code and the manufacturer's instructions.

❖ This section provides requirements for the design and installation of precast concrete foundations. See Section R404.5 for the design requirements for precast concrete walls. The materials used to produce precast concrete foundations must comply with Section R402.3.1. All requirements in the code for concrete foundations apply to precast concrete as well. Also, any manufacturer's instructions must be complied with.

R402.3.1 Precast concrete foundation materials. Materials used to produce precast concrete foundations shall meet the following requirements.

1. All concrete used in the manufacture of precast concrete foundations shall have a minimum compressive strength of 5,000 psi (34 470 kPa) at 28 days. Concrete exposed to a freezing and thawing environment shall be air entrained with a minimum total air content of 5 percent.
 2. Structural reinforcing steel shall meet the requirements of ASTM A615, A706 or A996. The minimum yield strength of reinforcing steel shall be 40,000 psi (Grade 40) (276 MPa). Steel reinforcement for precast concrete foundation walls shall have a minimum concrete cover of $\frac{3}{4}$ inch (19.1 mm).
 3. Panel-to-panel connections shall be made with Grade II steel fasteners.
 4. The use of nonstructural fibers shall conform to ASTM C1116.
 5. Grout used for bedding precast foundations placed upon concrete footings shall meet ASTM C1107.
- ❖ Precast concrete foundations are preengineered systems. This section prescribes the minimum quality for materials to be used in the manufacture of precast concrete foundations.
- R402.4 Masonry.** Masonry systems shall be designed and installed in accordance with this chapter and shall have a minimum specified compressive strength of 1,500 psi (10.3 MPa).
- ❖ The minimum compressive strength of 1,500 psi reflects the design assumption upon which the prescriptive masonry foundation tables of Section R404.1.2.1 are based.

SECTION R403 FOOTINGS

R403.1 General. All exterior walls shall be supported on continuous solid or fully grouted masonry or concrete footings, crushed stone footings, wood foundations, or other *approved* structural systems which shall be of sufficient design to accommodate all loads according to Section R301 and to transmit the resulting loads to the soil within the limitations as determined from the character of the soil. Footings shall be supported on undisturbed natural soils or engineered

fill. Concrete footing shall be designed and constructed in accordance with the provisions of Section R403 or in accordance with ACI 332.

❖ The provisions of this section include the general statement, also contained in Section R401.2, that a footing must be capable of supporting the required design loads. The section expands on this by referencing the character of the soil and the minimum extension below the frost line. The code mandates that footings be supported on undisturbed natural soil or engineered fill. The use of ACI 332 for concrete footing is permitted. ACI 332 provides additional technical details for the design and construction of concrete footings.

R403.1.1 Minimum size. The minimum width, W , and thickness, T , for concrete footings shall be in accordance with Tables R403.1(1) through R403.1(3) and Figure R403.1(1) or R403.1.3, as applicable. The footing width shall be based on the load-bearing value of the soil in accordance with Table R401.4.1. Footing projections, P , shall be not less than 2 inches (51 mm) and shall not exceed the thickness of the footing. Footing thickness and projection for fireplaces shall be in accordance with Section R1001.2. The size of footings supporting piers and columns shall be based on the tributary load and allowable soil pressure in accordance with Table R401.4.1. Footings for wood foundations shall be in accordance with the details set forth in Section R403.2, and Figures R403.1(2) and R403.1(3).

❖ Tables R403.1(1) through R403.1(3) specify minimum footing widths and thickness based on soil pressure, the number of stories supported and roof snow or live load. Figures R403.1(1) and R403.1.3 specify the details for plain and reinforced concrete footings with concrete or masonry stem walls. The limitation on the maximum projection of the footing, P , beyond the face of the foundation wall is particularly important for 6-inch-thick (152 mm) footings of plain concrete subjected to soil-bearing pressures on the order of 2,000 pounds per square foot (95.8 kPa). Projections in excess of the maximum allowable could result in the footing being cracked in a plane coinciding with the face of the foundation wall. A crack could occur if the allowable flexural tension stress of the concrete is exceeded. The size of isolated footings for piers and columns should be determined from the tributary (design) load supported using the presumptive soil values of Table R401.4.1.

TABLE R403.1(1). See page 4-8.

❖ In previous editions of the IRC, the minimum width of footings shown in Table R403.1 was too conservative for concrete footings. The table for minimum footing size has been expanded into three tables. Loading conditions are clarified to more accurately determine the footing size required. The new minimum footing may be smaller, the same size, or larger than the 2012 IRC required minimum footing. Often the new minimum footing is slightly larger than the 2012 minimum for light-frame construction. For buildings with veneer, the minimum footing may be smaller.

The new tables are Table R403.1(1), light-frame construction; Table R403.1(2), light-frame construction with veneer; and Table R403.1(3), cast-in-place concrete or fully grouted masonry wall construction. Note: The new tables apply to concrete footings only. The tables do not address grouted or solid masonry, crushed stone or wood footings.

The 2015 IRC minimum footing size tables are based on the following assumptions:

- 32-foot building width.
- Snow load or roof live load of 20 psf (the minimum allowed per Table R301.6), 30 psf, 50 psf and 70 psf (the maximum allowed prescriptively by the IRC in accordance with Section R301.2.3).
- 18 feet of tributary roof area.
- 16 feet of tributary floor area.
- 10-foot basement and first-floor height.
- 9-foot second-floor height.
- 8-foot third-floor height.

Note a allows interpolation of soil and snow load conditions. Note b accounts for an increase or decrease in building width allowing an increase or decrease in the footing width and thickness. The minimum footing thickness is 6 inches. The minimum footing width is 12 inches. Calculation of footing size may result in a smaller footing but the code requires a minimum 12 x 6 or 12 inches wide and 6 inches deep footing.

In addition, tables are based on the type of foundation. Categories include:

1. One, two and three stories built slab on grade (without a first-floor load).
2. One, two and three stories built over a crawl space (with a first-floor load and foundation wall/footing load).
3. One, two and three stories built with a basement (with a first-floor load and a basement wall load).

Previously, the table was silent on how to handle the extra load from a masonry or concrete basement

wall. In the new tables, footing size increase for homes with a crawl space or basement.

The width of the footing is provided based on the loads described above and the minimum footing projection. The tables are based on the following load case:

Total load (TL) equal to dead load (D) plus 75 percent of the snow or roof live load (S , R_{LL}):

$$TL = D + .75(S \text{ or } R_{LL})$$

In combining the two loads, a reduction is allowed in the live load.

If any of the following conditions exist in the area of the foundation, conventional spread footings should not be used, and a designed foundation may be necessary:

- Filled ground, except when properly compacted.
- Foundation soils subject to subsidence.
- Expansive soils such as those having a plasticity index of 15 or greater (see Section R403.1.8.1).
- Highly compressive clays.
- Unconfined sands and silts.

In cold weather, care must be taken that foundations are not placed on frozen soil, nor should such foundations be placed in freezing weather unless a method of verifying that the underlying soil is free of frost is employed and the foundations are properly protected against the weather.

PERMANENT WOOD FOUNDATION CRAWL SPACE SECTION

FOUNDATIONS

R403.1.2 Continuous footing in Seismic Design Categories D₀, D₁ and D₂. Exterior walls of buildings located in Seismic Design Categories D₀, D₁ and D₂ shall be supported by continuous solid or fully grouted masonry or concrete footings. Other footing materials or systems shall be designed in accordance with accepted engineering practice. All required interior *braced wall panels* in buildings located in Seismic Design Categories D₀, D₁ and D₂ with plan dimensions greater than 50 feet (15 240 mm) shall be supported by continuous solid or fully grouted masonry or concrete footings in accordance with Section R403.1.3.4, except for two-story buildings in Seismic Design Category D₂, in which all *braced wall panels*, interior and exterior, shall be supported on continuous foundations.

Exception: Two-story buildings shall be permitted to have interior *braced wall panels* supported on continuous foundations at intervals not exceeding 50 feet (15 240 mm) provided that:

1. The height of cripple walls does not exceed 4 feet (1219 mm).
2. First-floor braced wall panels are supported on doubled floor joists, continuous blocking or floor beams.

3. The distance between bracing lines does not exceed twice the building width measured parallel to the braced wall line.

❖ When a braced wall line is not supported by a continuous footing, the supporting floor (diaphragm) must distribute the lateral force to a resisting element (foundation). If a floor diaphragm is overloaded, it could lead to a failure, which in turn results in an incomplete load path. This section limits this condition for buildings in all high seismic regions. Where any of the overall plan dimensions of the building are greater than 50 feet (15 240 mm), all interior braced wall panels must be supported on continuous footings in any building located in Seismic Design Category (SDC) D₀, D₁ or D₂.

In previous editions of the code, provisions in Chapters 4 and 6 for continuous footings and foundations were widely separated and confusing. In Section R602.10.9.1, there was no specific guidance on what to do in SDC D₀ and D₁ below interior braced wall panels. Section R403.1.2 clarifies the foundation requirements under braced wall panels in all high-seismic regions. All requirements for footings in high-seismic regions are now located in Section R403.1.2 within the

SDC	NUMBER OF STORIES	WALL LOCATION	LENGTH OF PLAN DIMENSIONS	
			Both dimensions ≤ 50 ft	One or more dimensions > 50 ft
D ₀ , D ₁ , D ₂	One story	Exterior walls	Continuous footing required	
		Interior Walls	No continuous footings required	Continuous footings required below all interior braced wall panels
D ₀ , D ₁	Two stories	Exterior walls	Continuous footing required	
		Interior walls	No continuous footings required	Continuous footings are required below all interior braced wall panels unless the Section R403.1.2 exception is used. Then interior wall lines with braced wall panels may be supported according to the exception with footings below interior braced wall panels spaced a maximum of 50 ft or less.
D ₂	Two stories	Exterior walls	Continuous footing required	
		Interior walls	Continuous footings are required below all interior braced wall panels unless the Section R403.1.2 exception is used.	Continuous footings are required below all interior braced wall panels unless the Section R403.1.2 exception is used. Then interior wall lines with braced wall panels may be supported according to the exception with footings below interior braced wall panels spaced a maximum of 50 ft or less.

**Figure R403.1.2
CONTINUOUS FOOTING REQUIREMENTS IN HIGH-SEISMIC REGIONS**

foundation chapter. Section R403.1.2 requires continuous footings for the cases listed in Commentary Figure R403.1.2.

R403.1.3 Footing and stem wall reinforcing in Seismic Design Categories D₀, D₁, and D₂. Concrete footings located in Seismic Design Categories D₀, D₁ and D₂, as established in Table R301.2(1), shall have minimum reinforcement in accordance with this section and Figure R403.1.3. Reinforcement shall be installed with support and cover in accordance with Section R403.1.3.5.

- ❖ This section and Figure R403.1.3 specify minimal reinforcement for buildings classified as Seismic Design Category D₀, D₁ or D₂. Interconnection of stem walls and supporting foundations is necessary to resist the tendency of the wall to slip in an earthquake. In solid grouted masonry stem walls supported on concrete footings and at construction joints between concrete stem walls and their supporting footing, a minimum of one vertical No. 4 bar at 48 inches (1219 mm) spacing must be provided. Longitudinal reinforcement consisting of one No. 4 bar at the top of the stem wall and one No. 4 bar located 3 to 4 inches (76 to 102 mm) from the bottom of the footing must be provided. Masonry stem walls must be solid grouted. The footing and stem wall reinforcement material, location, support, cover and lap splices must comply with Section R403.1.3.5.

FIGURE R403.1.3. See page 4-16.

- ❖ See the commentary to Sections R403.1.1, R403.1.3 and R403.1.3.3.

R403.1.3.1 Concrete stem walls with concrete footings. In Seismic Design Categories D₀, D₁ and D₂ where a construction joint is created between a concrete footing and a concrete stem wall, a minimum of one No. 4 vertical bar shall be installed at not more than 4 feet (1219 mm) on center. The vertical bar shall have a standard hook and extend to the bottom of the footing and shall have support and cover as specified in Section R403.1.3.5.3 and extend a minimum of 14 inches (357 mm) into the stem wall. Standard hooks shall comply with Section R608.5.4.5. A minimum of one No. 4 horizontal bar shall be installed within 12 inches (305 mm) of the top of the stem wall and one No. 4 horizontal bar shall be located 3 to 4 inches (76 mm to 102 mm) from the bottom of the footing.

- ❖ See the commentary to Section R403.1.3.

R403.1.3.2 Masonry stem walls with concrete footings. In Seismic Design Categories D₀, D₁ and D₂ where a masonry stem wall is supported on a concrete footing, a minimum of one No. 4 vertical bar shall be installed at not more than 4 feet (1219 mm) on center. The vertical bar shall have a standard hook and extend to the bottom of the footing and shall have support and cover as specified in Section R403.1.3.5.3 and extend a minimum of 14 inches (357 mm) into the stem wall. Standard hooks shall comply with Section R608.5.4.5. A minimum of one No. 4 horizontal bar shall be installed within 12 inches (305 mm) of the top of the wall and one No.

4 horizontal bar shall be located 3 to 4 inches (76 mm to 102 mm) from the bottom of the footing. Masonry stem walls shall be solid grouted.

- ❖ See the commentary to Section R403.1.3.

R403.1.3.3 Slabs-on-ground with turned-down footings. In Seismic Design Categories D₀, D₁ and D₂, slabs on ground cast monolithically with turned-down footings shall have a minimum of one No. 4 bar at the top and the bottom of the footing or one No. 5 bar or two No. 4 bars in the middle third of the footing depth.

Where the slab is not cast monolithically with the footing, No. 3 or larger vertical dowels with standard hooks on each end shall be installed at not more than 4 feet (1219 mm) on center in accordance with Figure R403.1.3, Detail 2. Standard hooks shall comply with Section R608.5.4.5.

- ❖ For footings in Seismic Design Category D₀, D₁ or D₂, a slab-on-ground cast monolithically with a turned-down footing requires a No. 4 bar at the top and bottom of the footing or one No. 5 or two No. 4 bars to be placed in the middle third of the footing depth. Where the slab is not cast monolithically, vertical dowels must be placed at the construction joint as shown in Figure R403.1.3, Detail 2. These dowels are required to prevent damage due to slippage at the construction joint during a seismic event.

R403.1.3.4 Interior bearing and braced wall panel footings in Seismic Design Categories D₀, D₁ and D₂. In Seismic Design Categories D₀, D₁ and D₂, interior footings supporting bearing walls or *braced wall panels*, and cast monolithically with a slab on *grade*, shall extend to a depth of not less than 12 inches (305 mm) below the top of the slab.

- ❖ In buildings classified as Seismic Design Category D₀, D₁ or D₂, the code establishes the minimum depth below the top of slab for interior footings that support bearing or braced wall panels and are poured monolithically with the slab. This allows for the installation of anchor bolts, tie-downs, etc.

R403.1.3.5 Reinforcement. Footing and stem wall reinforcement shall comply with Sections R403.1.3.5.1 through R403.1.3.5.4.

- ❖ See the commentary to Section R403.1.3.

R403.1.3.5.1 Steel reinforcement. Steel reinforcement shall comply with the requirements of ASTM A615, A706 or A996. ASTM A996 bars produced from rail steel shall be Type R. The minimum yield strength of reinforcing steel shall be 40,000 psi (Grade 40) (276 MPa).

- ❖ See the commentary to Section R403.1.3.

R403.1.3.5.2 Location of reinforcement in wall. The center of vertical reinforcement in stem walls shall be located at the centerline of the wall. Horizontal and vertical reinforcement shall be located in footings and stem walls to provide the minimum cover required by Section R403.1.3.5.3.

- ❖ See the commentary to Section R403.1.3.

FOUNDATIONS

W = Width of footing, T = Thickness of footing and P = Projection per Section R403.1.1

NOTES:

- a. See Section R404.3 for sill requirements.
- b. See Section R403.1.6 for sill attachment.
- c. See Section R506.2.3 for vapor barrier requirements.
- d. See Section R403.1 for base.

FIGURE R403.1.3

REINFORCED CONCRETE FOOTINGS AND MASONRY AND CONCRETE STEM WALLS IN SDC D₀, D₁ AND D₂^{a, b, c, d, e, f}

R403.1.3.5.3 Support and cover. Reinforcement shall be secured in the proper location in the forms with tie wire or other bar support system to prevent displacement during the concrete placement operation. Steel reinforcement in concrete cast against the earth shall have a minimum cover of 3 inches (75 mm). Minimum cover for reinforcement in concrete cast in removable forms that will be exposed to the earth or weather shall be 1½ inches (38 mm) for No. 5 bars and smaller, and 2 inches (50 mm) for No. 6 bars and larger. For concrete cast in removable forms that will not be exposed to the earth or weather, and for concrete cast in stay-in-place forms, minimum cover shall be ¾ inch (19 mm).

❖ See the commentary to Section R403.1.3.

R403.1.3.5.4 Lap splices. Vertical and horizontal reinforcement shall be the longest lengths practical. Where splices are necessary in reinforcement, the length of lap splice shall be in accordance with Table R608.5.4.(1) and Figure R608.5.4(1). The maximum gap between noncontact parallel bars at a lap splice shall not exceed the smaller of one-fifth the required lap length and 6 inches (152 mm) [see Figure R608.5.4(1)].

❖ See the commentary to Section R403.1.3.

R403.1.3.6 Isolated concrete footings. In detached one- and two-family dwellings that are three stories or less in height and constructed with stud bearing walls, isolated plain concrete footings supporting columns or pedestals are permitted.

❖ This section permits isolated plain concrete footings for columns or pedestals since these are not used to support or anchor braced walls unless engineered.

R403.1.4 Minimum depth. Exterior footings shall be placed not less than 12 inches (305 mm) below the undisturbed

ground surface. Where applicable, the depth of footings shall also conform to Sections R403.1.4.1 through R403.1.4.2.

❖ Footings are required to extend below the ground surface a minimum of 12 inches (305 mm). This is considered a minimum depth to protect the footing from movement of the soil caused by freezing and thawing in mild climate areas. See Section R403.1.4.1 for general frost protection requirements.

Footing depths may also be influenced by adjacent footings at different elevations; the footing at a higher elevation imposes surcharge pressures on lower adjacent footings. One method of alleviating the surcharge pressures on lower adjacent footings is the use of the guidelines illustrated in Commentary Figure R403.1.4. Other methods based on a soil and foundation analysis are also acceptable.

R403.1.4.1 Frost protection. Except where otherwise protected from frost, foundation walls, piers and other permanent supports of buildings and structures shall be protected from frost by one or more of the following methods:

1. Extended below the frost line specified in Table R301.2.(1).
2. Constructed in accordance with Section R403.3.
3. Constructed in accordance with ASCE 32.
4. Erected on solid rock.

Exceptions:

1. Protection of freestanding *accessory structures* with an area of 600 square feet (56 m²) or less, of light-frame construction, with an eave height of 10 feet (3048 mm) or less shall not be required.

2. Protection of freestanding *accessory structures* with an area of 400 square feet (37 m²) or less, of other than light-frame construction, with an eave height of 10 feet (3048 mm) or less shall not be required.
3. Decks not supported by a dwelling need not be provided with footings that extend below the frost line.

Footings shall not bear on frozen soil unless the frozen condition is permanent.

❖ Buildings must not be founded on or within frozen ground. This provision prevents damage to the exterior walls and other walls bearing on the frozen soil. The volume changes (frost heave) that take place during freezing and thawing produce excessive stresses in the foundations and, as a result, may cause extensive damage to the walls that are supported.

Section R403.1.4.1, Frost Protection, contains the three acceptable ways of protecting the footings and foundations from frost: 1. Extend below the frost line; 2. Insulate the foundation according to the code's prescriptive frost protected shallow foundation requirements or the ASCE 32, *Design and Construction of Frost-protected Shallow Foundation*, performance standard; and 3. Erect the foundation on solid rock.

The frost-line depth is established by the authority having jurisdiction based on field experience and must be listed along with other design criteria in Table R301.2(1). Exterior foundations must extend below the frost line and a minimum of 12 inches (305 mm) below undisturbed soil. Foundations supported on rock or that are frost-protected in accordance with Section R403.3 are exempt from the extension below the frost line, but the 12-inch (305 mm) minimum still applies.

ASCE 32 contains requirements for:

1. A simplified method for heated buildings.
2. A more complicated performance method that permits trading off insulation for frost-susceptible fill or use of varying foundation depths.
3. Requirements for slabs-on-ground, crawl spaces (without outside vents), walk out basements and semi-heated buildings.
4. Requirements for unheated buildings that conserve heat from the ground with thick layers of insulation under the entire foundation and beyond it several feet; continuous walls and columns.
5. Special design conditions.

All the ASCE standard requirements are consistent with theory, widespread practice in Scandinavia, and the successful construction of thousands of buildings in the U.S.

Foundations are not to be placed on frozen soil because when the ground thaws, uneven settlement of the structure is apt to occur, thereby causing structural damage. This section does, however, permit footings to be constructed on permanently frozen soil. In permafrost areas, special precautions are neces-

sary to prevent heat from the structure from thawing the soil beneath the foundation.

R403.1.5 Slope. The top surface of footings shall be level. The bottom surface of footings shall not have a slope exceeding one unit vertical in 10 units horizontal (10-percent slope). Footings shall be stepped where it is necessary to change the elevation of the top surface of the footings or where the slope of the bottom surface of the footings will exceed one unit vertical in 10 units horizontal (10-percent slope).

❖ The code requires that the top surface of footings for buildings be essentially level. However, a slope of 1 unit vertical in 10 units horizontal (10-percent slope) is permitted for the bottom bearing surface. If the slope is steeper, the foundation must be stepped. Commentary Figure R403.1.5 schematically shows a stepped foundation. Although the code places no restriction on a stepped foundation, the figure shows a recommended overlap of the top of the foundation wall beyond the step in the foundation. It is larger than the vertical step in the foundation wall at that point. This recommendation is based on possible crack propagation at an angle of 45 degrees (0.79 rad).

R403.1.6 Foundation anchorage. Wood sill plates and wood walls supported directly on continuous foundations shall be anchored to the foundation in accordance with this section.

Cold-formed steel framing shall be anchored directly to the foundation or fastened to wood sill plates anchored to the foundation. Anchorage of cold-formed steel framing and sill plates supporting cold-formed steel framing shall be in accordance with this section and Section R505.3.1 or R603.3.1.

Wood sole plates at all exterior walls on monolithic slabs, wood sole plates of *braced wall panels* at building interiors on monolithic slabs and all wood sill plates shall be anchored to the foundation with minimum 1/2-inch-diameter (12.7 mm) anchor bolts spaced a maximum of 6 feet (1829 mm) on center or *approved* anchors or anchor straps spaced as required to provide equivalent anchorage to 1/2-inch-diameter (12.7 mm) anchor bolts. Bolts shall extend a minimum of 7 inches (178 mm) into concrete or grouted cells of concrete masonry units. The bolts shall be located in the middle third of the width of the plate. A nut and washer shall be tightened on each anchor bolt. There shall be a minimum of two bolts per plate section with one bolt located not more than 12 inches (305 mm) or less than seven bolt diameters from each end of the plate section. Interior bearing wall sole plates on monolithic slab foundation that are not part of a *braced wall panel* shall be positively anchored with *approved* fasteners. Sill plates and sole plates shall be protected against decay and termites where required by Sections R317 and R318.

Exceptions:

1. Walls 24 inches (610 mm) total length or shorter connecting offset braced wall panels shall be anchored to the foundation with a minimum of one anchor bolt located in the center third of the plate section and shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).

2. Connection of walls 12 inches (305 mm) total length or shorter connecting offset *braced wall panels* to the foundation without anchor bolts shall be permitted. The wall shall be attached to adjacent braced wall panels at corners as shown in Item 9 of Table R602.3(1).

❖ To prevent walls and floors from shifting under lateral loads, the code requires anchorage to the supporting foundation. Anchor bolts installed as specified in this section supply the minimum required capacity. Commentary Figure R403.1.6 illustrates anchorage of wood sill plates. The 1/2-inch (12.7 mm) bolts must extend into concrete or grouted cells of concrete masonry units. The anchor bolts must be located within the middle third of the plate width. It is common to see an anchor bolt placed near the edge of a wood sole plate. The general industry standard is for the bolt to be located at least two bolt diameters from the plate's edge, but there have been no provisions in the IRC to govern edge distance. The requirement for placement of a bolt within the middle third of the wood plate width allows some flexibility while providing for a minimum edge distance.

Testing has demonstrated that a bolt loses anchoring capacity when placed closer than 1 3/4 inches from

the plate's edge. Manufacturers of anchor bolts require a minimum plate edge distance of 1 3/4 inches in their installation and technical documents. This provision places an anchor bolt at least 1 1/8 inches from the edge of a 2 x 4 sill plate. With 2 x 6 construction, the bolt is a minimum of 1 3/4 inches from plate edge.

This anchorage applies at exterior walls in any seismic design category. Braced wall panels at building interiors are designed to resist in-plane shear forces comparable to braced wall panels at building exteriors, so equal anchorage is required. Use of approved fastening for anchorage is permitted where interior bearing-wall sole plates are not part of a braced wall panel. Where approved, other foundation anchorages are allowed if they are spaced to provide anchorage capacity equivalent to that of the 1/2-inch-diameter (12.7 mm) anchor bolts specified. In this case it would be necessary to use manufacturers' data, such as evaluation reports, to document the anchorage shear and tension capacities.

R403.1.6.1 Foundation anchorage in Seismic Design Categories C, D₀, D₁ and D₂. In addition to the requirements of Section R403.1.6, the following requirements shall apply to wood light-frame structures in Seismic Design Categories D₀,

FOUNDATIONS

D₁ and D₂ and wood light-frame townhouses in Seismic Design Category C.

1. Plate washers conforming to Section R602.11.1 shall be provided for all anchor bolts over the full length of required *braced wall lines* except where *approved* anchor straps are used. Properly sized cut washers shall be permitted for anchor bolts in wall lines not containing *braced wall panels*.
 2. Interior braced wall plates shall have anchor bolts spaced at not more than 6 feet (1829 mm) on center and located within 12 inches (305 mm) of the ends of each plate section when supported on a continuous foundation.
 3. Interior bearing wall sole plates shall have anchor bolts spaced at not more than 6 feet (1829 mm) on center and located within 12 inches (305 mm) of the ends of each plate section when supported on a continuous foundation.
 4. The maximum anchor bolt spacing shall be 4 feet (1219 mm) for buildings over two stories in height.
 5. Stepped cripple walls shall conform to Section R602.11.2.
 6. Where continuous wood foundations in accordance with Section R404.2 are used, the force transfer shall have a capacity equal to or greater than the connections required by Section R602.11.1 or the *braced wall panel* shall be connected to the wood foundations in accordance with the *braced wall panel-to-floor* fastening requirements of Table R602.3(1).
- ❖ The additional anchorage requirements of this section apply to light-frame wood structures classified as Seismic Design Category D₀, D₁ or D₂ and wood light-frame townhouses in Seismic Design Category C. These provisions were added following observations of past earthquakes, especially the 1994 Northridge earthquake in California. Considerable longitudinal splitting of sill plates occurred in that earthquake, resulting in substantial damage to the plates and subsequent loss

of lateral load capacity. Plate washers are required on each bolt along the full length of the braced wall line (see commentary, Section R602.11.1). Approved anchor straps are permitted to be substituted for the anchor bolts with plate washers. The anchor straps must comply with Exception 1 of Section R403.1.6.

R403.1.7 Footings on or adjacent to slopes. The placement of buildings and structures on or adjacent to slopes steeper than one unit vertical in three units horizontal (33.3-percent slope) shall conform to Sections R403.1.7.1 through R403.1.7.4.

- ❖ The provisions of the referenced sections apply to buildings placed on or adjacent to slopes steeper than one unit vertical in three units horizontal (33.3-percent slope) only.

R403.1.7.1 Building clearances from ascending slopes. In general, buildings below slopes shall be set a sufficient distance from the slope to provide protection from slope drainage, erosion and shallow failures. Except as provided in Section R403.1.7.4 and Figure R403.1.7.1, the following criteria will be assumed to provide this protection. Where the existing slope is steeper than one unit vertical in one unit horizontal (100-percent slope), the toe of the slope shall be assumed to be at the intersection of a horizontal plane drawn from the top of the foundation and a plane drawn tangent to the slope at an angle of 45 degrees (0.79 rad) to the horizontal. Where a retaining wall is constructed at the toe of the slope, the height of the slope shall be measured from the top of the wall to the top of the slope.

- ❖ Figure R403.1.7.1 provides the criteria for the location of foundations adjacent to the toe of ascending slopes not exceeding one unit vertical in one unit horizontal. Commentary Figure R403.1.7.2(1) illustrates the criteria for the determination of the location of the toe of the slope where the slope exceeds one unit vertical in one unit horizontal.

FIGURE R403.1.7.1. See page 4-21.

- ❖ The setback required by the code provides protection to the structure from shallow failures (sometimes

referred to as sloughing) and protection from erosion and slope drainage. Furthermore, the space provided by the setback provides access around the building and helps to create a light and open-air environment. The dimension from the toe of the slope to the face of the structure need to exceed 15 feet (4572 mm). Also refer to the commentary to Section R403.1.7.1.

R403.1.7.2 Footing setback from descending slope surfaces. Footings on or adjacent to slope surfaces shall be founded in material with an embedment and setback from the slope surface sufficient to provide vertical and lateral support for the footing without detrimental settlement. Except as provided for in Section R403.1.7.4 and Figure R403.1.7.1, the following setback is deemed adequate to meet the criteria. Where the slope is steeper than one unit vertical in one unit horizontal (100-percent slope), the required setback shall be measured from an imaginary plane 45 degrees (0.79 rad) to the horizontal, projected upward from the toe of the slope.

❖ In this section, the code restricts the placement of footings adjacent to or on descending slopes so that both vertical and lateral support are provided. The criteria for this condition are as shown in Figure R403.1.7.1. It

is possible to locate buildings closer to the slope than the indicated setback in Figure R403.1.7.1, and in fact it is possible to locate the footing of the structure on the slope itself. In these two cases, it will be necessary to provide an adequate depth of embedment of the footing so that the face of the footing at the bearing plane is set back from the edge of the slope at least the distance required by the code [H/3, but need not exceed 40 feet (12 192 mm)].

Commentary Figure R403.1.7.2(2) depicts the condition where the descending slope is steeper than one unit vertical in one unit horizontal and shows the proper location of the top of the slope as required by the code. The setback at the top of descending slopes will primarily provide lateral support for the foundations. The area so allocated also provides space for lot drainage away from the slope without creating too steep a drainage profile, which could create erosion problems. Furthermore, this space also provides for access around the building.

R403.1.7.3 Foundation elevation. On graded sites, the top of any exterior foundation shall extend above the elevation of

For SI: 1 foot = 304.8 mm.

FIGURE R403.1.7.1
FOUNDATION CLEARANCE FROM SLOPES

For SI: 1 degree = 0.01745 rad.

Figure R403.1.7.2(1)
BUILDINGS ADJACENT TO ASCENDING SLOPE EXCEEDING 1 TO 1

FOUNDATIONS

the street gutter at point of discharge or the inlet of an *approved* drainage device a minimum of 12 inches (305 mm) plus 2 percent. Alternate elevations are permitted subject to the approval of the *building official*, provided it can be demonstrated that required drainage to the point of discharge and away from the structure is provided at all locations on the site.

❖ Commentary Figure R403.1.7.3 depicts the requirements of the code in this item for the elevation for exterior foundations with respect to the street, gutter or point of inlet of a drainage device. The elevation of the street or gutter shown is that point at which drainage from the site reaches the street or gutter.

This requirement protects the building from water encroachment in case of unusually heavy rains and may be modified on the approval of the building official if the building official finds that positive drainage slopes are provided to drain water away from the building and that the drainage pattern is not subject to temporary flooding due to landscaping or other impediments to drainage.

R403.1.7.4 Alternate setbacks and clearances. Alternate setbacks and clearances are permitted, subject to the approval

of the *building official*. The *building official* is permitted to require an investigation and recommendation of a qualified engineer to demonstrate that the intent of this section has been satisfied. Such an investigation shall include consideration of material, height of slope, slope gradient, load intensity and erosion characteristics of slope material.

❖ This item provides that the building official may approve alternate setbacks and clearances from slopes provided the building official is satisfied that the intent of this section has been met. The code gives the building official authority to require a foundation investigation by a qualified geotechnical engineer. This section also specifies which parameters must be considered by the geotechnical engineer in such an investigation.

R403.1.8 Foundations on expansive soils. Foundation and floor slabs for buildings located on expansive soils shall be designed in accordance with Section 1808.6 of the *International Building Code*.

Exception: Slab-on-ground and other foundation systems which have performed adequately in soil conditions simi-

For SI: 1 degree = 0.01745 rad.

Figure R403.1.7.2(2)
BUILDINGS ADJACENT TO DESCENDING SLOPE EXCEEDING 1 TO 1

For SI: 1 degree = 0.01745 rad, 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure R403.1.7.3
DETERMINATION OF FOUNDATION ELEVATION ON GRADED SITES

lar to those encountered at the building site are permitted subject to the approval of the *building official*.

- ❖ Expansive soils are those that shrink and swell due to changes in moisture content. The resulting movements can be damaging to residential structures. The amount and depth of potential swelling that can occur in a clay material are to some extent functions of the cyclical moisture content in the soil. In dryer climates where the moisture content in the soil near the ground surface is low because of evaporation, there is a greater potential for extensive swelling than in the same soil in wetter climates where the variations of moisture content are not as severe.

When foundations or floor slabs are supported on soils determined to be expansive, the code defers to the *International Building Code*® (IBC®) provisions that address the design of foundations and slabs on expansive soil. The exception permits the use of systems that have demonstrated adequate performance with the approval of the building official.

R403.1.8.1 Expansive soils classifications. Soils meeting all four of the following provisions shall be considered expansive, except that tests to show compliance with Items 1, 2 and 3 shall not be required if the test prescribed in Item 4 is conducted:

1. Plasticity Index (PI) of 15 or greater, determined in accordance with ASTM D4318.
 2. More than 10 percent of the soil particles pass a No. 200 sieve (75 µm), determined in accordance with ASTM D422.
 3. More than 10 percent of the soil particles are less than 5 micrometers in size, determined in accordance with ASTM D422.
 4. Expansion Index greater than 20, determined in accordance with ASTM D4829.
- ❖ This section defines “expansive soil” as any plastic material with a PI of 15 or greater with more than 10 percent of the soil particles passing a No. 200 sieve and less than 5 micrometers in size. As an alternative, tests in accordance with ASTM D4829 can be used to determine whether a soil is expansive. The expansion index is a measure of the swelling potential of the soil.

R403.2 Footings for wood foundations. Footings for wood foundations shall be in accordance with Figures R403.1(2) and R403.1(3). Gravel shall be washed and well graded. The maximum size stone shall not exceed $\frac{3}{4}$ inch (19.1 mm). Gravel shall be free from organic, clayey or silty soils. Sand shall be coarse, not smaller than $\frac{1}{16}$ -inch (1.6 mm) grains and shall be free from organic, clayey or silty soils. Crushed stone shall have a maximum size of $\frac{1}{2}$ inch (12.7 mm).

- ❖ See Figures R403.1(2) and R403.1(3) and the commentary to Section R401.1.

R403.3 Frost-protected shallow foundations. For buildings where the monthly mean temperature of the building is maintained at a minimum of 64°F (18°C), footings are not required to extend below the frost line when protected from

frost by insulation in accordance with Figure R403.3(1) and Table R403.3(1). Foundations protected from frost in accordance with Figure R403.3(1) and Table R403.3(1) shall not be used for unheated spaces such as porches, utility rooms, garages and carports, and shall not be attached to basements or crawl spaces that are not maintained at a minimum monthly mean temperature of 64°F (18°C).

Materials used below *grade* for the purpose of insulating footings against frost shall be *labeled* as complying with ASTM C578.

- ❖ This section provides an alternative method of protecting foundations against frost heave, thus allowing foundations to be constructed above the frost line. Frost-protected foundations use insulation to reduce the heat loss at the slab edge. By holding heat from the dwelling in the ground under the foundation, the insulation, in effect, raises the frost line around the foundation.

The provisions require that the building be heated and that insulation be installed in accordance with the criteria specified in Figure R403.3(1) and Table R403.3(1) based on the air-freezing index established by Figure R403.3(2) or Table R403.3(2). As Figure R403.3(1) illustrates, these provisions apply only to slab-on-ground floors. Frost-protected shallow foundation (FPSF) designs for heated buildings are not to be used for unheated spaces. The provisions also prohibit the attachment of additions with FPSF to basements or crawl spaces that are not heated because, although unlikely, in very cold climates frost could penetrate under FPSFs from unheated basements or ventilated crawl spaces. The insulation values specified in this section are only for the purposes of exercising this option, and the Chapter 11 energy conservation provisions could result in slab-edge insulation with a greater degree of thermal resistance. Conversely, if slab-edge insulation is used to comply with Chapter 11, a builder may take advantage of that insulation to reduce the foundation depth in accordance with this section.

TABLE R403.3(1). See page 4-24.

- ❖ This table provides the required *R*-value of horizontal and vertical insulation based on the air-freezing index. In addition, it gives the minimum footing depth and the plan dimensions required for the horizontal insulation in Figures R403.3(1) and R403.3(3) (see commentary, Sections R403.3 and R403.3.1.1).

FIGURE R403.3(1). See page 4-24

- ❖ See the commentary to Section R403.3.

FIGURE R403.3(2). See page 4-25.

- ❖ This figure provides the criteria necessary to apply insulation requirements to Table R404.3. The note explains the term air-freezing index.

TABLE R403.3(2). See page 4-26.

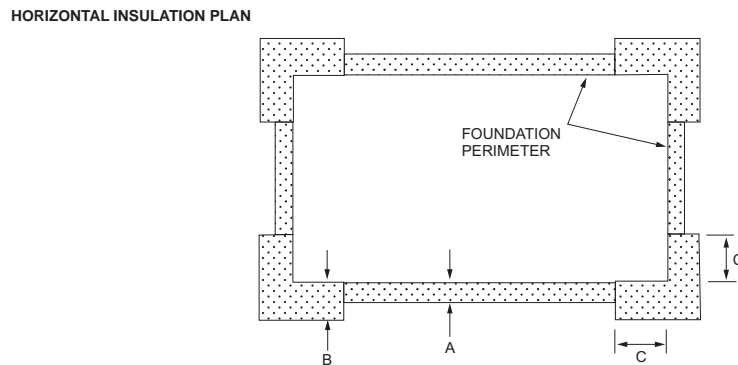

- ❖ This table is an alternative to Figure R403.3(2) for determining the air-freezing index. See the commentary to Section R403.3 and Table R403.3(1).

TABLE R403.3(1)
MINIMUM FOOTING DEPTH AND INSULATION REQUIREMENTS FOR FROST-PROTECTED FOOTINGS IN HEATED BUILDINGS^a

AIR FREEZING INDEX (°F-days) ^b	MINIMUM FOOTING DEPTH, D (inches)	VERTICAL INSULATION R-VALUE ^{c,d}	HORIZONTAL INSULATION R-VALUE ^{c,e}		HORIZONTAL INSULATION DIMENSIONS PER FIGURE R403.3(1) (inches)		
			Along walls	At corners	A	B	C
1,500 or less	12	4.5	Not required	Not required	Not required	Not required	Not required
2,000	14	5.6	Not required	Not required	Not required	Not required	Not required
2,500	16	6.7	1.7	4.9	12	24	40
3,000	16	7.8	6.5	8.6	12	24	40
3,500	16	9.0	8.0	11.2	24	30	60
4,000	16	10.1	10.5	13.1	24	36	60

For SI: 1 inch = 25.4 mm, °C = [(°F) - 32]/1.8.

- a. Insulation requirements are for protection against frost damage in heated buildings. Greater values may be required to meet energy conservation standards.
- b. See Figure R403.3(2) or Table R403.3(2) for Air Freezing Index values.
- c. Insulation materials shall provide the stated minimum *R*-values under long-term exposure to moist, below-ground conditions in freezing climates. The following *R*-values shall be used to determine insulation thicknesses required for this application: Type II expanded polystyrene-2.4*R* per inch; Type IV extruded polystyrene-4.5*R* per inch; Type VI extruded polystyrene-4.5*R* per inch; Type IX expanded polystyrene-3.2*R* per inch; Type X extruded polystyrene-4.5*R* per inch.
- d. Vertical insulation shall be expanded polystyrene insulation or extruded polystyrene insulation.
- e. Horizontal insulation shall be expanded polystyrene insulation or extruded polystyrene insulation.

For SI: 1 inch = 25.4 mm.

- a. See Table R403.3(1) for required dimensions and *R*-values for vertical and horizontal insulation and minimum footing depth.

FIGURE R403.3(1)
INSULATION PLACEMENT FOR FROST-PROTECTED FOOTINGS IN HEATED BUILDINGS

For SI: $^{\circ}\text{C} = [(^{\circ}\text{F}) - 32] / 1.8$.

Note: The air-freezing index is defined as cumulative degree days below 32°F . It is used as a measure of the combined magnitude and duration of air temperature below freezing. The index was computed over a 12-month period (July-June) for each of the 3,044 stations used in the above analysis. Dates from the 1951-80 period were fitted to a Weibull probability distribution to produce an estimate of the 100-year return period.

FIGURE R403.3(3). See page 4-31.

- ❖ This figure of insulation detail shows: 1. The maximum vertical distance between the top of the FPSF and the top of slab of adjacent unheated slab-on-ground structure; and 2. The minimum vertical distance from the top of the slab and the bottom of the insulation. The horizontal insulation plan shows placement of FPSF where it meets an unheated structure.

FIGURE R403.3(4). See page 4-32.

- ❖ This figure shows where extra insulation is required when a FPSF abuts a heated structure.

R403.3.1 Foundations adjoining frost-protected shallow foundations. Foundations that adjoin frost-protected shallow foundations shall be protected from frost in accordance with Section R403.1.4.

- ❖ This section requires that foundations that adjoin FPSFs be protected from frost according to the current requirements of Section R403.1.4, which requires that foundations extend below the frost line, be built on solid rock, or use FPSF designs. Each method prevents frost from heaving foundations. This language prevents the attachment of FPSFs to reinforced floating garage foundations, which may be permitted by some local codes to be placed at shallow depths with-

out insulating for frost protection (i.e., the foundation moves up and down with frost).

R403.3.1.1 Attachment to unheated slab-on-ground structure. Vertical wall insulation and horizontal insulation of frost-protected shallow foundations that adjoin a slab-on-ground foundation that does not have a monthly mean temperature maintained at a minimum of 64°F (18°C) shall be in accordance with Figure R403.3(3) and Table R403.3(1). Vertical wall insulation shall extend between the frost-protected shallow foundation and the adjoining slab foundation. Required horizontal insulation shall be continuous under the adjoining slab foundation and through any foundation walls adjoining the frost-protected shallow foundation. Where insulation passes through a foundation wall, it shall be either of a type complying with this section and having bearing capacity equal to or greater than the structural loads imposed by the building, or the building shall be designed and constructed using beams, lintels, cantilevers or other means of transferring building loads such that the structural loads of the building do not bear on the insulation.

- ❖ This section requires that a building with a FPSF be insulated to current FPSF requirements even where an unheated garage or other slab-on-ground is attached to it. The vertical and horizontal insulation must be in accordance with Figure 403.3(3) and Table R403.3(1)

and be continuous through the foundation of the unheated structure. The vertical wall insulation must extend between the FPSF and the adjoining slab foundation, and any required horizontal insulation must be continuous through any foundation walls adjoining the FPSF. No frost penetration or differential movement occurred with this construction in a HUD demonstration in Fargo, North Dakota. Deep foundations of unheated garages have been attached to hundreds of other buildings built on FPSFs in the U.S. In most cases the FPSF insulation has been placed continuously between the garage floor and the house FPSF; however, the insulation has not been continuous through the foundation walls of the unheated structures. In these buildings, no differential movement between the deep and shallow foundations has been reported.

Insulation passing through a foundation wall must comply with the requirements of Section R403.3, i.e., it must meet ASTM C578 and the requirements of Table R403.3(1), and the insulation must be of a type that has sufficient compressive strength to carry the load of the building. Alternatively, the building must be

designed to carry those loads over the insulation and not bear on it.

R403.3.1.2 Attachment to heated structure. Where a frost-protected shallow foundation abuts a structure that has a monthly mean temperature maintained at a minimum of 64°F (18°C), horizontal insulation and vertical wall insulation shall not be required between the frost-protected shallow foundation and the adjoining structure. Where the frost-protected shallow foundation abuts the heated structure, the horizontal insulation and vertical wall insulation shall extend along the adjoining foundation in accordance with Figure R403.3(4) a distance of not less than Dimension A in Table R403.3(1).

Exception: Where the frost-protected shallow foundation abuts the heated structure to form an inside corner, vertical insulation extending along the adjoining foundation is not required.

❖ This section stipulates that additions built on FPSFs need not be insulated where they join a heated structure because heat from both structures keeps the ground from freezing. However, where the FPSF abuts the heated building, the horizontal and vertical insulation must extend along the adjoining foundation to pre-

For SI: 1 inch = 25.4 mm.

a. See Table R403.3(1) for required dimensions and R-values for vertical and horizontal insulation.

FIGURE R403.3(3)
INSULATION PLACEMENT FOR FROST-PROTECTED FOOTINGS ADJACENT TO UNHEATED SLAB-ON-GROUND STRUCTURE

FIGURE R403.3(4)
INSULATION PLACEMENT FOR FROST-PROTECTED FOOTINGS ADJACENT TO HEATED STRUCTURE

vent cold from intruding under the slab through the foundation wall. The dimension of the insulation is related to the width of the horizontal insulation. This technique was shown to be effective by the U.S. Army Corps of Engineers Cold Regions Research and Engineering Laboratory (CRREL) on a FPSF addition to an airport control tower with a deep foundation in a severe Alaskan climate with a 13-foot (3962 mm) frost line.

An abutment at an inside corner is an exception. In this condition, both the building and the addition heat the ground, and extra insulation is not needed.

R403.3.2 Protection of horizontal insulation below ground. Horizontal insulation placed less than 12 inches (305 mm) below the ground surface or that portion of horizontal insulation extending outward more than 24 inches (610 mm) from the foundation edge shall be protected against damage by use of a concrete slab or asphalt paving on the ground surface directly above the insulation or by cementitious board, plywood rated for below-ground use, or other *approved* materials placed below ground, directly above the top surface of the insulation.

- ❖ This protection for the insulation prevents damage due to excavating (e.g., for landscaping purposes).

R403.3.3 Drainage. Final *grade* shall be sloped in accordance with Section R401.3. In other than Group I Soils, as detailed in Table R405.1, gravel or crushed stone beneath horizontal insulation below ground shall drain to daylight or into an *approved* sewer system.

- ❖ See Figure R403.3(1) and the commentary to Section R401.3.

R403.3.4 Termite protection. The use of foam plastic in areas of “very heavy” termite infestation probability shall be in accordance with Section R318.4.

- ❖ Studies have shown that rigid board insulation installed below grade, particularly in areas where the hazard associated with termite infestation is very heavy, creates a pathway for termites that cannot be blocked with currently available termiticide treatments. Because it provides a place for termites to burrow in

areas of very heavy termite infestation probability, the foam plastic insulation must be protected as stated in Section R320.5.

R403.4 Footings for precast concrete foundations. Footings for precast concrete foundations shall comply with Section R403.4.

- ❖ Footings for precast concrete foundations may be crushed stone or concrete complying with Section R403.4.1 or R403.4.2.

R403.4.1 Crushed stone footings. Clean crushed stone shall be free from organic, clayey or silty soils. Crushed stone shall be angular in nature and meet ASTM C33, with the maximum size stone not to exceed 1/2 inch (12.7 mm) and the minimum stone size not to be smaller than 1/16 inch (1.6 mm). Crushed stone footings for precast foundations shall be installed in accordance with Figure R403.4(1) and Table R403.4. Crushed stone footings shall be consolidated using a vibratory plate in a maximum of 8-inch (203 mm) lifts. Crushed stone footings shall be limited to Seismic Design Categories A, B and C.

- ❖ This section prescribes the material and installation requirements for crushed stone footing to be used for precast concrete foundations, as shown in Figure R403.4(1). The soil or the interior should not be excavated below the elevation of the top of the footing. Crushed stone footings installed in accordance with this section are limited in use to areas of low or moderate seismic hazards.

Table R403.4. See page 4-34.

- ❖ This table and Figure R403.4(1) prescribe the crushed stone footing size based on story height, load-bearing value of the soil and the precast foundation wall thickness. Table R403.4 prescribes the footing width required based on story height above grade, for buildings with “a story below grade,” i.e., basement and stories above grade, the additional load of the “story below grade” must be accounted for. The additional load will be the dead load of the basement wall plus any tributary load from the base-

ment floor load. As an example, a one-story building with a basement could conservatively use the two-story requirement rather than provide an engineered design.

FIGURE R403.4(1). See below.

❖ See the commentary to Section R403.4.1 and Table R403.4.

For SI: 1 inch = 25.4 mm, 1 plf = 14.6 N/m, 1 pound per square foot = 47.9 N/m².

a. Linear interpolation of stone depth between wall widths is permitted within each Load-Bearing Value of Soil (psf).

**SECTION R404
FOUNDATION AND RETAINING WALLS**

R404.1 Concrete and masonry foundation walls. Concrete foundation walls shall be selected and constructed in accordance with the provisions of Section R404.1.3. Masonry foundation walls shall be selected and constructed in accordance with the provisions of Section R404.1.2.

❖ Masonry and concrete foundation walls must be designed and constructed in accordance with Sections R404.1.2 and R404.1.3.

R404.1.1 Design required. Concrete or masonry foundation walls shall be designed in accordance with accepted engineering practice where either of the following conditions exists:

1. Walls are subject to hydrostatic pressure from ground water.
2. Walls supporting more than 48 inches (1219 mm) of unbalanced backfill that do not have permanent lateral support at the top or bottom.

❖ Walls subjected to hydrostatic pressure from groundwater and walls without permanent lateral support at the top or bottom are not specifically included in the code. This section specifies conditions under which foundation walls require design. Sections R404.1.2 and R404.1.3 cite the standards that are commonly used for "accepted engineering practice."

TABLE R404.1.1(1). See page 4-35.

❖ See the commentary to Section R404.1.2.1.

TABLE R404.1.1(2). See 4-36.

❖ See the commentary to Section R404.1.2.1.

TABLE R404.1.1(3). See 4-37.

❖ See the commentary to Section R404.1.2.1.

TABLE R404.1.1(4). See page 4-38.

❖ See the commentary to Section R404.1.2.1.

R404.1.2 Design of masonry foundation walls. Masonry foundation walls shall be designed and constructed in accordance with the provisions of this section or in accordance with the provisions of TMS 402/ACI 530/ASCE 5. When TMS 402/ACI 530/ASCE 5 or the provisions of this section are used to design masonry foundation walls, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the jurisdiction having authority.

When TMS 402/ACI 530/ASCE 5 or the provisions of this section are used to design masonry foundation walls, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the jurisdiction having authority.

❖ These provisions are for masonry foundation walls. Foundation walls should be in accordance with this section or designed in accordance with TMS 402/ACI 530/ASCE 5: *Building Code Requirements for Masonry Structures*.

Foundation walls are usually designed and constructed to carry the vertical loads from the structure above, resist wind and any lateral forces transmitted to the foundations, and sustain earth pressures exerted against the walls, including any forces that may be imposed by frost action.

Most states do not require the seal of an architect or engineer for small residential buildings. Check with the state authorities in the location of the project for local regulations.

TABLE R404.1.2(6). See page 4-43.

❖ See the commentary to Section R404.1.3.2.

TABLE R404.1.2(7). See page 4-44.

❖ See the commentary to Section R404.1.3.2.

TABLE R404.1.2(8). See page 4-45.

❖ See the commentary to Section R404.1.3.2.

TABLE R404.1.2(9). See page 4-46.

❖ See the commentary to Section R404.1.3.2.

R404.1.2.1 Masonry foundation walls. Concrete masonry and clay masonry foundation walls shall be constructed as set forth in Table R404.1.1(1), R404.1.1(2), R404.1.1(3) or R404.1.1(4) and shall also comply with applicable provisions of Section R606. In buildings assigned to Seismic Design Categories D₀, D₁ and D₂, concrete masonry and clay masonry foundation walls shall also comply with Section R404.1.4.1. Rubble stone masonry foundation walls shall be constructed in accordance with Sections R404.1.8 and R606.3.2. Rubble stone masonry walls shall not be used in Seismic Design Categories D₀, D₁ and D₂.

❖ Minimum thickness of concrete masonry and clay masonry foundation walls listed in Table R404.1.1(1) are predicated on the type of soil (see Table R405.1), the maximum heights of wall and unbalanced backfill (see Commentary Figure R404.1.1), and the type of wall system that is to be supported. The tabulated values are based on the assumption that the lateral loads will be carried by the walls through bending in the vertical direction. The ASTM standards for masonry units

regulate this minimum thickness of the units. The minimum thickness may be as much as 1/2 inch (12.7 mm) less than the required nominal thickness specified in the table.

Example:

From Table R404.1.1(1): an 8-foot-high (2438 mm) foundation wall constructed of hollow-unit masonry in a gravel-sand-clay mixture (SM) with a backfill height above the basement floor of 5 feet (1524 mm) would have to be minimum nominal thickness of 10 inches (254 mm). The actual wall thickness could be a minimum of 9 1/2 inches (241 mm).

The reinforcement specified in Tables R404.1.1(2) through R404.1.1(4) of the code is based on the nominal wall thickness, the type of soil, the height of the wall and the height of unbalanced fill. The height of unbalanced fill is measured as shown in Commentary Figure R404.1.1. The tabulated values are based on the assumption that lateral loads will be carried by the walls through bending, primarily in the vertical direction.

Additional (general) requirements for masonry construction found in Section R606 must be followed also. See Section R404.1.4.1 for buildings in Seismic Design Category D₀, D₁ or D₂, and for rubble stone masonry, see the commentary to Section R404.1.8.

	9	12 grout	Footnote e	Footnote e

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 Pa.

a. Mortar shall be Type M or S and masonry shall be laid in running bond. UngROUTED hollow masonry units are permitted except where otherwise indicated.

b. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.

c. Unbalanced backfill height is the difference in height between the exterior finish ground level and the lower of the top of the concrete footing that supports the foundation wall or the interior finish ground level. Where an interior concrete slab-on-grade is provided and is in contact with the interior surface of the foundation wall, measurement of the unbalanced backfill height from the exterior finish ground level to the top of the interior concrete slab is permitted.

d. Solid indicates solid masonry unit; grout indicates grouted hollow units.

e. Wall construction shall be in accordance with either Table R404.1.1(2), Table R404.1.1(3), Table R404.1.1(4), or a design shall be provided.

f. The use of this table shall be prohibited for soil classifications not shown.

	10 feet	#6 at 32	#6 at 16	#6 at 16

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot per foot = 0.157 kPa/mm.

- a. Mortar shall be Type M or S and masonry shall be laid in running bond.
- b. Alternative reinforcing bar sizes and spacings having an equivalent cross-sectional area of reinforcement per lineal foot of wall shall be permitted provided the spacing of the reinforcement does not exceed 72 inches in Seismic Design Categories A, B and C, and 48 inches in Seismic Design Categories D₀, D₁ and D₂.
- c. Vertical reinforcement shall be Grade 60 minimum. The distance, *d*, from the face of the soil side of the wall to the center of vertical reinforcement shall be not less than 5 inches.
- d. Soil classes are in accordance with the Unified Soil Classification System and design lateral soil loads are for moist conditions without hydrostatic pressure. Refer to Table R405.1.
- e. Unbalanced backfill height is the difference in height between the exterior finish ground level and the lower of the top of the concrete footing that supports the foundation wall or the interior finish ground level. Where an interior concrete slab-on-grade is provided and is in contact with the interior surface of the foundation wall, measurement of the unbalanced backfill height from the exterior finish ground level to the top of the interior concrete slab is permitted.
- f. The use of this table shall be prohibited for soil classifications not shown.

	9 feet 4 inches	#6 at 56	#6 at 40	#6 at 24
10 feet	4 feet (or less)	#4 at 56	#4 at 56	#4 at 56
	5 feet	#4 at 56	#4 at 56	#4 at 56
	6 feet	#4 at 56	#5 at 56	#5 at 56
	7 feet	#5 at 56	#6 at 56	#6 at 48
	8 feet	#5 at 56	#6 at 48	#6 at 40
	9 feet	#6 at 56	#6 at 40	#6 at 24
	10 feet	#6 at 48	#6 at 32	#6 at 24

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot per foot = 0.157 kPa/mm.

- Mortar shall be Type M or S and masonry shall be laid in running bond.
- Alternative reinforcing bar sizes and spacings having an equivalent cross-sectional area of reinforcement per lineal foot of wall shall be permitted provided the spacing of the reinforcement does not exceed 72 inches in Seismic Design Categories A, B and C, and 48 inches in Seismic Design Categories D₀, D₁ and D₂.
- Vertical reinforcement shall be Grade 60 minimum. The distance, d , from the face of the soil side of the wall to the center of vertical reinforcement shall be not less than 6.75 inches.
- Soil classes are in accordance with the Unified Soil Classification System and design lateral soil loads are for moist conditions without hydrostatic pressure. Refer to Table R405.1.
- Unbalanced backfill height is the difference in height between the exterior finish ground level and the lower of the top of the concrete footing that supports the foundation wall or the interior finish ground level. Where an interior concrete slab-on-grade is provided and is in contact with the interior surface of the foundation wall, measurement of the unbalanced backfill height from the exterior finish ground level to the top of the interior concrete slab is permitted.
- The use of this table shall be prohibited for soil classifications not shown.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot per foot = 0.157 kPa/mm.

- a. Mortar shall be Type M or S and masonry shall be laid in running bond.
- b. Alternative reinforcing bar sizes and spacings having an equivalent cross-sectional area of reinforcement per lineal foot of wall shall be permitted provided the spacing of the reinforcement does not exceed 72 inches in Seismic Design Categories A, B and C, and 48 inches in Seismic Design Categories D₀, D₁ and D₂.
- c. Vertical reinforcement shall be Grade 60 minimum. The distance, *d*, from the face of the soil side of the wall to the center of vertical reinforcement shall be not less than 8.75 inches.
- d. Soil classes are in accordance with the Unified Soil Classification System and design lateral soil loads are for moist conditions without hydrostatic pressure. Refer to Table R405.1.
- e. Unbalanced backfill height is the difference in height between the exterior finish ground level and the lower of the top of the concrete footing that supports the foundation wall or the interior finish ground levels. Where an interior concrete slab-on-grade is provided and in contact with the interior surface of the foundation wall, measurement of the unbalanced backfill height is permitted to be measured from the exterior finish ground level to the top of the interior concrete slab is permitted.
- f. The use of this table shall be prohibited for soil classifications not shown.

TABLE R404.1.2(1)
MINIMUM HORIZONTAL REINFORCEMENT FOR CONCRETE BASEMENT WALLS^{a, b}

MAXIMUM UNSUPPORTED HEIGHT OF BASEMENT WALL (feet)	LOCATION OF HORIZONTAL REINFORCEMENT
≤ 8	One No. 4 bar within 12 inches of the top of the wall story and one No. 4 bar near mid-height of the wall story.
> 8	One No. 4 bar within 12 inches of the top of the wall story and one No. 4 bar near third points in the wall story.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 kPa.

a. Horizontal reinforcement requirements are for reinforcing bars with a minimum yield strength of 40,000 psi and concrete with a minimum concrete compressive strength of 2,500 psi.

b. See Section R404.1.3.2 for minimum reinforcement required for foundation walls supporting above-grade concrete walls.

TABLE R404.1.2(2)
MINIMUM VERTICAL REINFORCEMENT FOR 6-INCH NOMINAL FLAT CONCRETE BASEMENT WALLS^{b, c, d, e, g, h, i, j, k}

	7	6 @ 43	6 @ 28	6 @ 20
	8	6 @ 31	6 @ 20	DR
	9	6 @ 24	6 @ 15	DR
	10	6 @ 19	DR	DR

For SI: 1 inch = 25.4 mm; 1 foot = 304.8 mm; 1 pound per square foot per foot = 0.1571 kPa²/m, 1 pound per square inch = 6.895 kPa.

NR = Not required.

a. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.

b. Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi concrete with a minimum specified compressive strength of 2,500 psi and vertical reinforcement being located at the centerline of the wall. See Section R404.1.3.3.7.2.

c. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).

d. Deflection criterion is $L/240$, where L is the height of the basement wall in inches.

e. Interpolation is not permitted.

f. Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.

g. NR indicates no vertical wall reinforcement is required, except for 6-inch-nominal walls formed with stay-in-place forming systems in which case vertical reinforcement shall be No. 4@48 inches on center.

h. See Section R404.1.3.2 for minimum reinforcement required for basement walls supporting above-grade concrete walls.

i. See Table R608.3 for tolerance from nominal thickness permitted for flat walls.

j. DR means design is required in accordance with the applicable building code, or where there is no code, in accordance with ACI 318.

k. The use of this table shall be prohibited for soil classifications not shown.

FOUNDATIONS

R404.1.3 Concrete foundation walls. Concrete foundation walls that support light-frame walls shall be designed and constructed in accordance with the provisions of this section, ACI 318, ACI 332 or PCA 100. Concrete foundation walls that support above-grade concrete walls that are within the applicability limits of Section R608.2 shall be designed and constructed in accordance with the provisions of this section, ACI 318, ACI 332 or PCA 100. Concrete foundation walls that support above-grade concrete walls that are not within the applicability limits of Section R608.2 shall be designed and constructed in accordance with the provisions of ACI 318, ACI 332 or PCA 100. When ACI 318, ACI 332, PCA 100 or the provisions of this section are used to design concrete foundation walls, project drawings, typical details and specifications are not required to bear the seal of the architect

or engineer responsible for design, unless otherwise required by the state law of the *jurisdiction* having authority.

❖ These provisions are for concrete foundation walls. Foundation walls should be in accordance with this section or designed in accordance with one of the following documents:

- ACI 318, *Building Code Requirements for Structural Concrete*
- ACI 332, *Requirements for Residential Concrete Construction*
- PCA100, *Prescriptive Design of Exterior Concrete Walls for One- and Two-family Dwellings*

Foundation walls are usually designed and constructed to carry the vertical loads from the structure

	9	6 @ 34	6 @ 22	6 @ 16
	10	6 @ 27	6 @ 17	6 @ 13

For SI: 1 inch = 25.4 mm; 1 foot = 304.8 mm; 1 pound per square foot per foot = 0.1571 kPa²/m, 1 pound per square inch = 6.895 kPa.

NR = Not required.

- Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.
- Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi, concrete with a minimum specified compressive strength of 2,500 psi and vertical reinforcement being located at the centerline of the wall. See Section R404.1.3.3.7.2.
- Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).
- NR indicates no vertical reinforcement is required.
- Deflection criterion is $L/240$, where L is the height of the basement wall in inches.
- Interpolation is not permitted.
- Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.
- See Section R404.1.3.2 for minimum reinforcement required for basement walls supporting above-grade concrete walls.
- See Table R608.3 for tolerance from nominal thickness permitted for flat walls.
- The use of this table shall be prohibited for soil classifications not shown.

above, resist wind and any lateral forces transmitted to the foundations, and sustain earth pressures exerted against the walls, including any forces that may be imposed by frost action.

Most states do not require the seal of an architect or engineer for small residential buildings. Check with the state authorities in the location of the project for local regulations.

R404.1.3.1 Concrete cross-section. Concrete walls constructed in accordance with this code shall comply with the shapes and minimum concrete cross-sectional dimensions required by Table R608.3. Other types of forming systems resulting in concrete walls not in compliance with this section and Table R608.3 shall be designed in accordance with ACI 318.

❖ The minimum thickness and cross-section dimension of concrete walls must comply with Section R404.1.3

and Table R608.3. Other sizes must be designed in accordance with ACI 318.

Unlike masonry units, which must be manufactured in accordance with an ASTM standard, there is no standard to require the minimum thickness of nominal 6-, 8-, 10-, or 12-inch (127 mm, 203 mm, 254 mm, or 305 mm) flat concrete wall. The actual as-built minimum thickness is permitted to be no more than 1/2 inch (12.7 mm) less than the nominal thickness. See Note d of Table R608.3.

The design strength of flat concrete walls is based on thicknesses of 5.5 (139.7 mm), 7.5 (180.5 mm), 9.5 (241.3 mm) and 11.5 inches (292.1 mm).

For waffle-grid and screen-grid minimum thickness, see Notes e, f and g of Table R608.3.

R404.1.3.2 Reinforcement for foundation walls. Concrete foundation walls shall be laterally supported at the top and bottom. Horizontal reinforcement shall be provided in accor-

NR = Not required.

- a. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.
- b. Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi concrete with a minimum specified compressive strength of 2,500 psi and vertical reinforcement being located at the centerline of the wall. See Section R404.1.3.3.7.2.
- c. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).
- d. NR indicates no vertical reinforcement is required.
- e. Deflection criterion is $L/240$, where L is the height of the basement wall in inches.
- f. Interpolation is not permitted.
- g. Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.
- h. See Section R404.1.3.2 for minimum reinforcement required for basement walls supporting above-grade concrete walls.
- i. See Table R608.3 for tolerance from nominal thickness permitted for flat walls.
- j. The use of this table shall be prohibited for soil classifications not shown.

FOUNDATIONS

dance with Table R404.1.2(1). Vertical reinforcement shall be provided in accordance with Table R404.1.2(2), R404.1.2(3), R404.1.2(4), R404.1.2(5), R404.1.2(6), R404.1.2(7) or R404.1.2(8). Vertical reinforcement for flat *basement* walls retaining 4 feet (1219 mm) or more of unbalanced backfill is permitted to be determined in accordance with Table R404.1.2(9). For *basement* walls supporting above-grade concrete walls, vertical reinforcement shall be the greater of that required by Tables R404.1.2(2) through R404.1.2(8) or by Section R608.6 for the above-grade wall. In buildings assigned to Seismic Design Category D₀, D₁ or D₂, concrete foundation walls shall also comply with Section R404.1.4.2.

❖ This section provides reinforcement requirements and tables for foundation walls constructed in accordance with Section R404.1.3. The tables provide the minimum required vertical and horizontal wall reinforcement for various lateral soil loads, wall heights, and unbalanced backfill heights. Vertical wall reinforcement tables are provided for foundation walls with

unsupported wall heights up to 10 feet (3048 mm). The unsupported wall height is the maximum clear vertical distance between the exterior finish grade or interior finish ground level or top of finish floor, whichever is lower, and the sill plate (see Commentary Figure R404.1.1).

The wall must be laterally supported at the top and bottom. The tables were developed in accordance with ACI 318.

The following design assumptions were used to analyze the walls:

1. Walls are simply supported at the top and bottom.
2. Walls contain no openings.
3. Lateral bracing is provided for the wall by the floors above and the floor slabs below.
4. Allowable deflection criterion is the laterally unsupported height of the wall, in inches, divided by 240.

TABLE R404.1.2(5)
MINIMUM VERTICAL WALL REINFORCEMENT FOR 6-INCH WAFFLE-GRID BASEMENT WALLS^{b, c, d, e, g, h, i, j}

	6	5 @ 38	6 @ 34	DR
	7	6 @ 36	DR	DR
	> 8	DR	DR	DR

For SI: 1 inch = 25.4 mm; 1 foot = 304.8 mm; 1 pound per square foot per foot = 0.1571 kPa²/m, 1 pound per square inch = 6.895 kPa.

- a. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.
- b. Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi concrete with a minimum specified compressive strength of 2,500 psi and vertical reinforcement being located at the centerline of the wall. See Section R404.1.3.3.7.2.
- c. Maximum spacings shown are the values calculated for the specified bar size. Where the bar used is Grade 60 and the size specified in the table, the actual spacing in the wall shall not exceed a whole-number multiple of 12 inches (i.e., 12, 24, 36 and 48) that is less than or equal to the tabulated spacing. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).
- d. Deflection criterion is $L/240$, where L is the height of the basement wall in inches.
- e. Interpolation is not permitted.
- f. Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.
- g. See Section R404.1.3.2 for minimum reinforcement required for basement walls supporting above-grade concrete walls.
- h. See Table R608.3 for thicknesses and dimensions of waffle-grid walls.
- i. DR means design is required in accordance with the applicable building code, or where there is no code, in accordance with ACI 318.
- j. The use of this table shall be prohibited for soil classifications not shown.

Tables R404.1.2(2) through R404.1.2(7) require the vertical steel to be located at the centerline of the wall. For flat concrete walls, Table R404.1.2(8) requires the steel to be located with a maximum cover of 1¹/₄ inches (31.75 mm) from the inside face of the wall (see Section R404.1.3.3.7.2). Tables R404.1.2(2) through R404.1.2(8) are based on reinforcing bars of Grade 60 (60,000 psi minimum yield strength). Table R404.1.2(9) provides for use of an alternate grade of steel and alternate bar size. See Section R404.1.4.2 for additional requirements for foundation walls in Seismic Design Categories D₀, D₁ and D₂.

R404.1.3.2.1 Concrete foundation stem walls supporting above-grade concrete walls. Foundation stem walls that

support above-grade concrete walls shall be designed and constructed in accordance with this section.

1. Stem walls not laterally supported at top. Concrete stem walls that are not monolithic with slabs-on-ground or are not otherwise laterally supported by slabs-on-ground shall comply with this section. Where unbalanced backfill retained by the stem wall is less than or equal to 18 inches (457 mm), the stem wall and above-grade wall it supports shall be provided with vertical reinforcement in accordance with Section R608.6 and Table R608.6(1), R608.6(2) or R608.6(3) for above-grade walls. Where unbalanced backfill retained by the stem wall is greater than 18 inches (457 mm), the stem wall and above-grade wall it supports shall be provided

- i. See Table R608.3 for thicknesses and dimensions of waffle-grid walls.
- j. DR means design is required in accordance with the applicable building code, or where there is no code, in accordance with ACI 318.
- k. The use of this table shall be prohibited for soil classifications not shown.

FOUNDATIONS

with vertical reinforcement in accordance with Section R608.6 and Table R608.6(4).

2. Stem walls laterally supported at top. Concrete stem walls that are monolithic with slabs-on-ground or are otherwise laterally supported by slabs-on-ground shall be vertically reinforced in accordance with Section R608.6 and Table R608.6(1), R608.6(2) or R608.6(3) for above-grade walls. Where the unbalanced backfill retained by the stem wall is greater than 18 inches (457 mm), the connection between the stem wall and the slab-on-ground, and the portion of the slab-on-ground providing lateral support for the wall shall be designed in accordance with PCA 100 or with accepted engineering practice. Where the unbalanced backfill retained by the stem wall is greater than 18 inches (457 mm), the minimum nominal thickness of the wall shall be 6 inches (152 mm).

❖ A stem wall is a foundation wall that supports an above-grade wall and retains unbalanced backfill

beneath the slab-on-ground of the first story above grade plane.

Stem walls supporting above-grade concrete walls must meet the following:

- Vertical reinforcement in accordance with Section R608.6 and Tables R608.6(1) through R608.6(3).
- Stem walls not laterally supported at the top and unbalanced backfill greater than 18 inches (457 mm), use Section R608.6 and Table R608.6(4).
- Stem walls laterally supported at the top and unbalanced backfill greater than 18 inches (457 mm), the connection to the slab-on-ground must be designed in accordance with PCA 100 or accepted engineering practice.

TABLE R404.1.2(7)
MINIMUM VERTICAL REINFORCEMENT FOR 6-INCH (152 mm) SCREEN-GRID BASEMENT WALLS^{b, c, d, e, g, h, i, j}

For SI: 1 inch = 25.4 mm; 1 foot = 304.8 mm; 1 pound per square foot per foot = 0.1571 kPa²/m, 1 pound per square inch = 6.895 kPa.

- a. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.
- b. Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi, concrete with a minimum specified compressive strength of 2,500 psi and vertical reinforcement being located at the centerline of the wall. See Section R404.1.3.3.7.2.
- c. Maximum spacings shown are the values calculated for the specified bar size. Where the bar used is Grade 60 and the size specified in the table, the actual spacing in the wall shall not exceed a whole-number multiple of 12 inches (i.e., 12, 24, 36 and 48) that is less than or equal to the tabulated spacing. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).
- d. Deflection criterion is $L/240$, where L is the height of the basement wall in inches.
- e. Interpolation is not permitted.
- f. Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.
- g. See Sections R404.1.3.2 for minimum reinforcement required for basement walls supporting above-grade concrete walls.
- h. See Table R608.3 for thicknesses and dimensions of screen-grid walls.
- i. DR means design is required in accordance with the applicable building code, or where there is no code, in accordance with ACI 318.
- j. The use of this table shall be prohibited for soil classifications not shown.

TABLE R404.1.2(8)

NR = Not required.

- a. Soil classes are in accordance with the Unified Soil Classification System. Refer to Table R405.1.
- b. Table values are based on reinforcing bars with a minimum yield strength of 60,000 psi.
- c. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R404.1.3.3.7.6 and Table R404.1.2(9).
- d. NR indicates no vertical wall reinforcement is required, except for 6-inch nominal walls formed with stay-in-place forming systems in which case vertical reinforcement shall be No. 4@48 inches on center.
- e. Allowable deflection criterion is $L/240$, where L is the unsupported height of the basement wall in inches.
- f. Interpolation is not permitted.
- g. Where walls will retain 4 feet or more of unbalanced backfill, they shall be laterally supported at the top and bottom before backfilling.
- h. Vertical reinforcement shall be located to provide a cover of $1\frac{1}{4}$ inches measured from the inside face of the wall. The center of the steel shall not vary from the specified location by more than the greater of 10 percent of the wall thickness or $\frac{3}{8}$ inch.
- i. Concrete cover for reinforcement measured from the inside face of the wall shall be not less than $\frac{3}{4}$ inch. Concrete cover for reinforcement measured from the outside face of the wall shall be not less than $1\frac{1}{2}$ inches for No. 5 bars and smaller, and not less than 2 inches for larger bars.
- j. DR means design is required in accordance with the applicable building code, or where there is no code, in accordance with ACI 318.
- k. Concrete shall have a specified compressive strength, f'_{cs} , of not less than 2,500 psi at 28 days, unless a higher strength is required by Footnote l or m.
- l. The minimum thickness is permitted to be reduced 2 inches, provided the minimum specified compressive strength of concrete, f'_{cs} , is 4,000 psi.
- m. A plain concrete wall with a minimum nominal thickness of 12 inches is permitted, provided minimum specified compressive strength of concrete, f'_{cs} , is 3,500 psi.
- n. See Table R608.3 for tolerance from nominal thickness permitted for flat walls.
- o. The use of this table shall be prohibited for soil classifications not shown.

48	48	48	32	48	48	31	48	21	32	45	22	34	15	23	32

For SI: 1 inch = 25.4 mm, 1 pound per square inch = 6.895 kPa.

- a. This table is for use with tables in Section R404.1.3.2 that specify the minimum bar size and maximum spacing of vertical wall reinforcement for foundation walls and above-grade walls. Reinforcement specified in tables in Section R404.1.3.2 is based on Grade 60 steel reinforcement.
- b. Bar spacing shall not exceed 48 inches on center and shall be not less than one-half the nominal wall thickness.
- c. For Grade 50 steel bars (ASTM A996, Type R), use spacing for Grade 40 bars or interpolate between Grades 40 and 60.

R404.1.3.2.2 Concrete foundation stem walls supporting light-frame above-grade walls. Concrete foundation stem walls that support light-frame above-grade walls shall be designed and constructed in accordance with this section.

1. Stem walls not laterally supported at top. Concrete stem walls that are not monolithic with slabs-on-ground or are not otherwise laterally supported by slabs-on-ground and retain 48 inches (1219 mm) or less of unbalanced fill, measured from the top of the wall, shall be constructed in accordance with Section R404.1.3. Foundation stem walls that retain more than 48 inches (1219 mm) of unbalanced fill, measured from the top of the wall, shall be designed in accordance with Sections R404.1.4 and R404.4.
 2. Stem walls laterally supported at top. Concrete stem walls that are monolithic with slabs-on-ground or are otherwise laterally supported by slabs-on-ground shall be constructed in accordance with Section R404.1.3. Where the unbalanced backfill retained by the stem wall is greater than 48 inches (1219 mm), the connection between the stem wall and the slab-on-ground, and the portion of the slab-on-ground providing lateral support for the wall, shall be designed in accordance with PCA 100 or in accordance with accepted engineering practice.
- ❖ Stem walls supporting light-frame above-grade walls must meet the following:
- Constructed in accordance with Section R404.1.3.
 - Not laterally supported at the top and unbalanced backfill greater than 48 inches (1219 mm), must be designed in accordance with Sections R404.1.1 and R404.4.
 - Laterally supported at the top and unbalanced backfill greater than 48 inches (1219 mm), must be designed in accordance with PCA 100 or accepted engineering practice.

R404.1.3.3 Concrete, materials for concrete, and forms. Materials used in concrete, the concrete itself and forms shall conform to requirements of this section or ACI 318.

- ❖ Concrete, materials for concrete and forms must comply with this section or ACI 318.

R404.1.3.3.1 Compressive strength. The minimum specified compressive strength of concrete, f'_c , shall comply with Section R402.2 and shall be not less than 2,500 psi (17.2 MPa) at 28 days in buildings assigned to Seismic Design Category A, B or C and 3000 psi (20.5 MPa) in buildings assigned to Seismic Design Category D₀, D₁ or D₂.

- ❖ The minimum specified compressive strength of concrete of 2,500 psi (17.2 MPa) is based on the minimum current practice, which corresponds to minimum compressive strength permitted by ACI 318 and the code. Table R404.1.2(8) provides adjustment factors in the footnotes that recognize the benefits of using higher strength concrete. For all buildings assigned to Seismic Design Category D₀, D₁ or D₂, a minimum specified compressive strength of concrete of 3,000 psi (20.7

MPa) is required, which is consistent with Chapter 21 of ACI 318.

R404.1.3.3.2 Concrete mixing and delivery. Mixing and delivery of concrete shall comply with ASTM C94 or ASTM C685.

- ❖ Concrete must be mixed and delivered in accordance with the requirements of *Specification for Ready-Mixed Concrete* (ASTM C94) or *Specification for Concrete Made by Volumetric Batching and Continuous Mixing* (ASTM C685). Test methods for uniformity of mixing are given in ASTM C94.

R404.1.3.3.3 Maximum aggregate size. The nominal maximum size of coarse aggregate shall not exceed one-fifth the narrowest distance between sides of forms, or three-fourths the clear spacing between reinforcing bars or between a bar and the side of the form.

Exception: When *approved*, these limitations shall not apply where removable forms are used and workability and methods of consolidation permit concrete to be placed without honeycombs or voids.

- ❖ The maximum aggregate size is based on requirements in ACI 318. These limitations on aggregate size are intended to result in concrete that can be placed such that it properly encases reinforcement and minimizes honeycombing and voids. The exception, which is also based on ACI 318, is limited to use with removable forms because proper placement and encasement of reinforcement can be verified through visual inspection after removal of forms.

R404.1.3.3.4 Proportioning and slump of concrete. Proportions of materials for concrete shall be established to provide workability and consistency to permit concrete to be worked readily into forms and around reinforcement under conditions of placement to be employed, without segregation or excessive bleeding. Slump of concrete placed in removable forms shall not exceed 6 inches (152 mm).

Exception: When *approved*, the slump is permitted to exceed 6 inches (152 mm) for concrete mixtures that are resistant to segregation, and are in accordance with the form manufacturer's recommendations.

Slump of concrete placed in stay-in-place forms shall exceed 6 inches (152 mm). Slump of concrete shall be determined in accordance with ASTM C143.

- ❖ The maximum slump requirements are based on current practice. Considerations included in the prescribed maximums are ease of placement, ability to fill cavities thoroughly and limiting the pressures exerted on the form by fresh concrete.

Where removable wall forms are used, maximum slump of concrete is 6 inches (152 mm). The maximum slump is based on experience with ease of placement, ability to fill cavities thoroughly and limiting the pressures exerted on the form by fresh concrete. The 6-inch (152 mm) maximum slump refers to the characteristics of the specified mixture proportions based on water/cementitious materials ratio only. The exception envisions the use of mid-range or high-range water-reduc-

ing admixtures to increase the slump above 6 inches (152 mm), since their use does not adversely affect the tendency of the aggregate to segregate.

The minimum slump requirement for walls cast in stay-in-place forms must be greater than 6 inches (152 mm). It is important that the concrete mix design utilize proper materials in the proper proportions so that the specified strength is achieved at the specified slump [i.e., greater than 6 inches (152 mm)]. Ordering a concrete mix at a lower slump [e.g., 4 inches (102 mm)] and adding water at the job site to increase the slump to more than 6 inches (152 mm) will adversely affect the strength of the concrete, and possibly jeopardize the safety of the structure. Normally it would be expected that a concrete mixture with a specified slump in excess of 6 inches (152 mm) would contain mid-range or high-range water-reducing admixtures so as to mitigate the possibility of segregation of the aggregate.

R404.1.3.3.5 Consolidation of concrete. Concrete shall be consolidated by suitable means during placement and shall be worked around embedded items and reinforcement and into corners of forms. Where stay-in-place forms are used, concrete shall be consolidated by internal vibration.

Exception: When *approved* for concrete to be placed in stay-in-place forms, self-consolidating concrete mixtures with slumps equal to or greater than 8 inches (203 mm) that are specifically designed for placement without internal vibration need not be internally vibrated.

- ❖ Where stay-in-place forms are used, concrete must be consolidated by internal vibration. A study by PCA determined that internal vibration is required for standard mix design with a slump between 4 inches (102 mm) and 8 inches (203 mm). Two of the mixtures were intended to be used without internal vibration and good results were obtained with both. One mixture utilized a high-range water-reducing admixture to achieve a slump between 8 inches (203 mm) and 10 inches (254 mm). The other contained a high-range water-reducing admixture and a viscosity-modifying admixture to achieve a self-consolidating concrete (SCC) with a slump in excess of 8 inches (203 mm). Slumps in excess of 8 inches (103 mm) should not be obtained by the use of water alone since segregation is likely.

R404.1.3.3.6 Form materials and form ties. Forms shall be made of wood, steel, aluminum, plastic, a composite of cement and foam insulation, a composite of cement and wood chips, or other *approved* material suitable for supporting and containing concrete. Forms shall provide sufficient strength to contain concrete during the concrete placement operation.

Form ties shall be steel, solid plastic, foam plastic, a composite of cement and wood chips, a composite of cement and foam plastic, or other suitable material capable of resisting the forces created by fluid pressure of fresh concrete.

- ❖ The materials listed are based on currently available removable and stay-in-place forming systems. From a structural design standpoint, the material can be anything that has sufficient strength and durability to contain the concrete during pouring and curing.

R404.1.3.3.6.1 Stay-in-place forms. Stay-in-place concrete forms shall comply with this section.

1. Surface burning characteristics. The flame-spread index and smoke-developed index of forming material, other than foam plastic, left exposed on the interior shall comply with Section R302. The surface burning characteristics of foam plastic used in insulating concrete forms shall comply with Section R316.3.
2. Interior covering. Stay-in-place forms constructed of rigid foam plastic shall be protected on the interior of the building as required by Section R316. Where gypsum board is used to protect the foam plastic, it shall be installed with a mechanical fastening system. Use of adhesives in addition to mechanical fasteners is permitted.
3. Exterior wall covering. Stay-in-place forms constructed of rigid foam plastics shall be protected from sunlight and physical damage by the application of an approved exterior wall covering complying with this code. Exterior surfaces of other stay-in-place forming systems shall be protected in accordance with this code.
4. Termite protection. In areas where the probability of termite infestation is “very heavy” as indicated by Table R301.2(1) or Figure R301.2(6), foam plastic insulation shall be permitted below grade on foundation walls in accordance with Section R318.4.
5. Flat ICF wall system forms shall conform to ASTM E2634.

- ❖ Materials that stay in place after concrete cures must be able to withstand the rigors of the environment. From a thermal standpoint, most stay-in-place form systems and some removable form systems that incorporate insulation into the wall before the concrete is placed provide enough insulating value to meet code requirements. However, some forming systems will require the addition of insulation to the interior or exterior of the concrete wall to meet code requirements for insulating value. The form material, except foam plastic, can be anything that meets the flame spread and smoke-developed indices of Section R302. Foam plastic must comply with Section R316.3. Covering foam plastic that would otherwise be exposed to the interior of the building must comply with Section R316. Adhesively attaching the gypsum board to the foam plastic as the only means of fastening is not permitted out of concern that when the adhesive is exposed to higher temperatures expected in a fire, it may soften and allow the gypsum board to delaminate from the foam plastic.

It is generally accepted that a monolithic concrete wall is a solid wall through which water and air cannot readily flow; however, there is a possibility that the concrete wall may have drying shrinkage cracks through which water may enter. Small gaps between stay-in-place form blocks are inherent in current screen-grid stay-in-place form walls and may allow water to enter the structure. As a result, a moisture barrier on the exterior face of the stay-in-place form wall is generally required and should be considered minimum accept-

able practice. See the requirements for concrete wall dampproofing and waterproofing in Sections R405 and R406.

Where the termite hazard is very heavy, foam plastic insulation may be installed below grade only if installed on the interior or if all walls, floors and ceilings are non-combustible material or treated wood or in accordance with Section R318.1 (see commentary, Section R403.3.4). Flat insulating concrete form (ICF) wall systems must comply with ASTM E2634.

R404.1.3.3.7 Reinforcement.

- ❖ This section prescribes the requirements for steel reinforcement for concrete foundation walls.

R404.1.3.3.7.1 Steel reinforcement. Steel reinforcement shall comply with the requirements of ASTM A615, A706, or A996. ASTM A996 bars produced from rail steel shall be Type R. In buildings assigned to Seismic Design Category A, B or C, the minimum yield strength of reinforcing steel shall be 40,000 psi (Grade 40) (276 MPa). In buildings assigned to Seismic Design Category D₀, D₁ or D₂, reinforcing steel shall comply with the requirements of ASTM A706 for low-alloy steel with a minimum yield strength of 60,000 psi (Grade 60) (414 MPa).

- ❖ The types of steel reinforcement permitted by this section are consistent with ACI 318. Type R is specified for ASTM A996 (rail steel) because the ASTM standard permits two designations. The type designated R is specified because it is the only one of the two that complies with the more stringent bend requirements of ACI 318. ASTM A615 Grade 60(420 MPa) reinforcing steel that complies with the additional criteria of Section 21.2.5 of ACI 318, or ASTM A706 (low-alloy) Grade 60 (420 MPa) reinforcing steel is required in all buildings assigned to Seismic Design Category D₀, D₁ or D₂ for improved ductility. This too is consistent with ACI 318.

R404.1.3.3.7.2 Location of reinforcement in wall. The center of vertical reinforcement in *basement* walls determined from Tables R404.1.2(2) through R404.1.2(7) shall be located at the centerline of the wall. Vertical reinforcement in *basement* walls determined from Table R404.1.2(8) shall be located to provide a maximum cover of 1¹/₄ inches (32 mm) measured from the inside face of the wall. Regardless of the table used to determine vertical wall reinforcement, the center of the steel shall not vary from the specified location by more than the greater of 10 percent of the wall thickness and ³/₈ inch (10 mm). Horizontal and vertical reinforcement shall be located in foundation walls to provide the minimum cover required by Section R404.1.3.3.7.4.

- ❖ The amount of reinforcement required by Tables R404.1.2(2) through R404.1.2(7) for a given condition of wall type, height, backfill height and design lateral soil load was computed based on the centroid of the vertical reinforcement being at the center of the wall. In engineering terms, the effective depth, *d*, is one-half the wall thickness. Table R404.1.2(8) is based on the vertical reinforcement being placed with a cover of 1.25 inches (32 mm) from the inside face of the wall. This greatly increases the effective depth, *d*, for the

thicker walls, thus significantly increasing the moment strength for a given amount of reinforcement. Use of Table R404.1.2(8) is restricted to situations where there are 4 feet (1.2 m) or more of unbalanced backfill to ensure that moment-reversal caused by outward acting wind pressure does not control the design. The vertical reinforcement must be placed within a tolerance of the larger of 10 percent of the wall thickness and ³/₈ inch (10 mm). The latter criterion is based on the tolerance on *d* in ACI 318 for members with effective depth, *d*, less than or equal to 8 inches (203 mm).

R404.1.3.3.7.3 Wall openings. Vertical wall reinforcement required by Section R404.1.3.2 that is interrupted by wall openings shall have additional vertical reinforcement of the same size placed within 12 inches (305 mm) of each side of the opening.

- ❖ If a wall opening interrupts reinforcement, additional reinforcement of equivalent area must be provided. Although the code does not elaborate, a good practice is to distribute this equivalent reinforcing symmetrically on either side of the opening.

R404.1.3.3.7.4 Support and cover. Reinforcement shall be secured in the proper location in the forms with tie wire or other bar support system to prevent displacement during the concrete placement operation. Steel reinforcement in concrete cast against the earth shall have a minimum cover of 3 inches (75 mm). Minimum cover for reinforcement in concrete cast in removable forms that will be exposed to the earth or weather shall be 1¹/₂ inches (38 mm) for No. 5 bars and smaller, and 2 inches (50 mm) for No. 6 bars and larger. For concrete cast in removable forms that will not be exposed to the earth or weather, and for concrete cast in stay-in-place forms, minimum cover shall be ³/₄ inch (19 mm). The minus tolerance for cover shall not exceed the smaller of one-third the required cover or ³/₈ inch (10 mm).

- ❖ Reinforcement should be adequately supported in the forms to prevent displacement by concrete placement or workers. Concrete cover as protection of reinforcement against weather and other effects is measured from the concrete surface to the outermost surface of the steel to which the cover requirement applies. The condition "concrete surfaces exposed to earth or weather" refers to direct exposure to moisture changes and not just to temperature changes. Stay-in-place forms provide an alternative method of protection from earth or weather and the minimum cover for concrete not exposed to weather or earth is allowed. The tolerance for cover is based on ACI 318 requirements.

R404.1.3.3.7.5 Lap splices. Vertical and horizontal wall reinforcement shall be the longest lengths practical. Where splices are necessary in reinforcement, the length of lap splice shall be in accordance with Table R608.5.4.(1) and Figure R608.5.4(1). The maximum gap between noncontact parallel bars at a lap splice shall not exceed the smaller of one-fifth the required lap length and 6 inches (152 mm) [See Figure R608.5.4(1)].

- ❖ Where continuous bars are not provided, lap splices are necessary to allow forces to be transferred be-

tween sections of rebar. The length of lap splices in Table R608.5.4(1) is based on ACI 318 requirements. Noncontact lap splices are permitted provided the spacing of lapped bars does not exceed the smaller of one-fifth the required lap length or 6 inches (152 mm). If individual bars in noncontact lap splices are too widely spaced, an unreinforced section is created. Forcing a potential crack to follow a zigzag line (5:1 slope) is considered a minimum precaution. These requirements are based on ACI 318. Figure R608.5.4(1) illustrates the code text requirements.

R404.1.3.3.7.6 Alternate grade of reinforcement and spacing. Where tables in Section R404.1.3.2 specify vertical wall reinforcement based on minimum bar size and maximum spacing, which are based on Grade 60 (414 MPa) steel reinforcement, different size bars or bars made from a different grade of steel are permitted provided an equivalent area of steel per linear foot of wall is provided. Use of Table R404.1.2(9) is permitted to determine the maximum bar spacing for different bar sizes than specified in the tables or bars made from a different grade of steel. Bars shall not be spaced less than one-half the wall thickness, or more than 48 inches (1219 mm) on center.

❖ See the commentary to Section R404.1.3.2.

R404.1.3.3.7.7 Standard hooks. Where reinforcement is required by this code to terminate with a standard hook, the hook shall comply with Section R608.5.4.5 and Figure R608.5.4(3).

❖ The hook requirements shown in Figure R608.5.4(3) are consistent with the ACI 318 requirements.

R404.1.3.3.7.8 Construction joint reinforcement. Construction joints in foundation walls shall be made and located to not impair the strength of the wall. Construction joints in plain concrete walls, including walls required to have not less than No. 4 bars at 48 inches (1219 mm) on center by Sections R404.1.3.2 and R404.1.4.2, shall be located at points of lateral support, and a minimum of one No. 4 bar shall extend across the construction joint at a spacing not to exceed 24 inches (610 mm) on center. Construction joint reinforcement shall have a minimum of 12 inches (305 mm) embedment on both sides of the joint. Construction joints in reinforced concrete walls shall be located in the middle third of the span between lateral supports, or located and constructed as required for joints in plain concrete walls.

Exception: Use of vertical wall reinforcement required by this code is permitted in lieu of construction joint reinforcement provided the spacing does not exceed 24 inches (610 mm), or the combination of wall reinforcement and No. 4 bars described above does not exceed 24 inches (610 mm).

❖ Construction joints must be located where they will cause the least weakness in the structure. The reinforcement required by this section is required to provide for transfer of shear and other forces through the construction joint. These provisions are consistent with ACI 318.

R404.1.3.3.8 Exterior wall coverings. Requirements for installation of masonry veneer, stucco and other wall cover-

ings on the exterior of concrete walls and other construction details not covered in this section shall comply with the requirements of this code.

❖ The commentary to exterior wall coverings is contained in the commentary to Chapter 7 of the code.

R404.1.3.4 Requirements for Seismic Design Category C. Concrete foundation walls supporting above-grade concrete walls in townhouses assigned to Seismic Design Category C shall comply with ACI 318, ACI 332 or PCA 100 (see Section R404.1.3).

❖ See the commentary to Section R404.1.3.

R404.1.4 Seismic Design Category D₀, D₁ or D₂.

❖ This section provides the requirement for masonry and concrete foundation walls in Seismic Design Category D₀, D₁ or D₂.

R404.1.4.1 Masonry foundation walls. In buildings assigned to Seismic Design Category D₀, D₁ or D₂, as established in Table R301.2(1), masonry foundation walls shall comply with this section. In addition to the requirements of Table R404.1.1(1), plain masonry foundation walls shall comply with the following:

1. Wall height shall not exceed 8 feet (2438 mm).
2. Unbalanced backfill height shall not exceed 4 feet (1219 mm).
3. Minimum nominal thickness for plain masonry foundation walls shall be 8 inches (203 mm).
4. Masonry stem walls shall have a minimum vertical reinforcement of one No. 4 (No. 13) bar located a maximum of 4 feet (1219 mm) on center in grouted cells. Vertical reinforcement shall be tied to the horizontal reinforcement in the footings.

Foundation walls, supporting more than 4 feet (1219 mm) of unbalanced backfill or exceeding 8 feet (2438 mm) in height shall be constructed in accordance with Table R404.1.1(2), R404.1.1(3) or R404.1.1(4). Masonry foundation walls shall have two No. 4 (No. 13) horizontal bars located in the upper 12 inches (305 mm) of the wall.

❖ This section places four restrictions on the requirements in Table R404.1.1(1) for plain masonry foundation walls in Seismic Design Category D₀, D₁ or D₂.

The code requires minimum vertical reinforcement of masonry stem walls in order for them to resist lateral earthquake forces. Any wall over 8 feet (2338 mm) or supporting more than 4 feet (1219 mm) of unbalanced backfill must be constructed with minimum vertical reinforcement in accordance with Tables R404.1.1(2) through R404.1.1(4) and have the specified longitudinal reinforcement.

R404.1.4.2 Concrete foundation walls. In buildings assigned to Seismic Design Category D₀, D₁ or D₂, as established in Table R301.2(1), concrete foundation walls that support light-frame walls shall comply with this section, and concrete foundation walls that support above-grade concrete walls shall comply with ACI 318, ACI 332 or PCA 100 (see Section R404.1.3). In addition to the horizontal reinforcement

required by Table R404.1.2(1), plain concrete walls supporting light-frame walls shall comply with the following.

1. Wall height shall not exceed 8 feet (2438 mm).
2. Unbalanced backfill height shall not exceed 4 feet (1219 mm).
3. Minimum thickness for plain concrete foundation walls shall be 7.5 inches (191 mm) except that 6 inches (152 mm) is permitted where the maximum wall height is 4 feet, 6 inches (1372 mm).

Foundation walls less than 7.5 inches (191 mm) in thickness, supporting more than 4 feet (1219 mm) of unbalanced backfill or exceeding 8 feet (2438 mm) in height shall be provided with horizontal reinforcement in accordance with Table R404.1.2(1), and vertical reinforcement in accordance with Table R404.1.2(2), R404.1.2(3), R404.1.2(4), R404.1.2(5), R404.1.2(6), R404.1.2(7) or R404.1.2(8). Where Tables R404.1.2(2) through R404.1.2(8) permit plain concrete walls, not less than No. 4 (No. 13) vertical bars at a spacing not exceeding 48 inches (1219 mm) shall be provided.

❖ This section contains the provisions for concrete foundation walls supporting light-frame construction in Seismic Design Category D_0 , D_1 or D_2 . Concrete foundation walls supporting above-grade concrete walls must comply with ACI 318, ACI 332 or PCA 100.

In addition to the horizontal reinforcing, this section places three restrictions on the use of plain concrete foundation walls in Seismic Design Category D_0 , D_1 or D_2 .

Any wall over 8 feet (2338 mm) or supporting more than 4 feet (1219 mm) of unbalanced backfill must be constructed with minimum vertical reinforcement in accordance with Tables R404.1.2(2) through R404.1.2(8). Where no vertical reinforcement is required in Tables R404.1.2(2) through R404.1.2(8), No. 4 vertical bars at 48 inches on center are required.

R404.1.5 Foundation wall thickness based on walls supported. The thickness of masonry or concrete foundation walls shall be not less than that required by Section R404.1.5.1 or R404.1.5.2, respectively.

❖ This section provides the requirement for minimum thickness of masonry and concrete foundation walls.

R404.1.5.1 Masonry wall thickness. Masonry foundation walls shall be not less than the thickness of the wall supported, except that masonry foundation walls of at least 8-inch (203 mm) nominal thickness shall be permitted under brick veneered frame walls and under 10-inch-wide (254 mm) cavity walls where the total height of the wall supported, including gables, is not more than 20 feet (6096 mm), provided the requirements of Section R404.1.1 are met.

❖ Other than the two exceptions noted, masonry foundation walls should be equal to or greater than the thickness of the wall supported. The first exception permits brick veneered frame wall to be supported on 8-inch (203 mm) nominal thickness foundation walls. The second exception permits 10-inch-wide (254 mm) cav-

ity walls with total height, including gables, of 20 feet (6096 mm) maximum to be supported on 8-inch (203 mm) nominal thickness foundation walls.

FIGURE R404.1.5(1). See page 4-52.

❖ This figure illustrates several requirements for pier and curtain wall foundations described in Section R404.1.5.3. The pier spacing of not more than 6 feet, 0 inches (1829 mm) on center establishes minimum lateral (horizontal) wall support similar to that of Section R606.6.4 (also see the commentary to Section R404.1.5.3).

R404.1.5.2 Concrete wall thickness. The thickness of concrete foundation walls shall be equal to or greater than the thickness of the wall in the *story* above. Concrete foundation walls with corbels, brackets or other projections built into the wall for support of masonry veneer or other purposes are not within the scope of the tables in this section.

Where a concrete foundation wall is reduced in thickness to provide a shelf for the support of masonry veneer, the reduced thickness shall be equal to or greater than the thickness of the wall in the *story* above. Vertical reinforcement for the foundation wall shall be based on Table R404.1.2(8) and located in the wall as required by Section R404.1.3.3.7.2 where that table is used. Vertical reinforcement shall be based on the thickness of the thinner portion of the wall.

Exception: Where the height of the reduced thickness portion measured to the underside of the floor assembly or sill plate above is less than or equal to 24 inches (610 mm) and the reduction in thickness does not exceed 4 inches (102 mm), the vertical reinforcement is permitted to be based on the thicker portion of the wall.

❖ Other than the reduced thickness for a shelf for masonry veneer, concrete foundation walls must be equal to or greater than the thickness of the wall in the *story* above.

It is common practice to reduce the thickness of foundation walls approximately 4 inches (102 mm) to form a shelf for the support of masonry veneer. Generally the shelf is not located at the floor assembly that provides lateral support for the top of the foundation wall. The exception permits the vertical reinforcement for the foundation wall to be based on the thicker portion of the wall provided the shelf is located not more than 24 inches (610 mm) below the underside of the floor assembly and the reduction in thickness does not exceed 4 inches (104 mm). This assures that the location of the reduction in thickness is not near the point of maximum moment, which for a foundation wall is generally in the lower one-half of the wall height.

R404.1.5.3 Pier and curtain wall foundations. Use of pier and curtain wall foundations shall be permitted to support light-frame construction not more than two stories in height, provided the following requirements are met:

1. All load-bearing walls shall be placed on continuous concrete footings placed integrally with the exterior wall footings.

FOUNDATIONS

2. The minimum actual thickness of a load-bearing masonry wall shall be not less than 4 inches (102 mm) nominal or $3\frac{3}{8}$ inches (92 mm) actual thickness, and shall be bonded integrally with piers spaced in accordance with Section R606.6.4.
3. Piers shall be constructed in accordance with Sections R606.7 and R606.7.1, and shall be bonded into the

load-bearing masonry wall in accordance with Section R606.13.1 or R606.13.1.1.

4. The maximum height of a 4-inch (102 mm) load-bearing masonry foundation wall supporting wood-frame walls and floors shall be not more than 4 feet (1219 mm).

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 degree = 0.0175 rad.

FIGURE R404.1.5(1)
FOUNDATION WALL CLAY MASONRY CURTAIN WALL WITH CONCRETE MASONRY PIERS

5. Anchorage shall be in accordance with Section R403.1.6, Figure R404.1.5(1), or as specified by engineered design accepted by the *building official*.
 6. The unbalanced fill for 4-inch (102 mm) foundation walls shall not exceed 24 inches (610 mm) for solid masonry or 12 inches (305 mm) for hollow masonry.
 7. In Seismic Design Categories D₀, D₁ and D₂, prescriptive reinforcement shall be provided in the horizontal and vertical direction. Provide minimum horizontal joint reinforcement of two No. 9 gage wires spaced not less than 6 inches (152 mm) or one 1/4-inch-diameter (6.4 mm) wire at 10 inches (254 mm) on center vertically. Provide minimum vertical reinforcement of one No. 4 bar at 48 inches (1220 mm) on center horizontally grouted in place.
- ❖ Pier and curtain wall foundations may be used to support light-frame construction for buildings in Seismic Design Category A, B, C, D₀, D₁ or D₂, provided several conditions are met. A curtain wall typically refers to a nonload-bearing wall, but within the limits established in this section, it may be used to support up to two stories of light-frame construction. Four-inch (102 mm) nominal masonry walls are limited to 4 feet (1219 mm) in height so that a thin wall does not fail laterally due to the vertical loads on the wall. In addition, no more than 2 feet (610 mm) of unbalanced fill is permitted for solid masonry and 1 foot (305 mm) of unbalanced fill for hollow masonry to prevent failure due to the pressures created by unbalanced fill. Additional requirements are shown in Figure R404.1.5(1). This type of foundation wall must be reinforced when located in Seismic Design Category D₀, D₁ or D₂.

R404.1.6 Height above finished grade. Concrete and masonry foundation walls shall extend above the finished *grade* adjacent to the foundation at all points a minimum of 4 inches (102 mm) where masonry veneer is used and a minimum of 6 inches (152 mm) elsewhere.

- ❖ The minimum distance above adjacent grade to which the foundation must be extended provides termite protection and minimizes the chance of decay resulting from moisture migrating to the wood framing. A reduced foundation extension is permitted when masonry veneer is used.

R404.1.7 Backfill placement. Backfill shall not be placed against the wall until the wall has sufficient strength and has been anchored to the floor above, or has been sufficiently braced to prevent damage by the backfill.

Exception: Bracing is not required for walls supporting less than 4 feet (1219 mm) of unbalanced backfill.

- ❖ Backfilling should not begin until a foundation wall is in suitable condition to resist lateral earth pressure. The wall must have sufficient strength, and the floor framing system should be in place and anchored to the foundation wall as shown in Commentary Figure R404.1.7 to minimize the chance of damage to the foundation wall resulting from placement of backfill against the foundation wall.

R404.1.8 Rubble stone masonry. Rubble stone masonry foundation walls shall have a minimum thickness of 16 inches (406 mm), shall not support an unbalanced backfill exceeding 8 feet (2438 mm) in height, shall not support a soil pressure greater than 30 pounds per square foot per foot (4.71 kPa/m), and shall not be constructed in Seismic Design Category

gories D₀, D₁, D₂ or townhouses in Seismic Design Category C, as established in Figure R301.2(2).

- ❖ Rubble stone masonry is masonry walls constructed of roughly shaped stones. See the definitions in the IBC. Rubble stone masonry is almost never used for foundation walls. This type of wall construction is permitted only in Seismic Design Category A or B, and detached one- and two-family dwelling in Seismic Design Category C. Furthermore, it is restricted to a maximum unbalanced backfill height of 8 feet (2438 mm) and must not be subjected to lateral soil pressures more than 30 pounds per square foot (1436 Pa).

R404.1.9 Isolated masonry piers. Isolated masonry piers shall be constructed in accordance with this section and the general masonry construction requirements of Section R606. Hollow masonry piers shall have a minimum nominal thickness of 8 inches (203 mm), with a nominal height not exceeding four times the nominal thickness and a nominal length not exceeding three times the nominal thickness. Where hollow masonry units are solidly filled with concrete or grout, piers shall be permitted to have a nominal height not exceeding ten times the nominal thickness. Footings for isolated masonry piers shall be sized in accordance with Section R403.1.1.

- ❖ Installing masonry pier foundations is a common construction method. This section provides prescriptive requirements for isolated masonry piers used as foundations for raised wood floor systems.

The requirements of this section provide prescriptive guidance for isolated masonry piers constructed inside a basement or crawl space. The requirements of Section R404.1.9 are based on the empirical design limits contained in the TMS 402/ACI 530/ASCE 5. The language is adopted from the paragraph on foundation piers in the National Concrete Masonry Association's (NCMA) TEK Note 5-3A, *Concrete Masonry Foundation Wall Details*. Further limits are provided for piers supporting floor girders, braced wall panels and for piers in high-seismic or flood-hazard areas. Taller masonry piers supporting an elevated deck, sunroom or other substantially raised portion of a dwelling are relegated to engineered design.

R404.1.9.1 Pier cap. Hollow masonry piers shall be capped with 4 inches (102 mm) of solid masonry or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout. Where required, termite protection for the pier cap shall be provided in accordance with Section R318.

- ❖ See the commentary to Section R404.1.9.

R404.1.9.2 Masonry piers supporting floor girders. Masonry piers supporting wood girders sized in accordance with Tables R602.7(1) and R602.7(2) shall be permitted in accordance with this section. Piers supporting girders for interior bearing walls shall have a minimum nominal dimension of 12 inches (305 mm) and a maximum height of 10 feet (3048 mm) from top of footing to bottom of sill plate or girder. Piers supporting girders for exterior bearing walls shall have a minimum nominal dimension of 12 inches (305

mm) and a maximum height of 4 feet (1220 mm) from top of footing to bottom of sill plate or girder. Girders and sill plates shall be anchored to the pier or footing in accordance with Section R403.1.6 or Figure R404.1.5(1). Floor girder bearing shall be in accordance with Section R502.6.

- ❖ See the commentary to Section R404.1.9.

R404.1.9.3 Masonry piers supporting braced wall panels. Masonry piers supporting *braced wall panels* shall be designed in accordance with accepted engineering practice.

- ❖ See the commentary to Section R404.1.9.

R404.1.9.4 Seismic design of masonry piers. Masonry piers in *dwellings* located in Seismic Design Category D₀, D₁ or D₂, and townhouses in Seismic Design Category C, shall be designed in accordance with accepted engineering practice.

- ❖ See the commentary to Section R404.1.9.

R404.1.9.5 Masonry piers in flood hazard areas. Masonry piers for *dwellings* in flood hazard areas shall be designed in accordance with Section R322.

- ❖ See the commentary to Section R404.1.9.

R404.2 Wood foundation walls. Wood foundation walls shall be constructed in accordance with the provisions of Sections R404.2.1 through R404.2.6 and with the details shown in Figures R403.1(2) and R403.1(3).

- ❖ This section covers the design and installation of a multicomponent wood foundation system. The construction is essentially a below-grade load-bearing wood frame system that serves not only as the enclosure for basements and crawl spaces but also as the structural foundation for the support of light-frame structures. See Figures R403.1(2) and R403.1(3) for typical installation details for wood foundation walls (also see commentary, Section R401.1).

Certain cold-weather precautions should be taken during the installation of the wood foundation system. The composite footing consisting of a wood plate supported on a bed of stone or sand fill should not be placed on frozen ground. While the bottom of the wood plate footing would normally be placed below the frost line (i.e., basement construction) under certain drainage conditions, AWC PWF permits the wood plate to be set above the frost level. The code official should verify that such an alternative design satisfies the intent of the code. Also important is the use of proper sealants during very cold weather. All manufacturers of sealants and bonding agents impose temperature restrictions on the use of their products. Only sealants and bonding agents specifically produced for cold weather conditions should be used.

R404.2.1 Identification. Load-bearing lumber shall be identified by the grade *mark* of a lumber grading or inspection agency which has been *approved* by an accreditation body that complies with DOC PS 20. In lieu of a grade *mark*, a certificate of inspection issued by a lumber grading or inspection agency meeting the requirements of this section shall be accepted. Wood structural panels shall conform to DOC PS 1

or DOC PS 2 and shall be identified by a grade *mark* or certificate of inspection issued by an *approved agency*.

- ❖ See the commentary to Sections R502.1 and R503.2.1 as well as Figures R502.1 and R503.2.1.

R404.2.2 Stud size. The studs used in foundation walls shall be 2-inch by 6-inch (51 mm by 152 mm) members. When spaced 16 inches (406 mm) on center, a wood species with an F_b value of not less than 1,250 pounds per square inch (8619 kPa) as listed in ANSI AWC NDS shall be used. When spaced 12 inches (305 mm) on center, an F_b of not less than 875 psi (6033 kPa) shall be required.

- ❖ This section specifies the minimum bending stress, F_b , for studs based on their spacing in a foundation wall. The appropriate wood species that meet this requirement can be found in the supplement to the ANSI/AWC NDS *National Design Specification for Wood Construction*.

R404.2.3 Height of backfill. For wood foundations that are not designed and installed in accordance with AWC PWF, the height of backfill against a foundation wall shall not exceed 4 feet (1219 mm). When the height of fill is more than 12 inches (305 mm) above the interior *grade* of a crawl space or

floor of a *basement*, the thickness of the plywood sheathing shall meet the requirements of Table R404.2.3.

- ❖ Table R404.2.3 specifies requirements for plywood based on height of backfill and plywood span (stud spacing) where the height of retained earth is more than 12 inches (305 mm) [see Figure R403.1(2)]. The backfill limits of Table R404.2.3 do not apply to wood foundations designed and installed in accordance with AWC PWF.

TABLE R404.2.3. See below.

- ❖ This table specifies the minimum grade and thickness of plywood based on the height of retained earth (fill) and the plywood span (see the commentary to Section R404.2.3).

R404.2.4 Backfilling. Wood foundation walls shall not be backfilled until the *basement* floor and first floor have been constructed or the walls have been braced. For crawl space construction, backfill or bracing shall be installed on the interior of the walls prior to placing backfill on the exterior.

- ❖ These provisions require that lateral support be in place prior to backfilling on the exterior.

TABLE R404.2.3
PLYWOOD GRADE AND THICKNESS FOR WOOD FOUNDATION CONSTRUCTION (30 pcf equivalent-fluid weight soil pressure)

HEIGHT OF FILL (inches)	STUD SPACING (inches)	FACE GRAIN ACROSS STUDS			FACE GRAIN PARALLEL TO STUDS		
		Grade ^a	Minimum thickness (inches)	Span rating	Grade ^a	Minimum thickness (inches) ^{b,c}	Span rating
24	12	B	15/32	32/16	A	15/32	32/16
					B	15/32 ^c	32/16
	16	B	15/32	32/16	A	15/32 ^c	32/16
					B	19/32 ^c (4, 5 ply)	40/20
36	12	B	15/32	32/16	A	15/32	32/16
					B	15/32 ^c (4, 5 ply)	32/16
	16	B	15/32 ^c	32/16	B	19/32 (4, 5 ply)	40/20
					A	19/32	40/20
48	12	B	15/32	32/16	B	23/32	48/24
					A	15/32 ^c	32/16
	16	B	19/32	40/20	B	19/32 ^c (4, 5 ply)	40/20
					A	19/32 ^c	40/20
					A	23/32	48/24

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per cubic foot = 0.1572 kN/m³.

a. Plywood shall be of the following minimum grades in accordance with DOC PS 1 or DOC PS 2:

- DOC PS 1 Plywood grades marked:
 - Structural I C-D (Exposure 1).
 - C-D (Exposure 1).
- DOC PS 2 Plywood grades marked:
 - Structural I Sheathing (Exposure 1).
 - Sheathing (Exposure 1).
- Where a major portion of the wall is exposed above ground and a better appearance is desired, the following plywood grades marked exterior are suitable:
 - Structural I A-C, Structural I B-C or Structural I C-C (Plugged) in accordance with DOC PS 1.
 - A-C Group 1, B-C Group 1, C-C (Plugged) Group 1 or MDO Group 1 in accordance with DOC PS 1.
 - Single Floor in accordance with DOC PS 1 or DOC PS 2.

b. Minimum thickness 15/32 inch, except crawl space sheathing shall have not less than 3/8 inch for face grain across studs 16 inches on center and maximum 2-foot depth of unequal fill.

c. For this fill height, thickness and grade combination, panels that are continuous over less than three spans (across less than three stud spacings) require blocking 16 inches above the bottom plate. Offset adjacent blocks and fasten through studs with two 16d corrosion-resistant nails at each end.

R404.2.5 Drainage and dampproofing. Wood foundation basements shall be drained and dampproofed in accordance with Sections R405 and R406, respectively.

❖ See Sections R405.2 and R406.3 of this commentary.

R404.2.6 Fastening. Wood structural panel foundation wall sheathing shall be attached to framing in accordance with Table R602.3(1) and Section R402.1.1.

❖ The fastening schedule must be followed for wall sheathing attachment. Also see the commentary to Section R402.1.1.

R404.3 Wood sill plates. Wood sill plates shall be a minimum of 2-inch by 4-inch (51 mm by 102 mm) nominal lumber. Sill plate anchorage shall be in accordance with Sections R403.1.6 and R602.11.

❖ Minimum 2-inch by 4-inch (51 mm by 102 mm) nominal sill plates are required, and should be anchored to the foundation as required by Section R403.1.6.

R404.4 Retaining walls. Retaining walls that are not laterally supported at the top and that retain in excess of 48 inches (1219 mm) of unbalanced fill, or retaining walls exceeding 24 inches (610 mm) in height that resist lateral loads in addition to soil, shall be designed in accordance with accepted engineering practice to ensure stability against overturning, sliding, excessive foundation pressure and water uplift. Retaining walls shall be designed for a safety factor of 1.5 against lateral sliding and overturning. This section shall not apply to foundation walls supporting buildings.

❖ This section provides design considerations for a retaining wall that retains in excess of 48 inches (610 mm) of unbalanced fill or retaining walls exceeding 24 inches in height that resist additional lateral loads such as vehicle surcharges or structures built on top of the wall that are subject to wind loads. The lateral pressure of the soil against the retaining wall is greatly influenced by soil moisture. Backfill is usually kept from being saturated for an extended length of time by placing drains near the base of the retaining wall to remove the water in the soil behind it.

R404.5 Precast concrete foundation walls.

❖ This section prescribes the design, drawings and identification requirements for precast concrete foundation walls.

R404.5.1 Design. Precast concrete foundation walls shall be designed in accordance with accepted engineering practice. The design and manufacture of precast concrete foundation wall panels shall comply with the materials requirements of Section R402.3 or ACI 318. The panel design drawings shall be prepared by a registered design professional where required by the statutes of the *jurisdiction* in which the project is to be constructed in accordance with Section R106.1.

❖ This section prescribes the minimum design and manufacture requirement for precast concrete foundation walls. The material required must comply with ACI 318 or Section R402.3 (see commentary, Section R402.3).

R404.5.2 Precast concrete foundation design drawings. Precast concrete foundation wall design drawings shall be submitted to the *building official* and *approved* prior to installation. Drawings shall include, at a minimum, the following information:

1. Design loading as applicable.
2. Footing design and material.
3. Concentrated loads and their points of application.
4. Soil bearing capacity.
5. Maximum allowable total uniform load.
6. Seismic design category.
7. Basic wind speed.

❖ This section prescribes the minimum design requirement for precast concrete foundations and must be shown on the design drawings that are submitted to the building official. Precast foundation systems are engineered products based on several design approaches including, but not limited to, stud and cavity, solid wall panel, composite panel and hollow core systems. This section provides minimum performance design criteria that all precast concrete foundation systems must meet.

R404.5.3 Identification. Precast concrete foundation wall panels shall be identified by a certificate of inspection *label* issued by an *approved* third-party inspection agency.

❖ This section requires identification by a certificate of inspection that should verify that precast foundation walls are designed to recognized engineering standards, manufactured in a plant under verified quality control, when installed will meet required performance criteria, and are neutral regarding the various design approaches and systems.

**SECTION R405
FOUNDATION DRAINAGE**

R405.1 Concrete or masonry foundations. Drains shall be provided around concrete or masonry foundations that retain earth and enclose habitable or usable spaces located below *grade*. Drainage tiles, gravel or crushed stone drains, perforated pipe or other *approved* systems or materials shall be installed at or below the area to be protected and shall discharge by gravity or mechanical means into an *approved* drainage system. Gravel or crushed stone drains shall extend not less than 1 foot (305 mm) beyond the outside edge of the footing and 6 inches (152 mm) above the top of the footing and be covered with an *approved* filter membrane material. The top of open joints of drain tiles shall be protected with strips of building paper. Except where otherwise recommended by the drain manufacturer, perforated drains shall be surrounded with an *approved* filter membrane or the filter membrane shall cover the washed gravel or crushed rock covering the drain. Drainage tiles or perforated pipe shall be placed on a minimum of 2 inches (51 mm) of washed gravel or crushed rock not less

than one sieve size larger than the tile joint opening or perforation and covered with not less than 6 inches (152 mm) of the same material.

Exception: A drainage system is not required where the foundation is installed on well-drained ground or sand-gravel mixture soils according to the Unified Soil Classification System, Group I soils, as detailed in Table R405.1.

- ❖ To allow free groundwater that may be present adjacent to the foundation wall to be drained away, drains are usually placed around houses to remove water and prevent leakage into habitable or usable spaces below grade. The top of the gravel or crushed stone drain, with or without drainage tile or perforated pipe, must be covered with an approved filter membrane. Drainage tiles are extremely important in areas having moderate to heavy rainfall and in soils having a low percolation rate. Perforated pipe has perforations around the entire pipe. The perforations will be subject to clogging if not protected. Except where otherwise recommended by the drain manufacturer, the code requires an approved filter membrane to surround the perforated drain pipe. As an alternate the code permits the wash gravel or crushed stone covering the perforated pipe to be covered with an approved filter membrane. The filter membrane allows water to pass through the perimeter drain tiles or pipes without allowing, or at least greatly reducing, the possibility of fine soil

materials entering the drainage system. A few examples of such systems are illustrated in Commentary Figures R405.1(1) and R405.1(2). The exception allows omission of the drainage system in Group I soils, which by definition exhibit good drainage characteristics as shown in Table R405.1.

TABLE R405.1. See below.

- ❖ This table provides soil properties based on the soil's classification in accordance with the United Soil Classification System. This method of identifying soil is determined in ASTM D2487, *Standard Classification of Soils for Engineering Purposes*. See the commentary to Section R405.1.

R405.1.1 Precast concrete foundation. Precast concrete walls that retain earth and enclose habitable or useable space located below-grade that rest on crushed stone footings shall have a perforated drainage pipe installed below the base of the wall on either the interior or exterior side of the wall, not less than 1 foot (305 mm) beyond the edge of the wall. If the exterior drainage pipe is used, an *approved* filter membrane material shall cover the pipe. The drainage system shall discharge into an *approved* sewer system or to daylight.

- ❖ A perforated drainage pipe is required where crushed stone footing is used with precast concrete foundation walls that enclose habitable or usable space. It is important that the perforated drainage pipe be located

TABLE R405.1
PROPERTIES OF SOILS CLASSIFIED ACCORDING TO THE UNIFIED SOIL CLASSIFICATION SYSTEM

SOIL GROUP	UNIFIED SOIL CLASSIFICATION SYSTEM SYMBOL	SOIL DESCRIPTION	DRAINAGE CHARACTERISTICS ^a	FROST HEAVE POTENTIAL	VOLUME CHANGE POTENTIAL EXPANSION ^b
Group I	GW	Well-graded gravels, gravel sand mixtures, little or no fines	Good	Low	Low
	GP	Poorly graded gravels or gravel sand mixtures, little or no fines	Good	Low	Low
	SW	Well-graded sands, gravelly sands, little or no fines	Good	Low	Low
	SP	Poorly graded sands or gravelly sands, little or no fines	Good	Low	Low
	GM	Silty gravels, gravel-sand-silt mixtures	Good	Medium	Low
	SM	Silty sand, sand-silt mixtures	Good	Medium	Low
Group II	GC	Clayey gravels, gravel-sand-clay mixtures	Medium	Medium	Low
	SC	Clayey sands, sand-clay mixture	Medium	Medium	Low
	ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity	Medium	High	Low
	CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays	Medium	Medium	Medium to Low
Group III	CH	Inorganic clays of high plasticity, fat clays	Poor	Medium	High
	MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts	Poor	High	High
Group IV	OL	Organic silts and organic silty clays of low plasticity	Poor	Medium	Medium
	OH	Organic clays of medium to high plasticity, organic silts	Unsatisfactory	Medium	High
	Pt	Peat and other highly organic soils	Unsatisfactory	Medium	High

For SI: 1 inch = 25.4 mm.

- a. The percolation rate for good drainage is over 4 inches per hour, medium drainage is 2 inches to 4 inches per hour, and poor is less than 2 inches per hour.
- b. Soils with a low potential expansion typically have a plasticity index (PI) of 0 to 15, soils with a medium potential expansion have a PI of 10 to 35 and soils with a high potential expansion have a PI greater than 20.

FOUNDATIONS

at least 1 foot (305 mm) away from the edge of the wall. This is similar to the drainage requirement of Section R405.1 except it is limited to perforated drainage pipe and there is no exception for omission when installed in Group I soils.

R405.2 Wood foundations. Wood foundations enclosing habitable or usable spaces located below *grade* shall be adequately drained in accordance with Sections R405.2.1 through R405.2.3.

❖ As does Section R405.1, this section gives specific drainage requirements for wood foundations. Also refer to the commentary to Section R401.1.

R405.2.1 Base. A porous layer of gravel, crushed stone or coarse sand shall be placed to a minimum thickness of 4 inches (102 mm) under the *basement* floor. Provision shall be made for automatic draining of this layer and the gravel or crushed stone wall footings.

❖ See Figure R403.1(2). This requirement for drainage under the basement floor is similar to those in Sections R504.2.1 (wood floor) and R506.2.2 (concrete floor).

R405.2.2 Vapor retarder. A 6-mil-thick (0.15 mm) polyethylene vapor retarder shall be applied over the porous layer with the *basement* floor constructed over the polyethylene.

❖ See Figure R403.1(2). Also see the commentary to Section R506.2.3.

R405.2.3 Drainage system. In other than Group I soils, a sump shall be provided to drain the porous layer and footings. The sump shall be not less than 24 inches (610 mm) in diameter or 20 inches square (0.0129 m²), shall extend not less

than 24 inches (610 mm) below the bottom of the *basement* floor and shall be capable of positive gravity or mechanical drainage to remove any accumulated water. The drainage system shall discharge into an *approved* sewer system or to daylight.

❖ Except for Group I soils, which exhibit good drainage (see Table R405.1), a sump is necessary to drain the footing (see Section R403.2) and porous layer (see Section R405.2.1). Also see Figure R403.1(2).

SECTION R406 FOUNDATION WATERPROOFING AND DAMP-PROOFING

R406.1 Concrete and masonry foundation damp-proofing.

Except where required by Section R406.2 to be waterproofed, foundation walls that retain earth and enclose interior spaces and floors below *grade* shall be damp-proofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished grade. Masonry walls shall have not less than $\frac{3}{8}$ inch (9.5 mm) portland cement parging applied to the exterior of the wall. The parging shall be damp-proofed in accordance with one of the following:

1. Bituminous coating.
2. Three pounds per square yard (1.63 kg/m²) of acrylic modified cement.
3. One-eighth-inch (3.2 mm) coat of surface-bonding cement complying with ASTM C887.
4. Any material permitted for waterproofing in Section R406.2.

5. Other approved methods or materials.

Exception: Parging of unit masonry walls is not required where a material is approved for direct application to the masonry.

Concrete walls shall be dampproofed by applying any one of the listed dampproofing materials or any one of the waterproofing materials listed in Section R406.2 to the exterior of the wall.

❖ To minimize moisture in the form of water vapor from entering below-ground spaces from the outside, dampproofing of the exterior foundation walls is necessary, unless waterproofing is required by Section R406.2. Although the terms “waterproofing” and “dampproof-

ing” both relate to moisture protection, they are sometimes misapplied in the sense that “waterproofing” is used when “dampproofing” is really meant. Dampproofing does not give the same degree of moisture protection as does waterproofing. Methods of dampproofing for masonry and concrete foundation walls are shown in Commentary Figures R406.1(1) and R406.1(2).

Dampproofing installations generally consist of the application of one or more coatings of impervious compounds that are intended to prevent the passage of water vapor through walls or other building elements. Dampproofing may also restrict the flow of water under slight pressure.

FOUNDATIONS

R406.2 Concrete and masonry foundation waterproofing.

In areas where a high water table or other severe soil-water conditions are known to exist, exterior foundation walls that retain earth and enclose interior spaces and floors below *grade* shall be waterproofed from the higher of (a) the top of the footing or (b) 6 inches (152 mm) below the top of the basement floor, to the finished *grade*. Walls shall be waterproofed in accordance with one of the following:

1. Two-ply hot-mopped felts.
2. Fifty-five-pound (25 kg) roll roofing.
3. Six-mil (0.15 mm) polyvinyl chloride.
4. Six-mil (0.15 mm) polyethylene.
5. Forty-mil (1 mm) polymer-modified asphalt.
6. Sixty-mil (1.5 mm) flexible polymer cement.
7. One-eighth-inch (3 mm) cement-based, fiber-reinforced, waterproof coating.

8. Sixty-mil (1.5 mm) solvent-free liquid-applied synthetic rubber.

Exception: Organic-solvent-based products such as hydrocarbons, chlorinated hydrocarbons, ketones and esters shall not be used for ICF walls with expanded polystyrene form material. Use of plastic roofing cements, acrylic coatings, latex coatings, mortars and pargings to seal ICF walls is permitted. Cold-setting asphalt or hot asphalt shall conform to Type C of ASTM D449. Hot asphalt shall be applied at a temperature of less than 200°F (93°C).

All joints in membrane waterproofing shall be lapped and sealed with an adhesive compatible with the membrane.

❖ Foundation walls that retain earth and enclose interior spaces and floors and extend below ground water level (seasonal or otherwise) require a positive means of preventing moisture migration. Waterproofing installa-

Figure R406.1(1)
DAMPPROOFING OF MASONRY FOUNDATION WALL
[see also Figure R405.1(1)]

For SI: 1 inch = 25.4 mm.

Figure R406.1(2)
DAMPPROOFING OF CONCRETE FOUNDATION WALL
[see also Figure R405.1(1)]

tions consist of the application of a combination of sealing materials and impervious coatings used on walls or other building elements to prevent the passage of moisture in either a vapor or liquid form under conditions of significant hydrostatic pressure. Methods for waterproofing concrete and masonry foundation walls are shown in Commentary Figure R406.2.

R406.3 Dampproofing for wood foundations. Wood foundations enclosing habitable or usable spaces located below *grade* shall be dampproofed in accordance with Sections R406.3.1 through R406.3.4.

❖ The requirements for dampproofing wood foundation walls are shown in Figure R403.1(2). These requirements for sealing the plywood panel joints, installing a moisture barrier and installing porous fill can minimize the intrusion of water into a basement or usable space. Also refer to the commentary to Section R401.1.

R406.3.1 Panel joint sealed. Plywood panel joints in the foundation walls shall be sealed full length with a caulking compound capable of producing a moistureproof seal under the conditions of temperature and moisture content at which it will be applied and used.

❖ See the commentary to Section R406.3.

R406.3.2 Below-grade moisture barrier. A 6-mil-thick (0.15 mm) polyethylene film shall be applied over the below-*grade* portion of exterior foundation walls prior to backfilling. Joints in the polyethylene film shall be lapped 6 inches (152 mm) and sealed with adhesive. The top edge of the polyethylene film shall be bonded to the sheathing to form a seal. Film areas at *grade* level shall be protected from mechanical damage and exposure by a pressure-preservative treated lumber or plywood strip attached to the wall several inches above

finished *grade* level and extending approximately 9 inches (229 mm) below *grade*. The joint between the strip and the wall shall be caulked full length prior to fastening the strip to the wall. Where approved, other coverings appropriate to the architectural treatment shall be permitted to be used. The polyethylene film shall extend down to the bottom of the wood footing plate but shall not overlap or extend into the gravel or crushed stone footing.

❖ See the commentary to Section R406.3.

R406.3.3 Porous fill. The space between the excavation and the foundation wall shall be backfilled with the same material used for footings, up to a height of 1 foot (305 mm) above the footing for well-drained sites, or one-half the total back-fill height for poorly drained sites. The porous fill shall be covered with strips of 30-pound (13.6 kg) asphalt paper or 6-mil (0.15 mm) polyethylene to permit water seepage while avoiding infiltration of fine soils.

❖ See the commentary to Section R406.3.

R406.3.4 Backfill. The remainder of the excavated area shall be backfilled with the same type of soil as was removed during the excavation.

❖ See the commentary to Sections R404.2.4 and R406.3.

R406.4 Precast concrete foundation system dampproofing. Except where required by Section R406.2 to be waterproofed, precast concrete foundation walls enclosing habitable or usable spaces located below *grade* shall be dampproofed in accordance with Section R406.1.

❖ See the commentary to Sections R406.1 and R406.2.

R406.4.1 Panel joints sealed. Precast concrete foundation panel joints shall be sealed full height with a sealant meeting

FOUNDATIONS

ASTM C920, Type S or M, *Grade NS*, Class 25, Use NT, M or A. Joint sealant shall be installed in accordance with the manufacturer's instructions.

- ❖ All joints between precast concrete panels must be sealed in order to afford proper dampproofing or waterproofing. This section specifies the sealant material and the requirement to install the sealant in accordance with the manufacturer's instructions.

SECTION R407 COLUMNS

R407.1 Wood column protection. Wood columns shall be protected against decay as set forth in Section R317.

- ❖ See the commentary to Section R319.

R407.2 Steel column protection. All surfaces (inside and outside) of steel columns shall be given a shop coat of rust-inhibitive paint, except for corrosion-resistant steel and steel treated with coatings to provide corrosion resistance.

- ❖ The requirements of this section protect steel columns from the adverse effects of corrosion.

R407.3 Structural requirements. The columns shall be restrained to prevent lateral displacement at the bottom end. Wood columns shall be not less in nominal size than 4 inches by 4 inches (102 mm by 102 mm). Steel columns shall be not less than 3-inch-diameter (76 mm) Schedule 40 pipe manufactured in accordance with ASTM A53 Grade B or *approved* equivalent.

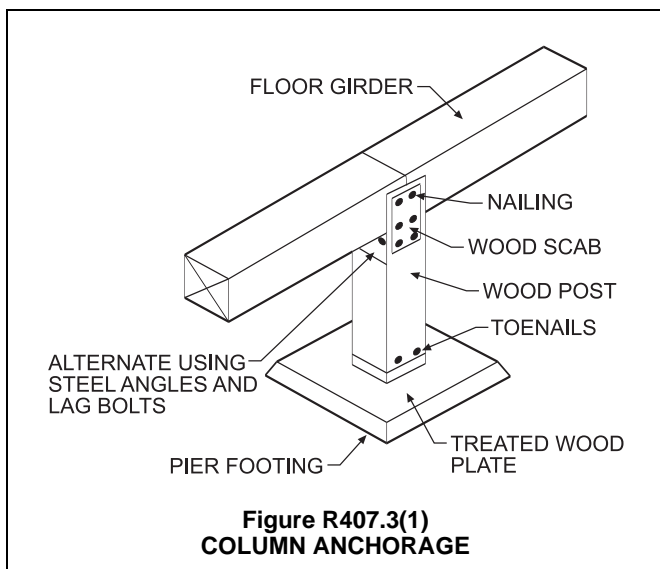

Exception: In Seismic Design Categories A, B and C, columns not more than 48 inches (1219 mm) in height on a pier or footing are exempt from the bottom end lateral displacement requirement within under-floor areas enclosed by a continuous foundation.

- ❖ Columns must be designed in accordance with accepted engineering practice. Minimum sizes for wood and steel columns are specified to reduce concerns about the structural capacity of slender columns. To minimize the chance of accidentally displacing col-

umns supporting beams or girders, a means of mechanically anchoring a column is required [see Commentary Figures R407.3(1), R407.3(2) and R407.3(3)]. If prefabricated metal-wood connectors are used, they should be installed in accordance with the manufacturer's instructions.

SECTION R408 UNDER-FLOOR SPACE

R408.1 Ventilation. The under-floor space between the bottom of the floor joists and the earth under any building (except space occupied by a *basement*) shall have ventilation openings through foundation walls or exterior walls. The minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m²) for each 150 square feet (14 m²) of under-floor space area, unless the ground surface is covered by a Class 1 vapor retarder material. Where a Class 1 vapor retarder material is used, the minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m²) for each 1,500 square feet (140 m²) of under-floor space

area. One such ventilating opening shall be within 3 feet (914 mm) of each corner of the building.

❖ Raised floor construction results in an under-floor space, commonly referred to as a “crawl space.” To control condensation within crawl space areas and thus reduce the chance of dry rot, natural ventilation of such spaces by reasonably distributed openings through foundation walls or exterior walls is required. Condensation is a function of the geographical location and climatic conditions; therefore, the dependence on ventilating openings through the foundation wall or exterior wall may run counter to energy conservation measures. The use of a vapor retarder material on the ground surface inhibits the flow of moisture from the ground surface into the crawl space and thus reduces the need for ventilation. Commentary Figure R408.1 illustrates the use of openings through the foundation walls.

R408.2 Openings for under-floor ventilation. The minimum net area of ventilation openings shall be not less than 1 square foot (0.0929 m²) for each 150 square feet (14 m²) of under-floor area. One ventilation opening shall be within 3 feet (915 mm) of each corner of the building. Ventilation openings shall be covered for their height and width with any of the following materials provided that the least dimension of the covering shall not exceed $\frac{1}{4}$ inch (6.4 mm):

1. Perforated sheet metal plates not less than 0.070 inch (1.8 mm) thick.
2. Expanded sheet metal plates not less than 0.047 inch (1.2 mm) thick.
3. Cast-iron grill or grating.
4. Extruded load-bearing brick vents.
5. Hardware cloth of 0.035 inch (0.89 mm) wire or heavier.

6. Corrosion-resistant wire mesh, with the least dimension being $\frac{1}{8}$ inch (3.2 mm) thick.

Exception: The total area of ventilation openings shall be permitted to be reduced to $\frac{1}{1,500}$ of the under-floor area where the ground surface is covered with an *approved* Class I vapor retarder material and the required openings are placed to provide cross ventilation of the space. The installation of operable louvers shall not be prohibited.

❖ Installing a covering material over the ventilation opening keeps animals such as rodents or vermin from entering the crawl space. Several options are provided and they all must have openings that have no dimension exceeding $\frac{1}{4}$ inch (6.4 mm). The area of the ventilation opening accounts for net free area of the covering material used to protect the ventilation opening. For some covering materials the net free area can be up to 50 percent less than the gross area of the ventilation opening.

The use of a vapor retarder material on the ground surface inhibits the flow of moisture from the ground surface into the crawl space and thus reduces, if not virtually eliminates, the need for ventilation. Therefore, the exception provides for a drastic reduction in the amount of ventilation openings required. While the vapor retarder may significantly reduce the moisture accumulation, ventilation openings are still required but may be equipped with manual dampers to permit them to be closed during the coldest weeks of the year in northern climates.

The following is an example of the area calculation:

Example 1:

A house has a crawl space area of 1,300 square feet (121 m²). The amount of ventilation opening

required is $1,300/150 = 8.7$ square feet (0.805 m^2) \times 144 square inches per square foot = 1,252 square inches (0.81 m^2). This is the total net clear area of opening required that must be distributed among all the openings. An 8-inch by 16-inch (203 mm by 406 mm) opening provides 128 square inches (0.83 m^2). Ten 8 by 16-inch (203 mm by 406 mm) openings will provide 1,280 square inches (0.83 m^2) which is greater than the 1,252 square inches (0.81 m^2) required.

The following is an example of using the exception:

Example 2:

In Example 1, the required amount opening area (1252 square inches) may be reduced by a factor of 10 to 125.2 square inches ($80,826 \text{ mm}^2$) if an approved Class I vapor retarder is used on the ground surface of the crawl space in accordance with the exception. Note that opening placement must provide cross ventilation.

R408.3 Unvented crawl space. Ventilation openings in under-floor spaces specified in Sections R408.1 and R408.2 shall not be required where the following items are provided:

1. Exposed earth is covered with a continuous Class I vapor retarder. Joints of the vapor retarder shall overlap by 6 inches (152 mm) and shall be sealed or taped. The edges of the vapor retarder shall extend not less than 6 inches (152 mm) up the stem wall and shall be attached and sealed to the stem wall or insulation.
 2. One of the following is provided for the under-floor space:
 - 2.1. Continuously operated mechanical exhaust ventilation at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m^2) of crawl space floor area, including an air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.
 - 2.2. *Conditioned air* supply sized to deliver at a rate equal to 1 cubic foot per minute (0.47 L/s) for each 50 square feet (4.7 m^2) of under-floor area, including a return air pathway to the common area (such as a duct or transfer grille), and perimeter walls insulated in accordance with Section N1102.2.11 of this code.
 - 2.3. Plenum in existing structures complying with Section M1601.5, if under-floor space is used as a plenum.
- ❖ This section lists several conditions under which the ventilation openings through the foundation walls are not required. The exposed earth of the under-floor area must be covered with a continuous Class I vapor retarder. See the commentary to Section R202 for the definition of "Vapor retarder class." If the perimeter walls are insulated, either a continuously operating mechanical exhaust vent or conditioned air must be

provided in order to eliminate the ventilation openings.

Elimination of the ventilation openings is permitted in existing structures when the under-floor space is used as a plenum. Under-floor plenums are prohibited in new construction (see commentary, Section M1601.5).

R408.4 Access. Access shall be provided to all under-floor spaces. Access openings through the floor shall be a minimum of 18 inches by 24 inches (457 mm by 610 mm). Openings through a perimeter wall shall be not less than 16 inches by 24 inches (407 mm by 610 mm). Where any portion of the through-wall access is below *grade*, an areaway not less than 16 inches by 24 inches (407 mm by 610 mm) shall be provided. The bottom of the areaway shall be below the threshold of the access opening. Through wall access openings shall not be located under a door to the residence. See Section M1305.1.4 for access requirements where mechanical *equipment* is located under floors.

❖ The provisions of this section require access to all under-floor spaces. Access is required for continuing maintenance of the building and for inspection and repair of such items as plumbing, mechanical systems or electrical system runs within the crawl space. This section addresses the different conditions encountered in accessing an under-floor space through the floor system or the foundation wall. Where the access opening is through the floor, an opening of not less than 18 inches by 24 inches (457 mm by 610 mm) is required. Where the access opening is through the foundation wall, an opening of not less than 16 inches by 24 inches (406 mm by 610 mm) is required. See Commentary Figure R408.1. The 16- and 24-inch (406 mm and 610 mm) dimensions are to work with standard CMU coursing. Where mechanical equipment is located under the floor, the minimum access opening must comply with Section M1305.1.4.

R408.5 Removal of debris. The under-floor *grade* shall be cleaned of all vegetation and organic material. All wood forms used for placing concrete shall be removed before a building is occupied or used for any purpose. All construction materials shall be removed before a building is occupied or used for any purpose.

❖ Vegetation, stumps, roots and other matter left in an excavation around a building are major causes of termite infestation and moisture problems. As such material decays, the ground settles, negating the original drainage plan. Even before decay, the material provides pockets for water accumulation, which can have subsequent destructive impact on the structure. To eliminate a natural attraction to termites, insects or animals, all vegetation and organic material must be cleared.

R408.6 Finished grade. The finished *grade* of under-floor surface shall be permitted to be located at the bottom of the footings; however, where there is evidence that the groundwater table can rise to within 6 inches (152 mm) of the finished floor at the building perimeter or where there is evidence that the surface water does not readily drain from the building site, the *grade* in the under-floor space shall be

as high as the outside finished *grade*, unless an *approved* drainage system is provided.

- ❖ To circumvent moisture accumulation in the crawl space area, the grade in the under-floor space must be at the same elevation as grade outside of the building if the groundwater table can rise to within 6 inches (152 mm) of the finished floor elevation or the surface water does not readily drain from the site. An alternative would be an approved drainage system.

R408.7 Flood resistance. For buildings located in flood hazard areas as established in Table R301.2(1):

1. Walls enclosing the under-floor space shall be provided with flood openings in accordance with Section R322.2.2.
2. The finished ground level of the under-floor space shall be equal to or higher than the outside finished ground level on at least one side.

Exception: Under-floor spaces that meet the requirements of FEMA TB 11-1.

- ❖ To minimize hydrostatic loads by allowing the free inflow and outflow of floodwaters, buildings in flood hazard areas (A Zones) that have walls enclosing under-floor spaces are to have flood openings in those walls. This provision alerts the designer that flood openings are to be provided in addition to standard ventilation openings. This requirement applies only to buildings in flood hazard areas not subject to high-velocity wave action. Buildings in coastal high-hazard areas subject to high-velocity wave action may have enclosed areas below the design flood elevation, but only if those walls are intended to break away as specified in Section R324.3.4.

The provisions of this section require the elevation of the finished ground level of the under-floor space to be at or above the elevation of the outside finished ground level on at least one side. In flood hazard areas, if the floor of an enclosed area, including a crawl space, is below the exterior grade on all sides, then the building is considered to have a basement and Section R322 requires basements to be elevated to or above the required elevation. Note that an under-floor space may be partially below grade. As long as the interior finished ground level is at or above the exterior finished grade on at least one side, then a basement is not created. Section R408.6 requires the grade in under-floor spaces to be as high as the outside finished grade unless an approved drainage system is provided. Section R408.7, Item 2, clarifies that use of a drainage system should not be permitted in flood hazard areas because a basement (below grade on all sides) would be created. The exception permits the use of FEMA TB 11, which permits the elevation of the under-floor space to be below the elevation of the outside finished ground level with limitations on maximum depth below grade (top of footing no more than 2 feet below grade) and maximum foundation wall height (no more than 4 feet from top of footing to top of wall). Use of FEMA TB

11 will result in flood insurance rates higher than for buildings that have the finished ground level of the under-floor space at or above the elevation of the outside finished ground level on at least one side.

Chapter 5: Floors

General Comments

Section R501 provides the scope of the chapter and states the general performance requirements for floor systems. The floor systems covered in the code consist of four different types: wood floor framing, wood floors on the ground, steel floor framing and concrete slabs on the ground. Section R502 addresses wood floor framing criteria and includes prescriptive tables from which the size of the joists can be determined based on the span and species of wood.

Section R503 specifies floor-sheathing requirements. Section R504 governs wood floors constructed on ground that would serve as part of a wood foundation system described in Chapter 4. This system relies on pressure-preservative-treated wood to resist the damage from exposure to moisture from contact with the ground. Section R505 contains cold-formed steel floor framing provisions, which include prescriptive criteria that greatly simplify the use of cold-formed steel framing in a floor system. Section R506 contains requirements for concrete slab-on-ground floors. Concrete slab-on-grade construction requires a minimum 3.5-inch-thick (89 mm) slab and a vapor retarder in most cases.

The primary consideration of this chapter is the structural integrity of the floor system. In a two-family dwelling, a floor that separates dwelling units must be a fire-resistance-rated assembly in accordance with Section R302.3. Such a floor must conform to the conditions of the floor assembly's listing in addition to the require-

ments of this chapter. Section R507 provides prescriptive requirements for exterior decks of wood-framed construction and the connection to the main building. This section also addresses the use of plastic composites for deck construction.

Purpose

Chapter 5 provides the requirements for the design and construction of floor systems that will be capable of supporting minimum required design loads. This chapter covers four different types: wood floor framing, wood floors on the ground, steel floor framing and concrete slabs on the ground. Allowable span tables are provided that greatly simplify the determination of joist, girder and sheathing sizes for raised floor systems of wood framing and cold-formed steel framing. This chapter also contains prescriptive requirements for exterior decks of wood-framed construction.

The floor system must also serve as a diaphragm; therefore, it plays a key role in resisting lateral loads from earthquakes and/or wind. Although this chapter does not base floor system requirements on these loads, floor systems constructed as required in this chapter will perform this function. Chapter 6 of the code accounts for these loads by varying the spacing of the supporting braced wall lines or shear walls based on seismic design category and basic wind speed or, in selected cases, specifying additional diaphragm requirements.

SECTION R501 GENERAL

R501.1 Application. The provisions of this chapter shall control the design and construction of the floors for buildings, including the floors of *attic* spaces used to house mechanical or plumbing fixtures and *equipment*.

❖ Floors (including attic floors) that house mechanical equipment or plumbing fixtures (see the definition in Chapter 2) must comply with this chapter.

R501.2 Requirements. Floor construction shall be capable of accommodating all loads in accordance with Section R301 and of transmitting the resulting loads to the supporting structural elements.

❖ This is a general performance statement that requires the floor system to support the design loads and provide the necessary load path to supporting elements.

SECTION R502 WOOD FLOOR FRAMING

R502.1 General. Wood and wood-based products used for load-supporting purposes shall conform to the applicable provisions of this section.

❖ Sections R502.1.1 through R502.1.7 contain the prescriptive requirements for wood and wood-based products used in wood floor framing.

R502.1.1 Sawn lumber. Sawn lumber shall be identified by a grade *mark* of an accredited lumber grading or inspection agency and have design values certified by an accreditation body that complies with DOC PS 20. In lieu of a grade *mark*, a certificate of inspection issued by a lumber grading or inspection agency meeting the requirements of this section shall be accepted.

❖ Load-carrying wood members must be identified to verify their conformance to a minimum quality control

standard. The required grade mark must reflect the following information:

1. The species.
2. The grade.
3. The moisture content (MC) at time of grading: S-Dry or S-Gm, MC15, KD15, or KD19. S-Gm indicates that the moisture content was in excess of 19 percent at the time of grading, and KD indicates kiln dried.
4. The grading agency.
5. The mill name or mill number.
6. In the case of independent agencies, the rules used for grading.

For examples of grade marks, see Commentary Figure R502.1.

R502.1.1.1 Preservative-treated lumber. Preservative treated dimension lumber shall also be identified as required by Section R317.2.

❖ Grade marks as described in Section R502.1.1 must also include the quality mark of an agency accredited in the ALSC treated wood program. See Commentary

Figure R502.1.1 for an example of a preservative-treated-lumber grade mark.

R502.1.1.2 End-jointed lumber. *Approved* end-jointed lumber identified by a grade mark conforming to Section R502.1.1 shall be permitted to be used interchangeably with solid-sawn members of the same species and grade. End-jointed lumber used in an assembly required elsewhere in this code to have a fire-resistance rating shall have the designation “Heat Resistant Adhesive” or “HRA” included in its grade mark.

❖ End-jointed lumber is generally considered equivalent to solid sawn lumber, provided it is properly identified by a grade mark. The key is verifying proper end use. For instance, grade marks including the phrase “STUD USE ONLY” denote finger-jointed lumber that is limited to stud use and/or bending or tension stresses of short duration loads such as wind and seismic. Structural finger joints, on the other hand, allow horizontal as well as vertical applications. When end-jointed lumber is used in fire-resistance-rated assemblies, the adhesive used in the end joint must be heat-resistant adhesive (HRA).

The American Lumber Standards Committee (ALSC) recently added elevated-temperature performance requirements for end-jointed lumber adhesives intended for use in fire-resistance-rated assemblies.

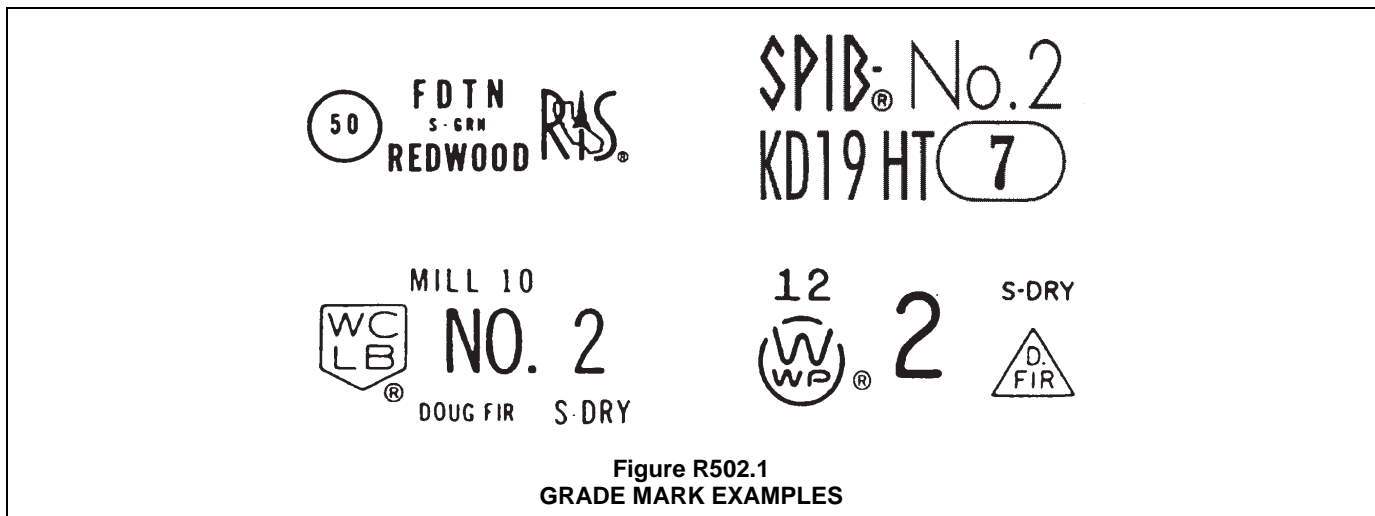

Figure R502.1
GRADE MARK EXAMPLES

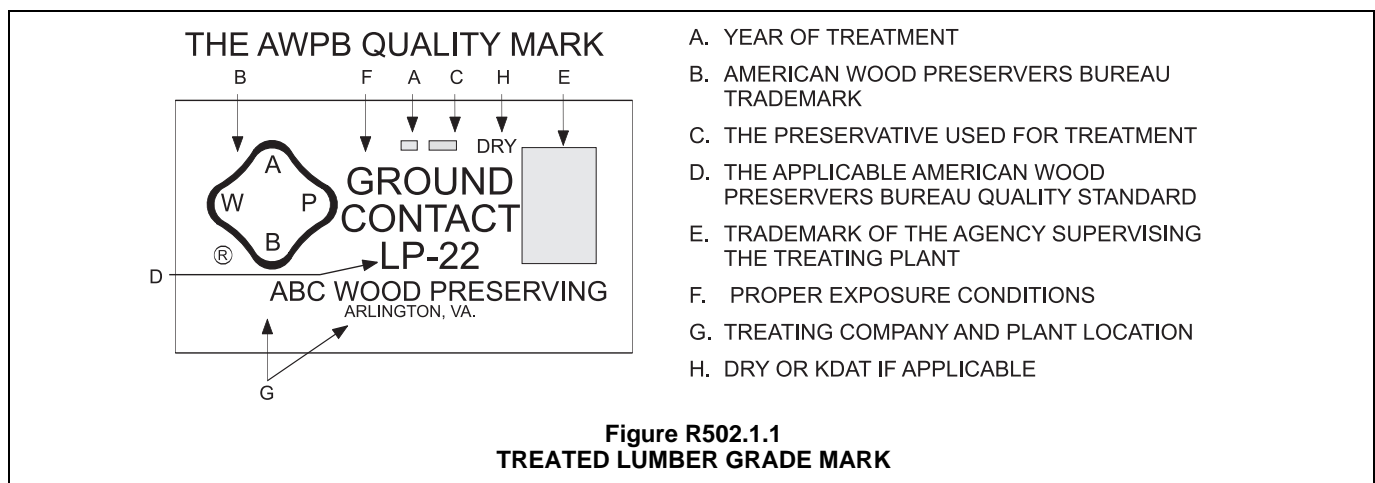

Figure R502.1.1
TREATED LUMBER GRADE MARK

End-jointed lumber manufactured with adhesives that meet the new requirements is being designated as “heat resistant adhesive” or “HRA” on the grade stamp. HRAs are required to be qualified in accordance with one of two new ASTM standards, ASTM D7374-08, *Practice for Evaluating Elevated Temperature Performance of Adhesives Used in End-Jointed Lumber* and ASTM D7470-08, *Practice for Evaluating Elevated Temperature Performance of End-Jointed Lumber Studs*. End-jointed lumber manufactured with HRAs under an auditing program of an ALSC-accredited grading agency is allowed to carry the HRA mark on the grade stamp. End-jointed lumber manufactured with an adhesive not qualified as an HRA will be designated as “non-heat resistant adhesive” or “non-HRA” on the grade stamp. Lumber carrying the HRA mark is permitted to be used interchangeably with solid-sawn members of the same species and grade in fire-rated applications.

R502.1.2 Prefabricated wood I-joists. Structural capacities and design provisions for prefabricated wood I-joists shall be established and monitored in accordance with ASTM D5055.

❖ Prefabricated wood I-joists are some of the many engineered wood products currently available. These structural members consist of sawn lumber or structural composite lumber flanges bonded to wood structural panel webs, forming an I-shaped cross section. Because these products are widely used in residential floor construction, ASTM D5055, *Standard Specification for Establishing and Monitoring Structural Capacities of Prefabricated Wood I-joists*, is referenced as the applicable standard.

This standard does not specify the makeup of the component materials or how they must be assembled. Each manufacturer must develop product specifications and construction details for its products. These are subject to qualification tests, which are conducted or witnessed by qualified, independent agencies. The best results are used to establish the following design values:

- Allowable bending moment.
- Allowable shear.
- Member stiffness (EI).
- Sheer deflection factor (K).
- Allowable reactions.
- Bearing length requirements.
- Web stiffener requirements.
- A chart detailing the size, location, shape and spacing of any holes permitted in the web.

R502.1.3 Structural glued laminated timbers. Glued laminated timbers shall be manufactured and identified as required in ANSI/AITC A190.1 and ASTM D3737.

❖ This section requires that glulam timbers be manufactured following ANSI/AITC A190.1 and ASTM D3737. Knowing these standards makes it easier to determine that the product found in the field will meet the design requirements.

R502.1.4 Structural log members. Structural log members shall comply with the provisions of ICC-400.

❖ The material requirements for structural logs, such as stress grading, grade mark or Certificate of Inspection, must be in accordance with ICC 400 *Standard on the Design and Construction of Log Structures*.

R502.1.5 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

❖ ASTM D5456 is the standard by which structural composite lumber is evaluated. Products manufactured to this standard are increasingly available in the marketplace and are being used in residential construction. These products are being used as beams, headers, long-length studs, floor and roof framing and other applications where high strength, long length and/or dimensional stability make sawn lumber unacceptable.

Recognition of the appropriate standard on the identification marks required by the code will provide the designer, builder, plans examiner and building inspector with the assurance that structural composite lumber products are being manufactured with the appropriate quality control systems in place and that the design properties of the product are properly derived and maintained during production.

R502.1.6 Cross-laminated timber. Cross-laminated timber shall be manufactured and identified as required by ANSI/APA PRG 320.

❖ Cross-laminated timber (CLT) was first developed in Europe nearly 20 years ago, where it has been used extensively. It is generally analogous to large section members currently associated with heavy timber. Although the primary use is for nonresidential construction it is currently being used in some residential applications. As a new product in North America, ANSI/APA PRG 320 provides a consensus manufacturing standard for cross-laminated timber.

R502.1.7 Engineered wood rim board. Engineered wood rim boards shall conform to ANSI/APA PRR 410 or shall be evaluated in accordance with ASTM D7672. Structural capacities shall be in accordance with ANSI/APA PRR 410 or established in accordance with ASTM D7672. Rim boards conforming to ANSI/APA PRR 410 shall be marked in accordance with that standard.

❖ Engineered rim board is a key structural element in wood floor construction where both structural load path through the perimeter member and dimensional change compatibility are design considerations. Both ANSI/APA PRR 410 and ASTM D7672 address the fundamental requirements for testing and evaluation of engineered rim board. PRR 410 also includes performance categories for engineered wood products used in engineered rim board applications. Under PRR 410, products are assigned a grade based on performance category (e.g., categories based on structural capacity) and will bear a mark in accordance with the grade. In contrast, ASTM D7672 is applicable for determination of product-specific rim board performance (i.e., struc-

FLOORS

tural capacities) for engineered wood products that may be recognized in manufacturers' literature or product evaluation reports.

R502.2 Design and construction. Floors shall be designed and constructed in accordance with the provisions of this chapter, Figure R502.2 and Sections R317 and R318 or in accordance with ANSI AWC NDS.

❖ Design and construction of wood floors must be in accordance with the prescriptive requirements of this section or where required in accordance with ANSI AWC NDS, *National Design Specification for Wood Construction*. Figure R502.2 includes section references to provisions that apply to typical elements of floor systems.

R502.2.1 Framing at braced wall lines. A load path for lateral forces shall be provided between floor framing and braced wall panels located above or below a floor, as specified in Section R602.10.8.

❖ At braced wall panels, joists and blocking are an essential part of a complete lateral load path for either wind or seismic loads. These framing members are needed to accomplish the framing to framing connections specified in Table R602.3(1) and Section R602.10.8. Section R602.10.8 specifies the framing required for a complete load path for these conditions. Section R602.10.8 addresses the framing needed when braced wall panels occur above or below a floor and when floor framing is parallel to a braced wall panel.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R502.2
FLOOR CONSTRUCTION

R502.2.2 Blocking and subflooring. Blocking for fastening panel edges or fixtures shall be a minimum of utility grade lumber. Subflooring shall be a minimum of utility grade lumber, No. 4 common grade boards or wood structural panels as specified in Section R503.2. Fireblocking shall be of any grade lumber.

- ❖ Allowing the use of lower lumber grades in blocking and subflooring in these instances results in possible economies.

R502.3 Allowable joist spans. Spans for floor joists shall be in accordance with Tables R502.3.1(1) and R502.3.1(2). For other grades and species and for other loading conditions, refer to the AWC STJR.

- ❖ Tables R502.3.1(1) and R502.3.1(2) contain allowable floor joist spans for common lumber species and grades based on design loads and joist spacing. The span tables have been updated from the 2012 IRC to account for changes in design values for Douglas fir-larch, Hem-fir and Southern pine. The allowable spans for some grades of Southern pine have been reduced from that in the 2012 IRC. The allowable spans for some grades of Douglas fir-larch and Hem-fir have been increased from that in the 2012 IRC.

The reduced design values for visually-graded Southern pine lumber were approved by the American Lumber Standards Committee (ALSC) in 2013. Values are a result of 2 years of testing current lumber available on the market to identify what changes had occurred in the strength of the Southern pine lumber inventory.

Although the increased design values for Douglas fir-larch and Hem-fir were approved in the 1990s, the values were never incorporated into the *International Building Code*® (IBC®) and IRC allowable span tables. Recent testing of current stock has validated the 1990's values.

The 2015 IRC span tables are now in agreement with the wood standards' span tables with the revisions for Southern pine, Douglas fir-larch and Hem-fir. The new design values apply only to new construction. The integrity of existing structures designed and built using design values meeting the applicable building codes in effect at the time of permitting does not change.

The tables provide spans for dead loads of 10 or 20 psf (479 Pa or 958 Pa). The weight of the floor joist is included in the 10 or 20 psf (479 Pa or 958 Pa) dead load.

The dead load of the floor assembly must not exceed 10 psf (479 Pa) for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁ and D₂ (see commentary, Section R301.2.2.2.1).

The referenced standard may be used for grades and species of lumber not included in these tables.

Table R502.3.1(1) covers sleeping rooms where the design live load is 30 pounds per square foot (psf) (1.44 kPa) per Table R301.5. This includes attics with fixed stair access. It is important to identify the intended use because an attic space used as a bonus room, for

example, could require use of a 40-pounds-per-square-foot (1.92 kPa) live load. Table 502.3.1(2) covers rooms other than sleeping rooms where the design load is 40 pounds per square foot (1.92 kPa) in accordance with Table R301.5.

Example:

A floor has a design live load of 40 psf (1.92 kPa) and a dead load of 10 psf (0.48 kPa). The joists span 17 feet, 6 inches (5334 mm). Find the required joist size using Douglas-Fir Larch #2 lumber and a joist spacing of 16 inches (406 mm).

Solution:

In Table R502.3.1(2), which is based on LL = 40 psf (1.92 kPa), find 16-inch (406 mm) joist spacing in the left hand column. Locate Douglas Fir-Larch #2 and under DL = 10 psf (0.48 kPa) look for an allowable span of 17 feet, 6 inches (5334 mm) or greater. Note that the allowable span for 2 inch by 12 inch (51 mm by 305 mm) is 18 feet, 1 inch (5512 mm). Therefore, use 2-inch by 12-inch (51 mm by 305 mm) joists at 16-inch (406 mm) spacing.

The span tables account for a uniform load condition. They will also permit isolated concentrated loads such as nonbearing partitions offset from a support by a distance less than or equal to the joist depth. They may not support large concentrated loads such as ones that result from an entire kitchen utility wall or bathtubs parallel to joists. In such instances, additional joists and other adequate supports must be installed.

R502.3.1 Sleeping areas and attic joists. Table R502.3.1(1) shall be used to determine the maximum allowable span of floor joists that support sleeping areas and *attics* that are accessed by means of a fixed stairway in accordance with Section R311.7 provided that the design live load does not exceed 30 pounds per square foot (1.44 kPa) and the design dead load does not exceed 20 pounds per square foot (0.96 kPa). The allowable span of ceiling joists that support *attics* used for limited storage or no storage shall be determined in accordance with Section R802.4.

- ❖ See the commentary to Section R502.3.

TABLE R502.3.1(1). See pages 5-6 and 5-7.

- ❖ This table provides allowable joist spans for common lumber species, grades and joist sizes. The spans are applicable to residential sleeping areas. Use of this table is similar to the use described in the example in Section R502.3 (see commentary, Section R502.3).

TABLE R502.3.1(2). See pages 5-8 and 5-9.

- ❖ See the commentary to Section R502.3.

R502.3.2 Other floor joists. Table R502.3.1(2) shall be used to determine the maximum allowable span of floor joists that support other areas of the building, other than sleeping rooms and *attics*, provided that the design live load does not exceed 40 pounds per square foot (1.92 kPa) and the design dead load does not exceed 20 pounds per square foot (0.96 kPa).

- ❖ See the commentary to Section R502.3.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

Note: Check sources for availability of lumber in lengths greater than 20 feet.

a. End bearing length shall be increased to 2 inches.

b. Dead load limits for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁, and D₂ shall be determined in accordance with Section R301.2.2.2.1.

FLOORS

R502.3.3 Floor cantilevers. Floor cantilever spans shall not exceed the nominal depth of the wood floor joist. Floor cantilevers constructed in accordance with Table R502.3.3(1) shall be permitted where supporting a light-frame bearing wall and roof only. Floor cantilevers supporting an exterior balcony are permitted to be constructed in accordance with Table R502.3.3(2).

❖ The cantilever span is permitted to be equal to the nominal depth of the joist without additional limitations. This provides for load transfer to the support by direct bearing so that shear and bending of the joist is not a concern.

Larger cantilevers are permitted in accordance with the limitations of the appropriate table for floor joists supporting an exterior balcony or a light-frame bearing wall and roof.

TABLE R502.3.3(1). See below.

❖ This table provides the prescriptive span and uplift requirements for cantilever wood floor joists supporting a light-frame bearing wall and roof only. The permitted cantilever span ranges from 15 to 48 inches (331 to 1219 mm) based on the limitations prescribed in the table and in the notes.

TABLE R502.3.3(2). See Page 5-11.

❖ This table provides the prescriptive span and uplift requirements for cantilever wood floor joists supporting an exterior balcony. The table was developed based on an engineered design consistent with the requirements of the IBC. A live load of 60 psf (2.87 kPa) is used for the cantilevered portion of the floor joists and is combined with anticipated dead loads and snow loads. Snow loads vary up to 70 psf (3.35 kPa) and include consideration of drifted snow from an adjacent roof. Deflections are limited to the values specified in Table 1604.3 of the IBC. As indicated in Note b, the ratio of backspan to cantilever span is limited to a minimum of 2:1.

R502.4 Joists under bearing partitions. Joists under parallel bearing partitions shall be of adequate size to support the load. Double joists, sized to adequately support the load, that are separated to permit the installation of piping or vents shall be full depth solid blocked with lumber not less than 2 inches (51 mm) in nominal thickness spaced not more than 4 feet (1219 mm) on center. Bearing partitions perpendicular to joists shall not be offset from supporting girders, walls or par-

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- a. Tabulated values are for clear-span roof supported solely by exterior bearing walls.
- b. Spans are based on No. 2 Grade lumber of Douglas fir-larch, hem-fir, and spruce-pine-fir for repetitive (three or more) members. No. 1 or better shall be used for southern pine.
- c. Ratio of backspan to cantilever span shall be not less than 3:1.
- d. Connections capable of resisting the indicated uplift force shall be provided at the backspan support.
- e. Uplift force is for a backspan to cantilever span ratio of 3:1. Tabulated uplift values are permitted to be reduced by multiplying by a factor equal to 3 divided by the actual backspan ratio provided (3/backspan ratio).
- f. See Section R301.2.2.2.5, Item 1, for additional limitations on cantilevered floor joists for detached one- and two-family dwellings in Seismic Design Category D₀, D₁, or D₂ and townhouses in Seismic Design Category C, D₀, D₁ or D₂.
- g. A full-depth rim joist shall be provided at the unsupported end of the cantilever joists. Solid blocking shall be provided at the supported end. Where the cantilever length is 24 inches or less and the building is assigned to Seismic Design Category A, B or C, solid blocking at the support for the cantilever shall not be required.
- h. Linear interpolation shall be permitted for building widths and ground snow loads other than shown.

titions more than the joist depth unless such joists are of sufficient size to carry the additional load.

- ❖ Where floor joists support bearing partitions, the joists must be of adequate size [see Commentary Figure R502.4(1)] for an example. This provides added support for the additional load from the bearing partition above. Alternatively, a beam of adequate size may also be substituted for the double joist.

Where piping or vents must penetrate the floor system, the double joists must be separated to allow the pipe or vent to pass through. In this case, full-depth solid blocking spaced a maximum of 4 feet (1219 mm) on center, as shown in Commentary Figure R502.4(2), is required so that the two joists will function as a combined member without twisting.

Bearing partitions oriented perpendicular to joists cannot be offset from supporting girders, walls or partitions more than the depth of the joists unless the joists are of sufficient size to carry the additional load.

R502.5 Allowable girder and header spans. The allowable spans of girders and headers fabricated of dimension lumber shall not exceed the values set forth in Tables R602.7(1), R602.7(2) and R602.7(3).

- ❖ Tables R602.7(1) and R602.7(2) list allowable spans for girders. These tables also apply to header spans and are referenced in Section R602.7 for that purpose. See Commentary Figure R502.5(1) and the following example for girder span-spacing relationships.

Example:

Assuming two equal floor joist spans of 10 feet (3048 mm) as indicated in Figure R502.5(1) (only one joist span and the two supporting girders are

shown for clarity), determine the maximum span for a double 2-inch by 10-inch (51 mm by 254 mm) interior girder supporting one floor only.

Solution:

Table R602.7(2) contains the information for an interior girder supporting one floor only. For a double 2-inch by 10-inch (51 mm by 254 mm) girder and a building width of 20 feet (6096 mm), the maximum allowable girder span is read directly from Table R602.7(2) as 7 feet (2134 mm).

TABLE R502.3.3(2)
CANTILEVER SPANS FOR FLOOR JOISTS SUPPORTING EXTERIOR BALCONY^{a, b, e, f}

MEMBER SIZE	SPACING	MAXIMUM CANTILEVER SPAN (uplift force at backspan support in lbs.) ^{c, d}		
		Ground Snow Load		
		≤ 30 psf	50 psf	70 psf
2 × 8	12"	42" (139)	39" (156)	34" (165)
2 × 8	16"	36" (151)	34" (171)	29" (180)
2 × 10	12"	61" (164)	57" (189)	49" (201)
2 × 10	16"	53" (180)	49" (208)	42" (220)
2 × 10	24"	43" (212)	40" (241)	34" (255)
2 × 12	16"	72" (228)	67" (260)	57" (268)
2 × 12	24"	58" (279)	54" (319)	47" (330)

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa.

- a. Spans are based on No. 2 Grade lumber of Douglas fir-larch, hem-fir, and spruce-pine-fir for repetitive (three or more) members. No.1 or better shall be used for southern pine.
- b. Ratio of backspan to cantilever span shall be not less than 2:1.
- c. Connections capable of resisting the indicated uplift force shall be provided at the backspan support.
- d. Uplift force is for a backspan to cantilever span ratio of 2:1. Tabulated uplift values are permitted to be reduced by multiplying by a factor equal to 2 divided by the actual backspan ratio provided (2/backspan ratio).
- e. A full-depth rim joist shall be provided at the unsupported end of the cantilever joists. Solid blocking shall be provided at the supported end. Where the cantilever length is 24 inches or less and the building is assigned to Seismic Design Category A, B or C, solid blocking at the support for the cantilever shall not be required.
- f. Linear interpolation shall be permitted for ground snow loads other than shown.

R502.6 Bearing. The ends of each joist, beam or girder shall have not less than 1½ inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on masonry or concrete except where supported on a 1-inch by 4-inch (25 mm by 102 mm) ribbon strip and nailed to the adjacent stud or by the use of approved joist hangers. The bearing on masonry or concrete shall be direct, or a sill plate of 2-inch-minimum (51 mm) nominal thickness shall be provided under the joist, beam or girder. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm).

❖ This section establishes minimum lengths of bearing for several alternative support systems to provide for the transfer of floor loads to supporting elements. These minimum requirements are based on anticipated loads and the allowable compressive stresses perpendicular to the grain for beam sizes and grades typical for wood-frame construction in addition to consideration of shear failure of the masonry. For joists, beams or girders bearing on wood or metal, the minimum bearing shown in Commentary Figure R502.6(1) must be provided.

As an alternative, the members may be supported by a 1-inch by 4-inch (25 mm by 102 mm) ribbon strip when joists are nailed to adjacent studs as shown in Commentary Figure R502.6(3) or by the use of approved joist hangers as shown in Commentary Figure R502.6(4).

When joists, beams or girders bear on masonry, a minimum bearing of 3 inches (76 mm) is required, as shown in Commentary Figure R502.6(2).

Where joists, beams or girders span across masonry or concrete piers, full bearing of not less than

3 inches (76 mm) directly on the masonry or concrete pier is required. The code permits a sill plate of 2-inch (51 mm) minimum nominal thickness in lieu of bearing directly on the masonry or concrete. This will allow for the condition where the elevation of the top of the pier is below the elevation of the bottom of the joist, beam or girder and the joist, beam or girder is not bearing directly on the masonry or concrete. The minimum nominal bearing area of 48 square inches (0.03 m²) is required to provide a bearing area on top of hollow masonry walls or piers.

R502.6.1 Floor systems. Joists framing from opposite sides over a bearing support shall lap not less than 3 inches (76 mm) and shall be nailed together with a minimum three 10d face nails. A wood or metal splice with strength equal to or greater than that provided by the nailed lap is permitted.

❖ To provide a concentric application of load from the joist to supporting beams or girders, joists framing from opposite sides of a beam or girder are required to lap at least 3 inches (76 mm) or the opposing joists are to be tied together with a wood or metal splice (see Commentary Figure R502.6.1).

R502.6.2 Joist framing. Joists framing into the side of a wood girder shall be supported by *approved* framing anchors or on ledger strips not less than nominal 2 inches by 2 inches (51 mm by 51 mm).

❖ For joists framed into the side of a wood beam or girder, the joists must be supported by approved framing anchors, as shown in Commentary Figure R502.6.2(1), or by ledger strips having a minimum nominal dimension of 2 inches (51 mm), as shown in Commentary Figure R502.6.2(2).

R502.7 Lateral restraint at supports. Joists shall be supported laterally at the ends by full-depth solid blocking not less than 2 inches (51 mm) nominal in thickness; or by attachment to a full-depth header, band or rim joist, or to an adjoining stud or shall be otherwise provided with lateral support to prevent rotation.

Exceptions:

1. Trusses, structural composite lumber, structural glued-laminated members and I-joists shall be sup-

ported laterally as required by the manufacturer's recommendations.

2. In Seismic Design Categories D₀, D₁ and D₂, lateral restraint shall be provided at each intermediate support.

❖ Bridging, blocking or some other acceptable means of holding a joist in place is required so the floor joists do not twist out of the plane of the applied load. Lateral support at the ends of joists provide an additional function by transferring lateral loads to the supporting elements. Lateral support at ends may be provided by full-depth solid blocking not less than 2 inches (51 mm) in thickness, or the ends of joists may be nailed or bolted to a full-depth header, band or rim joist or to an adjoining stud as shown in Commentary Figure R502.7.

The requirements for lateral restraint of engineered wood products may require restraint other than that required for solid-sawn joists. Exception 1 requires restraint of the engineered wood products to be as required by the manufacturer's recommendations. Lateral restraint at each intermediate support is required for joists in Seismic Design Categories D₀, D₁ and D₂.

R502.7.1 Bridging. Joists exceeding a nominal 2 inches by 12 inches (51 mm by 305 mm) shall be supported laterally by solid blocking, diagonal bridging (wood or metal), or a continuous 1 inch by 3 inch (25.4 mm by 76 mm) strip nailed across the bottom of joists perpendicular to joists at intervals not exceeding 8 feet (2438 mm).

Exception: Trusses, structural composite lumber, structural glued-laminated members and I-joists shall be sup-

ported laterally as required by the manufacturer's recommendations.

- ❖ In addition to the lateral support at the ends, joists must have intermediate lateral support at intervals not exceeding 8 feet (2438 mm). Intermediate blocking is not required for joists 2 inches by 12 inches (51 mm by 305 mm) or smaller. The intermediate lateral support may be provided by solid blocking, diagonal bridging or wood bridging not less than 1 inch by 3 inches (25 mm

by 76 mm) nominal, nailed to the bottom of the joist. Commentary Figure R502.7.1 illustrates the various alternatives for intermediate lateral support.

The requirements for bridging of engineered wood products may require bridging other than that required for solid-sawn joists. Exception 1 requires bridging of the engineered wood products to be as required by the manufacturer's recommendations.

R502.8 Cutting, drilling and notching. Structural floor members shall not be cut, bored or notched in excess of the limitations specified in this section. See Figure R502.8.

❖ Some designs and installation practices require that limited notching and cutting occur. Notching should be avoided when possible, and holes bored in beams and joists create the same problems as notches. When necessary, the holes should be located in areas with the least stress concentration, generally along the neutral axis of the joist. Limitations on the allowable cutting and notching of wood floor joists are meant to retain structural or functional integrity.

R502.8.1 Sawn lumber. Notches in solid lumber joists, rafters and beams shall not exceed one-sixth of the depth of the member, shall not be longer than one-third of the depth of the

member and shall not be located in the middle one-third of the span. Notches at the ends of the member shall not exceed one-fourth the depth of the member. The tension side of members 4 inches (102 mm) or greater in nominal thickness shall not be notched except at the ends of the members. The diameter of holes bored or cut into members shall not exceed one-third the depth of the member. Holes shall not be closer than 2 inches (51 mm) to the top or bottom of the member, or to any other hole located in the member. Where the member is also notched, the hole shall not be closer than 2 inches (51 mm) to the notch.

❖ Cutting and notching limitations are illustrated in Figure R502.8. Additionally, the tension side of members with a thickness of 4 inches (102 mm) or more can be notched at the ends only (see commentary, Section R502.8).

For SI: 1 inch = 25.4 mm.

FIGURE R502.8
CUTTING, NOTCHING AND DRILLING

R502.8.2 Engineered wood products. Cuts, notches and holes bored in trusses, structural composite lumber, structural glue-laminated members, cross-laminated timber members or I-joists are prohibited except where permitted by the manufacturer’s recommendations or where the effects of such alterations are specifically considered in the design of the member by a *registered design professional*.

- ❖ Cutting and notching limitations for sawn lumber do not apply to engineered wood products. Structural composite lumber is a generic term which encompasses a variety of engineered composite wood products including laminated veneer lumber (LVL). Also, included in the term are laminated strand lumber (LSL), parallel strand lumber (PSL), and oriented strand lumber (OSL). The prohibitions in this section apply to all of these products.

Engineered wood products must not be cut, notched or bored unless those alterations are considered in the design of the member. That consideration must come from either the manufacturer and be reflected in use recommendations (which is common in I-joists, permitting some limited alterations to webs) or from a registered design professional.

R502.9 Fastening. Floor framing shall be nailed in accordance with Table R602.3(1). Where posts and beam or girder construction is used to support floor framing, positive connections shall be provided to ensure against uplift and lateral displacement.

- ❖ Commentary Figure R502.9 shows various methods of accomplishing the mandatory positive connection between post and beam or girder construction.

R502.10 Framing of openings. Openings in floor framing shall be framed with a header and trimmer joists. Where the header joist span does not exceed 4 feet (1219 mm), the header joist shall be a single member the same size as the floor joist. Single trimmer joists shall be used to carry a single header joist that is located within 3 feet (914 mm) of the trimmer joist bearing. Where the header joist span exceeds 4 feet (1219 mm), the trimmer joists and the header joist shall be doubled and of sufficient cross section to support the floor joists framing into the header.

- ❖ Where larger floor openings are necessary, adequate load-carrying transfer capability must be provided. Header joists the same size as floor joists may be used for spans not exceeding 4 feet (1219 mm), as shown in Commentary Figure R502.10(1). Trimmers must also be doubled to carry the additional load, unless the header joist is located within 3 feet (914 mm) of the trimmer joist bearing.

Where the header joist span exceeds 4 feet (1219 mm), a larger load-carrying capability is required. The header and trimmer joists must be doubled and be of sufficient size to support floor joist framing as illustrated in Commentary Figure R502.10(2).

In some cases, nailing would be insufficient to transfer vertical loads. Therefore, positive connections as shown in Commentary Figure R502.10(3) must be used. These hangers are required when the header joist span exceeds 6 feet (1829 mm).

Figure R502.9
POSITIVE CONNECTION BETWEEN POSTS AND GIRDERS

R502.11 Wood trusses.

R502.11.1 Design. Wood trusses shall be designed in accordance with *approved* engineering practice. The design and manufacture of metal-plate-connected wood trusses shall comply with ANSI/TPI 1. The truss design drawings shall be prepared by a registered professional where required by the statutes of the *jurisdiction* in which the project is to be constructed in accordance with Section R106.1.

❖ The code contains no prescriptive provisions for the design and installation of wood trusses. A design that conforms to accepted engineering practice is required. Recognizing the extensive use of trusses in residential construction, the code references ANSI/TPI 1, *National Design Standard for Metal-plate-connected Wood Truss Construction*. The standard contains regulations for the design and installation of metal-plate-connected wood trusses, including the procedures for full-scale tests and testing methods for evaluating metal plate connectors. In addition to adequate design, it is important that the trusses be handled and erected properly so that the performance capability of the trusses is not compromised. A truss member should never be cut without approval from the design engineer.

Usually trusses are delivered in bundles, which reduces the potential for damage. Slings and spreader bars sized for the load should be used to reduce stresses caused by sway and bending.

Shop drawings showing the lumber schedule, design loads and panel point details (size, location and attachment of plates) should be filed with the building permit application and should be available at the time of inspection.

R502.11.2 Bracing. Trusses shall be braced to prevent rotation and provide lateral stability in accordance with the requirements specified in the *construction documents* for the building and on the individual truss design drawings. In the

absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practices, such as, the SBCA *Building Component Safety Information (BCSI) Guide to Good Practice for Handling, Installing & Bracing of Metal Plate Connected Wood Trusses*.

❖ To prevent collapse during construction and until permanent bracing is installed, trusses should be adequately braced temporarily. When braced for use, trusses should be positioned as vertical as possible; tilted trusses will not perform as required.

R502.11.3 Alterations to trusses. Truss members and components shall not be cut, notched, spliced or otherwise altered in any way without the approval of a registered *design professional*. Alterations resulting in the addition of load that exceed the design load for the truss, shall not be permitted without verification that the truss is capable of supporting the additional loading.

❖ Addition of loads in excess of the design load is allowed only if the additional capacity of the truss can be verified. Also see the commentary to Section R502.8.2.

R502.11.4 Truss design drawings. Truss design drawings, prepared in compliance with Section R502.11.1, shall be submitted to the *building official* and *approved* prior to installation. Truss design drawings shall be provided with the shipment of trusses delivered to the job site. Truss design drawings shall include, at a minimum, the information specified as follows:

1. Slope or depth, span and spacing.
2. Location of all joints.
3. Required bearing widths.
4. Design loads as applicable:
 - 4.1. Top chord live load.
 - 4.2. Top chord dead load.

- 4.3. Bottom chord live load.
- 4.4. Bottom chord dead load.
- 4.5. Concentrated loads and their points of application.
- 4.6. Controlling wind and earthquake loads.
- 5. Adjustments to lumber and joint connector design values for conditions of use.
- 6. Each reaction force and direction.
- 7. Joint connector type and description, such as size, thickness or gage, and the dimensioned location of each joint connector except where symmetrically located relative to the joint interface.
- 8. Lumber size, species and grade for each member.
- 9. Connection requirements for:
 - 9.1. Truss-to-girder-truss.
 - 9.2. Truss ply-to-ply.
 - 9.3. Field splices.
- 10. Calculated deflection ratio and/or maximum description for live and total load.
- 11. Maximum axial compression forces in the truss members to enable the building designer to design the size, connections and anchorage of the permanent continuous lateral bracing. Forces shall be shown on the truss drawing or on supplemental documents.
- 12. Required permanent truss member bracing location.

❖ See the definition in Chapter 2 and the commentary to Section R502.11.1.

R502.12 Draftstopping required. Draftstopping shall be provided in accordance with Section R302.12.

❖ See the commentary to Section R302.12.

R502.13 Fireblocking required. Fireblocking shall be provided in accordance with Section R302.11.

❖ See the commentary to Section R302.11.

**SECTION R503
FLOOR SHEATHING**

R503.1 Lumber sheathing. Maximum allowable spans for lumber used as floor sheathing shall conform to Tables R503.1, R503.2.1.1(1) and R503.2.1.1(2).

❖ Table R503.1 sets forth the required thickness of lumber used as floor sheathing. The allowable spans are based on the floor sheathing thickness, joist spacing and the orientation of the sheathing with respect to the joist. Commentary Figures R503.1(1) and R503.1(2) show floor sheathing applications that are perpendicular and diagonal to the joist.

**TABLE R503.1
MINIMUM THICKNESS OF LUMBER FLOOR SHEATHING**

JOIST OR BEAM SPACING (inches)	MINIMUM NET THICKNESS	
	Perpendicular to joist	Diagonal to joist
24	1 ¹¹ / ₁₆	3 ³ / ₄
16	5 ⁵ / ₈	5 ⁵ / ₈
48 ^a	1 ¹ / ₂ T & G	N/A
54 ^b		
60 ^c		

For SI: 1 inch = 25.4 mm, 1 pound per square inch = 6.895 kPa.

N/A = Not applicable.

- a. For this support spacing, lumber sheathing shall have a minimum F_b of 675 and minimum E of 1,100,000 (see ANSI AWC NDS).
- b. For this support spacing, lumber sheathing shall have a minimum F_b of 765 and minimum E of 1,400,000 (see ANSI AWC NDS).
- c. For this support spacing, lumber sheathing shall have a minimum F_b of 855 and minimum E of 1,700,000 (see ANSI AWC NDS).

❖ See the commentary to Section R503.1.

**Figure R503.1(1)
FLOOR SHEATHING AS SUBFLOORING**

R503.1.1 End joints. End joints in lumber used as subflooring shall occur over supports unless end-matched lumber is used, in which case each piece shall bear on not less than two joists. Subflooring shall be permitted to be omitted where joist spacing does not exceed 16 inches (406 mm) and a 1-inch (25 mm) nominal tongue-and-groove wood strip flooring is applied perpendicular to the joists.

- ❖ When lumber is to be used as subflooring, adequate load-carrying capability and continuity must be provided through either the proper placement of end joints over supports or the use of end-matched lumber as illustrated in Commentary Figure R503.1.1.

R503.2 Wood structural panel sheathing.

- ❖ Wood structural panels are manufactured with fully waterproof adhesive and include plywood, oriented strand board (OSB) and composite panels made up of a combination of wood veneers and reconstructed

wood layers. Additional information on wood structural panels is available from the APA—The Engineered Wood Association (formerly the American Plywood Association), other trade groups and manufacturers.

Plywood is a wood structural panel manufactured by gluing three or more cross-laminated wood layers together. Plywood may be manufactured in accordance with PS 1 or PS 2. It is inspected, and if it is certified, the trademark of an approved testing and grading agency is stamped on it.

OSB panels are fabricated out of multiple layers of wood flakes or strands called “furnish.” Like the layers in plywood, these layers of furnish are oriented 90 degrees (1.57 rad) to each other. This gives OSB panels properties that are very similar to those of plywood.

Composite panels are structural panels made up of a combination of wood veneers and wood-based materials. The wood veneer usually forms the two outer layers and may also be used in the core of the panel. These layers of veneer and furnish may be cross laminated.

Both OSB and composite panels are manufactured in accordance with PS 2. They are inspected, and if they are certified, the trademark of an approved testing and grading agency is stamped on them. The grade stamps of plywood, OSB and composite panels are almost identical in appearance, and in most cases, wood structural panels can be specified without regard to specific panel type.

Wood structural panels can be manufactured with Exterior, Exposure 1, Exposure 2 and Interior exposure durability classifications. Exterior and Exposure 1 are by far the most common classifications and both are manufactured with the same class of fully waterproof adhesives. Exterior panels are intended for applications subject to permanent exposure to the weather or moisture. Exposure 1 panels are intended for applications where long construction delays may be expected prior to protection being installed. Exposure 2 panels may be used for protected applications that

are not continuously exposed to high humidity conditions. Interior panels may be used only for permanently protected interior applications. Exposure 2 and Interior panels are not readily available.

The intended end use of wood structural panels is designated in their grade-marking stamp.

R503.2.1 Identification and grade. Wood structural panel sheathing used for structural purposes shall conform to DOC PS 1, DOC PS 2, CSA O437 or CSA O325. Panels shall be identified for grade, bond classification and Performance Category by a grade mark or certificate of inspection issued by an approved agency. The Performance Category value shall be used as the “nominal panel thickness” or “panel thickness” wherever referenced in this code.

❖ Plywood that performs a load-carrying function in floor construction must conform to a known quality control standard; therefore, a method of identifying the limitations under which the plywood may be used is needed. This is accomplished by a grade mark or certificate of inspection issued by an approved agency. Examples of plywood grade marks are shown in Commentary Figure R503.2.1.

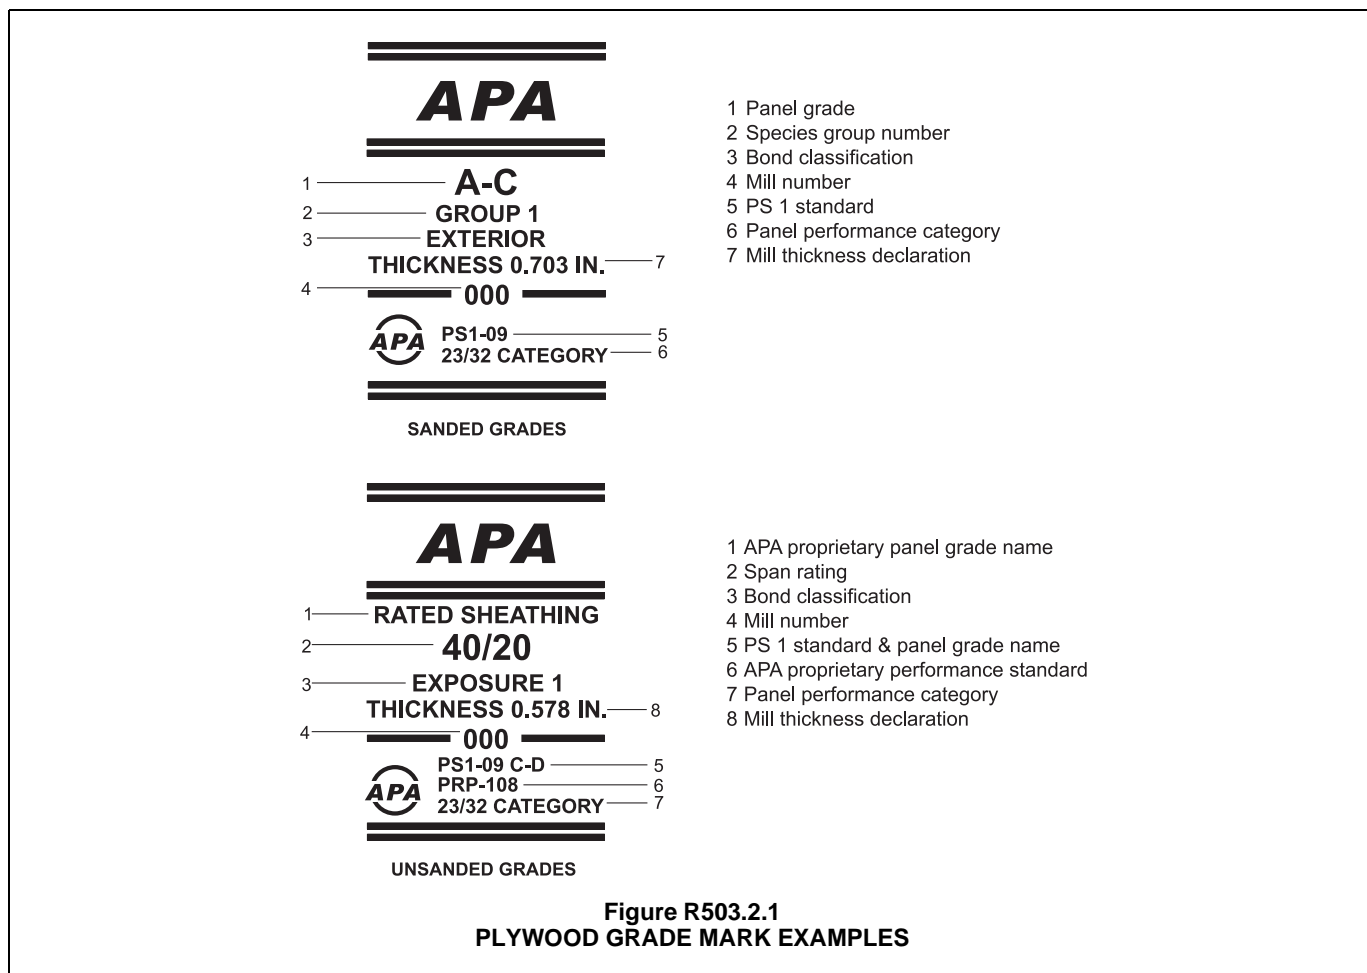

R503.2.1.1 Subfloor and combined subfloor underlayment. Where used as subflooring or combination subfloor underlayment, wood structural panels shall be of one of the grades specified in Table R503.2.1.1(1). Where sanded ply-

wood is used as combination subfloor underlayment, the grade, bond classification, and Performance Category shall be as specified in Table R503.2.1.1(2).

❖ This section specifies grades of wood structural panels when they are used as subflooring or combination subflooring underlayment. It also addresses the use of sanded plywood as a combination subfloor underlayment.

A floor system could consist of three elements: 1. A subfloor; 2. An underlayment or a combination subfloor/underlayment system; and 3. A finished floor surface material. A finished surfacing material may be wood-strip flooring; tongue-and-groove flooring or various types of resilient flooring coverings such as vinyl, tile or carpeting.

Wood structural panels are manufactured for use as either structural subfloor or combination subfloor underlayment. The allowable spans for structural subflooring and combination subfloor underlayment are based on the wood structural panels' face grain strength axis parallel to its supporting member, or they are based on the panels being continuous over two or more spans, with a face grain placed perpendicular to the supports. These qualifications are critical in determining the permissible spans. Most wood structural panels are considerably stronger when their face grain is parallel to the

FLOORS

supports and continuous over two or more spans. Panels with multiple spans have greater capacity than those that are simply supported between the two joists.

TABLE R503.2.1.1(1). See below.

❖ The maximum spans for wood structural panel floor and roof sheathing are limited by the stresses and deflection imposed by the design live loads. For convenience, the trademarks of the inspection agencies include a span rating, which appears as two numbers separated by a slash (32/16 or 48/24, for example). The first number represents the maximum recommended span for roof sheathing when the panels are applied with the long dimension (strength axis) across three or more supports and the edges are blocked or

when other support required by the table is provided. The second number indicates the maximum recommended span when the panel is used for structural floor sheathing with the panels applied with the long dimension (strength axis) across three or more supports. Single panels intended for single floor applications will be marked with a single number representing this span.

The edges of the wood structural panels between floor supports are prevented from moving relative to each other by tongue and groove panel edges, the addition of wood blocking or by the use of an approved underlayment or structural finished floor system.

TABLE R503.2.1.1(1)
ALLOWABLE SPANS AND LOADS FOR WOOD STRUCTURAL PANELS FOR ROOF AND SUBFLOOR SHEATHING AND COMBINATION SUBFLOOR UNDERLAYMENT^{a, b, c}

SPAN RATING	MINIMUM NOMINAL PANEL THICKNESS (inch)	ALLOWABLE LIVE LOAD (psf) ^{h, 1}		MAXIMUM SPAN (inches)		LOAD (pounds per square foot, at maximum span)		MAXIMUM SPAN (inches)
		SPAN @ 16" o.c.	SPAN @ 24" o.c.	With edge support ^d	Without edge support	Total load	Live load	
Sheathing^e		Roof^f						Subfloor^l
16/0	3/8	30	—	16	16	40	30	0
20/0	3/8	50	—	20	20	40	30	0
24/0	3/8	100	30	24	20 ^g	40	30	0
24/16	7/16	100	40	24	24	50	40	16
32/16	15/32, 1/2	180	70	32	28	40	30	16 ^h
40/20	19/32, 5/8	305	130	40	32	40	30	20 ^{h, i}
48/24	23/32, 3/4	—	175	48	36	45	35	24
60/32	7/8	—	305	60	48	45	35	32
Underlayment, C-C plugged, single floor^e		Roof^f						Combination subfloor underlayment^k
16 o.c.	19/32, 5/8	100	40	24	24	50	40	16 ⁱ
20 o.c.	19/32, 5/8	150	60	32	32	40	30	20 ^{h, j}
24 o.c.	23/32, 3/4	240	100	48	36	35	25	24
32 o.c.	7/8	—	185	48	40	50	40	32
48 o.c.	1 3/32, 1 1/8	—	290	60	48	50	40	48

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa.

- a. The allowable total loads were determined using a dead load of 10 psf. If the dead load exceeds 10 psf, then the live load shall be reduced accordingly.
- b. Panels continuous over two or more spans with long dimension (strength axis) perpendicular to supports. Spans shall be limited to values shown because of possible effect of concentrated loads.
- c. Applies to panels 24 inches or wider.
- d. Lumber blocking, panel edge clips (one midway between each support, except two equally spaced between supports where span is 48 inches), tongue-and-groove panel edges, or other approved type of edge support.
- e. Includes Structural I panels in these grades.
- f. Uniform load deflection limitation: 1/180 of span under live load plus dead load, 1/240 of span under live load only.
- g. Maximum span 24 inches for 15/32- and 1/2-inch panels.
- h. Maximum span 24 inches where 3/4-inch wood finish flooring is installed at right angles to joists.
- i. Maximum span 24 inches where 1.5 inches of lightweight concrete or approved cellular concrete is placed over the subfloor.
- j. Unsupported edges shall have tongue-and-groove joints or shall be supported with blocking unless minimum nominal 1/4-inch-thick wood panel-type underlayment, fiber-cement underlayment with end and edge joints offset not less than 2 inches or 1/2 inches of lightweight concrete or approved cellular concrete is placed over the subfloor, or 3/4-inch wood finish flooring is installed at right angles to the supports. Fiber-cement underlayment shall comply with ASTM C1288 or ISO 8336 Category C. Allowable uniform live load at maximum span, based on deflection of 1/360 of span, is 100 psf.
- k. Unsupported edges shall have tongue-and-groove joints or shall be supported by blocking unless nominal 1/4-inch-thick wood panel-type underlayment, fiber-cement underlayment with end and edge joints offset not less than 2 inches or 3/4-inch wood finish flooring is installed at right angles to the supports. Fiber-cement underlayment shall comply with ASTM C1288 or ISO 8336 Category C. Allowable uniform live load at maximum span, based on deflection of 1/360 of span, is 100 psf, except panels with a span rating of 48 on center are limited to 65 psf total uniform load at maximum span.
- l. Allowable live load values at spans of 16 inches on center and 24 inches on center taken from reference standard APA E30, APA Engineered Wood Construction Guide. Refer to reference standard for allowable spans not listed in the table.

TABLE R503.2.1.1(2)
ALLOWABLE SPANS FOR SANDED
PLYWOOD COMBINATION SUBFLOOR UNDERLAYMENT^a

IDENTIFICATION	SPACING OF JOISTS (inches)		
	16	20	24
Species group ^b	—	—	—
1	1/2	5/8	3/4
2, 3	5/8	3/4	7/8
4	3/4	7/8	1

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa.

- a. Plywood continuous over two or more spans and face grain perpendicular to supports. Unsupported edges shall be tongue-and-groove or blocked except where nominal 1/4-inch-thick wood panel-type underlayment, fiber-cement underlayment or 3/4-inch wood finish floor is used. Fiber-cement underlayment shall comply with ASTM C 1288 or ISO 8336 Category C. Allowable uniform live load at maximum span based on deflection of 1/360 of span is 100 psf.
- b. Applicable to all grades of sanded exterior-type plywood.

❖ For exterior-type sanded plywood grades, the thickness required for a specific span is related to the species grouping of the panel used. For example, species Group 1 may be 1/2 inch (12.7 mm) for 16-inch (406 mm) joist spacing, but Group 4 will require a thickness of 3/4 inch (19.1 mm) for the same span.

When the panels are used as a combination subfloor/underlayment, extra precautions should be observed in attaching the panels to the floor framing. Joints in adjacent panels should not be continuous and should not occur at locations where the orientation of the joist supports is different.

R503.2.2 Allowable spans. The maximum allowable span for wood structural panels used as subfloor or combination subfloor underlayment shall be as set forth in Table R503.2.1.1(1), or APA E30. The maximum span for sanded plywood combination subfloor underlayment shall be as set forth in Table R503.2.1.1(2).

❖ Table R503.2.1.1(1) indicates spans for plywood and wood structural panels used as subflooring. This table also covers roof sheathing and is referenced in Section

R803.2.2 for that purpose. The span limitations are predicated on the grade of plywood used. In the case of rated sheathing used as structural subflooring, the maximum span is easily identified through the panel span rating (identification index). Where the panel span rating is stamped on the sheet of plywood, the denominator represents the allowable span of the plywood floor sheathing [see Commentary Figure R503.2.2(1)]. An illustration of the limitations imposed by Notes j and k to Table R503.2.1.1(1) on combination subfloor underlayment applications is illustrated in Commentary Figure R503.2.2(2). Allowable increases in the maximum span for certain span ratings are permitted as described in Notes h and i to Table R503.2.1.1(1).

In lieu of using Table R503.2.1.1(1), the code permits the use of APA E30, *Engineered Wood Construction Guide*.

When plywood combination subfloor underlayment is to be used, the allowable span as listed in Table R503.2.1.1(2) is applicable to underlayment grade C-C plugged and sanded exterior-type plywood of specific species.

R503.2.3 Installation. Wood structural panels used as subfloor or combination subfloor underlayment shall be attached to wood framing in accordance with Table R602.3(1) and shall be attached to cold-formed steel framing in accordance with Table R505.3.1(2).

❖ This section refers to the wood framing fastener schedule in Chapter 6 and the cold-formed steel floor-fastening schedule in Table R505.3.1(2).

R503.3 Particleboard.

❖ Particleboard is a generic term given to panels manufactured from cellulosic materials, usually wood in the form of discrete pieces and particles rather than fibers. The particles and pieces are combined with synthetic resins and other binders and bonded together under heat and pressure. Particleboard must conform to ANSI A208.1.

Figure R503.2.2(2)
COMBINATION SUBFLOOR UNDERLAYMENT ALTERNATIVES

R503.3.1 Identification and grade. Particleboard shall conform to ANSI A208.1 and shall be so identified by a grade mark or certificate of inspection issued by an *approved agency*.

❖ Particleboard used in floor construction that performs a load-carrying function must conform to a known quality control standard. To this end, a grade mark or certificate of inspection issued by an approved agency identifies the limitations under which the particleboard may be used. Commentary Figure R503.3.1 shows an example of a particleboard grade mark.

Figure R503.3.1
PARTICLEBOARD GRADE MARK EXAMPLE

The particleboard grades in ANSI A208.1 are identified by a letter followed by a hyphen and a digit or another letter. A letter, number or term following the grade designation identifies special performance characteristics. The first letter has the following meaning:

- H: High density (above 50 lb/ft³) (801 kg/m³).
- M: Medium density (40-50 lb/ft³) (641-801 kg/m³).
- LD: Low density (below 40 lb/ft³) (641 kg/m³).
- D: Manufactured home decking.
- PBU: Underlayment.

The digit or letter following the hyphen indicates the grade identification within a particular description. For example, 2 indicates medium-density particleboard, Grade 2.

R503.3.2 Floor underlayment. Particleboard floor underlayment shall conform to Type PBU and shall be not less than 1/4 inch (6.4 mm) in thickness.

❖ Particleboard is often used over a structural subfloor to provide a smooth, even surface under textile or resilient-type finish floors. Particleboard must conform to Type PBU with a minimum thickness of 1/4 inch (6.4 mm).

R503.3.3 Installation. Particleboard underlayment shall be installed in accordance with the recommendations of the

manufacturer and attached to framing in accordance with Table R602.3(1).

- ❖ Particleboard used as underlayment only is not subject to span limitations because the plywood or lumber subflooring provides the load-carrying capability for the floor system; the particleboard has a nonstructural role. However, joints in particleboard should not occur over joints in the subfloor; the joints should be staggered.

SECTION R504 PRESSURE PRESERVATIVE- TREATED WOOD FLOORS (ON GROUND)

R504.1 General. Pressure preservative treated-wood *basement* floors and floors on ground shall be designed to withstand axial forces and bending moments resulting from lateral soil pressures at the base of the exterior walls and floor live and dead loads. Floor framing shall be designed to meet joist deflection requirements in accordance with Section R301.

- ❖ As indicated in the commentary to Section R404.1.1, lateral soil pressure loads are carried by the foundation walls through bending in the vertical direction. The resulting forces (reactions) are resisted by the basement floor and the first floor above. This section stipulates the requirements for basement wood-floor framing in order for it to resist the applied loads at the base of the foundation wall. It is implicit that this type of floor would be used in conjunction with wood foundations described in Section R401.1.

R504.1.1 Unbalanced soil loads. Unless special provision is made to resist sliding caused by unbalanced lateral soil loads, wood *basement* floors shall be limited to applications where the differential depth of fill on opposite exterior foundation walls is 2 feet (610 mm) or less.

- ❖ The requirements of foundation walls permit up to 4 feet (1219 mm) of unbalanced fill (see Table R404.2.3). When exterior foundation walls on opposite sides of a building support an equal (or nearly equal) height of unbalanced fill, sliding is not a concern. When there is a difference in the amount of fill supported, however, there is a net horizontal force that must be resisted; otherwise, sliding may occur. To limit this unbalanced force, the height of differential fill is accordingly limited to 2 feet (610 mm) for this floor system.

R504.1.2 Construction. Joists in wood *basement* floors shall bear tightly against the narrow face of studs in the foundation wall or directly against a band joist that bears on the studs. Plywood subfloor shall be continuous over lapped joists or over butt joints between in-line joists. Sufficient blocking shall be provided between joists to transfer lateral forces at the base of the end walls into the floor system.

- ❖ These construction requirements provide a load path for the horizontal force described in the previous section.

R504.1.3 Uplift and buckling. Where required, resistance to uplift or restraint against buckling shall be provided by inte-

rior bearing walls or properly designed stub walls anchored in the supporting soil below.

- ❖ This is a general caution that the effects of uplift forces on the floor system, which could result from fluctuations in the water table, should be considered.

R504.2 Site preparation. The area within the foundation walls shall have all vegetation, topsoil and foreign material removed, and any fill material that is added shall be free of vegetation and foreign material. The fill shall be compacted to ensure uniform support of the pressure preservative treated-wood floor sleepers.

- ❖ This requirement is similar to Section R506.2. See the commentary to Section R506.2.2.

R504.2.1 Base. A minimum 4-inch-thick (102 mm) granular base of gravel having a maximum size of $\frac{3}{4}$ inch (19.1 mm) or crushed stone having a maximum size of $\frac{1}{2}$ inch (12.7 mm) shall be placed over the compacted earth.

- ❖ This requirement is similar to Section R506.2.2. See the commentary to Section R506.2.2.

R504.2.2 Moisture barrier. Polyethylene sheeting of minimum 6-mil (0.15 mm) thickness shall be placed over the granular base. Joints shall be lapped 6 inches (152 mm) and left unsealed. The polyethylene membrane shall be placed over the pressure preservative treated-wood sleepers and shall not extend beneath the footing plates of the exterior walls.

- ❖ See the commentary to Section R506.2.2 concerning application of the moisture barrier.

R504.3 Materials. Framing materials, including sleepers, joists, blocking and plywood subflooring, shall be pressure-preservative treated and dried after treatment in accordance with AWPA U1 (Commodity Specification A, Use Category 4B and Section 5.2), and shall bear the *label* of an accredited agency.

- ❖ To resist potential decay, wood floor material is to be treated in accordance with AWPA U1, use category system: *User Specification for Treated Wood*. The wood materials must be treated as Use Category 413 (UC413), Commodity Specification A, in accordance with AWPA U1. Also the material must bear the label of an accredited agency to ensure that the treated wood is produced under an accredited quality auditing program.

SECTION R505 COLD-FORMED STEEL FLOOR FRAMING

R505.1 Cold-formed steel floor framing. Elements shall be straight and free of any defects that would significantly affect structural performance. Cold-formed steel floor framing members shall be in accordance with the requirements of this section.

- ❖ The provisions of this section apply to the construction of floor systems using cold-formed steel framing, which is a type of construction made up in part or entirely of steel structural members cold formed to

FLOORS

shape from sheet or strip steel. The general shape of the framing members is in the form of the letter "C" (C-shape) and is described in further detail in Section R505.2. The use of cold-formed steel-framed designs not consistent with these provisions is beyond the scope of this code, and an analysis by a design professional is recommended.

R505.1.1 Applicability limits. The provisions of this section shall control the construction of cold-formed steel floor framing for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist span, not greater than 40 feet (12 192 mm) in width parallel to the joist span and less than or equal to three stories above grade plane. Cold-formed steel floor framing constructed in accordance with the provisions of this section shall be limited to sites where the ultimate design wind speed is less than 139 miles per hour (62 m/s), Exposure Category B or C, and the ground snow load is less than or equal to 70 pounds per square foot (3.35 kPa).

❖ Commentary Figure R505.1.1 depicts building limitations. These limits are repeated in Section R603.1.1 for

walls and in Section R804.1.1 for roofs. Cold-formed steel floor framing constructed in accordance with the provisions of this section must be limited to sites with a maximum design wind speed of 110 miles per hour (49 m/s); Exposure B, or C and a maximum ground snow load of 70 pounds per square foot (3.35 kPa).

R505.1.2 In-line framing. Where supported by cold-formed steel framed walls in accordance with Section R603, cold-formed steel floor framing shall be constructed with floor joists located in-line with load-bearing studs located below the joists in accordance with Figure R505.1.2 and the tolerances specified as follows:

1. The maximum tolerance shall be $\frac{3}{4}$ inch (19.1 mm) between the centerline of the horizontal framing member and the centerline of the vertical framing member.
2. Where the centerline of the horizontal framing member and bearing stiffener are located to one side of the centerline of the vertical framing member, the maximum tolerance shall be $\frac{1}{8}$ inch (3 mm) between the web of

the horizontal framing member and the edge of the vertical framing member.

- ❖ In-line framing is the preferred framing method because it provides a direct load path for the transfer of forces from joists to studs. In-line framing maximizes framing alignment in order to minimize secondary moments on the framing members, taking into account that the track cannot function as a load-transfer member. The 3/4-inch (19 mm) alignment value is accepted industry practice and addresses those conditions where two framing members (e.g., roof rafter and ceiling joist) are to be aligned over a wall stud. Where the bearing stiffener is located on the backside of the joist, the web of the joist cannot be more than 1/8 inch (3 mm) from the edge of the wall stud. In the absence of in-line framing, a load distribution member, such as a structural track, may be required for this force transfer.

R505.1.3 Floor trusses. Cold-formed steel trusses shall be designed, braced and installed in accordance with AISI S100, Section D4. In the absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practices, such as the SBCA *Cold-Formed Steel Building Component Safety Information (CFSBCSI), Guide to Good Practice for Handling, Installing & Bracing of Cold-Formed Steel Trusses*. Truss members shall not be notched, cut or altered in any manner without an approved design.

- ❖ The code contains no prescriptive provisions for the design and installation of cold-formed steel trusses. A

design is required that complies with accepted engineering practice. Recognizing the extensive use of trusses in residential construction, the code references AISI S100, Section D4. Section D4 of AISI S100 specifies the criteria for the design of cold-formed steel light-frame construction and requires trusses to be designed in accordance with AISI S214. The standard provides regulations for the design and installation of cold-formed steel trusses, including quality assurance and the procedures for full-scale tests. In addition to adequate design, it is important that the handling and erection of the trusses be performed properly so that the performance capability of the trusses is not compromised. A truss member must never be cut, notched or altered without approval from the design professional.

R505.2 Structural framing. Load-bearing cold-formed steel floor framing members shall be in accordance with this section.

- ❖ Sections R505.2.1 through R505.2.6 specify the requirements for cold-formed steel sections used for floor framing.

R505.2.1 Material. Load-bearing cold-formed steel framing members shall be cold formed to shape from structural quality sheet steel complying with the requirements of ASTM A 1003: Structural Grades 33 Type H and 50 Type H.

- ❖ Load-bearing steel framing members must have a legible label, stencil stamp or embossment. This identifi-

For SI: 1 inch = 25.4 mm.

FIGURE R505.1.2
IN-LINE FRAMING

FLOORS

ation allows for verification that materials installed are consistent with the design and meet the provisions of the code.

R505.2.2 Corrosion protection. Load-bearing cold-formed steel framing shall have a metallic coating complying with ASTM A1003 and one of the following:

1. A minimum of G 60 in accordance with ASTM A653.
2. A minimum of AZ 50 in accordance with ASTM A792.

❖ The specified metallic coatings correspond to requirements in the referenced material standards. The minimum coating designations assume normal exposure conditions that are best defined as having the framing members enclosed within a building envelope or wall assembly within a controlled environment. When more severe exposure conditions are probable, such as industrial or marine atmospheres, consideration should be given to specifying a heavier coating.

R505.2.3 Dimension, thickness and material grade. Load-bearing cold-formed steel floor framing members shall comply with Figure R505.2.3(1) and with the dimensional and thickness requirements specified in Table R505.2.3. Additionally, all C-shaped sections shall have a minimum flange width of 1.625 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be $\frac{1}{2}$ inch (12.7 mm). Track sections shall comply with Figure R505.2.3(2) and shall have a minimum flange width of $1\frac{1}{4}$ inch (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified.

❖ C-shaped joists must comply with Figure R505.2.3(1) and the dimensional and minimum thickness requirements of Table R505.2.3. Note a to Table R505.2.3 explains the meaning of the alphanumeric member designation used for all steel framing members in the code. This system replaces the varied designation approaches that were used by each individual manufacturer. In addition, the designation is used to identify not only a specific steel framing member, but also the section properties of that same member through the use of the product technical information document. The flange width of C-shaped sections must be from $1\frac{1}{2}$ inches to 2 inches with a minimum lip of $\frac{1}{2}$ inch.

Steel track sections are to serve in nonload-bearing applications only and are shown in Figure R505.2.3(2). They must have a minimum flange width of $1\frac{1}{4}$ inches (32 mm).

Steel thickness is expressed in mils, which pertains to the base metal thickness measured prior to painting or the application of metallic (corrosion-resistant) coatings. The base metal thickness is typically stamped or embossed on the member by the manufacturer. Table R505.2.3 also references the equivalent thickness in inches.

Minimum Grade 33 ksi steel must be used where the thickness is 33 mil or 43 mil. Where the thickness is 54 mil or 68 mil, the minimum grade must be Grade 50 ksi steel.

FIGURE R505.2.3(1). See below.

❖ See the commentary to Section R505.2.3.

FIGURE R505.2.3(2). See below.

❖ See the commentary to Section R505.2.3.

TABLE R505.2.3. See page 5-31.

❖ See the commentary to Section R505.2.3.

FIGURE R505.2.3(1)
C-SHAPED SECTION

FIGURE R505.2.3(2)
TRACK SECTION

**TABLE R505.2.3
COLD-FORMED STEEL JOIST SIZES AND THICKNESS**

MEMBER DESIGNATION ^a	WEB DEPTH (inches)	MINIMUM BASE STEEL THICKNESS mil (inches)
550S162-t	5.5	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
800S162-t	8	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
1000S162-t	10	43 (0.0428), 54 (0.0538), 68 (0.0677)
1200S162-t	12	43 (0.0428), 54 (0.0538), 68 (0.0677)

For SI: 1 inch = 25.4 mm, 1 mil = 0.0254 mm.

a. The member designation is defined by the first number representing the member depth in 0.01 inch, the letter “S” representing a stud or joist member, the second number representing the flange width in 0.01 inch, and the letter “t” shall be a number representing the minimum base metal thickness in mils.

R505.2.4 Identification. Load-bearing cold-formed steel framing members shall have a legible *label*, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer’s identification.
2. Minimum base steel thickness in inches (mm).
3. Minimum coating designation.
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

❖ Load-bearing steel framing members must have a legible label, stencil, stamp or embossment. This allows for verification that the materials installed are consistent with the design and meet the code requirements.

R505.2.5 Fastening. Screws for steel-to-steel connections shall be installed with a minimum edge distance and center-to-center spacing of $\frac{1}{2}$ inch (12.7 mm), shall be self-drilling tapping, and shall conform to ASTM C1513. Floor sheathing shall be attached to cold-formed steel joists with minimum No. 8 self-drilling tapping screws that conform to ASTM C1513. Screws attaching floor sheathing to cold-formed steel joists shall have a minimum head diameter of 0.292 inch (7.4 mm) with countersunk heads and shall be installed with a minimum edge distance of $\frac{3}{8}$ inch (9.5 mm). Gypsum board ceilings shall be attached to cold-formed steel joists with minimum No. 6 screws conforming to ASTM C954 or ASTM C1513 with a bugle head style and shall be installed in accordance with Section R702. For all connections, screws shall extend through the steel a minimum of three exposed threads. All fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

❖ Fasteners meeting the referenced standards and installed in accordance with this section provide the necessary load capacity consistent with these prescriptive provisions. This section specifies self-drilling tapping screws conforming to ASTM C1513, *Specification for Steel Tapping Screws for Cold-formed Steel Framing Connection*, for all steel-to-steel connections as well as for fastening floor sheathing to steel joists. All fasteners must have rust-inhibitive coating or be manufactured from material not susceptible to corrosion. Gypsum board must be attached to steel joists with No. 6 screws (minimum) conforming to ASTM C954, *Standard Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal*

Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness, or ASTM C1513. See Section R702 for installation. For all connections, screws must extend through the steel a minimum of three exposed threads.

R505.2.6 Web holes, web hole reinforcing and web hole patching. Web holes, web hole reinforcing, and web hole patching shall be in accordance with this section.

❖ Sections R505.2.6.1 through R505.2.6.3 specify the criteria for web holes, web hole reinforcing, and web hole patching in floor joists.

R505.2.6.1 Web holes. Web holes in floor joists shall comply with all of the following conditions:

1. Holes shall conform to Figure R505.2.6.1.
2. Holes shall be permitted only along the centerline of the web of the framing member.
3. Holes shall have a center-to-center spacing of not less than 24 inches (610 mm).
4. Holes shall have a web hole width not greater than 0.5 times the member depth, or $2\frac{1}{2}$ inches (64.5 mm).
5. Holes shall have a web hole length not exceeding $4\frac{1}{2}$ inches (114 mm).
6. Holes shall have a minimum distance between the edge of the bearing surface and the edge of the web hole of not less than 10 inches (254 mm).

Framing members with web holes not conforming to the above requirements shall be reinforced in accordance with Section R505.2.6.2, patched in accordance with Section R505.2.6.3 or designed in accordance with accepted engineering practices.

❖ To allow for routing utilities through steel-framed floors, holes (also referred to as penetrations, utility holes and punchouts) are permitted in the webs of floor joists. To avoid adversely affecting the strength of floor joists, the web holes are limited to the locations along the centerline of the web of the framing member, as illustrated in Figure R505.2.6.1.

To avoid overstressing the joist web through high shear, these web holes must occur more than 10 inches (254 mm) from the edge of a load-bearing surface. Patching of web holes must extend at least 1 inch (25 mm) beyond all edges of the hole, and it must be fastened to the web with No. 8 screws having a mini-

imum edge distance of 1/2 inch (12.7 mm). Framing members with web holes exceeding these limits must be reinforced, patched or designed in accordance with accepted engineering practice (see commentary, Sections R505.2.6.2 and R505.2.6.3.)

FIGURE R505.2.6.1. See below.

❖ See the commentary to Section R505.2.6.1.

R505.2.6.2 Web hole reinforcing. Reinforcement of web holes in floor joists not conforming to the requirements of Section R505.2.6.1 shall be permitted if the hole is located fully within the center 40 percent of the span and the depth and length of the hole does not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shape section with a hole that does not exceed the web hole size limitations of Section R505.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of 1/2 inch (12.7 mm).

❖ Web holes that are not within the criteria of Section R505.2.6.1 are permitted if they are reinforced and comply with the criteria of this section.

The reinforcing provisions of this section were developed based on engineering judgement and accepted engineering practice and confirmed by testing.

R505.2.6.3 Hole patching. Patching of web holes in floor joists not conforming to the requirements in Section R505.2.6.1 shall be permitted in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practices where web holes exceed the following size limits:
 - 1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.

- 1.2. The length of the hole, measured along the web, exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R505.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R505.2.6.3. The steel patch shall, as a minimum, be of the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of 1/2 inch (12.7 mm).

❖ Framing members with web holes exceeding the limits, outlined in Item 1 of this section must be replaced or designed in accordance with accepted engineering practice. Framing members with web holes within the limits of Item 1, but exceeding the limits of Section R505.2.6.1, must be patched in accordance with Item 2 of this section (see commentary, Section R505.2.6.1).

FIGURE R505.2.6.3. See page 5-33.

❖ See the commentary to Section R505.2.6.3.

R505.3 Floor construction. Cold-formed steel floors shall be constructed in accordance with this section.

❖ Load-bearing steel-framing members must be cold formed to shape from structural quality sheet steel complying with appropriate material standards. The steel grades specified have the ductility and strength to meet these provisions. For more detailed information refer to the *AISI Specification for Design of Cold-formed Steel Structural Members Commentary*.

R505.3.1 Floor to foundation or load-bearing wall connections. Cold-formed steel framed floors shall be anchored to foundations, wood sills or load-bearing walls in accordance with Table R505.3.1(1) and Figure R505.3.1(1), R505.3.1(2),

For SI: 1 inch = 25.4 mm.

FIGURE R505.2.6.1
FLOOR JOIST WEB HOLES

R505.3.1(3), R505.3.1(4), R505.3.1(5) or R505.3.1(6). Anchor bolts shall be located not more than 12 inches (305 mm) from corners or the termination of bottom tracks. Continuous cold-formed steel joists supported by interior load-bearing walls shall be constructed in accordance with Figure R505.3.1(7). Lapped cold-formed steel joists shall be constructed in accordance with Figure R505.3.1(8). End floor joists constructed on foundation walls parallel to the joist span shall be doubled unless a C-shaped bearing stiffener, sized in accordance with Section R505.3.4, is installed web-to-web with the floor joist beneath each supported wall stud,

For SI: 1 inch = 25.4 mm.

**FIGURE R505.2.6.3
FLOOR JOIST WEB HOLE PATCH**

as shown in Figure R505.3.1(9). Fastening of cold-formed steel joists to other framing members shall be in accordance with Section R505.2.5 and Table R505.3.1(2).

❖ This section provides minimum fastening requirements for attachment of steel floor framing to foundations, wood sills and both exterior and interior load-bearing walls. Figures R505.3.1(1) through R505.3.1(6) illustrate exterior wall conditions; thus, the corresponding connection requirements in Table R505.3.1(1) vary based on a site's basic wind speed and seismic design category. End joists must be doubled or have a C-shaped bearing stiffener beneath each wall stud as depicted in Figure R505.3.1(9). In the event these criteria give rise to requirements that are different from those in the table, the more restrictive would govern. Figures R505.3.1(7) and R505.3.1(8) illustrate the minimum connection requirements for floor joists supported by interior load-bearing walls in conjunction with the first line of Table R505.3.1(2).

TABLE R505.3.1(1). See below.

❖ See the commentary to Section R505.3.1 as well as Figures R505.3.1(1) through R505.3.1(6).

TABLE R505.3.1(2). See page 5-34.

❖ In addition to the other connections covered under Section R505.3.1, Table R505.3.1(2) provides the fastening requirements for tracks at the end of floor joists and for subfloor-to-floor joists.

FIGURE 505.3.1(1). See page 5-34.

❖ Figure R505.3.1(1) depicts connection requirements for steel floor joists at exterior steel bearing walls. The minimum number of screws through either the joist

**TABLE R505.3.1(1)
FLOOR TO FOUNDATION OR BEARING WALL CONNECTION REQUIREMENTS^{a, b}**

FRAMING CONDITION	BASIC ULTIMATE WIND SPEED (mph) AND EXPOSURE	
	110 mph Exposure Category C or less than 139 mph Exposure Category B	Less than 139 mph Exposure Category C
Floor joist to wall track of exterior wall in accordance with Figure R505.3.1(1)	2-No. 8 screws	3-No. 8 screws
Rim track or end joist to load-bearing wall top track in accordance with Figure R505.3.1(1)	1-No. 8 screw at 24 inches o.c.	1-No. 8 screw at 24 inches o.c.
Rim track or end joist to wood sill in accordance with Figure R505.3.1(2)	Steel plate spaced at 4 feet o.c. with 4-No. 8 screws and 4-10d or 6-8d common nails	Steel plate spaced at 2 feet o.c. with 4-No. 8 screws and 4-10d or 6-8d common nails
Rim track or end joist to foundation in accordance with Figure R505.3.1(3)	1/2 inch minimum diameter anchor bolt and clip angle spaced at 6 feet o.c. with 8-No. 8 screws	1/2 inch minimum diameter anchor bolt and clip angle spaced at 4 feet o.c. with 8-No. 8 screws
Cantilevered joist to foundation in accordance with Figure R505.3.1(4)	1/2 inch minimum diameter anchor bolt and clip angle spaced at 6 feet o.c. with 8-No. 8 screws	1/2 inch minimum diameter anchor bolt and clip angle spaced at 4 feet o.c. with 8-No. 8 screws
Cantilevered joist to wood sill in accordance with Figure R505.3.1(5)	Steel plate spaced at 4 feet o.c. with 4-No. 8 screws and 4-10d or 6-8d common nails	Steel plate spaced at 2 feet o.c. with 4-No. 8 screws and 4-10d or 6-8d common nails
Cantilevered joist to exterior load-bearing wall track in accordance with Figure R505.3.1(6)	2-No. 8 screws	3-No. 8 screws

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm.

a. Anchor bolts are to be located not more than 12 inches from corners or the termination of bottom tracks such as at door openings or corners. Bolts extend a minimum of 15 inches into masonry or 7 inches into concrete. Anchor bolts connecting cold-formed steel framing to the foundation structure are to be installed so that the distance from the center of the bolt hole to the edge of the connected member is not less than one and one-half bolt diameters.

b. All screw sizes shown are minimum.

FLOORS

flange, clip angle or bent stiffener should be selected from the first row of Table R505.3.1(1) based on the seismic design category or wind speed and exposure. Similarly, if these joists cantilever beyond the wall as illustrated in Figure R505.3.1(7), the required number of screws should be selected from the seventh row of Table R505.3.1(1).

FIGURE 505.3.1(2). See page 5-35.

❖ Figures R505.3.1(2) and R505.3.1(5) depict the connection requirements of steel floor framing to a wood sill, which, in turn, is anchored to the foundation. Details such as the spacing of the clip angle and anchor bolt should be selected from the appropriate row of Table R505.3.1(1) [see Figure R505.3.1(1)].

FIGURE 505.3.1(3). See page 5-35.

❖ Figures R505.3.1(3) and R505.3.1(4) depict requirements for anchoring steel floor framing directly to concrete or masonry foundations. Details such as the spacing of the clip angle and anchor bolt should be

selected from the appropriate row of Table R505.3.1(1) [see Figure R505.3.1(1)].

FIGURE 505.3.1(4). See page 5-36.

FIGURE R505.3.1(9)
BEARING STIFFENERS FOR END JOISTS

R505.3.2 Minimum floor joist sizes. Floor joist size and thickness shall be determined in accordance with the limits set forth in Table R505.3.2 for single or continuous spans. Where continuous joist members are used, the interior bearing supports shall be located within 2 feet (610 mm) of mid-span of the cold-formed steel joists, and the individual spans shall not exceed the spans in Table R505.3.2. Floor joists shall have a bearing support length of not less than 1½ inches (38 mm) for exterior wall supports and 3½ inches (89 mm) for interior wall supports. Tracks shall be not less than 33 mils (0.84 mm) thick except when used as part of a floor header or trimmer in accordance with Section R505.3.8. Bearing stiffeners shall be installed in accordance with Section R505.3.4.

❖ Table R505.3.2 lists the allowable clear spans for single or continuous-span steel floor joists. Where continuous span is used the interior bearing support must be located within 2 feet of mid-span. The continuous span must be arranged as illustrated in Commentary Figure R505.3.2 and the spans must not exceed the limits in Table R505.3.2. The tabulated spans are based on dead loads of 10 psf (0.48 kPa) and design live loads of 30 psf (1.44 kPa) or 40 psf (1.92 kPa). The following example illustrates use of the table.

Example:

Steel floor joists spaced at 16 inches (406 mm) on center support a floor live load of 40 psf (1.92 kPa), a dead load of 10 psf (0.48 kPa) and span

17 feet, 6 inches (5334 mm). Determine the required joist size and minimum grade of steel.

Solution:

In Table R505.3.2 under 40 psf (1.92 kPa), find the live load column headed 16 inches (406 mm). Read down this column to find the first span greater than 17 feet, 6 inches (5334 mm), which is 18 feet, 2 inches (5537 mm). The required joist is 1000S162-54. Since the thickness is 54 mil, the steel must be minimum Grade 50 ksi.

TABLE R505.3.2. See below.

❖ See the commentary and example to Section R505.3.2.

R505.3.3 Joist bracing and blocking. Joist bracing and blocking shall be in accordance with this section.

❖ Sections R505.3.3.1 through R505.3.3.4 provide the requirements for joist top flange bracing, joist bottom flange bracing/blocking, blocking at interior bearing supports and blocking at cantilevers.

R505.3.3.1 Joist top flange bracing. The top flanges of cold-formed steel joists shall be laterally braced by the application of floor sheathing fastened to the joists in accordance with Section R505.2.5 and Table R505.3.1(2).

❖ The application of floor sheathing to steel floor joists in accordance with Table R505.3.1(2) and Section R505.2.5 of the code allows the transfer of loads to the

TABLE R505.3.2
ALLOWABLE SPANS FOR COLD-FORMED STEEL JOISTS—SINGLE OR CONTINUOUS SPANS^{a, b, c, d, e}

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, 1 mil = 0.0254 mm.

a. Deflection criteria: $L/480$ for live loads, $L/240$ for total loads.

b. Floor dead load = 10 psf.

c. Table provides the maximum clear span in feet and inches.

d. Bearing stiffeners are to be installed at all support points and concentrated loads.

e. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thickness. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thickness.

FLOORS

joists and provides the necessary lateral bracing for the top flanges of those joists.

R505.3.3.2 Joist bottom flange bracing/blocking. Floor joists with spans that exceed 12 feet (3658 mm) shall have the bottom flanges laterally braced in accordance with one of the following:

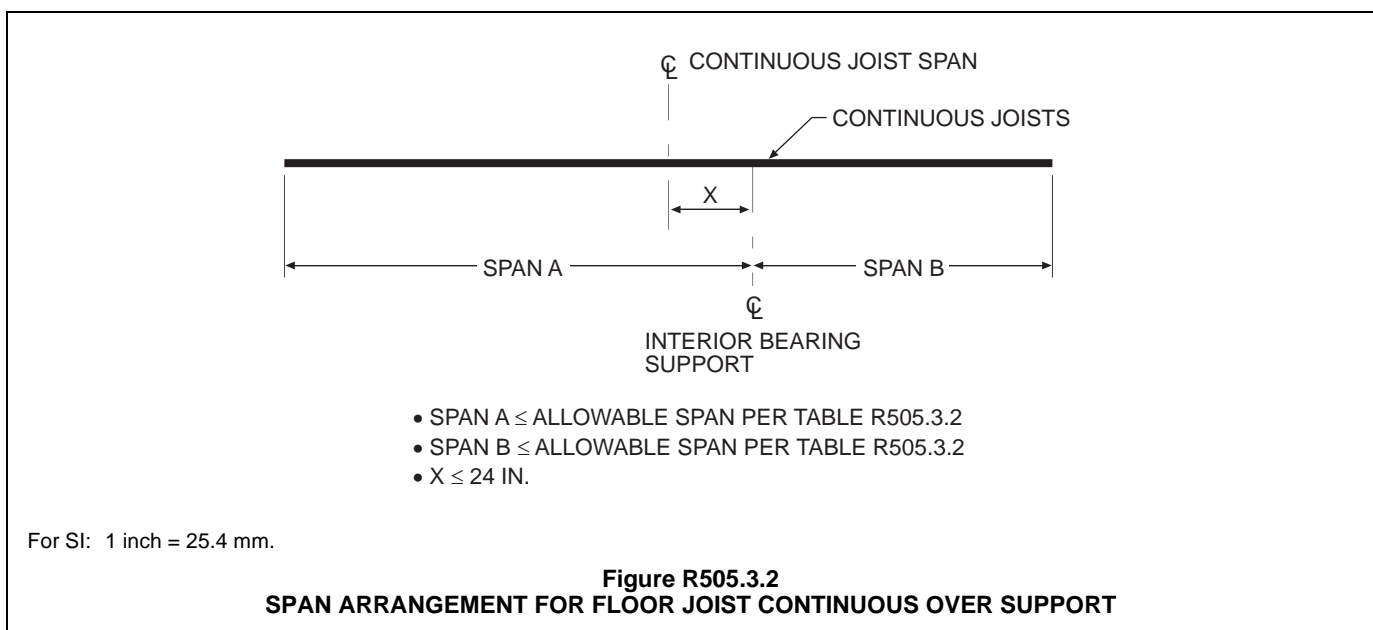

1. Gypsum board installed with minimum No. 6 screws in accordance with Section R702.
 2. Continuous steel straps installed in accordance with Figure R505.3.3.2(1). Steel straps shall be spaced at a maximum of 12 feet (3658 mm) on center and shall be at least 1½ inches (38 mm) in width and 33 mils (0.84 mm) in thickness. Straps shall be fastened to the bottom flange of each joist with one No. 8 screw, fastened to blocking with two No. 8 screws, and fastened at each end (of strap) with two No. 8 screws. Blocking in accordance with Figure R505.3.3.2(1) or R505.3.3.2(2) shall be installed between joists at each end of the continuous strapping and at a maximum spacing of 12 feet (3658 mm) measured along the continuous strapping (perpendicular to the joist run). Blocking shall also be located at the termination of all straps. As an alternative to blocking at the ends, anchoring the strap to a stable building component with two No. 8 screws shall be permitted.
- ❖ Steel floor joists with spans greater than 12 feet (3658 mm) are more prone to overturning and therefore must also have the bottom flanges laterally braced either with gypsum board or continuous steel strapping as illustrated in Figure R505.3.3.2(1) of the code. Strap bracing requires the installation of solid blocking or bridging (X-bracing) [see Figure R505.3.3.2(1) or R505.3.3.2(2)] in line with the straps at the termination of all straps and at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the joist run.

R505.3.3.3 Blocking at interior bearing supports. Blocking is not required for continuous back-to-back floor joists at bearing supports. Blocking shall be installed between every other joist for single continuous floor joists across bearing supports in accordance with Figure R505.3.1(7). Blocking shall consist of C-shape or track section with a minimum thickness of 33 mils (0.84 mm). Blocking shall be fastened to each adjacent joist through a 33-mil (0.84 mm) clip angle, bent web of blocking or flanges of web stiffeners with two No. 8 screws on each side. The minimum depth of the blocking shall be equal to the depth of the joist minus 2 inches (51 mm). The minimum length of the angle shall be equal to the depth of the joist minus 2 inches (51 mm).

❖ Blocking must be installed between the joists, at the interior bearing support, for a single continuous floor joist. Blocking is not required at the bearing support for back-to-back floor joists [see Figure R505.3.1(7)].

R505.3.3.4 Blocking at cantilevers. Blocking shall be installed between every other joist over cantilever bearing supports in accordance with Figure R505.3.1(4), R505.3.1(5) or R505.3.1(6). Blocking shall consist of C-shape or track section with minimum thickness of 33 mils (0.84 mm). Blocking shall be fastened to each adjacent joist through bent web of blocking, 33 mil clip angle or flange of web stiffener with two No. 8 screws at each end. The depth of the blocking shall be equal to the depth of the joist. The minimum length of the angle shall be equal to the depth of the joist minus 2 inches (51 mm). Blocking shall be fastened through the floor sheathing and to the support with three No. 8 screws (top and bottom).

❖ Blocking must be installed between every other joist at the cantilever support [see Figure R505.3.1(4), R505.3.1(5) or R505.3.1(6)].

For SI: 1 mil = 0.0254, 1 inch = 25.4 mm.

**FIGURE R505.3.3.2(1)
JOIST BLOCKING (SOLID)**

For SI: 1 mil = 0.0254, 1 inch = 25.4 mm.

**FIGURE R505.3.3.2(2)
JOIST BLOCKING (STRAP)**

R505.3.4 Bearing stiffeners. Bearing stiffeners shall be installed at each joist bearing location in accordance with this section, except for joists lapped over an interior support not carrying a load-bearing wall above. Floor joists supporting jamb studs with multiple members shall have two bearing stiffeners in accordance with Figure R505.3.4(1). Bearing stiffeners shall be fabricated from a C-shaped, track or clip angle member in accordance with the one of following:

1. C-shaped bearing stiffeners:
 - 1.1. Where the joist is not carrying a load-bearing wall above, the bearing stiffener shall be a minimum 33 mil (0.84 mm) thickness.
 - 1.2. Where the joist is carrying a load-bearing wall above, the bearing stiffener shall be not less than the same designation thickness as the wall stud above.
2. Track bearing stiffeners:
 - 2.1. Where the joist is not carrying a load-bearing wall above, the bearing stiffener shall be a minimum 43 mil (1.09 mm) thickness.
 - 2.2. Where the joist is carrying a load-bearing wall above, the bearing stiffener shall be not less than one designation thickness greater than the wall stud above.

The minimum length of a bearing stiffener shall be the depth of member being stiffened minus $\frac{3}{8}$ inch (9.5 mm). Each bearing stiffener shall be fastened to the web of the member it is stiffening as shown in Figure R505.3.4(2).

❖ Stiffeners (also referred to as transverse stiffeners or web stiffeners) at points of bearing provide resistance

to web crippling in the joist. This section provides the option to use C-shaped or track section stiffening. These stiffeners are illustrated in Figure R505.3.4(2), but a stiffener can be installed on either side of the web of a joist as depicted in Figures R505.3.1(1) through R505.3.1(9). Two bearing stiffeners are required to be located where jamb studs are supported by the floor joist [see Figure R505.3.4(1)].

All bearing stiffeners are to be fastened in accordance with Figure R505.3.4(2).

**FIGURE R505.3.4(1)
BEARING STIFFENERS UNDER JAMB STUDS**

**FIGURE R505.3.4(2)
BEARING STIFFENER**

For SI: 1 inch = 25.4 mm.

R505.3.5 Cutting and notching. Flanges and lips of load-bearing cold-formed steel floor framing members shall not be cut or notched.

- ❖ Flanges and lips of load-bearing steel floor framing members must not be cut or notched because this would affect their structural integrity. The only holes permitted in steel floor joists are those that conform to Section R505.2.6.

R505.3.6 Floor cantilevers. Floor cantilevers for the top floor of a two- or three-story building or the first floor of a one-story building shall not exceed 24 inches (610 mm). Cantilevers, not exceeding 24 inches (610 mm) and supporting two stories and roof (first floor of a two-story building), shall be permitted provided that all cantilevered joists are doubled (nested or back-to-back). The doubled cantilevered joists shall extend not less than 6 feet (1829 mm) toward the inside and shall be fastened with not less than two No. 8 screws spaced at 24 inches (610 mm) on center through the webs (for back-to-back) or flanges (for nested joists).

- ❖ The maximum permitted floor cantilever is 24 inches (610 mm). Floor cantilevers that support a roof only are permitted to be single joist conforming to the allowable span requirements of Section R505.3.2.

Where a cantilever floor supports two stories and a roof all cantilever joists must be doubled (nested or back to back). Double joist consists of members of the same size and material thickness as that for single joist in accordance with the allowable span requirements of Section R505.3.2. The double joist must extend a minimum of 6 feet (1829 mm) within the building.

R505.3.7 Splicing. Joists and other structural members shall not be spliced. Splicing of tracks shall conform to Figure R505.3.7.

- ❖ Splicing of structural members is not permitted except when lapped joists occur at interior bearing points.

Splicing of tracks is allowed because they are not permitted to act as load-carrying members (see Figure R505.3.7). The exception to this would be under lateral loads from wind and earthquakes. In this case, the floor system must act as a diaphragm, with tracks serving as diaphragm chords. To provide continuity and carry the anticipated chord force, the splice must be as shown in Figure R505.3.7.

R505.3.8 Framing of floor openings. Openings in floors shall be framed with header and trimmer joists. Header joist spans shall not exceed 6 feet (1829 mm) or 8 feet (2438 mm) in length in accordance with Figure R505.3.8(1) or R505.3.8(2), respectively. Header and trimmer joists shall be fabricated from joist and track members, having a minimum size and thickness at least equivalent to the adjacent floor joists, and shall be installed in accordance with Figures R505.3.8(1), R505.3.8(2), R505.3.8(3) and R505.3.8(4). Each header joist shall be connected to trimmer joists with four 2-inch by 2-inch (51-mm by 51-mm) clip angles. Each clip angle shall be fastened to both the header and trimmer joists with four No. 8 screws, evenly spaced, through each leg of the clip angle. The clip angles shall have a thickness not less than that of the floor joist. Each track section for a built-up header or trimmer joist shall extend the full length of the joist (continuous).

- ❖ Recognizing that floor openings are necessary for such things as stairways and utility chases, the code provides prescriptive criteria for framing these openings. This section provides prescriptive design for floor openings 6 feet (1829 mm) and 8 feet (2438 mm) in length. These requirements for openings in floors are illustrated in Figures R505.3.8(1) through R505.3.8(4).

For SI: 1 inch = 25.4 mm.

SECTION R506 CONCRETE FLOORS (ON GROUND)

R506.1 General. Concrete slab-on-ground floors shall be designed and constructed in accordance with the provisions of this section or ACI 332. Floors shall be a minimum 3½ inches (89 mm) thick (for expansive soils, see Section R403.1.8). The specified compressive strength of concrete shall be as set forth in Section R402.2.

❖ For weathering requirements, see the commentary to Sections R301.2 and R402.2. Commentary Figure R506.1 shows the requirements of this section.

R506.2 Site preparation. The area within the foundation walls shall have all vegetation, top soil and foreign material removed.

❖ Removal of construction debris and foreign materials, such as lumber formwork, stakes, tree stumps and other vegetation, limits the attraction of termites, insects and vermin. Top soil and soil vegetation should also be removed because such top soil is generally loosely compacted or so full of vegetation that soil settlement will occur when the vegetation decays. For concrete slabs placed on uncompacted fill or on large quantities of foreign materials, differential settlement may take place as a result of subsequent compaction of the soil, which can result in cracking of the floor slab and the interior wall/ceiling finishes.

R506.2.1 Fill. Fill material shall be free of vegetation and foreign material. The fill shall be compacted to ensure uniform support of the slab, and except where *approved*, the fill depths shall not exceed 24 inches (610 mm) for clean sand or gravel and 8 inches (203 mm) for earth.

❖ To minimize differential settlement caused by consolidation of uncompacted fill and the problems associated with differential settlement, any fill beneath a concrete slab must be compacted. Properly compacted fill, besides minimizing settlement, increases the soil load-bearing characteristics and soil stability and reduces water penetration. The amount of compaction for fill is not specifically stipulated. Generally, fill soils should be compacted to 95-percent maximum density as determined by a Standard Proctor Test (ASTM D698). Compaction requirements for expansive soils should be

determined from an engineering analysis.

Soil may be compacted using equipment appropriate to the type of material being compacted, with lifts not exceeding 8 inches (203 mm). In general, thinner layers produce better compaction of fill, regardless of the type of soil being compacted.

R506.2.2 Base. A 4-inch-thick (102 mm) base course consisting of clean graded sand, gravel, crushed stone, crushed concrete or crushed blast-furnace slag passing a 2-inch (51 mm) sieve shall be placed on the prepared subgrade where the slab is below *grade*.

Exception: A base course is not required where the concrete slab is installed on well-drained or sand-gravel mixture soils classified as Group I according to the United Soil Classification System in accordance with Table R405.1.

❖ Slabs need to be protected from the penetration of water and water vapor from below to prevent damage to interior finish material. Additionally, the effectiveness of thermal insulation at the slab may be adversely affected because of moisture. A 4-inch (102 mm) minimum granular base course is placed over the fill or undisturbed soil for slabs below grade to provide a capillary stop for water rising through the soil and into the slab. A base course is especially necessary when the site soil is other than gravel or clean sand. Both surface and groundwater problems must be addressed. Proper site preparation, selection of adequate fill and base course materials, and the installation of a vapor barrier minimize potential moisture problems associated with slab-on-grade construction.

R506.2.3 Vapor retarder. A 6-mil (0.006 inch; 152 µm) polyethylene or *approved* vapor retarder with joints lapped not less than 6 inches (152 mm) shall be placed between the concrete floor slab and the base course or the prepared subgrade where no base course exists.

Exception: The vapor retarder is not required for the following:

1. Garages, utility buildings and other unheated *accessory structures*.
2. For unheated storage rooms having an area of less than 70 square feet (6.5 m²) and carports.

3. Driveways, walks, patios and other flatwork not likely to be enclosed and heated at a later date.
4. Where *approved* by the *building official*, based on local site conditions.

❖ Although good quality, uncracked concrete is practically impermeable to the passage of water (unless the water is under a considerable pressure), concrete is not impervious to the passage of water vapors. If the surface of the slab is not sealed, water vapor will pass through the slab. If a floor finish such as linoleum, vinyl tile, wood flooring or any type of covering is placed on top of the slab, the moisture will be trapped in the slab. If the floor finish is adhered to the concrete, it may eventually loosen and buckle or blister.

Many of the moisture problems associated with enclosed slabs-on-ground can be minimized by installing a vapor retarder. When required, vapor retarders of either single- or multiple-layer membranes should be acceptable if the vapor retarder is properly installed with lapped joints and the barrier is not punctured during construction.

R506.2.4 Reinforcement support. Where provided in slabs-on-ground, reinforcement shall be supported to remain in place from the center to upper one-third of the slab for the duration of the concrete placement.

❖ The code does not require reinforcement for the concrete slab-on-ground floors. When reinforcement is provided, common practice is to use welded wire fabric. The welded wire fabric frequently is left on the ground during the pour and not picked up. When lifted up by construction personnel, it is often not in a proper or consistent location, with some on the ground and some near the top of the slab. This section does not require installation of reinforcement; however, if it is installed, it must be properly located in the slab, or its benefit is lost.

SECTION R507 EXTERIOR DECKS

R507.1 Decks. Wood-framed decks shall be in accordance with this section or Section R301 for materials and conditions not prescribed herein. Where supported by attachment to an exterior wall, decks shall be positively anchored to the primary structure and designed for both vertical and lateral loads.

Such attachment shall not be accomplished by the use of toenails or nails subject to withdrawal. Where positive connection to the primary building structure cannot be verified during inspection, decks shall be self-supporting. For decks with cantilevered framing members connections to exterior walls or other framing members shall be designed and constructed to resist uplift resulting from the full live load specified in Table R301.5 acting on the cantilevered portion of the deck.

❖ If an exterior wall is used to support a deck, the deck framing must be positively attached to the building structure. This connection design must include a consideration of both vertical and lateral loads, and the

connection must be available for inspection. If it is not, this method of support is not permitted and the deck must be self-supporting.

If a deck has cantilevered framing, the framing must have a connection to its support that is designed to resist any uplift resulting from the full live load acting on the cantilevered span only. This load condition will produce maximum uplift at the support opposite the cantilevered end.

R507.2 Deck ledger connection to band joist. Deck ledger connections to band joists shall be in accordance with this section, Tables R507.2 and R507.2.1, and Figures R507.2.1(1) and R507.2.1(2). For other grades, species, connection details and loading conditions, deck ledger connections shall be designed in accordance with Section R301.

❖ This section contains the prescriptive design for positive anchorage of a deck attached to the primary structure. The design is for vertical loads only [50 psf (2394 Pa) maximum] on the deck. Section R507.2.1 specifies the material requirements for the deck ledger. Deck ledgers must not support the girders supporting deck joists. The deck ledger is prohibited from being supported by stone or masonry veneer.

Researchers at Virginia Tech University and Washington State University have tested simulated deck-ledger to house-band-joist connections in their respective laboratories. A practical range of pressure-preservative-treated (PPT) deck ledger lumber (incised Hem-fir and Southern pine) was attached to a simulated Spruce-pine-fir band joist by $\frac{1}{2}$ -inch (12.7 mm) lag screws or bolts with washers. The ledger connection tests did not include carriage bolts; therefore, an engineered design of the ledger connection is required if carriage bolts are used. The deck ledger was separated from the house band joist by placing a piece of $\frac{15}{32}$ -inch wall sheathing in the connection, and in another test case for bolts only, a $\frac{1}{2}$ -inch (12.7 mm) stack of washers was inserted into the connection to produce a drainage plane. The specimens were tested to failure and the average test results were divided by a factor of 3.0, intended to provide an adequate in-service safety factor, and further divided by 1.6 to convert from a “test duration” to a “normal duration” of 10 years recognized by the NDS and IBC as the proper duration for an occupancy live load.

The test was made with two different band joists, a 2-inch (51 mm) nominal Spruce-pine-fir and a 1-inch by $9\frac{1}{2}$ -inch Douglas fir-laminated (DFL) veneer. Section R507.2.2 permits the DFL band joist in lieu of the 2-inch (51 mm) nominal. Due to the limited investigation into the performance of composite-type band joists (only DFL was evaluated) and the possibility of band joists entering the market being a lower quality than what was tested at Washington State University, engineered wood band joists are not included in the scope of the fastener spacing table. Instead, the attachment must be designed in accordance with accepted engineering practice where an engineered wood product is used as the band joist. The maximum distance between the face of the band joist and the deck ledger must not

FLOORS

exceed 1 inch (25 mm). Note e of Table R507.2 will permit $\frac{1}{2}$ -inch thickness of stacked washers to substitute for $\frac{1}{2}$ inch of allowable sheathing thickness where combined with wood structural panel or lumber sheathing if the 1-inch distance is not exceeded.

Penetration of moisture at the interface of the deck and the exterior of the house can be detrimental to the connectors. For this reason, Section R502.2.3 requires the connectors to be hot-dipped galvanized or stainless steel.

The on-center spacing of the fasteners as shown in Table R507.2.1 and Figures R507.2.1(1) and R507.2.1(2) is the closest spacing for the two cases of deck ledger lumber tested. In deck construction, a joist hanger or angle connector is commonly installed at the end of the ledger board to support the deck rim joist. Often these members are double 2x members [3-inch (76 mm) nominal width]. The spacing of 2 inches to 5 inches (51 mm to 127 mm) from the ends will allow the installer flexibility to locate the lag screw or bolt so that it does not interfere with the installation of the joist hanger or structural connector. Five inches (127 mm) will accommodate an inverted flange double 2x joist hanger.

TABLE R507.2. See below.

- ❖ See the commentary to Sections R507.2 and R507.2.1.

R507.2.1 Ledger details. Deck ledgers installed in accordance with Section R507.2 shall be a minimum 2-inch by 8-inch (51 mm by 203 mm) nominal, pressure-preservative-treated southern pine, incised pressure-preservative-treated Hem-fir, or approved, naturally durable, No. 2 grade or better lumber. Deck ledgers installed in accordance with Section R507.2 shall not support concentrated loads from beams or girders. Deck ledgers shall not be supported on stone or masonry veneer.

- ❖ See the commentary to Section R507.2.

TABLE 507.2.1. See below.

- ❖ See the commentary to Section R507.2.1.

FIGURE R507.2.1(1). See page 49.

- ❖ See the commentary to Section R507.2.

FIGURE R507.2.1(2). See page 49.

- ❖ See the commentary to Section R507.2.

R507.2.2 Band joist details. Band joists attached by a ledger in accordance with Section R507.2 shall be a minimum 2-inch-nominal (51 mm), solid-sawn, spruce-pine-fir lumber or a minimum 1-inch by $9\frac{1}{2}$ -inch (25 mm \times 241 mm) dimensional, Douglas fir, laminated veneer lumber. Band joists attached by a ledger in accordance with Section R507.2 shall be fully supported by a wall or sill plate below.

- ❖ See the commentary to Section R507.2.

TABLE R507.2
DECK LEDGER CONNECTION TO BAND JOIST^{a, b}
(Deck live load = 40 psf, deck dead load = 10 psf, snow load \leq 40 psf)

CONNECTION DETAILS	JOIST SPAN						
	6' and less	6'1" to 8'	8'1" to 10'	10'1" to 12'	12'1" to 14'	14'1" to 16'	16'1" to 18'
	On-center spacing of fasteners						
$\frac{1}{2}$ -inch diameter lag screw with $\frac{1}{2}$ -inch maximum sheathing ^{c, d}	30	23	18	15	13	11	10
$\frac{1}{2}$ -inch diameter bolt with $\frac{1}{2}$ -inch maximum sheathing ^d	36	36	34	29	24	21	19
$\frac{1}{2}$ -inch diameter bolt with 1-inch maximum sheathing ^c	36	36	29	24	21	18	16

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- Ledgers shall be flashed in accordance with Section R703.4 to prevent water from contacting the house band joist.
- Snow load shall not be assumed to act concurrently with live load.
- The tip of the lag screw shall fully extend beyond the inside face of the band joist.
- Sheathing shall be wood structural panel or solid sawn lumber.
- Sheathing shall be permitted to be wood structural panel, gypsum board, fiberboard, lumber or foam sheathing. Up to $\frac{1}{2}$ -inch thickness of stacked washers shall be permitted to substitute for up to $\frac{1}{2}$ inch of allowable sheathing thickness where combined with wood structural panel or lumber sheathing.

TABLE R507.2.1
PLACEMENT OF LAG SCREWS AND BOLTS IN DECK LEDGERS AND BAND JOISTS

MINIMUM END AND EDGE DISTANCES AND SPACING BETWEEN ROWS				
	TOP EDGE	BOTTOM EDGE	ENDS	ROW SPACING
Ledger ^a	2 inches ^d	$\frac{3}{4}$ inch	2 inches ^b	$1\frac{5}{8}$ inches ^b
Band Joist ^c	$\frac{3}{4}$ inch	2 inches	2 inches ^b	$1\frac{5}{8}$ inches ^b

For SI: 1 inch = 25.4 mm.

- Lag screws or bolts shall be staggered from the top to the bottom along the horizontal run of the deck ledger in accordance with Figure R507.2.1(1).
- Maximum 5 inches.
- For engineered rim joists, the manufacturer's recommendations shall govern.
- The minimum distance from bottom row of lag screws or bolts to the top edge of the ledger shall be in accordance with Figure R507.2.1(1).

R507.2.3 Ledger to band joist fastener details. Fasteners used in deck ledger connections in accordance with Table R507.2 shall be hot-dipped galvanized or stainless steel and shall be installed in accordance with Table R507.2.1 and Figures R507.2.1(1) and R507.2.1(2).

❖ See the commentary to Section R507.2.

R507.2.4 Deck lateral load connection. The lateral load connection required by Section R507.1 shall be permitted to be in accordance with Figure R507.2.3(1) or R507.2.3(2). Where the lateral load connection is provided in accordance with Figure R507.2.3(1), hold-down tension devices shall be installed in not less than two locations per deck, within 24 inches of each end of the deck. Each device shall have an allowable stress design capacity of not less than 1,500 pounds (6672 N). Where the lateral load connections are provided in accordance with Figure R507.2.3(2), the hold-down tension devices shall be installed in not less than four locations per

deck, and each device shall have an allowable stress design capacity of not less than 750 pounds (3336 N).

❖ The code requires decks that are supported by attachment to an exterior wall to be positively anchored to the primary structure, and be designed for both vertical and lateral loads. The vertical and lateral loads referred to are code-prescribed loads such as dead, live, wind and seismic loads. The magnitude of the lateral loads to be resisted is not specified and must be determined in accordance with accepted engineering practice.

Attachment only to the band joist may not be sufficient for the lateral loads. Positive anchorage of the deck joist to the floor framing addresses this potential failure. Figures R507.2.3(1) and R507.2.3(2) show typical hold-down devices that provide a positive connection to the floor framing in order to resist the lateral loads. Figure R507.2.3(1) is based on a similar figure

*DISTANCE SHALL BE PERMITTED TO BE REDUCED TO 4.5" IF LAG SCREWS ARE USED OR BOLT SPACING IS REDUCED TO THAT OF LAG SCREWS TO ATTACH 2 X 8 LEDGERS TO 2 X 8 BAND JOISTS.

For SI: 1 inch = 25.4 mm.

FIGURE R507.2.1(1)
PLACEMENT OF LAG SCREWS AND BOLTS IN LEDGERS

For SI: 1 inch = 25.4 mm.

FIGURE R507.2.1(2)
PLACEMENT OF LAG SCREWS AND BOLTS IN BAND JOISTS

from FEMA 232. The number required and actual design of the connection to resist the lateral loads must be determined in accordance with accepted engineering practice. Where Figure R507.2.3(1) is used, a minimum of two hold-down devices, located within 24 inches of each end of the deck, with a design capacity of 1,500 pounds (6672 N) each, are required.

Figure R507.2.3(2) provides an alternative prescriptive method to achieve an acceptable lateral load connection for residential decks. For new or replacement decks on existing homes, builders or homeowners must often remove interior sheet rock on ceilings in order to install hold-down tension devices as required by Figure R507.2.3(1). Figure R507.2.3(2) achieves an acceptable lateral load connection between the deck and primary structure by permitting the installation of surface-mounted hold-down connection devices spread out along the length of the ledger and precludes the need to make expensive and unnecessary ceiling repairs. Where Figure R507.2.3(2) is used, a minimum of four hold-down devices, with one located within 24 inches of each end of the deck, with a design capacity of 750 pounds each, are required.

Where Figure R507.2.3(1) or R507.2.3(2) is not used, the quantity and load capacity must comply with the engineered design.

FIGURE 507.2.3(1). See below.

❖ See the commentary to Section R507.2.4.

FIGURE 507.2.3(2). See page 5-51.

❖ See the commentary to Section R507.2.4.

R507.3 Plastic composite deck boards, stair treads, guards, or handrails. Plastic composite exterior deck boards, stair treads, guards and handrails shall comply with the requirements of ASTM D7032 and the requirements of Section 507.3.

❖ Plastic composite, as defined in Section R202, is a generic designation that refers to wood/plastic composites and plastic lumber. Plastic composite (PC) materials, commonly used in exterior deck boards, guards and handrails, must be rated for appropriate performance criteria. These materials have a widespread acceptance for residential construction, and labeling requirements for PCs allow the safe application of these materials in exterior deck systems. The referenced standard, ASTM D7032, includes performance evaluations, such as flexural tests, ultraviolet-resistance tests, freeze-thaw-resistance tests, biodegradation tests, fire-performance tests, creep-recovery tests, mechanical fastener holding tests and slip-resistance tests. The standard also includes considerations of the effects of temperature and moisture, concentrated loads and fire propagation tests.

Section R507.3.1 clarifies mandatory labeling requirements for plastic composites. Each deck board and stair tread, similar to pressure-preservative-treated wood, is required to have a label. The required label would be applied on an end or on a face (side) of each board. Product labels will show verification of compliance with ASTM D7032 and provide the appropriate performance information. For example, deck board labels would identify the allowable load and

For SI: 1 inch = 25.4 mm.

FIGURE 507.2.3(1)
DECK ATTACHMENT FOR LATERAL LOADS

span [e.g., 40 psf load on a 16-inch (406 mm) span would be expressed as "16/40"]. Handrails and guard-rail systems, which are more often supplied as "kits" in packages, require labels on the items or on the packaging. The maximum span (maximum vertical post spacing) is required to be on the label, as is verifying compliance with ASTM D7032.

Section 507.3.5 includes the requirement for the installation of these PC products in accordance with the manufacturer's instructions, which is the best way to ensure that PCs perform to the required design loads, and installation instructions are an integral part of the manufacturer's labeling program.

The flame spread index of these PC materials is limited to 200 when tested in accordance with ASTM E84 or UL723. This is a measure of how rapid a fire will spread for these PC materials and is consistent with the requirements for interior finish material used throughout the building (see commentary, Section R302.9).

R507.3.1 Labeling. Plastic composite deck boards and stair treads, or their packaging, shall bear a label that indicates compliance to ASTM D7032 and includes the allowable load and maximum allowable span determined in accordance with ASTM D7032. Plastic or composite handrails and guards, or their packaging, shall bear a label that indicates compliance to ASTM D7032 and includes the maximum allowable span determined in accordance with ASTM D7032.

❖ See the commentary to Section R507.3.

R507.3.2 Flame spread index. Plastic composite deck boards, stair treads, guards, and handrails shall exhibit a flame spread index not exceeding 200 when tested in accordance with ASTM E84 or UL 723 with the test specimen remaining in place during the test.

Exception: Plastic composites determined to be noncombustible.

❖ See the commentary to Section R507.3.

R507.3.3 Decay resistance. Plastic composite deck boards, stair treads, guards and handrails containing wood, cellulosic or other biodegradable materials shall be decay resistant in accordance with ASTM D 7032.

❖ See the commentary to Section R507.3.

R507.3.4 Termite resistance. Where required by Section 318, plastic composite deck boards, stair treads, guards and handrails containing wood, cellulosic or other biodegradable materials shall be termite resistant in accordance with ASTM D7032.

❖ See the commentary to Section R507.3.

507.3.5 Installation of plastic composites. Plastic composite deck boards, stair treads, guards and handrails shall be installed in accordance with this code and the manufacturer's instructions.

❖ See the commentary to Section R507.3.

R507.4 Decking. Maximum allowable spacing for joists supporting decking shall be in accordance with Table R507.4. Wood decking shall be attached to each supporting member with not less than (2) 8d threaded nails or (2) No. 8 wood screws.

❖ Sections R507.4, R507.5, R507.6 and R507.7 provide the prescriptive design and details for deck boards, joist spacing, joist span, deck beam span, bearing requirements for joist and beams and connection of deck beam to deck post. Tables R507.4, R507.5 and R507.6 are based on wet use and treated or incised lumber. The span tables for wood floors in Section R502 are not appropriate for exterior wood-framed decks. Also, additional wood species that are not in Section R502 have been included. Table R507.4 provides for the deck boards to be either perpendicular or diagonal to the joist. The maximum angle of the diagonal deck board is 45 degrees from perpendicular.

The new tables are based on wood capacity using the *National Design Specification for Wood Construc-*

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**FIGURE R507.2.3(2)
DECK ATTACHMENT FOR LATERAL LOADS**

tion (NDS). The deck joist and beam tables assume No. 2 grade wood, wet use and incising, when applicable. Incising is done to assist chemical additives to soak deeper into preservative-treated lumber. Incising is only assumed in lumber species that are preservative treated, such as Douglas fir-larch and Hem-fir and resistant to pressure treatment. Southern pine more easily absorbs preservatives during the pressure treating process and does not require incising.

Bearing requirements in Section R507.7 are consistent with bearing requirements in Section R502.6.

R507.5 Deck joists. Maximum allowable spans for wood deck joists, as shown in Figure R507.5, shall be in accordance with Table R507.5. Deck joists shall be permitted to cantilever not greater than one-fourth of the actual, adjacent joist span.

❖ See the commentary to Section R507.4.

R507.5.1 Lateral restraint at supports. Joist ends and bearing locations shall be provided with lateral restraint to prevent rotation. Where lateral restraint is provided by joist hangers or blocking between joists, their depth shall equal not less than 60 percent of the joist depth. Where lateral restraint is provided by rim joists, they shall be secured to the end of each joist with not less than (3) 10d (3-inch × 0.128-inch) nails or (3) No. 10 × 3-inch (76 mm) long wood screws.

❖ See the commentary to Section R507.4.

R507.6 Deck Beams. Maximum allowable spans for wood deck beams, as shown in Figure R507.6, shall be in accordance with Table R507.6. Beam plies shall be fastened with two rows of 10d (3-inch × 0.128-inch) nails minimum at 16 inches (406 mm) on center along each edge. Beams shall be permitted to cantilever at each end up to one-fourth of the actual beam span. Splices of multispans beams shall be located at interior post locations.

❖ See the commentary to Section R507.4.

R507.7 Deck joist and deck beam bearing. The ends of each joist and beam shall have not less than 1½ inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on concrete or masonry for the entire width of the beam. Joist framing into the side of a ledger board or beam shall be supported by approved joist hangers. Joists bearing on a beam shall be connected to the beam to resist lateral displacement.

❖ See the commentary to Section R507.4.

R507.7.1 Deck post to deck beam. Deck beams shall be attached to deck posts in accordance with Figure R507.7.1 or by other equivalent means capable to resist lateral displacement.

Manufactured post-to-beam connectors shall be sized for the post and beam sizes. All bolts shall have washers under the head and nut.

Exception: Where deck beams bear directly on footings in accordance with Section R507.8.1.

❖ See the commentary to Section R507.4.

R507.8 Deck posts. For single-level wood-framed decks with beams sized in accordance with Table R507.6, deck post size shall be in accordance with Table R507.8.

❖ Sections R507.8 and R507.8.1 contain prescriptive provisions for sizing wood posts and connecting the post to the foundation for a deck. The post-sizing provisions are presented in Table R507.8. Posts must be restrained at the bottom to prevent lateral displacement. The lateral restraint may be provided by a minimum post-to-footing connection based on the manufacturer's requirements for connections supplying lateral restraint or embedding the post 12 inches or greater into the soil or concrete piers. The minimum footing depth and connection requirement adds an additional provision useful in determining whether a deck meets minimum safety requirements. See Section R317.1.4 for decay resistance of wood columns.

Note: While Section R507 adds details needed for building a residential deck, the section does not cover all the details required to build a deck.

**TABLE R507.8
DECK POST HEIGHT^a**

DECK POST SIZE	MAXIMUM HEIGHT ^a
4 × 4	8'
4 × 6	8'
6 × 6	14'

For SI: 1 foot = 304.8 mm.

a. Measured to the underside of the beam.

R507.8.1 Deck post to deck footing. Posts shall bear on footings in accordance with Section R403 and Figure R507.8.1. Posts shall be restrained to prevent lateral displacement at the bottom support. Such lateral restraint shall be provided by manufactured connectors installed in accordance with Section R507 and the manufacturers' instructions or a minimum post embedment of 12 inches (305 mm) in surrounding soils or concrete piers.

❖ See the commentary to Section R507.8.

**TABLE R507.4
MAXIMUM JOIST SPACING**

MATERIAL TYPE AND NOMINAL SIZE	MAXIMUM ON-CENTER JOIST SPACING	
	Perpendicular to joist	Diagonal to joist ^a
1¼-inch-thick wood	16 inches	12 inches
2-inch-thick wood	24 inches	16 inches
Plastic composite	In accordance with Section R507.3	In accordance with Section R507.3

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 degree = 0.01745 rad.

a. Maximum angle of 45 degrees from perpendicular for wood deck boards.

Chapter 6: Wall Construction

General Comments

Chapter 6 contains provisions that regulate the design and construction of walls. The wall construction covered in Chapter 6 consists of five different types: wood framed, cold-formed steel framed, masonry, concrete and structural insulated panel (SIP). The primary concern of this chapter is the structural integrity of wall construction and transfer of all imposed loads to the supporting structure.

Section R601 contains the scope, as well as the performance expectations for walls. Section R602 addresses wood wall framing. Section R603 addresses cold-formed steel wall framing. Section R604 specifies requirements for wood-structural-panel wall sheathing. Section R605 provides requirements for particleboard used as wall sheathing. Section R606 states the general requirements pertaining to masonry wall construction. Section R607 specifies requirements for wall panels of glass unit masonry. Section R608 addresses prescriptive requirements for concrete wall construction with stay-in-place or removable forms. Section R609 contains the criteria for the performance of exterior windows and doors. Section R610 contains the provisions for SIP wall construction.

In certain instances a wall must have a fire-resistance rating. Where this is necessary, the wall system must be

a tested assembly, and any conditions specific to the installation of the assembly must apply as well. Examples of these provisions include:

- Exterior walls based on location on property (see Section R302).
- Walls serving as dwelling unit separations in two-family dwellings (see Section R302.3).
- Common wall between townhouses (see Section R302.2).

Purpose

This chapter provides the requirements for the design and construction of wall systems that are capable of supporting the minimum design vertical loads (dead, live and snow loads) and lateral loads (wind or seismic loads). This chapter contains the prescriptive requirements for wall bracing and/or shear walls to resist the imposed lateral loads due to wind and seismic.

Chapter 6 also regulates exterior windows and doors installed in walls. The chapter contains criteria for the performance of exterior windows and doors and includes provisions for window sill height, testing and labeling, vehicular access doors, wind-borne debris protection and anchorage details.

SECTION R601 GENERAL

R601.1 Application. The provisions of this chapter shall control the design and construction of walls and partitions for buildings.

❖ This section establishes the scope of the chapter.

R601.2 Requirements. Wall construction shall be capable of accommodating all loads imposed in accordance with Section R301 and of transmitting the resulting loads to the supporting structural elements.

❖ This is a general performance statement, requiring that walls support the required design loads and provide an adequate load path to supporting elements.

R601.2.1 Compressible floor-covering materials. Compressible floor-covering materials that compress more than $\frac{1}{32}$ inch (0.8 mm) when subjected to 50 pounds (23 kg) applied over 1 inch square (645 mm) of material and are greater than $\frac{1}{8}$ inch (3.2 mm) in thickness in the uncompressed state shall not extend beneath walls, partitions or columns, which are fastened to the floor.

❖ Although it is preferable to fasten walls directly to the supporting structure, this provision allows them to be

installed over finish floor materials that meet the specified criteria.

SECTION R602 WOOD WALL FRAMING

R602.1 General. Wood and wood-based products used for load-supporting purposes shall conform to the applicable provisions of this section.

❖ Sections R602.1.1 through R602.1.10 contain the prescriptive requirements for wood and wood-based products used in wood wall framing.

R602.1.1 Sawn lumber. Sawn lumber shall be identified by a grade mark of an accredited lumber grading or inspection agency and have design values certified by an accreditation body that complies with DOC PS 20. In lieu of a grade mark, a certification of inspection issued by a lumber grading or inspection agency meeting the requirements of this section shall be accepted.

❖ Sawn lumber performing a load-carrying function must conform to a minimum quality control standard. To verify this, load-bearing lumber must be properly identified to indicate that the grades and species meet the minimum requirements specified in this chapter. Commen-

tary Figure R602.1.1 shows the information contained in a grade mark. For more examples, see Commentary Figure R502.1. For examples of marks for wood structural panels, see Commentary Figure R503.2.1.

R602.1.2 End-jointed lumber. Approved end-jointed lumber identified by a grade mark conforming to Section R602.1 shall be permitted to be used interchangeably with solid-sawn members of the same species and grade. End-jointed lumber used in an assembly required elsewhere in this code to have a fire-resistance rating shall have the designation “Heat Resistant Adhesive” or “HRA” included in its grade mark.

❖ End-jointed lumber that has been fabricated in accordance with nationally recognized standards can be used interchangeably with solid-sawn members, provided that the species and grade of the wood are comparable. Commentary Figure R602.1.2(1) shows end-jointed lumber, which is also referred to as “finger-jointed” (see commentary, Section R502.1.1.2).

End-jointed lumber carrying the HRA mark, indicating it has been joined using heat-resistant adhesive, is permitted to be used interchangeably with solid-sawn

members of the same species and grade in fire-rated applications. End-jointed lumber manufactured with an adhesive not qualified as a heat-resistant adhesive will be designated as “non-heat resistant adhesive” or “non-HRA” on the grade stamp. Commentary Figure R602.1.2(2) shows the HRA mark included in a grade stamp.

R602.1.3 Structural glued-laminated timbers. Glued-laminated timbers shall be manufactured and identified as required in ANSI/AITC A190.1 and ASTM D3737.

❖ Glued laminated (gluelam) timbers are engineered wood elements consisting of layers of plywood plies with varying grades of plywood through the thickness of the member. The strength of the members and the use of the members (beams, studs, etc.) are based on different combinations of plywood veneer grades, called layups. The design, testing and manufacture of different layups for different applications are standardized in the referenced standards. The standards also address the identification of these timbers, which is useful at the construction site during inspection.

INTERPRETING GRADE STAMPS

MOST GRADE STAMPS, EXCEPT THOSE FOR ROUGH LUMBER OR HEAVY TIMBERS, CONTAIN FIVE BASIC ELEMENTS:

(B)

A. THE TRADEMARK INDICATES AGENCY QUALITY SUPERVISION.

B. MILL IDENTIFICATION – FIRM NAME, BRAND OR ASSIGNED MILL NUMBER.

C. GRADE DESIGNATION – GRADE NAME, NUMBER OR ABBREVIATION.

D. SPECIAL IDENTIFICATION – INDICATES SPECIES INDIVIDUALLY OR IN COMBINATION.

E. CONDITION OF SEASONING AT TIME OF SURFACING:

- S-DRY – 19% MAX MOISTURE CONTENT
- MC 15 – 15% MAX MOISTURE CONTENT
- S-GRN – OVER 19% MOISTURE CONTENT (UNSEASONED)

Figure R602.1.1
GRADE STAMP EXAMPLE FOR DIMENSIONAL LUMBER

R602.1.4 Structural log members. Structural log members shall comply with the provisions of ICC 400.

- ❖ The material requirements for structural logs, such as stress grading, grade mark or Certificate of Inspection must be in accordance with ICC 400, *Standard on the Design and Construction of Log Structures*.

R602.1.5 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

- ❖ Structural composite lumber (SCL) is an engineered wood product using veneer sheets or strands of wood glued together to form structural beams, columns, studs, or sheathing. The strength and use of the members depends upon the size and thickness of the strands, the use of veneer sheets, and the orientation of the strand or veneer. Design, testing and manufacture of the engineered lumber are standardized in ASTM D5456, the referenced standard for SCL.

R602.1.6 Cross-laminated timber. Cross-laminated timber shall be manufactured and identified as required by ANSI/APA PRG 320.

- ❖ Cross-laminated timber (CLT) was first developed in Europe nearly 20 years ago, where it has been used extensively. It is generally analogous to large section members currently associated with heavy timber. Although the primary use is for nonresidential construction, CLT is currently being used in some residential applications. As a new product in North America, ANSI/APA PRG 320 provides a consensus manufacturing standard for cross-laminated timber.

R602.1.7 Engineered wood rim board. Engineered wood rim boards shall conform to ANSI/APA PRR 410 or shall be evaluated in accordance with ASTM D7672. Structural capacities shall be in accordance with either ANSI/APA PRR 410 or established in accordance with ASTM D7672. Rim boards conforming to ANSI/APA PRR 410 shall be marked in accordance with that standard.

- ❖ Engineered rim board is a key structural element in wood floor construction where both structural load path through the perimeter member and dimensional change compatibility are design considerations. Both ANSI/APA PRR 410 and ASTM D7672 address the fundamental requirements for testing and evaluation of engineered rim board, PRR 410 also includes performance categories for engineered wood products used

in engineered rim board applications. Under PRR 410, products are assigned a grade based on performance category (e.g., categories based on structural capacity) and will bear a mark in accordance with the grade. In contrast, ASTM D7672 is applicable for determination of product-specific rim board performance (i.e., structural capacities) for engineered wood products that may be recognized in manufacturer's literature or product evaluation reports.

R602.1.8 Wood structural panels. Wood structural panel sheathing shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325. Panels shall be identified for grade, bond classification, and performance category by a grade mark or certificate of inspection issued by an approved agency.

- ❖ To verify the acceptability of wood structural panel products, this section requires labeling in accordance with the referenced standards. The purpose is the same as the purpose of Section R602.1.1 for sawn lumber. This label provides the inspector with the necessary information to determine the acceptability of the wood structural panel (see commentary, Sections R503.2 and R503.2.1).

R602.1.9 Particleboard. Particleboard shall conform to ANSI A208.1. Particleboard shall be identified by the grade mark or certificate of inspection issued by an approved agency.

- ❖ Particleboard is a generic term given to panels manufactured from cellulosic materials, usually wood in the form of discrete pieces and particles rather than fibers. The particles and pieces are combined with synthetic resins and other binders and bonded together under heat and pressure. Particleboard must conform to ANSI A208 (see commentary, Section R503.3.1).

R602.1.10 Fiberboard. Fiberboard shall conform to ASTM C208. Fiberboard sheathing, where used structurally, shall be identified by an approved agency as conforming to ASTM C208.

- ❖ All fiberboard must meet the requirements of ASTM C208, as well as being verminproof, resistant to rot-producing fungi and water repellent. This standard gives physical requirements for construction grades of fiberboard, including sheathing grade and roof-insulating grade. The sheathing grade of fiberboard is further broken down into regular and intermediate densities.

WALL CONSTRUCTION

R602.2 Grade. Studs shall be a minimum No. 3, standard or stud grade lumber.

Exception: Bearing studs not supporting floors and non-bearing studs shall be permitted to be utility grade lumber, provided the studs are spaced in accordance with Table R602.3(5).

❖ A minimum grade of No. 3, standard, or stud grade lumber is specified for studs in conventional wood-framed walls to maintain minimum load-carrying capabilities. The maximum size of standard grade lumber is limited to 2 to 4 inches (51 to 102 mm) nominal in thickness and 4 inches (102 mm) in width. Thus, a 4-inch by 6-inch (102 mm by 152 mm) piece of dimensional lumber would not be available in the standard grade.

To allow more economical use of lumber for bearing studs not supporting floors and nonbearing studs, the exception permits the use of utility grade lumber, provided that the studs are spaced according to the limits established in Table R602.3(5). Note “a” of the table places a more restrictive limit on utility grade stud spacing where permitted in a load-bearing application.

R602.3 Design and construction. Exterior walls of wood-frame construction shall be designed and constructed in accordance with the provisions of this chapter and Figures R602.3(1) and R602.3(2), or in accordance with AWC NDS. Components of exterior walls shall be fastened in accordance with Tables R602.3(1) through R602.3(4). Wall sheathing shall be fastened directly to framing members and, where placed on the exterior side of an exterior wall, shall be capable of resisting the wind pressures listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) and shall conform to the requirements of Table R602.3(3). Wall sheathing used only for exterior wall covering purposes shall comply with Section R703.

Studs shall be continuous from support at the sole plate to a support at the top plate to resist loads perpendicular to the wall. The support shall be a foundation or floor, ceiling or roof diaphragm or shall be designed in accordance with accepted engineering practice.

Exception: Jack studs, trimmer studs and cripple studs at openings in walls that comply with Tables R602.7(1) and R602.7(2).

❖ Figures R602.3(1) and R602.3(2) in conjunction with the minimum nailing requirements of Tables R602.3(1) and R602.3(2) provide typical wall-framing details for construction of exterior walls. Walls must be in accordance with this section or American Wood Council (AWC) *National Design Specification (NDS)* (AWC NDS).

All exterior wall coverings must be capable of resisting the wind pressures required by Section R301.2.1.

Wall sheathing used only for exterior wall covering purposes shall comply with Section R703. Wall sheathing used for structural purposes, i.e., wall bracing, must comply with Section R602.10 or R602.12. All wood structural panels used for sheathing on exterior walls must be fastened in accordance with Table R602.3(3).

For wood structural panel sheathing used for interior walls, the fastening is in accordance with Table

R602.3(1). The 6d common nail fastening for the wood structural panels in Table R602.3(1) is not adequate for the wind pressures required by Section R301.2.

The studs for exterior walls must be continuous from the support at the bottom to the support at the top, i.e., stacked framing that forms a “hinge” is not permitted. There is no prescriptive design in the code for stacked framing. Exterior wall framing that is stacked and forms a “hinge” must be engineered. The exception for continuity of studs is for jack studs, trimmer studs, and cripple studs at openings.

R602.3.1 Stud size, height and spacing. The size, height and spacing of studs shall be in accordance with Table R602.3(5).

Exceptions:

1. Utility grade studs shall not be spaced more than 16 inches (406 mm) on center, shall not support more than a roof and ceiling, and shall not exceed 8 feet (2438 mm) in height for exterior walls and load-bearing walls or 10 feet (3048 mm) for interior non-load-bearing walls.
2. Where snow loads are less than or equal to 25 pounds per square foot (1.2 kPa), and the ultimate design wind speed is less than or equal to 130 mph (58.1 m/s), 2-inch by 6-inch (38 mm by 14 mm) studs supporting a roof load with not more than 6 feet (1829 mm) of tributary length shall have a maximum height of 18 feet (5486 mm) where spaced at 16 inches (406 mm) on center, or 20 feet (6096 mm) where spaced at 12 inches (304.8 mm) on center. Studs shall be minimum No. 2 grade lumber.

❖ Table R602.3(5) lists required stud spacing based on the stud size and loading condition.

Exception 1 addresses the fact that utility grade lumber is lower in strength and quality and therefore requires tighter spacing and shorter lengths in exterior walls. Note that the minimum grade lumber for application of Table R602.3(5) is, by implication, stud grade or standard grade.

Exception 2 has been revised to eliminate Table R602.3.1. The exception specifies the criteria for tall walls, walls up to 20 feet maximum height. Previously Table R602.3.1 was a source of confusion. Note b of Table R602.3.1, referring to engineering loads and properties, was confusing and often misunderstood. Tall walls meeting Exception 2 do not require engineering. Note that Exception 2 does not apply in locations with more than 25 psf snow load, 2 × 4 construction or roof tributary widths greater than 6 feet. The process for determining whether wall studs, a wall or a story must be engineered based on stud height now checks:

1. Table R602.3(5),
2. Section R602.10, and if necessary
3. Section R602.3.1, Exception 2.

If wall studs fail to meet the requirements of the three sections, the wall or story must be engineered.

Example: Prescriptive Tall Walls

In the three cases below, a tall wall meeting the code's limits are illustrated.

Case 1: 2 × 6 continuous studs used in an 18-foot gable end wall

The gable end wall studs do not support a roof load. They form a nonload-bearing wall. From Table R602.3(5), nonbearing walls may have studs up to 20 feet tall when using 2 × 6 lumber.

Case 2: 2 × 6 continuous studs used in a 20-foot tall wall supporting a projection (roof framing parallel to wall)

The studs used for a two-story projection where the roof framing runs parallel to the wall will carry a roof load. If the studs can meet all the limits of Section R602.3.1 Exception 2, then no engineering of the wall is required. The following four limits must be met:

1. Snow load ≤ 25 psf
2. Wind speed ≤ 130 mph
3. 2 × 6 construction
4. Roof load tributary width ≤ 6 feet

Assuming the first three conditions are met, the roof load tributary width limit is determined as follows:

Roof load tributary width describes the width of the roof surface that will transfer live or snow loads to nearby walls. To determine tributary width in a roof, measure the total distance between roof supports, typically walls in residential construction, and divide the distance in half. If walls supporting the roof are 12 feet apart or less (a roof tributary width of 6 feet), Exception 2 limits are met.

Case 3: 2 × 6 continuous studs used in a variable height wall supporting a projection (roof framing perpendicular to wall)

The studs where the roof framing runs perpendicular to the wall do not carry a roof load. They form a nonload-bearing wall. From Table R602.3(5), nonbearing walls may have studs up to 20 feet tall when using 2 × 6 lumber.

TABLE R602.3(1). See page 6-8 through 6-11.

- ❖ The fastener schedule provides minimum nailing requirements (i.e., size, spacing) for connecting building elements used in wood framed construction. For wood structural panels, both edge nailing and intermediate (field) nailing are specified. In addition to the nailing for wood structural panels, fasteners are specified for gypsum wall sheathing, cellulosic fiberboard wall sheathing and combination subfloor underlayment.

FIGURE R602.3(1). See page 6-13.

- ❖ This is a schematic wood-framed building section that shows code provisions for wood floor systems as well as wall construction.

TABLE R602.3(2). See page 6-11 and 6-12.

- ❖ This table offers alternatives to the nailing specified for wood structural panels in Table R602.3(1).

FIGURE R602.3(2). See page 6-14.

- ❖ This figure is an elevation of typical wood-framed wall construction showing several code provisions as well as illustrating features such as cripple walls.

TABLE R602.3(3). See page 6-12.

- ❖ In 2009, this table updated the previous wood structural panel wall sheathing table to include requirements for the wind pressures specified in Section R301.2.1. The $\frac{5}{16}$ -inch (8 mm) wood structural panels have been deleted since they are currently a very small fraction of the panels produced today. While they have been the minimum panel thickness specified for many applications over the years, the building industry has shifted away from them due to manufacturing efficiencies and marketplace demand. The de facto minimum has become $\frac{3}{8}$ inch (9.5 mm).

This table provides the minimum thickness, maximum wall stud spacing and fastening for wood structural panels used for sheathing on exterior walls. See Table R602.3(1) for wood structural panel sheathing

for interior walls.

The previous Table R602.3(3) in the code gave recommended minimum panel thicknesses for wall panel sheathing. It was adequate most of the time but in higher wind regions (still within the range of the code) the panel thicknesses and orientations recommended in the table and footnotes may not provide the minimum protection to the home and inhabitants that is currently required in Section R301.2.1. Analysis conducted by the APA—The Engineered Wood Association (APA) staff indicates that in the extreme wind regions covered by the code [less than 140 mph ultimate design wind speed] and with more severe exposures (C and D) the minimum thicknesses recommendations given in the previous Table R603.3(3), Wood Structural Panel Wall Sheathing, were insufficient in thickness and attachment. This new table provides the requirements to ensure that this important part of the structural system is correct. The analysis considered panel bending, stiffness, nail withdrawal and nail head pull through as well as the wind pressure requirements of Section R301.2.1. Note that the impact to most will be minimal because the most commonly used wood structural panel sheathing thickness in the US is $7/16$ inch (11 mm). As can be seen in the new table, this sheathing thickness is satisfactory for ultimate design wind speeds up to 140 mph in all but Exposure D conditions. Most builders will only see the requirement for 8d nails as a change, and this is already the nail required for roof sheathing applications.

TABLE R602.3(4). See page 6-13.

- ❖ The allowable spans for particleboard wall sheathing listed in Table R602.3(4) are for wall sheathing that is not exposed to weather. The panels may be applied with the long dimension parallel or perpendicular to the studs.
- ❖ **TABLE R602.3(5).** See page 6-15.
- ❖ This table provides the allowed stud spacing in bearing walls up to 10 feet (3048 mm) high as stated in Section R602.3.1. As described in Note a, increases in unsupported height are permitted where justified by an engineering analysis. The “unsupported height” of a stud is really the distance between points of lateral support, which generally occurs at each floor level.

Bearing walls must be sheathed on at least one side or bridging installed with a spacing of 4 feet or less vertically.

This table was updated in 2009 to include a habitable attic assembly. See Section R202 for the definition of “Attic, habitable.” This update permits the addition of a habitable attic without considering it as a story load on the studs. The basis of the limit of how much habitable attic load the wall can support is a 32-foot (9754 mm) span with 2 by 4 wall studs. Where the span exceeds 32 feet (9754 mm), the wall stud must be 2 by 6 or designed in accordance with accompanying engineering practice.

R602.3.2 Top plate. Wood stud walls shall be capped with a double top plate installed to provide overlapping at corners and intersections with bearing partitions. End joints in top plates shall be offset not less than 24 inches (610 mm). Joints in plates need not occur over studs. Plates shall be not less than 2-inches (51 mm) nominal thickness and have a width not less than the width of the studs.

Exception: A single top plate used as an alternative to a double top plate shall comply with the following:

1. The single top plate shall be tied at corners, intersecting walls, and at in-line splices in straight wall lines in accordance with Table R602.3.2.
 2. The rafters or joists shall be centered over the studs with a tolerance of not more than 1 inch (25 mm).
 3. Omission of the top plate is permitted over headers where the headers are adequately tied to adjacent wall sections in accordance with Table R602.3.2.
- ❖ Plates are the horizontal elements of walls capping the top of walls and framing the bottom of stud walls. They are called plates because they are laid flat, with the deeper dimension horizontal. In building construction applications, top plates must be a nominal 2-inch (51 mm) thickness.

Double top plates serve three major functions:

1. They overlap at corners and bearing wall intersections, providing a means of tying the building together. (Note that the overlap is not required at intersections with nonbearing interior walls.)

TABLE R602.3.2
SINGLE TOP-PLATE SPLICE CONNECTION DETAILS

CONDITION	TOP-PLATE SPLICE LOCATION			
	Corners and intersecting walls		Butt joints in straight walls	
	Splice plate size	Minimum nails each side of joint	Splice plate size	Minimum nails each side of joint
Structures in SDC A-C; and in SDC D ₀ , D ₁ and D ₂ with braced wall line spacing less than 25 feet	3" × 6" × 0.036" galvanized steel plate or equivalent	(6) 8d box (2 $1/2$ " × 0.113") nails	3' × 12" × 0.036" galvanized steel plate or equivalent	(12) 8d box (2 $1/2$ " × 0.113") nails
Structures in SDC D ₀ , D ₁ and D ₂ , with braced wall line spacing greater than or equal to 25 feet	3" × 8" by 0.036" galvanized steel plate or equivalent	(9) 8d box (2 $1/2$ " × 0.113") nails	3' × 16" × 0.036" galvanized steel plate or equivalent	(18) 8d box (2 $1/2$ " × 0.113") nails

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

2. They serve as beams to support joists and rafters that are not located directly over the studs.
3. They serve as chords for floor and roof diaphragms.

Along with provisions for stud size and spacing limitations, this section requires the installation of double top plates to provide a continuous tie along the tops of the walls. With the advent of wider wall framing to accommodate increased thickness of insulation, a desire to save on material costs led to the allowance of a single top plate alternative. The exception permits the use of a single top plate in bearing and exterior walls as long as adequate top-plate ties are provided. In addition, joists or rafters framing into the wall must be placed more closely to the vertical stud below. This is necessary to limit the bending stress in the top plate. The single top plate exception is illustrated in Commentary Figure R602.3.2.

There are two double top plate splices specified in Item 13 of Table R602.3(1) that establish the minimum capacity required to provide an adequate tension splice. The first is adequate for braced wall line spacing of less than 25 feet. The second is for braced wall line spacing equal to or greater than 25 feet in SDC D₀, D₁ or D₂. Aside from simply providing continuity between wall segments, the top-plate splice also acts as a tension tie (often called a collector or drag strut) to distribute the roof and floor shear loads into the bracing elements often spaced as much as 20 feet apart.

The exception to Section R602.3.2 for a single top plate has been updated to include splice connection details that provide equivalent capacity to the double top plate splice. Table R602.3.2 provides the prescriptive splice plate sizes and minimum number and size of nails that must be provided at each side of the joint.

R602.3.3 Bearing studs. Where joists, trusses or rafters are spaced more than 16 inches (406 mm) on center and the bearing studs below are spaced 24 inches (610 mm) on center, such members shall bear within 5 inches (127 mm) of the studs beneath.

Exceptions:

1. The top plates are two 2-inch by 6-inch (38 mm by 140 mm) or two 3-inch by 4-inch (64 mm by 89 mm) members.
 2. A third top plate is installed.
 3. Solid blocking equal in size to the studs is installed to reinforce the double top plate.
- ❖ The bottom plate serves to anchor the wall to the floor, and studs are attached to it by end nailing or toe-nailing. The basic requirements of this section are shown in Commentary Figures R602.3.3(1) and R602.3.3(3). The code permits three options (exceptions) to account for loading that must be resisted by the double top plate when the stud spacing is 24 inches (610 mm) on center. Exception 1 is an increase in the minimum top plate size. Exception 2 is to provide a third plate. Exception 3 is solid blocking used as reinforcement for a double plate, installed so that the load from the framing members above is transferred to the supporting studs. Commentary Figures R602.3.3(2) and R602.3.3(4) illustrate Exceptions 1 and 3.

R602.3.4 Bottom (sole) plate. Studs shall have full bearing on a nominal 2-by (51 mm) or larger plate or sill having a width not less than to the width of the studs.

- ❖ This provision requires that studs bear on an adequately sized bottom plate. This allows the bottom plate to serve as a nailing surface for the wall sheathing while controlling compression perpendicular to the grain on the sill. If too great, this stress could result in crushing.

NOTE: BEARING OR EXTERIOR WALL

For SI: 1 inch = 25.4 mm.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s; 1 ksi = 6.895 MPa.

(continued)

**TABLE R602.3(1)—continued
FASTENING SCHEDULE**

- a. Nails are smooth-common, box or deformed shanks except where otherwise stated. Nails used for framing and sheathing connections shall have minimum average bending yield strengths as shown: 80 ksi for shank diameter of 0.192 inch (20d common nail), 90 ksi for shank diameters larger than 0.142 inch but not larger than 0.177 inch, and 100 ksi for shank diameters of 0.142 inch or less.
- b. Staples are 16 gage wire and have a minimum $\frac{7}{16}$ -inch on diameter crown width.
- c. Nails shall be spaced at not more than 6 inches on center at all supports where spans are 48 inches or greater.
- d. Four-foot by 8-foot or 4-foot by 9-foot panels shall be applied vertically.
- e. Spacing of fasteners not included in this table shall be based on Table R602.3(2).
- f. Where the ultimate design wind speed is 130 mph or less, nails for attaching wood structural panel roof sheathing to gable end wall framing shall be spaced 6 inches on center. Where the ultimate design wind speed is greater than 130 mph, nails for attaching panel roof sheathing to intermediate supports shall be spaced 6 inches on center for minimum 48-inch distance from ridges, eaves and gable end walls; and 4 inches on center to gable end wall framing.
- g. Gypsum sheathing shall conform to ASTM C1396 and shall be installed in accordance with GA 253. Fiberboard sheathing shall conform to ASTM C208.
- h. Spacing of fasteners on floor sheathing panel edges applies to panel edges supported by framing members and required blocking and at floor perimeters only. Spacing of fasteners on roof sheathing panel edges applies to panel edges supported by framing members and required blocking. Blocking of roof or floor sheathing panel edges perpendicular to the framing members need not be provided except as required by other provisions of this code. Floor perimeter shall be supported by framing members or solid blocking.
- i. Where a rafter is fastened to an adjacent parallel ceiling joist in accordance with this schedule, provide two toe nails on one side of the rafter and toe nails from the ceiling joist to top plate in accordance with this schedule. The toe nail on the opposite side of the rafter shall not be required.

For SI: 1 inch = 25.4 mm.

- a. Nail is a general description and shall be permitted to be T-head, modified round head or round head.
- b. Staples shall have a minimum crown width of 7/16-inch on diameter except as noted.
- c. Nails or staples shall be spaced at not more than 6 inches on center at all supports where spans are 48 inches or greater. Nails or staples shall be spaced at not more than 12 inches on center at intermediate supports for floors.
- d. Fasteners shall be placed in a grid pattern throughout the body of the panel.
- e. For 5-ply panels, intermediate nails shall be spaced not more than 12 inches on center each way.
- f. Hardboard underlayment shall conform to CPA/ANSI A135.4
- g. Specified alternate attachments for roof sheathing shall be permitted where the ultimate design wind speed is less than 130 mph. Fasteners attaching wood structural panel roof sheathing to gable end wall framing shall be installed using the spacing listed for panel edges.
- h. Fiber-cement underlayment shall conform to ASTM C1288 or ISO 8336, Category C.

TABLE R602.3(3)
REQUIREMENTS FOR WOOD STRUCTURAL PANEL WALL SHEATHING USED TO RESIST WIND PRESSURES^{a, b, c}

MINIMUM NAIL		MINIMUM WOOD STRUCTURAL PANEL SPAN RATING	MINIMUM NOMINAL PANEL THICKNESS (inches)	MAXIMUM WALL STUD SPACING (inches)	PANEL NAIL SPACING		ULTIMATE DESIGN WIND SPEED V _{ult} (mph)		
Size	Penetration (inches)				Edges (inches o.c.)	Field (inches o.c.)	Wind exposure category		
							B	C	D
6d Common (2.0" × 0.113")	1.5	24/0	3/8	16	6	12	140	115	110
8d Common (2.5" × 0.131")	1.75	24/16	7/16	16	6	12	170	140	135
				24	6	12	140	115	110

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s.

- a. Panel strength axis parallel or perpendicular to supports. Three-ply plywood sheathing with studs spaced more than 16 inches on center shall be applied with panel strength axis perpendicular to supports.
- b. Table is based on wind pressures acting toward and away from building surfaces in accordance with Section R301.2. Lateral bracing requirements shall be in accordance with Section R602.10.
- c. Wood structural panels with span ratings of Wall-16 or Wall-24 shall be permitted as an alternate to panels with a 24/0 span rating. Plywood siding rated 16 o.c. or 24 o.c. shall be permitted as an alternate to panels with a 24/16 span rating. Wall-16 and Plywood siding 16 o.c. shall be used with studs spaced not more than 16 inches on center.

TABLE R602.3(4)
ALLOWABLE SPANS FOR PARTICLEBOARD WALL SHEATHING^a

THICKNESS (inch)	GRADE	STUD SPACING (inches)	
		When siding is nailed to studs	When siding is nailed to sheathing
$\frac{3}{8}$	M-1 Exterior glue	16	—
$\frac{1}{2}$	M-2 Exterior glue	16	16

For SI: 1 inch = 25.4 mm.

a. Wall sheathing not exposed to the weather. If the panels are applied horizontally, the end joints of the panel shall be offset so that four panel corners will not meet. All panel edges must be supported. Leave a $\frac{1}{16}$ -inch gap between panels and nail not less than $\frac{3}{8}$ inch from panel edges.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R602.3(1)
TYPICAL WALL, FLOOR AND ROOF FRAMING

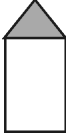

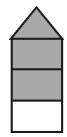

WALL CONSTRUCTION

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

SIZE, HEIGHT AND SPACING OF WOOD STUDS^a**

STUD SIZE (inches)	BEARING WALLS					NONBEARING WALLS	
	Laterally unsupported stud height ^a (feet)	Maximum spacing when supporting a roof-ceiling assembly or a habitable attic assembly, only (inches)	Maximum spacing when supporting one floor, plus a roof-ceil- ing assembly or a hab- itable attic assembly (inches)	Maximum spacing when supporting two floors, plus a roof-ceil- ing assembly or a hab- itable attic assembly (inches)	Maximum spacing when supporting one floor height ^a (inches)	Laterally unsupported stud height ^a (feet)	Maximum spacing (inches)
							
2 × 3 ^b	—	—	—	—	—	10	16
2 × 4	10	24 ^c	16 ^c	—	24	14	24
3 × 4	10	24	24	16	24	14	24
2 × 5	10	24	24	—	24	16	24
2 × 6	10	24	24	16	24	20	24

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

- a. Listed heights are distances between points of lateral support placed perpendicular to the plane of the wall. Bearing walls shall be sheathed on not less than one side or bridging shall be installed not greater than 4 feet apart measured vertically from either end of the stud. Increases in unsupported height are permitted where in compliance with Exception 2 of Section R602.3.1 or designed in accordance with accepted engineering practice.
- b. Shall not be used in exterior walls.
- c. A habitable attic assembly supported by 2 × 4 studs is limited to a roof span of 32 feet. Where the roof span exceeds 32 feet, the wall studs shall be increased to 2 × 6 or the studs shall be designed in accordance with accepted engineering practice.

NOTE: NO LIMIT ON RAFTER OR BOTTOM OF TRUSS LOCATION

For SI: 1 inch = 25.4 mm.

R602.3.5 Braced wall panel uplift load path. Braced wall panels located at exterior walls that support roof rafters or trusses (including stories below top story) shall have the framing members connected in accordance with one of the following:

1. Fastening in accordance with Table R602.3(1) where:
 - 1.1. The ultimate design wind speed does not exceed 115 mph (51 m/s), the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet (9754 mm) or less.
 - 1.2. The net uplift value at the top of a wall does not exceed 100 plf (146 N/mm). The net uplift value shall be determined in accordance with Section R802.11 and shall be permitted to be reduced by 60 plf (86 N/mm) for each full wall above.
 2. Where the net uplift value at the top of a wall exceeds 100 plf (146 N/mm), installing approved uplift framing connectors to provide a continuous load path from the top of the wall to the foundation or to a point where the uplift force is 100 plf (146 N/mm) or less. The net uplift value shall be as determined in Item 1.2.
 3. Wall sheathing and fasteners designed to resist combined uplift and shear forces in accordance with accepted engineering practice.
- ❖ As Section R602.3.5 is currently written, braced wall panels on the exterior walls that support roof framing require an uplift load path. As braced wall panels on floors below support the upper braced wall panels, uplift requirements must also be met at the lower floors. The intention of this section is to provide an adequate load path for the lateral-force-resisting system of the structure (wall bracing) as a minimum. From an engineering perspective, however, this provision appears to be incomplete because uplift loads are possible at the end of every roof truss or rafter, whether it bears on a bracing panel or not. To provide for the appropriate attachment of roof framing to the support-

ing walls for the whole structure, the uplift requirements of Chapter 6 must be used in conjunction with the requirements of Section R802.11, as discussed below.

The prescriptive nailing provisions in Table R602.3(1), Item 6, specify three 16d toenails for the “rafter or roof truss to plate” connection. Based on historical performance, this prescriptive schedule is deemed to provide sufficient attachment for ultimate design wind speed of 115 mph (51 m/s) winds, Exposure B, 5:12 roof pitch or greater, and a roof span of 32 feet (9754 mm) or less. For this reason, the minimum connection required by Table R602.3(1), Item 6 is adequate for uplift resistance within the parameters stated in Section R602.3.5, Item 1.

From Section R602.3.5, Item 1.1, it can be inferred that the Table R602.3(1), Item 6 prescriptive nailing requirements provide 100 pounds (45 kg) of net uplift (plf) (146 N/mm) resistance to properly attached roofs. No additional attachment is required until the uplift loads specified in Table R802.11 exceed this amount. In addition, Section R602.3.5, Item 1.2, provides the effective weight of each full wall above the wall-to-floor connection in question as 60 plf (86 N/mm). This amount can be subtracted from the uplift amount, as the uplift requirement for each lower floor is calculated (see the example in this section). Given this information, the user is able to use the truss or rafter connection uplift force provided in Table R802.11 and its notes to compute the net uplift requirement for a structure at a given location.

When the uplift resistance of the roof framing provided in Table R802.11 is reduced by the number of walls above the connection in question or the location in the structure, and the net result is less than 100 pounds per linear foot (146 N/mm), the prescriptive nailing requirements of Table R602.3(1) are deemed to be sufficient to provide an adequate load path.

When the uplift resistance of the roof framing pro-

vided in Table R802.11 is reduced by the number of walls above the connection in question or the location in the structure, and the net result is greater than 100 plf (146 N/mm), the prescriptive nailing requirements of Table R602.3(1) are insufficient to provide an adequate load path and the following options are available:

1. Installation of an approved uplift framing anchor of sufficient capacity to resist the net uplift force.
2. Section R104.11 permits engineering design to be used to determine other nailing schedules or details that may provide sufficient uplift resistance.
3. Engineering analysis can be used to determine the wind uplift capacity in lieu of Table R802.11. Such analysis can take into account heavier roofing materials and other details not accounted for in the tables.
4. Other referenced documents, such as the American Wood Council's (AWC) *Wood Frame Construction Manual for One- and Two-family Dwellings*, can be used to generate uplift requirements and prescriptive hold-down requirements.

Example:

What is the net uplift capacity for each level of a two-story home located in a 140 mph Exposure B wind zone? The width of the house is 32 feet (9754 mm) the house has no roof overhangs, the roof pitch is 4:12 and the roof framing is at 24 inches (610 mm) on center.

Solution:

From Table R802.11, the wind uplift acting at the roof-to-second story wall is 480 pounds per connection.

- Capacity of the roof-to-second-story wall connection—There is no wall above this connection, so the uplift at this point is 480 pounds per connection. Table R602.3(1), Item 6 attachment schedule provides 200 pounds (90 kg) per connector of uplift resistance. If this attachment schedule is used, a connector with a minimum capacity of [480 pounds per connector—200 pounds (90 kg) per connector =] 280 pounds per connector is required. If this attachment schedule is not used, a connector with the full 480 pound capacity is required.
- Capacity of the second-story to first-story connection—As each lineal foot of wall contributes 60 pounds of uplift (86 N/mm) resistance, and there are 2 feet (610 mm) of wall per connector [roof framing/connectors on 24-inch (610 mm) centers], the uplift requirement for the second-story to first-story connection will be [480 - (2 × 60) =] 360 pounds (175 kg) per connector.
- Capacity of the first-story to foundation connection—In this case, there are two stories above the connection, and each lineal foot of wall con-

tributes 60 pounds of uplift (86 N/mm) resistance, and there are 2 feet (610 mm) of wall per connector (roof framing/connectors on 24-inch (610 mm) centers). The uplift requirement for the first-story to foundation connection will be [480 - (2 × 2 × 60) =] 240 pounds per connector.

While not specified in the code, it is reasonable to assume that Table R602.3(1) nailing schedules provide at least some of this uplift resistance at the second-to-first and first-to-foundation locations. The use of 100 pounds per foot (0.34 kg/m) for the capacity of the Table R602.3(1) connections at these two locations is probably as reasonable as the assumption that Table R602.3(1), Items 1-6 provide 100 plf (146 N/m) uplift resistance capacity. From a historical perspective, these second to first-story and first-story to foundation connections as specified have been as effective as the roof-to-top story connections. As noted elsewhere, deviations from the code provisions should be approved by the building official.

R602.4 Interior load-bearing walls. Interior load-bearing walls shall be constructed, framed and fireblocked as specified for exterior walls.

- ❖ Interior load-bearing walls must be designed and constructed using the criteria for exterior walls. Thus, Table R602.3(5) should be used to establish stud spacing of walls up to 10 feet (3048 mm) high, and Section R602.3.1, Exception 2 applies to walls over 10 feet (3048 mm).

R602.5 Interior nonbearing walls. Interior nonbearing walls shall be permitted to be constructed with 2-inch by 3-inch (51 mm by 76 mm) studs spaced 24 inches (610 mm) on center or, where not part of a *braced wall line*, 2-inch by 4-inch (51 mm by 102 mm) flat studs spaced at 16 inches (406 mm) on center. Interior nonbearing walls shall be capped with not less than a single top plate. Interior nonbearing walls shall be fireblocked in accordance with Section R602.8.

- ❖ The code permits reduced stud sizes, increased stud spacing and capping with a single top plate in interior nonbearing partitions. These allowances are based on minimal superimposed vertical loads.

R602.6 Drilling and notching of studs. Drilling and notching of studs shall be in accordance with the following:

1. Notching. Any stud in an exterior wall or bearing partition shall be permitted to be cut or notched to a depth not exceeding 25 percent of its width. Studs in nonbearing partitions shall be permitted to be notched to a depth not to exceed 40 percent of a single stud width.
2. Drilling. Any stud shall be permitted to be bored or drilled, provided that the diameter of the resulting hole is not more than 60 percent of the stud width, the edge of the hole is not more than $\frac{5}{8}$ inch (16 mm) to the edge of the stud, and the hole is not located in the same section as a cut or notch. Studs located in exterior walls or bearing partitions drilled over 40 percent and up to 60 percent

shall be doubled with not more than two successive doubled studs bored. See Figures R602.6(1) and R602.6(2).

Exception: Use of *approved* stud shoes is permitted where they are installed in accordance with the manufacturer's recommendations.

- ❖ This section addresses the allowable drilling and notching of studs used to frame partitions. See Figures R602.6(1) and R602.6(2) for examples of permitted drilling and notching of studs in exterior walls, bearing walls and nonbearing walls. These limitations retain the structural integrity of the studs. Where stud shoes are used, the exception allows drilling and notching to

be in accordance with the approved manufacturer's instructions.

FIGURE R602.6(1). See below.

- ❖ See the commentary to Section R602.6.

FIGURE R602.6(2). See page 6-20.

- ❖ See the commentary to Section R602.6.

R602.6.1 Drilling and notching of top plate. When piping or ductwork is placed in or partly in an exterior wall or interior load-bearing wall, necessitating cutting, drilling or notching of the top plate by more than 50 percent of its width, a galvanized metal tie not less than 0.054 inch thick (1.37 mm)

For SI: 1 inch = 25.4 mm.

Note: Condition for exterior and bearing walls.

FIGURE R602.6(1)
NOTCHING AND BORED HOLE LIMITATIONS FOR EXTERIOR WALLS AND BEARING WALLS

WALL CONSTRUCTION

(16 ga) and 1½ inches (38 mm) wide shall be fastened across and to the plate at each side of the opening with not less than eight 10d (0.148 inch diameter) nails having a minimum length of 1½ inches (38 mm) at each side or equivalent. The metal tie must extend a minimum of 6 inches past the opening. See Figure R602.6.1.

Exception: When the entire side of the wall with the notch or cut is covered by wood structural panel sheathing.

- ❖ In many cases, drilling or notching of the top plate is necessary to allow plumbing, heating or other pipes to be placed within the exterior walls and load-bearing interior walls. When cutting the top plate by more than one-half its width is necessary, strapping across the plates as illustrated in Figure R602.6.1, is required to provide top plate continuity and to retain the structural integrity of the wall system as a whole.

In the case of a double top plate, only the upper of the two plates needs to have a strap installed as described.

The top plate functions as a collector as part of the lateral load path. It collects the lateral loads, due to wind and seismic, from the roof or floor diaphragm and distributes them along the wall into the wall bracing. In doing so, the top plate is subjected to tension or compression due to the lateral loads in the plane of the wall.

Removal of any top plate material due to cutting, drilling or notching will reduce the tension/compression capacity of the top plate.

This section provides a prescriptive design that allows removal of 50 percent or less of the top plate material without replacing the material.

If more than 50 percent is removed, a metal strap is

For SI: 1 inch = 25.4 mm.

FIGURE R602.6(2)
NOTCHING AND BORED HOLE LIMITATIONS FOR INTERIOR NONBEARING WALLS

required to replace the material removed as shown in Figure R602.6.1.

Common practice is to notch the top plate as shown in Figure R602.6.1.

This section does not specifically state the amount of top plate material that must remain. However, Section R602.6 requires $\frac{5}{8}$ inch (16 mm) minimum to edge for holes in studs. This can be used as a guideline since this is for the compression load and assuming the metal strap is for the tension load.

For notching as shown in Figure R602.6.1, at least $\frac{5}{8}$ inch (16 mm) of the top plate should remain.

For a bored hole, $\frac{5}{8}$ inch (16 mm) should remain on at least one edge. The edge with less than $\frac{5}{8}$ inch (16 mm) will require the tension strap.

Notching or boring holes outside those guidelines will require a design in accordance with accepted engineering practices.

FIGURE R602.6.1. See below.

❖ See the commentary to Section R602.6.1.

R602.7 Headers. For header spans, see Tables R602.7(1), R602.7(2) and R602.7(3).

❖ Section R602.7 has been reorganized to combine single and multiple headers into one table. The 2012 IRC Tables R502.5(1) and R502.5(2) were moved from Chapter 5 to Section R602.7 and renumbered as Tables R602.7(1) and R602.7(2). Because the tables are frequently referenced in the wall provisions and the tables are used for headers more frequently than for girders, this change makes the tables conveniently located for header sizing. 2012 IRC Table R602.7.1 is combined with Table R502.5(1) to give a single table containing 1, 2 and 3 ply headers in 2015 IRC Table R602.7(1). The table also contains minimum jack stud requirements for all header options.

The single-ply header spans have been recalculated based on #2 grade hem-fir values. The single-ply spans are slightly longer than those in the 2012 IRC. Tables R602.7(1) and R602.7(2) are based on minimum design values for #2 grade of Douglas fir-larch, hem-fir and spruce-pine fir and #1 or better grade of southern pine.

New Table R602.7(3) has been added to provide girder and header spans for open porches. The table is based on post construction to support headers for porches with an 8 foot or 14 foot depth. The span lengths are based on the 2005 AWC NDS.

At a wall opening, headers transfer loads received from the wall and floors or roof to the foundation. Openings such as doors or windows within bearing walls must be framed with headers of sufficient size to span the opening and transfer loads to jack studs. Commentary Figure R602.7 illustrates a double header over a door opening. Tables R602.7(1) and R602.7(2) of the code are used to determine allowable spans for headers as well as girders. These tables are applicable to openings in bearing walls but are not applicable to nonbearing walls. See Section R602.7.4 for headers in nonbearing walls. Table R602.7(1) is to be used for headers over openings in exterior bearing walls. Table R602.7(2) is to be used for headers over openings in interior bearing walls. Where wood girders are used in a basement of a one-story dwelling, Table R602.7(2) may be used to prescriptively size the basement girders (the space between supporting columns may be viewed as openings).

Example:

You wish to size a header in the exterior wall of a one-story house that is 30 feet (9144 mm) wide. The open-

For SI: 1 inch = 25.4 mm.

FIGURE R602.6.1
TOP PLATE FRAMING TO ACCOMMODATE PIPING

ing size is 8 feet (2438 mm). Southern pine is the wood species common for the area, and the ground-snow loading is 20 pounds per square foot (958 Pa).

Solution:

Table R602.7(1) lists, for a 30 psf (1436 Pa) snow load and a building width of 36 feet (10 973 mm), a triple 2 by 10 inch (51 mm by 254 mm) header; it will span 8 feet, 2 inches (2489 mm). No. 1 grade or better must be used for southern pine.

TABLE R602.7(1). See page 6-23.

❖ See the commentary to Section R602.7.1.

TABLE R602.7(2). See page 6-25.

❖ See the commentary to Section R602.7.2.

R602.7.1 Single member headers. Single headers shall be framed with a single flat 2-inch-nominal (51 mm) member or wall plate not less in width than the wall studs on the top and bottom of the header in accordance with Figures R602.7.1(1) and R602.7.1(2) and face nailed to the top and bottom of the header with 10d box nails (3 inches × 0.128 inches) spaced 12 inches on center.

❖ Single-ply headers under limited loading conditions allow an increase in the energy efficiency of a dwelling. Installation of a single header results in a greater thickness of cavity insulation to reduce heat loss through the header in exterior walls.

The single-ply header configuration prescribed in Table R602.7(1) may be used for small openings. Use is limited to headers supporting roof and ceiling or roof, ceiling and one floor. Two figures clarify the installation details for single-ply headers with two different top plate conditions. In Figure R602.7.1(1), a cripple wall may be built above the header to finish out the space between the top plate and header. In Figure R602.7.1(2), the header fills the entire space between the top plate above the header and the plate below the header. In both cases the plates must be face nailed to

the header as specified in Section R602.7.1. This nailing serves as a means of stiffening the header to limit out-of-plane buckling under gravity loads.

FIGURE R602.7.1(1). See below.

❖ See the commentary to Section R602.7.1.

FIGURE R602.7.1(2). See below.

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa.

- a. Spans are given in feet and inches.
- b. No. 1 or better grade lumber shall be used for southern pine. Other tabulated values assume #2 grade lumber.
- c. Building width is measured perpendicular to the ridge. For widths between those shown, spans are permitted to be interpolated.
- d. NJ = Number of jack studs required to support each end. Where the number of required jack studs equals one, the header is permitted to be supported by an approved framing anchor attached to the full-height wall stud and to the header.
- e. Use 30 psf ground snow load for cases in which ground snow load is less than 30 psf and the roof live load is equal to or less than 20 psf.

2-2 × 12	14-4	10-10	11-8	8-10	10-1	7-8	11-11	9-0

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- a. Spans are given in feet and inches.
- b. Tabulated values assume #2 grade lumber, wet service and incising for refractory species. Use 30 psf ground snow load for cases in which ground snow load is less than 30 psf and the roof live load is equal to or less than 20 psf.
- c. Porch depth is measured horizontally from building face to centerline of the header. For depths between those shown, spans are permitted to be interpolated.

WALL CONSTRUCTION

R602.7.2 Rim board headers. Rim board header size, material and span shall be in accordance with Table R602.7(1). Rim board headers shall be constructed in accordance with Figure R602.7.2 and shall be supported at each end by full-height studs. The number of full-height studs at each end shall be not less than the number of studs displaced by half of the header span based on the maximum stud spacing in accordance with Table R602.3(5). Rim board headers supporting concentrated loads shall be designed in accordance with accepted engineering practice.

❖ This section prescribes the requirements for sawn lumber rim board headers. Rim board headers improve the energy efficiency of wall framing by allowing a greater thickness of cavity insulation. Rim board header size, material and span are in accordance with Table R602.7(1). Rim board headers must be constructed in accordance with Figure R602.7.2. Full-height studs at each end must be used to support this type of header. The design does not include support of concentrated loads. Spans for engineered wood rim boards are not included and must be in accordance with the manufacturer's installation instructions.

R602.7.3 Wood structural panel box headers. Wood structural panel box headers shall be constructed in accordance with Figure R602.7.3 and Table R602.7.3.

❖ Wood structural panel box headers are used in some construction and are an efficient way of carrying load over an opening. The box header must be built in accordance with the criteria specified in Figure

R602.7.3 and Table R602.7.3. Spans of box headers are established based on the construction of the header, the header depth, and the depth of the house. Note a to the table explains the depth criterion, which is based on a single story with a clear-span trussed roof or a two-story in which part of the load from the floors and roofs is supported by interior bearing walls. House depth is based on the span from the header to an interior bearing wall or the opposing exterior wall.

TABLE R602.7.3. See page 6-27.

❖ See the commentary to Section R602.7.3.

FIGURE R602.7.3. See page 6-27.

❖ See the commentary to Section R602.7.3.

R602.7.4 Nonbearing walls. Load-bearing headers are not required in interior or exterior nonbearing walls. A single flat 2-inch by 4-inch (51 mm by 102 mm) member shall be permitted to be used as a header in interior or exterior nonbearing walls for openings up to 8 feet (2438 mm) in width if the vertical distance to the parallel nailing surface above is not more than 24 inches (610 mm). For such nonbearing headers, cripples or blocking are not required above the header.

❖ In walls that are not supporting significant loads, the code provides a simple (more economical) option for constructing headers.

R602.7.5 Supports for headers. Headers shall be supported on each end with one or more jack studs or with approved framing anchors in accordance with Table R602.7(1) or

For SI: 25.4 mm = 1 inch.

FIGURE R602.7.2
RIM BOARD HEADER CONSTRUCTION

R602.7(2). The full-height stud adjacent to each end of the header shall be end nailed to each end of the header with four-16d nails (3.5 inches × 0.135 inches). The minimum number of full-height studs at each end of a header shall be in accordance with Table R602.7.5.

❖ Section R602.7.5 prescribes the required supports for headers. All headers must be supported by one or more jack studs or approved framing anchors. Additionally one or more full-height studs are required at each end of the header. Rim joist headers are only supported by full-height headers in accordance with Section R602.7.2.

The intent of the minimum full-height stud requirements is to provide structural integrity in resisting loads

by compensating for removal of full-height layout studs over the span of the wall opening. Full-height studs are used to stabilize a header by nailing the first stud into the end of the header preventing header rotation. The number of full-height studs required is based on out-of-plane wind and gravity loads. An out-of-plane wind load is the load a wall resists due to wind pressing directly on it. Gravity loads passing down from the roof or wall above are transferred by both king studs and headers. Gravity loads passing through the header are then transferred by trimmers, or jack studs to the foundation or story below.

The minimum number of full-height studs required at each end of the header is listed in Table R602.7.5. The minimum number of full-height studs is based on

TABLE R602.7.3
MAXIMUM SPANS FOR WOOD STRUCTURAL PANEL BOX HEADERS^a

HEADER CONSTRUCTION ^b	HEADER DEPTH (inches)	HOUSE DEPTH (feet)				
		24	26	28	30	32
Wood structural panel—one side	9	4	4	3	3	—
	15	5	5	4	3	3
Wood structural panel—both sides	9	7	5	5	4	3
	15	8	8	7	7	6

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Spans are based on single story with clear-span trussed roof or two story with floor and roof supported by interior-bearing walls.

b. See Figure R602.7.3 for construction details.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

NOTES:

- a. The top and bottom plates shall be continuous at header location.
- b. Jack studs shall be used for spans over 4 feet.
- c. Cripple spacing shall be the same as for studs.
- d. Wood structural panel faces shall be single pieces of 1⁵/₃₂-inch-thick Exposure 1 (exterior glue) or thicker, installed on the interior or exterior or both sides of the header.
- e. Wood structural panel faces shall be nailed to framing and cripples with 8d common or galvanized box nails spaced 3 inches on center, staggering alternate nails 1/2 inch. Galvanized nails shall be hot-dipped or tumbled.

FIGURE R602.7.3
TYPICAL WOOD STRUCTURAL PANEL BOX HEADER CONSTRUCTION

header span and maximum stud spacing in order to maintain the number of studs displaced by the opening over which the header spans. The previous requirement for only one full height at each end of longer headers is appropriate for shorter header spans but inadequate for longer header spans.

The maximum stud spacing in accordance with Table R602.3(5) is specifically listed in the column heading to make clear that the maximum stud spacing, not actual stud spacing, is the determining factor for the number of required full-height studs at each end of the header. In construction, actual stud spacing is often 16 inches on center; however, the maximum stud spacing often permitted in the code is 24 inches on center. If the actual stud spacing is used and is less than the maximum stud spacing in accordance with Table R602.3(5), the required number of full-height studs at each end of the header would be overestimated.

TABLE R602.7.5
MINIMUM NUMBER OF FULL HEIGHT STUDS
AT EACH END OF HEADERS IN EXTERIOR WALLS

HEADER SPAN (feet)	MAXIMUM STUD SPACING (inches) [per Table R602.3(5)]	
	16	24
≤ 3'	1	1
4'	2	1
8'	3	2
12'	5	3
16'	6	4

R602.8 Fireblocking required. Fireblocking shall be provided in accordance with Section R302.11.

❖ See the commentary to Section R302.11.

R602.9 Cripple walls. Foundation cripple walls shall be framed of studs not smaller than the studding above. When exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional story.

Cripple walls with a stud height less than 14 inches (356 mm) shall be continuously sheathed on one side with wood structural panels fastened to both the top and bottom plates in accordance with Table R602.3(1), or the cripple walls shall be constructed of solid blocking.

Cripple walls shall be supported on continuous foundations.

❖ A cripple wall is a framed stud extending from the top of foundation to the underside of the floor framing above the foundation. Should these foundation studs exceed 4 feet (1219 mm) in height, the partial-height wall must, for purposes of stud sizing, be sized as if the partial-height wall were an additional story. Such a condition may occur in buildings of a split-level type with floor levels partially below grade or in buildings with under-floor crawl spaces larger than the minimum specified. See Figure R602.3(2). The rationale for the wall being considered an additional story is based on the load capacity of studs of a particular size changing

as the unsupported length is increased.

The minimum length of 14 inches (356 mm) for cripple wall studs provides sufficient clear space for required nailing of the framing. If the wood-framed foundation wall does not permit the installation of foundation studs of such a length, wood structural panel sheathing must be applied, or a solid-blocking method of construction may be used.

R602.10 Wall bracing. Buildings shall be braced in accordance with this section or, when applicable, Section R602.12. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

❖ All buildings must be braced to resist lateral loads due to wind and seismic forces. Wall construction must include bracing to resist imposed lateral loads resulting from wind or seismic loading and to provide stability to the structure. When subjected to wind loads, the upper portion of the structure moves horizontally while the lower portion is restrained at ground level. During an earthquake, the ground motion displaces the foundation while the top portion of the structure tries to remain stationary. In both of these cases the bracing resists the differential movement and thus prevents or limits damage to the building.

This section provides the prescriptive requirements for conventional construction of wall bracing to resist the lateral wind and seismic loads within the scope of the code. For buildings, or portions of buildings, that do not meet the bracing requirements of this section, an engineered design in accordance with the *International Building Code*® (IBC®) or other referenced standard is required in accordance with Section R301.1.

Wall bracing for lateral loads due to wind speed is required for all buildings. Wall bracing for lateral loads due to seismic loading is required for townhouses in Seismic Design Category (SDC) C and all buildings in SDC D₀, D₁ and D₂ as defined in Section R301.2.2. Buildings in Seismic Design Categories A, B or, for detached one- and two-family dwellings, SDC C, are only required to meet wind provisions. Dwellings and townhouses in these seismic design categories are exempt from all seismic provisions.

For walls to meet wall bracing requirements, a continuous lateral load path must be prescribed for the building. It is very important to understand the concept of a lateral load path because it helps make sense of the prescriptive requirements in the code. In short, the lateral load path is simply the path that the lateral or horizontal load takes as it passes through the structure, including components and connections, on its way to the ground.

The lateral load path for wind loads is simpler to visualize than the load path for seismic loads. Commentary Figure R602.10 provides a basic example of the lateral load path resulting from wind loading. The load is shown acting on a windward receiving wall, and its subsequent load path through the building. For simplicity,

the suction pressure on the leeward receiving wall is not included in this illustration.

As shown in Commentary Figure R602.10, there are six critical parts in the load path for a simple rectangular structure. The critical parts of the lateral load path addressed in this section are Items 4, 5 and 6 of Commentary Figure R602.10.

From a lateral load perspective, the walls support the roof and floor diaphragms through the use of bracing panels. The type, amount and number of bracing panels are, of course, dependent on the magnitude of the lateral load. Stronger resistance (greater numbers of bracing panels) and reduced braced wall line spacing (interior braced wall lines) may be required in areas of high wind and/or seismic activity.

Failure of a braced wall line is evidenced by racking of the wall line. Racking occurs when a rectangular wall deforms to a parallelogram shape, in which the top and the bottom of the wall remain horizontal but the sides are no longer vertical. The purpose of wall bracing is to prevent such failures.

The wall bracing section is organized to address one bracing topic per subsection. Intermittent and continuous sheathing methods are combined into a single section. Section R602.12 offers a simplified prescriptive approach for wall bracing in low-wind, low-seismic regions.

A portion of the commentary on the wall bracing provisions is based on information found in “A Guide to the IRC Wood Wall Bracing Provisions.” This guide, with versions written for the 2006, 2009, 2012 and 2015 IRC, is a joint publication by ICC and APA and provides a more extensive explanation and application of the wall bracing provisions.

R602.10.1 Braced wall lines. For the purpose of determining the amount and location of bracing required in each story level of a building, *braced wall lines* shall be designated as straight lines in the building plan placed in accordance with this section.

❖ The definition of a “Braced wall line” from Section R202 is:

BRACED WALL LINE. A straight line through the building plan that represents the location of the lateral resistance provided by the wall bracing.

Information about braced wall lines—length, spacing, and orientation—is in Section R602.10.1. Commentary Figure R602.10.1(1) shows two braced wall lines (1 and 2) in the longitudinal direction and three braced wall lines (A, B and C) in the transverse direction. Each wall line is made up of a number of braced wall panels. Not every braced wall line has to be continuous, as shown in braced wall line B. Furthermore,

- 1 Windward receiving wall carries load to foundation at bottom of wall and roof diaphragm at top of wall
- 2 Connections at bottom and top of wall transfer these loads into the foundation and diaphragm
- 3 Roof or floor diaphragm carries load to bracing walls
- 4 Connections between roof/floor and wall transfers load from diaphragm to bracing walls
- 5 Bracing wall carries load from diaphragm to foundation
- 6 Transfer of loads from the shear walls to the foundation

Figure R602.10
CRITICAL PARTS OF THE LATERAL LOAD PATH

the code permits offsets of up to 4 feet (1219 mm) from the braced wall line (see Section R602.10.1.2). If sections of a braced wall line are offset by 4 feet (1219 mm) or less, they are assumed to act in combination to resist lateral load. If the sections are farther than 4 feet (1219 mm) from the braced wall line, they must be considered as separate braced wall lines. Offsets in braced wall lines are further discussed in Section R602.10.1.2.

Braced wall lines may include interior walls, as braced wall line B in Commentary Figure R602.10.1(1) illustrates. An interior braced wall line may be required—depending on the size of the house, the wind speed, or seismic design category—to supplement the exterior braced wall lines. Interior braced wall lines have requirements similar to exterior wall lines in terms of bracing length, panel location, wall line offsets and attachments.

The effective (imaginary) braced wall line, a concept introduced in Commentary Figure R602.10.1(2), is based on the principle that a braced wall line does not

have to coincide with a physical wall line. The designated wall line location may be within a grouping of wall line sections and assumed to provide a line of lateral resistance somewhere near the center of the wall sections. This concept is illustrated in Commentary Figure R602.10.1(2).

R602.10.1.1 Length of a braced wall line. The length of a braced wall line shall be the distance between its ends. The end of a braced wall line shall be the intersection with a perpendicular braced wall line, an angled braced wall line as permitted in Section R602.10.1.4 or an exterior wall as shown in Figure R602.10.1.1.

❖ In Section R602.10.1.1, the definition of a braced wall line (BWL) is the distance between the most distant ends of the wall lines included in the braced wall line. If a wall line segment is angled and 8 feet (2438 mm) or less in length, the projected length of the angled wall segment may also count as part of the length of the braced wall line. There is no longer a requirement to draw projections of braced wall lines beyond the end of

an intersecting wall line. The end of the building determines a braced wall line's end point.

The braced wall line length is the distance between the most distant ends of the wall lines included in the braced wall line. The braced wall line does not need to be extended to intersect other braced wall lines in the plans. Note BWL A in Commentary Figure R602.10.1.1. BWL A is not required to continue beyond the end of the physical wall line. Instead, the braced wall line and the physical wall line end at the perpendicular exterior wall on the left side of the building. Changes to this provision have allowed a decrease of nearly 50 percent for the BWL A length in Commentary Figure R602.10.1.1.

FIGURE R602.10.1.1. See below.

❖ See the commentary to Sections R602.10.1.1 and R602.10.1.2.

R602.10.1.2 Offsets along a braced wall line. Exterior walls parallel to a braced wall line shall be offset not more than 4 feet (1219 mm) from the designated braced wall line location as shown in Figure R602.10.1.1. Interior walls used as bracing shall be offset not more than 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1.

❖ Many home designs feature offsets along the braced wall line length. Figure R602.10.1.1 shows offsets, braced wall line spacing and placement. A designated braced wall line is not required to be placed on a wall line in the plans. It may be placed between two or more wall lines. For wall line offsets, the limit is a maximum of 4 feet (1219 mm) from the braced wall line to a phys-

ical wall line requiring a braced panel. The maximum distance of a wall line segment to either side of the braced wall line is 4 feet (1219 mm).

R602.10.1.3 Spacing of braced wall lines. The spacing between parallel braced wall lines shall be in accordance with Table R602.10.1.3. Intermediate braced wall lines through the interior of the building shall be permitted.

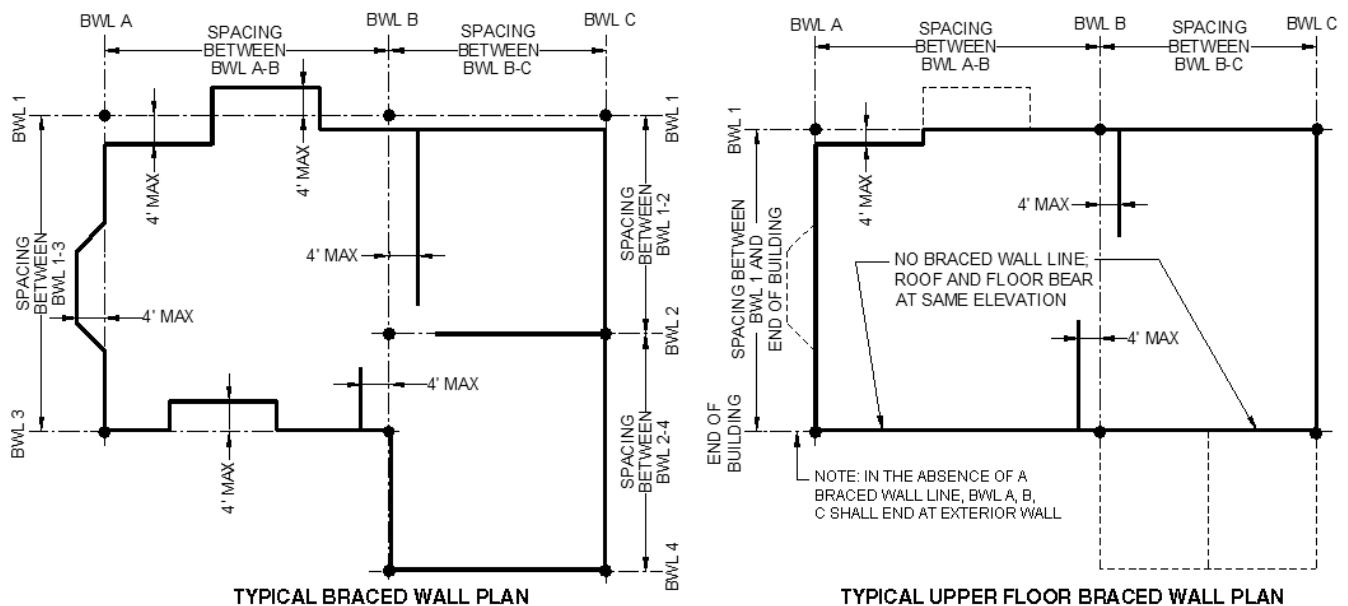

❖ All BWL spacing information is located in Table R602.10.1.3. The limitation of 60 feet (18 287 mm) for wind requirements and 25 feet (7620 mm) for seismic requirements for BWL spacing is unchanged.

For townhouses in SDC C, braced wall lines must not be spaced more than 35 feet (10 668 mm) apart. However, an exception permits spacing up to 50 (15 239 mm) feet with certain limitations.

- The exception permits an increase up to 50 feet (15 239 mm) provided the length of the required wall bracing has been increased in accordance with Table R602.10.3(4) for braced wall lines spaced greater than 35 feet (10 668 mm).

For structures in SDC D₀, D₁ or D₂, braced wall lines must not be spaced more than 25 feet (7620 mm) apart. However, two exceptions permit a spacing of 35 feet (10 668 mm) with certain limitations.

- The first permits an increase to 35 feet (10 668 mm) for a single room up to 900 feet square (84 m²) where the spacing between all other braced wall lines does not exceed 25 feet (7620 mm).
- The second permits an increase to 35 feet (10 668 mm) provided the length of the required wall

For SI: 1 foot = 304.8 mm.

FIGURE R602.10.1.1
BRACED WALL LINES

WALL CONSTRUCTION

bracing has been increased in accordance with Table R602.10.3(4) for the braced wall lines spaced greater than 25 feet (7620 mm), the aspect ratio of the floor above or roof diaphragm does not exceed 3:1, and the top plate, of the braced wall line is spliced as specified.

Table R602.10.3(4) provides bracing adjustments for braced wall line spacing up to 50 feet (15 239 mm) for SDC C townhouses and for BWL spacing of 30 and 35 feet (9144 and 10 668 mm) for structures in SDC D₀, D₁ or D₂.

TABLE R602.10.1.3. See below.

❖ See the commentary to Section R602.10.1.3.

R602.10.1.4 Angled walls. Any portion of a wall along a braced wall line shall be permitted to angle out of plane for a maximum diagonal length of 8 feet (2438 mm). Where the

angled wall occurs at a corner, the length of the braced wall line shall be measured from the projected corner as shown in Figure R602.10.1.4. Where the diagonal length is greater than 8 feet (2438 mm), it shall be considered a separate braced wall line and shall be braced in accordance with Section R602.10.1.

❖ This provision allows the sheathing in a diagonal wall to be “counted” towards the total bracing length for a single braced wall line. Note that the angled portion of the wall line must be less than or equal to 8 feet (2438 mm) in length. If it is greater than 8 feet (2438 mm) in length, it must be considered its own braced wall line.

Note that the provision does not permit “double dipping”: the bracing on an angled wall may be applied towards the total bracing length required for only one braced wall line connected to the angled wall line.

Angled wall lines may be counted as part of a braced

TABLE R602.10.1.3
BRACED WALL LINE SPACING

APPLICATION	CONDITION	BUILDING TYPE	BRACED WALL LINE SPACING CRITERIA	
			Maximum Spacing	Exception to Maximum Spacing
Wind bracing	Ultimate design wind speed 100 mph to < 140 mph	Detached, townhouse	60 feet	None
Seismic bracing	SDC A – C	Detached	Use wind bracing	
	SDC A – B	Townhouse	Use wind bracing	
	SDC C	Townhouse	35 feet	Up to 50 feet when length of required bracing per Table R602.10.3(3) is adjusted in accordance with Table R602.10.3(4).
	SDC D ₀ , D ₁ , D ₂	Detached, townhouses, one- and two-story only	25 feet	Up to 35 feet to allow for a single room not to exceed 900 square feet. Spacing of all other braced wall lines shall not exceed 25 feet.
	SDC D ₀ , D ₁ , D ₂	Detached, townhouse	25 feet	Up to 35 feet when length of required bracing per Table R602.10.3(3) is adjusted in accordance with Table R602.10.3(4).

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 mile per hour = 0.447 m/s.

wall line when 8 feet (2438 mm) long or less. The projected length of the braced wall line should be added to the total wall line length. Commentary Figure R602.10.1.4(1) gives the projected braced wall line length to add to the braced wall line length for 4, 6, and 8-foot (1219, 1829, and 2438 mm) long angled wall lines. If an angled wall line is longer than 8 feet (2438 mm), it should be considered a separate braced wall line. See Commentary Figure R602.10.1.4(2) for the projected angled wall length.

What if the angled wall contains the entryway of the house and there is not sufficient space for bracing panels? The length of the angled entryway still counts towards the length of the wall line, and the 10 foot (3048 mm) rule (see Section R602.10.2.2) also applies. When the length of the angled wall shown in Commentary Figure R602.10.1.4(2) is less than 10 feet (3048 mm) bracing panels are not required in the angled wall section, provided that the other requirements of Section R602.10.2.2 are met.

What happens if the angled wall segment is greater than 10 feet (3048 mm)? Whenever the length of the angled wall is greater than 8 feet (2438 mm), the angled wall provision of Section R602.10.1.4 no longer applies and the angled wall is considered its own wall line which must be braced accordingly, as shown in Commentary Figure R602.10.1.4(3). This can be a difficult proposition when using the 2015 code because of the need for “braced wall line spacing” in accordance with both the wind and seismic bracing tables. If no parallel angled line is available to measure between, then determining the correct distance to use for the braced wall line spacing becomes

a matter of interpretation. A reasonable solution is to run a perpendicular line from the center of the angled wall until it intersects a braced wall line and use that distance as the braced wall line spacing.

If there are no bracing elements in the angled wall segment and the first braced wall panel is a distance greater than 10 feet (3048 mm) from the end of the wall line, an engineered solution will be required for the entire wall line.

FIGURE R602.10.1.4. See below.

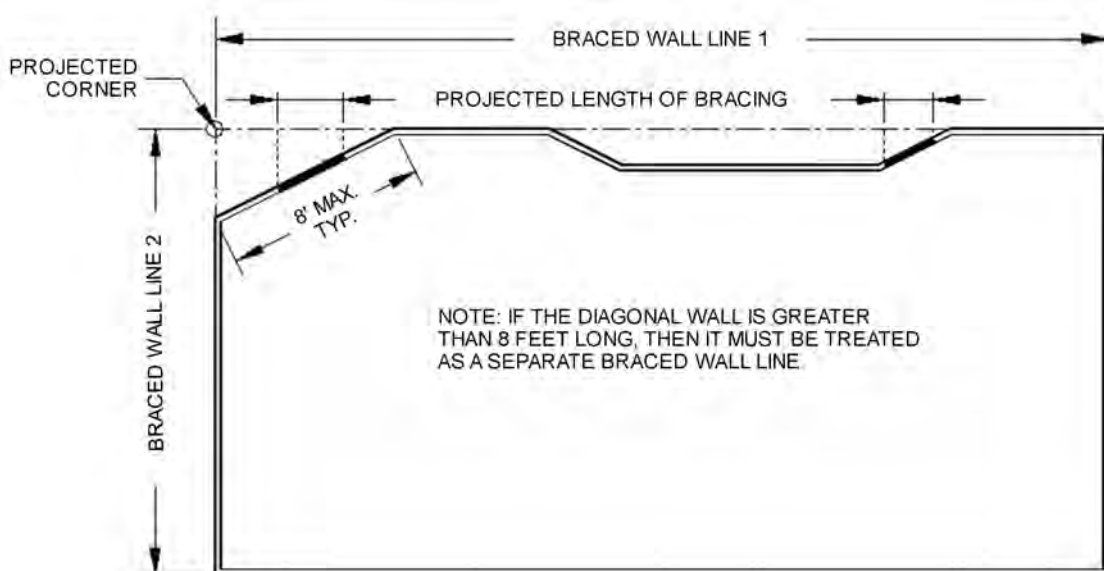

❖ See the commentary to Section R602.10.1.4.

R602.10.2 Braced wall panels. *Braced wall panels* shall be full-height sections of wall that shall not have vertical or horizontal offsets. *Braced wall panels* shall be constructed and placed along a *braced wall line* in accordance with this section and the bracing methods specified in Section R602.10.4.

❖ The definition of a braced wall panel (BWP), information on BWP location, and the minimum required num-

ANGLE FROM BWL (DEGREES)	PROJECTED BWL LENGTH FROM ANGLED WALL LINE (feet)		
	4	6	8

**FIGURE R602.10.1.4
ANGLED WALLS**

ber of BWPs in a wall line are now in one section. The BWP definition has been clarified to limit panels to areas of a wall line with no vertical or horizontal irregularities.

The definition of a braced wall panel, from Section R202, is:

BRACED WALL PANEL. A full-height section of wall constructed to resist in-plane shear loads through interaction of framing members, sheathing material and anchors. The panel's length meets the requirements of its particular bracing method and contributes toward the total amount of bracing required along its braced wall line in accordance with Section R602.10.2.

Put in simpler terms, braced wall panel describes a code-qualified bracing element. The name is probably derived from the fact that most of the recognized methods of bracing use panel-type products. Even let-in bracing is often referred to as a bracing panel. "Panel" is somewhat of a misnomer since it actually describes a wall "section," "segment" or "unit." As such, the terms braced wall section, braced wall segment and bracing unit are often used interchangeably.

Each braced wall panel must extend the full height of the wall—from the bottom plate to the top of the double top plates. A "panel" may be constructed from more than one piece of sheathing. For example, a 6-foot-long (1829 mm) braced wall panel may be con-

Figure R602.10.1.4(2)
PROJECTED ANGLE WALL LENGTH

Figure R602.10.1.4(3)
ANGLED WALL GREATER THAN 8 FEET IN LENGTH

structed by joining a 4-foot-long (1219 mm) panel with a 2-foot-long (610 mm) panel.

Braced wall panels have a height and a length dimension. The permitted height of a braced wall panel ranges from 8 to 12 feet (2438 to 3658 mm). In some cases, the panel height is limited to 10 feet (3048 mm). The length dimension is measured parallel to the length of the wall. For example, the length of a 4 by 8 oriented strand board (OSB) bracing panel placed with the 8-foot (2438 mm) dimension in the up-and-down direction is 4 feet (1219 mm). Knowing the length of a braced wall panel is important because the various bracing methods have different required minimum lengths. Also, the combined length of individual braced wall panels must total or exceed a required minimum length for the braced wall line.

R602.10.2.1 Braced wall panel uplift load path. The bracing lengths in Table R602.10.3(1) apply only when uplift loads are resisted in accordance with Section R602.3.5.

- ❖ The wall bracing section assumes that all wall lines with braced panels have been nailed to prescriptive requirements for the uplift load path. When uplift connection is not as specified in Section R602.3.5, the required wall bracing in Tables R602.10.3(1) and R602.10.3(3) does not apply and the wall lines will need engineering to determine bracing requirements. Refer to Section R602.3.5 for more information on the requirements of uplift load paths for braced wall panels.

R602.10.2.2 Locations of braced wall panels. A *braced wall panel* shall begin within 10 feet (3810 mm) from each end of a *braced wall line* as determined in Section R602.10.1.1. The distance between adjacent edges of *braced wall panels* along a *braced wall line* shall be not greater than 20 feet (6096 mm) as shown in Figure R602.10.2.2.

- ❖ Braced wall panels are to begin within 10 feet (3048 mm) of the end of the braced wall line in SDC A, B and C and all wind speeds for buildings that are allowed to be designed in accordance with the IRC. The panels may be inset up to 10 feet (3048 mm) from both ends of a wall line for all intermittent and continuous sheathing bracing methods, as shown in Figure R602.10.2.2. If bracing is located more than 10 feet (3048 mm) from either end of a braced wall line, the wall line requires an engineered design for lateral loads.

The maximum distance between two braced wall panels is measured from edge to edge. Previous codes measured braced wall panel distances on center. The 25-foot (7620 mm) braced wall panel spacing requirement was straightforward when 4-foot (1219 mm) braced wall panels were used; however, the intent of the requirement needed to be considered when dealing with longer lengths of bracing or continuously sheathed bracing methods. The intent is that unbraced wall lengths longer than 21 feet (6401 mm) (measured between adjacent bracing panel edges) are not permitted. Given this interpretation, for example, the center of a 4-foot (1219 mm) section within an 8-foot (2438 mm) braced wall panel can be used as the

measuring point for determining the 25-foot (7620 mm) maximum distance. In such a case, measuring 21 feet (6401 mm) between bracing panels may be the easier method of determining the maximum braced wall panel spacing.

Without this interpretation, the permissible distance between bracing segments would decrease as the length of the segments increased. This was not the intent of the code. As long as the distance between braced wall panels did not yield unbraced wall lengths of greater than 21 feet (6401 mm), the code's braced wall panel spacing requirements were satisfied.

Changing to a measurement of distance from panel edge to panel edge is intended to simplify calculations. The previous provision of braced wall panel spacing of 25 feet (7620 mm) on center is now a distance of 20 feet (6096 mm) edge to edge. This reduces maximum panel spacing by 1 foot (305 mm), but allows all measurements to be edge to edge distances.

FIGURE R602.10.2.2. See page 6-36.

- ❖ See the commentary to Section R602.10.2.2

R602.10.2.2.1 Location of braced wall panels in Seismic Design Categories D₀, D₁ and D₂. Braced wall panels shall be located at each end of a braced wall line.

Exception: Braced wall panels constructed of Method WSP or BV-WSP and continuous sheathing methods as specified in Section R602.10.4 shall be permitted to begin not more than 10 feet (3048 mm) from each end of a braced wall line provided each end complies with one of the following:

1. A minimum 24-inch-wide (610 mm) panel for Methods WSP, CS-WSP, CS-G and CS-PF is applied to each side of the building corner as shown in End Condition 4 of Figure R602.10.7.
 2. The end of each braced wall panel closest to the end of the braced wall line shall have an 1,800 lb (8 kN) hold-down device fastened to the stud at the edge of the braced wall panel closest to the corner and to the foundation or framing below as shown in End Condition 5 of Figure R602.10.7.
- ❖ To further simplify the provisions, in SDC D₀, D₁ and D₂, braced wall panels must be placed at the ends of the braced wall line. Using Method WSP, if a hold-down or end panel is used, an exception allows braced panels to begin up to 10 feet (3048 mm) from the end of the braced wall line. In previous codes, the allowable offset was 8 feet (2438 mm). To simplify the provisions, all braced wall panel inset distances are a maximum of 10 feet (3048 mm) from the end of the wall line. In all seismic design categories, the distance from wall end to braced wall panel is measured from wall end to panel edge.

Note that a 10-foot (3048 mm) maximum panel distance is permitted at each end if either a hold-down is placed at the panel edge or a 24-inch (610 mm) end panel is provided. If two braced wall lines meet at a corner and along one wall line the first panel is displaced from the corner, then both braced wall lines lose the

WALL CONSTRUCTION

structural effect of the return corner. In this case, both wall lines must be anchored with a 1,800 pound (8 kN) hold-down device.

For wind and seismic requirements, offset of braced wall panels may now be up to 10 feet (3048 mm) from each end of the braced wall line if all provisions are met.

R602.10.2.3 Minimum number of braced wall panels.

Braced wall lines with a length of 16 feet (4877 mm) or less shall have not less than two *braced wall panels* of any length or one *braced wall panel* equal to 48 inches (1219 mm) or more. *Braced wall lines* greater than 16 feet (4877 mm) shall have not less than two *braced wall panels*.

❖ Minimum bracing length for short wall lines is now provided in the code. A braced wall line of 16 feet (4877 mm) or less in length may have one braced wall panel when it is at least 48 inches (1219 mm) long. A braced wall line of 16 feet (4877 mm) or less may alternatively have two qualifying braced wall panels from the tables in Section R602.10 that are less than 48 inches (1219 mm) in length. Braced wall panel spacing and maximum edge distances are illustrated in Figure R602.10.2.2. All distances are measured from a braced wall panel's edge.

R602.10.3 Required length of bracing. The required length of bracing along each *braced wall line* shall be determined as follows:

1. All buildings in Seismic Design Categories A and B shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
2. Detached buildings in Seismic Design Category C shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
3. Townhouses in Seismic Design Category C shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4), respectively.
4. All buildings in Seismic Design Categories D₀, D₁ and D₂ shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4), respectively.

Only *braced wall panels* parallel to the *braced wall line* shall contribute toward the required length of bracing of that *braced wall line*. *Braced wall panels* along an angled wall meeting the minimum length requirements of Tables R602.10.5 and R602.10.5.2 shall be permitted to contribute

For SI: 1 foot = 304.8 mm.

FIGURE R602.10.2.2
LOCATION OF BRACED WALL PANELS

its projected length toward the minimum required length of bracing for the *braced wall line* as shown in Figure R602.10.1.4. Any *braced wall panel* on an angled wall at the end of a *braced wall line* shall contribute its projected length for only one of the *braced wall lines* at the projected corner.

Exception: The length of wall bracing for dwellings in Seismic Design Categories D_0 , D_1 and D_2 with stone or masonry veneer installed in accordance with Section R703.8 and exceeding the first-story height shall be in accordance with Section R602.10.6.5.

❖ The required length of bracing is determined from either Table R602.10.3(1) or R602.10.3(3). Table R602.10.3(1) specifies the required bracing based on ultimate design wind speed. The required wind bracing length values have changed slightly from the 2012 code. This is due to the use of the new ultimate design wind speed to calculate the bracing requirement. Table R602.10.3(3) specifies the required bracing based on the seismic design category. Each process for determining required bracing length includes adjustment factors. These adjustment factors—modifications to the amount of bracing based on variations in the structural geometry—are in tables following the bracing requirements tables. Adjustment factors vary for the wind and seismic tables. It is important to note that neglecting an adjustment factor can result in insufficient bracing for a specific application. For example, the wind bracing tables are based on a roof eave-to-ridge height of 10 feet (3048 mm). If the roof height of a given single-story structure is 15 feet (4572 mm) and the adjustment factor is ignored, the wall bracing will be insufficient by 30 percent. For this reason, all adjustment factors in Tables R602.10.3(2) and R602.10.3(4) must be considered carefully.

For wind bracing, Table R602.10.3(1), the user inputs braced wall line spacing to determine the required bracing length in feet, regardless of building length. Basing the bracing requirement on the width of the building (the braced wall line spacing) is appropriate for wind. Wind pushes against a building in the same manner that it pushes against a sail on a boat. When wind acts on the building width, the length of the building (dimension parallel to the wind) is irrelevant to determining the bracing required to resist that wind load. In other words, a short building that is 35 feet (10 668 mm) wide has the same “sail area”—and receives the same wind load—as a long building that is 35 feet (10 668 mm) wide. Therefore, if the short building requires 12 feet (3658 mm) of bracing, the long building also requires 12 feet (3658 mm) of bracing.

As illustrated in Commentary Figure R602.10.3(1), the information in the wind bracing table is based on:

- Exposure Category B.
- 30-foot (9144 mm) mean roof height.
- 10-foot (3048 mm) eave-to-ridge height.
- 10-foot (3048 mm) wall height per story.
- Two braced wall lines per direction of wind.

Notes to Tables R602.10.3(1), Bracing Requirements Based on Wind Speed, and R602.10.3(3), Bracing Requirements Based on Seismic Design Category, must be followed. After selection of a required bracing length from Table R602.10.3(1) or (3), check the notes at the bottom of the tables for additional requirements and then go to Table R602.10.3(2) or (4) for applicable adjustment factors.

In Table R602.10.3(1), Note b clarifies additional requirements for Method LIB. While all intermittent

WALL CONSTRUCTION

bracing methods shall have gypsum board on at least one side of the wall (see Section R602.10.4.3), Note b requires that Method LIB have gypsum board installed on at least one side in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board at the Method LIB location on either side of the wall. Spacing of fasteners at panel edges may not exceed 8 inches (203 mm).

Note c permits using an average spacing for braced wall line spacing.

Table R602.10.3(2), Wind Adjustment Factors to the Required Length of Wall Bracing, contains adjustment factors to accommodate variations from the table's assumptions for the wide range of residential structures covered by the code. The adjustment factors are described below:

- Exposure category—Note that the wind-bracing table is based on Exposure Category B. The exposure category for a given jurisdiction can be obtained from the local building department. [Refer to Table R301.2(1) of the locally adopted version of the IRC.]

As the number of stories increases (increasing the mean roof height); the adjustment factors increase. This is to accommodate the increased exposure and larger sail area of the structure. The following two adjustment factors account for increased sail area.

- Eave-to-ridge height—Eave-to-ridge height is an important consideration because it increases the sail area of a structure, therefore increasing the wind load on the structure, as illustrated in Commentary Figure R602.10.3(2). Increasing eave-to-ridge height by as little as 5 feet (1524 mm), from 10 to 15 feet (3048 to 4572 mm) for example, can increase the required bracing panel length by up to 30 percent. Note that as

the number of stories increases the contribution of the roof eave-to-ridge height to the sail area decreases.

- Wall height—Like eave-to-ridge height, increasing the sail area of the structure by making it taller increases the wind load on the structure, thus requiring more bracing. Because the bracing wind table assumes a 10-foot (3048 mm) wall height, taller walls require an adjustment to increase the amount of required bracing, while shorter walls are permitted an adjustment to decrease the amount of required bracing. This adjustment can be applied to each story individually. For example, in a house with a first story wall height of 9 feet (2743 mm) and a second-story wall height of 8 feet (2438 mm), the bracing amount for the first story can be reduced by 5 percent, and the bracing amount for the second story reduced by 10 percent.
- Number of braced wall lines (per plan direction)—At first glance this adjustment factor may give the impression that adding additional interior bracing walls is a disadvantage because the amount of bracing in the wall lines must increase. However, the values in Table R602.10.3(1) are based on the spacing of the braced wall lines. If, for example, the distance between two exterior walls in a home design requires a length of bracing that cannot be accommodated by the exterior wall lines alone, a braced wall line may be added through the interior of the structure. In this case, because the spacing of the braced wall lines decreases, the amount of bracing required for the braced wall lines also decreases. The adjustment factor is applied to the reduced amount of bracing for

the braced wall lines. This method is conservative [see Commentary Figure R602.10.3(3)]. Only the interior wall lines receive loads from the floor or roof along both sides of the wall line. The exterior wall lines have tributary loads from only one side of the wall line. But at this time, all wall lines require the increase in bracing. Interior wall lines double the lateral load carried by adjacent exterior wall lines, but the required adjustment factors do not require a 200-percent increase in bracing. Rather, the dwelling is assumed to be tied together sufficiently by connections to allow loads to be transferred to both wall lines.

- Additional 800-pound (363 kg) hold-down device—In developing the new wind-bracing provisions, braced wall panels only supporting the roof above them (one-story buildings and the top story of multistory buildings) were recognized to be more effective in resisting wind forces when a hold-down was installed at the base of each panel. The use of an 800-pound (363 kg) hold-down device, installed in accordance with the manufacturer's recommendations, increases the capacity of bracing methods when supporting roof loads only. A 20-percent reduction in the length of bracing is permitted due to the increased capacity achieved by adding a hold-down device. Note that the hold-downs must be used at both ends of every bracing panel in the wall line and the hold-down anchorage must extend through all lower floors (if any) to provide a continuous load path until anchored into the foundation.
- Interior gypsum board finish—The wind bracing table was developed based on balancing the wind load acting on the structure against the strength of the bracing material providing resis-

tance. The bracing lengths are based on the assumption that gypsum wall board is applied on the inside surface of braced wall panels. The addition of gypsum wall board, even though not attached with the same quantity of fasteners as Method GB bracing, does add strength and stiffness to the bracing; therefore, in cases in which gypsum board is not applied on the inside surface of braced wall panels, an adjustment must be made. In modern residential construction, the absence of gypsum board finish material is only likely to occur at gable end walls (above the plate) and at exterior garage walls. Typically, in either of these applications, it is not difficult to increase the amount of bracing because these walls are not likely to have many openings. Note this adjustment factor is used with Methods DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G and CS-SFB.

- Gypsum board fastening—Using the bracing lengths as stated from the Method GB column in Table R602.10.3(1) requires both sides of the braced wall line to be constructed to meet the requirements of Method GB bracing, including type and quantity of fasteners.

When fastener spacing is reduced to 4 inches (102 mm) on center at all panel ends, edges and intermediate supports with horizontal joints blocked, the required length of Method GB bracing may be multiplied by a factor of 0.7 for wind applications only. The reduction may be applied to single-sided or double-sided Method GB.

For seismic bracing [Table R602.10.3(3)], the user inputs the length of the braced wall line to determine the amount of bracing required. Bracing for seismic loads is determined based on the length of the braced wall line. When determining the amount of bracing

WALL CONSTRUCTION

required to resist seismic forces, the length of the building parallel to the direction of loading is the most important consideration. This is because mass is generally evenly distributed along the length and width of a building. For a given building width, the long building has more mass—and thus receives greater earthquake forces—than the short building. As a result, the long building requires a greater amount of bracing.

To determine whether a dwelling requires seismic bracing, Section R301.2.2 should be reviewed. Section R301.2.2 exempts detached one- and two-family dwellings in SDC A, B and C and townhouses in SDC A and B from the seismic provisions of the code. In these cases, only the wind bracing requirements must be met.

As illustrated in Commentary Figure R602.10.3(4), the information in Table R602.10.3(3), the seismic bracing table, is based on:

- Soil site classification D.
- 10-foot (3048 mm) wall height.

- 10 psf (479 Pa) floor dead load.
- 15 psf (718 Pa) roof and ceiling dead load.
- Braced wall line spacing of 25 feet (7620 mm) or less.

Table R602.10.3(3) is based on soil Site Class D, which is defined in Section 1613.5.2 of the IBC. When the soil properties are not known in sufficient detail to determine a specific soil site class, site Class D shall be used unless the building official or geotechnical data determines that Site Class E or F is present. If Site Class E or F is present, IBC Section 1613.5, provides a methodology for determining the site SDS and converting it into a SDC that can be used directly in Table R602.10.3(3). Note c clarifies how to determine the bracing where the braced wall line length is greater than 50 feet.

Table R602.10.3(4) includes adjustment factors to accommodate variations from these assumptions for the wide range of residential structures covered by the code.

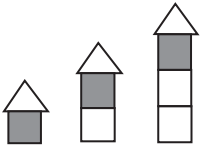

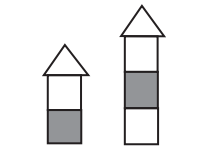

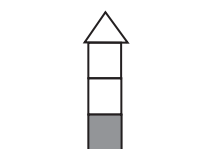

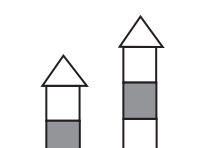

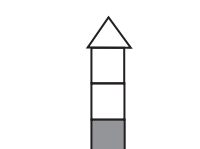

Each of the adjustments described in Table R602.10.3(4) is explained below:

- Story height (see Section R301.3)—The amount of bracing required for seismic loads is directly related to the mass/weight of the structure. As a wall gets taller, its mass increases, thus requiring more bracing to resist the resulting seismic loads.
- Braced wall line spacing, townhouses in SDC C—This adjustment factor applies to townhouses in SDC C. Townhouses in SDC C are permitted to have a 35- to 50-foot (10 668 mm to 15 240 mm) braced wall line spacing using this adjustment factor.
- Braced wall line spacing in SDC D₀, D₁ and D₂—The 25-foot (7620 mm) braced wall line spacing applies to one- and two-family dwellings and townhouses in SDC D₀, D₁ and D₂. However, for one room only per dwelling unit, the 25-foot (7620 mm) braced wall line spacing for these structures can be increased to a maximum of 35 feet (10 668 mm).
- Wall dead load - Table R602.10.3(3) is based on a wall weight of 8 to 15 pounds per square feet (338 to 718 Pa). If a lighter weight wall is used, a reduction is permitted in the amount of bracing required. (Again, more mass requires more bracing and less mass requires less bracing.) Note that a standard wood-framed stud wall has a weight of 11 to 12 psf (527 to 575 Pa) (see Table C3-1 of ASCE 7).
- Roof/ceiling dead load for wall supporting—Table R602.10.3(3) is based on a roof/ceiling weight of 15 pounds per square feet (718 Pa) or less. As the roof weight/mass increases, so does the amount of bracing required. Note that a standard wood-framed roof ceiling with light-weight asphalt or wood shingles has a weight that varies between 10 and 15 psf (479 to 718 Pa) (Table C3-1 of ASCE 7).
- Roof/ceiling dead load adjustment factors vary depending on how many floors exist below the roof. If the building is a single-story structure, the effect of the additional weight on the roof is greater than when the building is three stories tall. The adjustment factors are dependent upon the number of stories in the structure. From Table R602.10.3(4), for a single-story building the adjustment factor for roof loads greater than 15 psf (718 Pa) is 1.2. For a two-story or three-story building, the adjustment factor is 1.1.
- Walls with stone or masonry veneer, townhouses in SDC C—This is a case of more mass requiring more bracing. This adjustment factor applies only to townhouses in SDC C. The adjustment factor varies based on story height. Any intermittent or continuous sheathing method may be used.
The adjustment factor for wall bracing length for the bottom of a two-story and bottom two stories of a three-story townhouse is 1.5. This increase applies only when veneer extends more than one story in height. The top story of a multi-story house does not require an increase in bracing for masonry and stone veneer regardless of veneer height.
- Walls with stone or masonry veneer in SDC D₀, D₁ and D₂—This is another case of more mass requiring more bracing. Section R602.10.6.5 describes the limits and requirements for wall bracing in SDC D₀-D₂ with walls with stone and masonry veneer in one- and two-family dwellings. Townhouses in SDC D₀, D₁ and D₂ with stone or masonry veneer exceeding the first story height must be designed in accordance with accepted engineering practice.
- Interior gypsum board finish—The seismic bracing table was developed based on balancing the seismic forces acting on the structure against the strength of the bracing material providing resistance. The bracing lengths are based on the assumption that gypsum wall board is applied on the inside surface of braced wall panels. The addition of gypsum wall board, even though not attached with the same quantity of fasteners as Method GB bracing, does add strength and stiffness to the bracing; therefore, in cases in which gypsum board is not applied on the inside surface of braced wall panels, an adjustment must be made. In modern residential construction, the absence of gypsum board finish material is only likely to occur at gable end walls (above the plate) and at exterior garage walls. Typically, in either of these applications, it is not difficult to increase the amount of bracing because these walls are not likely to have many openings. This factor is applied when the following methods are used without interior gypsum board finish - DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, or CS-SFB [SDC C only and winds less than 100 mph (45 m/s)].

TABLES R602.10.3(1) through R602.10.3(4). See pages 6-42 through 6-48.

			C	1.40	
			D	1.70	
2	Roof eave-to-ridge height	Roof only	≤ 5 feet	0.70	All methods
			10 feet	1.00	
			15 feet	1.30	
			20 feet	1.60	
		Roof + 1 floor	≤ 5 feet	0.85	
			10 feet	1.00	
			15 feet	1.15	
			20 feet	1.30	
		Roof + 2 floors	≤ 5 feet	0.90	
			10 feet	1.00	
			15 feet	1.10	
			20 feet	Not permitted	
3	Wall height adjustment	Any story	8 feet	0.90	All methods
			9 feet	0.95	
			10 feet	1.00	
			11 feet	1.05	
			12 feet	1.10	
4	Number of braced wall lines (per plan direction) ^c	Any story	2	1.00	All methods
			3	1.30	
			4	1.45	
			≥ 5	1.60	
5	Additional 800-pound hold-down device	Top story only	Fastened to the end studs of each braced wall panel and to the foundation or framing below	0.80	DWB, WSP, SFB, PBS, PCP, HPS
6	Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.40	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB
7	Gypsum board fastening	Any story	4 inches o.c. at panel edges, including top and bottom plates, and all horizontal joints blocked	0.7	GB

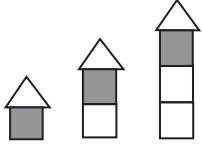

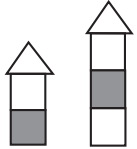

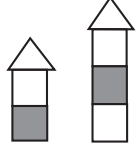

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 4.48 N.

a. Linear interpolation shall be permitted.

b. The total adjustment factor is the product of all applicable adjustment factors.

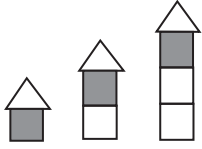

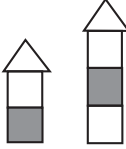

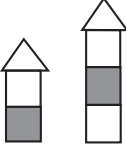

c. The adjustment factor is permitted to be 1.0 when determining bracing amounts for intermediate braced wall lines provided the bracing amounts on adjacent braced wall lines are based on a spacing and number that neglects the intermediate braced wall line.

			1.5		
			1.5		
7	Walls with stone or masonry veneer, detached one- and two-family dwellings in SDC D ₀ – D ₂ ^{d, f}	Any story	See Table R602.10.6.5	BV-WSP	
8	Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.5	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB

For SI: 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- a. Linear interpolation shall be permitted.
- b. The total length of bracing required for a given wall line is the product of all applicable adjustment factors.
- c. The length-to-width ratio for the floor/roof *diaphragm* shall not exceed 3:1. The top plate lap splice nailing shall be in accordance with Table R602.3(1), Item 13.
- d. Applies to stone or masonry veneer exceeding the first story height.
- e. The adjustment factor for stone or masonry veneer shall be applied to all exterior *braced wall lines* and all *braced wall lines* on the interior of the building, backing or perpendicular to and laterally supported veneered walls.
- f. See Section R602.10.6.5 for requirements where stone or masonry veneer does not exceed the first-story height.

R602.10.4 Construction methods for braced wall panels.

Intermittent and continuously sheathed *braced wall panels* shall be constructed in accordance with this section and the methods listed in Table R602.10.4.

❖ There are 12 intermittent and four continuously sheathed bracing methods included in Table R602.10.4, each with its own minimum length and installation requirements. Each method lists minimum thickness requirements and connection criteria separated into fastener type and spacing requirements. The last three intermittent methods are alternate methods for bracing along a wall line or adjacent to a garage opening. The purpose of the alternate methods is to provide a narrow-length option for sections of wall line with less than 48 inches (1219 mm) of space requiring a braced panel.

The nomenclature for the abbreviations used for the bracing methods is based on the following:

- Abbreviations for the intermittent methods come from the material used to make the braced wall panel.
- Alternate method abbreviations come from the braced panel names.
- Continuously sheathed methods each start with CS (e.g., Method CS-PF is the continuously sheathed portal frame bracing method).

The term “intermittent” is used to identify bracing methods that provide braced wall panels placed in discrete locations along a braced wall line, while the term “continuous” is used to identify bracing methods that require the whole wall line to be sheathed. The first nine intermittent methods abbreviations are:

1. Let-in bracing (Method LIB)
2. $\frac{5}{8}$ -inch (16 mm) diagonal wood boards (Method DWB)
3. Wood structural panel (plywood or OSB) (Method WSP)
4. $\frac{7}{16}$ -inch (11.1 mm) wood structural panel with stone or masonry veneer (Method BV-WSP)
5. $\frac{1}{2}$ -inch (12.7 mm) structural fiberboard sheathing (Method SFB)
6. $\frac{1}{2}$ -inch (12.7 mm) gypsum board (Method GB)
7. Particleboard sheathing (Method PBS)
8. Portland cement plaster (Method PCP)
9. Hardboard panel siding (Method HPS)

As the name implies, intermittent bracing methods are meant to be used intermittently along the wall line. For these methods, the minimum length required for a single braced wall panel segment ranges from 48 to 96 inches (1219 to 2438 mm).

Three alternative methods are also classified as intermittent bracing methods because, while structurally different from the traditional methods, these meth-

ods are designed to be used intermittently and can be substituted for any of the traditional bracing methods on a one-for-one basis (they may be intermixed with other intermittent bracing methods along the same wall line). The intermittent alternate braced methods are designated as:

1. Alternate braced wall (Method ABW)
2. Portal frame with hold-downs (Method PFH)
3. Portal frame at garage (Method PFG)

The minimum lengths for methods ABW and PFH range from 16 to 40 inches (406 to 1016 mm). Either may be substituted for any intermittent bracing method permitted in Table R602.10.4. For the purposes of computing the required length of bracing, a single unit of either method is equivalent to 4 feet (1219 mm). Both utilize prefabricated metal hold-downs, in addition to anchor bolts, to connect the bracing panel to the foundation below.

Bracing method PFG is a type of portal frame that does not require hold-downs, has a minimum length of 24 inches (610 mm), may only be used in SDC A, B and C and may only be used adjacent to a garage door. For the purposes of computing the required length of bracing, a single unit of this method is equivalent to 1.5 times its actual length.

The four continuous bracing methods require continuous sheathing on all wall areas of the wall line. As walls with continuous sheathing are generally considered to be stiffer and stronger than similar walls with intermittent bracing, the continuous methods allow for bracing solutions that are narrower than the widths required for the intermittent methods.

Three of these bracing methods are for use with continuous wood structural panel sheathing.

Method CS-WSP, continuously sheathed wood structural panel, requires all braced wall lines, including areas above and below openings and gable ends, to be fully sheathed with a minimum of $\frac{3}{8}$ -inch (9.5 mm) wood structural panel sheathing.

Method CS-G, continuously sheathed wood structural panel adjacent to garage openings, is a narrow-length panel that can be used with Method CS-WSP. This method permits the use of a panel length as short as 24 inches (610 mm) for an 8-foot (2438 mm) wall, but because the length of the wall is linked to an aspect ratio, the segment is required to get longer as the wall gets taller.

Pay particular attention to Notes b and c in Table R602.10.4. Note b does not permit the use of 4:1 aspect ratio narrow wall panels on more than one wall of a garage. In other words, the braced panel may only be used around the garage door opening. If garage door openings occur in two walls of the garage, only one wall may use this braced panel. This should not be interpreted to mean that narrow wall segments cannot be used on both sides of a garage door within a single wall; rather, that is their designed use.

The note also restricts 4:1 aspect ratio narrow wall segments to supporting roofs only, and further restricts the dead load of the roof covering to 3 pounds per square foot (144 Pa) for SDC D₀, D₁, and D₂. This minimizes the seismic weight (mass) of the roof in a seismic event by limiting the roof covering to relatively light roofing materials. Note c requires a header above a garage opening adjacent to Method CS-G panels. The opening is not permitted to be full height next to this panel. Use Table R602.7(1) to select a header for the opening.

For purposes of determining length of bracing in a wall line with Method CS-G, use the actual length of the narrow braced wall panels. Of course, the required length of bracing must be met for any wall in the structure: this provision simply allows the use of smaller segments to make up the required length of bracing.

Method CS-PF, continuously sheathed portal frame, has been in the code since the 2006 edition where it was listed as a note in Table R602.10.5, Length Requirements for Braced Wall Panels in a Continuously Sheathed Wall. In the 2009 edition it was redefined as a bracing method and only permitted when using Method CS-WSP.

The fourth continuously sheathed method, Method CS-SFB, was added to the 2009 edition of the code. It is very similar to Method CS-WSP except that there are restrictions as to where it may be used. Method CS-SFB is not permitted to be used in SDC D₀, D₁ or D₂.

When using Method CS-SFB, the entire length of the braced wall line (including areas above and below openings and gable ends, if applicable) must be fully sheathed with a minimum of 1/2-inch (13 mm) structural fiberboard sheathing.

The length of bracing for continuous sheathing is determined from the continuous sheathing column of Tables R602.10.3(1) and R602.10.3(3). Only full-height braced wall panels in accordance with Section R602.10.5 are to be counted toward the minimum required length of bracing.

Methods CS-WSP and CS-SFB bracing lengths are based on the adjacent clear opening height as shown in Figure R602.10.5. Note that for Methods CS-WSP and CS-SFB the minimum panel length is aspect-ratio linked (the minimum bracing length increases as the wall height increases). This is done to ensure that as the wall gets taller, it remains sufficiently stiff.

Method CS-G and Method CS-PF, although continuously sheathed methods, are based on the use of wood structural panel sheathing and are not applicable for Method CS-SFB.

Lastly, Note a of Table R602.10.4 prohibits the use of adhesives in moderate-to-high seismic areas (SDC C, D₀, D₁ and D₂). The intent of this provision is that only sheathing used as a part of a braced wall segment, as described in Table R602.10.4, shall not be attached with adhesives. Note that detached one- and two-family dwellings are exempt from seismic rules in SDC C. Only townhouses in SDC C must meet this

provision. This provision does not apply to Section R602.10.4.3 (braced wall panel interior finish material). While the interior finish is a required part of the bracing panel segment, its contribution to the overall bracing strength is relatively minor, and is actually predicated on the fastener spacing used in conjunction with the adhesive attachment of gypsum wall board.

TABLE R602.10.4. See page 6-52 and 6-53.

❖ See the commentary to Section R602.10.3.

R602.10.4.1 Mixing methods. Mixing of bracing methods shall be permitted as follows:

1. Mixing intermittent bracing and continuous sheathing methods from story to story shall be permitted.
 2. Mixing intermittent bracing methods from *braced wall line* to *braced wall line* within a story shall be permitted. In regions within Seismic Design Categories A, B and C where the ultimate design wind speed is less than or equal to 130 mph (58m/s), mixing of intermittent bracing and continuous sheathing methods from braced wall line to braced wall line within a story shall be permitted.
 3. Mixing intermittent bracing methods along a *braced wall line* shall be permitted in Seismic Design Categories A and B, and detached dwellings in Seismic Design Category C, provided the length of required bracing in accordance with Table R602.10.3(1) or R602.10.3(3) is the highest value of all intermittent bracing methods used.
 4. Mixing of continuous sheathing methods CS-WSP, CS-G and CS-PF along a *braced wall line* shall be permitted. Intermittent methods ABW, PFH and PFG shall be permitted to be used along a *braced wall line* with continuous sheathed methods.
 5. In Seismic Design Categories A and B, and for detached one- and two-family dwellings in Seismic Design Category C, mixing of intermittent bracing methods along the interior portion of a *braced wall line* with continuous sheathing methods CS-WSP, CS-G and CS-PF along the exterior portion of the same braced wall line shall be permitted. The length of required bracing shall be the highest value of all intermittent bracing methods used in accordance with Table R602.10.3(1) or R602.10.3(3) as adjusted by Tables R602.10.3(2) and R602.10.3(4), respectively. The requirements of Section R602.10.7 shall apply to each end of the continuously sheathed portion of the braced wall line.
- ❖ For detached one- and two-family dwellings and townhouses in SDC A and B, and detached dwellings in SDC C, braced wall lines which have sections of both exterior and interior wall line may now mix continuous sheathing made of wood structural panels on the exterior portion of the wall line with intermittent bracing methods along the interior of the braced wall line. This is commonly used for a continuously sheathed exterior

of wood structural panel with interior wall lines sheathed in gypsum board intermittent braced wall panels.

Commentary Figure R602.10.4.1 shows the mixing possibilities and their limitations.

The 2015 edition permits mixing of bracing methods as follows:

1. Story-to-story. Mixing any bracing methods from story-to-story is permitted. An example is using Method CS-WSP (continuously sheathed wood structural panel) bracing on the bottom two stories of a three-story building while using Method PBS (particleboard sheathing) or Method GB (gypsum board) bracing on the top story.
2. Braced wall line to braced wall line within one story. A builder is permitted to use different bracing methods on different walls within a story. For example, in a “window wall,” a designer may use Method WSP bracing along one wall line of a story because its lower bracing length requirements can help to accommodate additional windows. On the other walls having fewer windows, the designer may use Method GB or another intermittent bracing method.

Mixing any bracing methods with continuously sheathed methods from one wall line to another is permitted in SDC A, B or C and where the basic wind speeds are 130 mph (58 m/s) or less.

In regions of SDC D₀-D₂ or wind speeds above 130 mph, intermittent bracing methods may change from wall line to wall line. When using continuously sheathed methods, all exterior wall lines must be continuously sheathed.

For the 2009 code, it was determined that in high seismic and high wind zones, all exterior walls of a given level must be continuously sheathed if a single wall on that level is continuously sheathed. However, walls inside the build-

ing or walls on other levels may use whatever bracing meets the requirements for that wall or level.

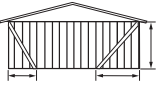

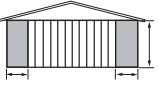

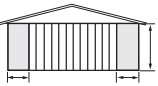

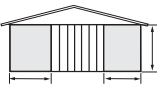

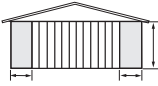

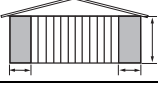

3. Mixing in one braced wall line. For one- and two-family dwellings in SDC A, B and C, and for townhouses in SDC A and B, mixing intermittent bracing methods within a braced wall line is permitted. The length of the required bracing for the braced wall line with mixed sheathing types must have the greatest required bracing length, with all applicable adjustment factors applied, of all types of bracing used in that wall line.
4. Mixing continuous sheathing methods in one wall line. Mixing of continuous sheathing methods CS-WSP, CS-G and CS-PF along a braced wall line is permitted as these methods assume use in a continuously sheathed wood structural panel wall line. For example, the braced wall line at the front of a house might have CS-WSP along the majority of the wall line with CS-PF at the garage opening. Also, the three intermittent alternate bracing methods, ABW, PFH and PFG are permitted to be mixed with the CS-WSP method.
5. Mixing intermittent and continuous sheathing methods in one wall line. In SDC A-C for detached one- and two-family dwellings and SDC A-B for townhouses, mixing of intermittent bracing methods along the interior portion of a braced wall line with continuous sheathing methods CS-WSP, CS-G and CS-PF along the exterior portion of the same braced wall line is permitted. The length of required bracing is the highest value of all intermittent bracing methods used with all applicable adjustment factors applied. The requirements of Section R602.10.7 apply to each end of the continuously sheathed portion of the braced wall line.

MIXING LOCATIONS	MIXING LIMITATIONS	SDC A-B	SDC C DETACHED	SDC C TOWNHOUSES	SDC D ₀ -D ₂
Story to Story	Mixing intermittent & continuously sheathed methods	X	X	X	X
BWL to BWL	Mixing intermittent methods	X	X	X	X
BWL to BWL	Mixing intermittent & continuously sheathed methods	X	X	X	NP
Within BWL	Mixing intermittent methods in a single wall line	X	X	NP	NP
Within BWL	Mixing continuously sheathed methods using wood structural panels only (Mixing CS-WSP, CS-G, CS-PF, ABW, PFH & PFG)	X	X	X	X
Within BWL	Mixing an intermittent method on an interior portion & CS-WSP, CS-PF, and CS-G on an exterior portion of a wall line	X	X	NP	NP

BWL = Braced Wall Line, NP = Not Permitted.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 degree = 0.0175 rad, 1 pound per square foot = 47.8 N/m², 1 mile per hour = 0.447 m/s.

- a. Adhesive attachment of wall sheathing, including Method GB, shall not be permitted in Seismic Design Categories C, D₀, D₁ and D₂.
- b. Applies to panels next to garage door opening where supporting gable end wall or roof load only. Shall only be used on one wall of the garage. In Seismic Design Categories D₀, D₁ and D₂ roof covering dead load shall not exceed 3 psf.
- c. Garage openings adjacent to a Method CS-G panel shall be provided with a header in accordance with Table R602.7(1). A full-height clear opening shall not be permitted adjacent to a Method CS-G panel.
- d. Method CS-SFB does not apply in Seismic Design Categories D₀, D₁ and D₂.
- e. Method applies to detached one- and two-family dwellings in Seismic Design Categories D₀ through D₂ only.

R602.10.4.2 Continuous sheathing methods. Continuous sheathing methods require structural panel sheathing to be used on all sheathable surfaces on one side of a *braced wall line* including areas above and below openings and gable end walls and shall meet the requirements of Section R602.10.7.

- ❖ The definition of a continuously sheathed braced wall line from Section R202 is:

BRACED WALL LINE, CONTINUOUSLY SHEATHED. A braced wall line with structural sheathing applied to all sheathable surfaces including the areas above and below openings.

The four continuous bracing methods require continuous sheathing on all wall areas of the wall line. As walls with continuous sheathing are generally considered to be stiffer and stronger than similar walls with intermittent bracing, the continuous methods allow for bracing solutions that are narrower than the widths required for the intermittent methods. Mixing of continuous bracing with intermittent bracing is allowed as specified in Section R602.10.4.1 (see commentary, Section R602.10.4.1).

R602.10.4.3 Braced wall panel interior finish material. *Braced wall panels* shall have gypsum wall board installed on the side of the wall opposite the bracing material. Gypsum wall board shall be not less than 1/2 inch (12.7 mm) in thickness and be fastened with nails or screws in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum wall board. Spacing of fasteners at panel edges for gypsum wall board opposite Method LIB bracing shall not exceed 8 inches (203 mm). Interior finish material shall not be glued in Seismic Design Categories D₀, D₁ and D₂.

Exceptions:

1. Interior finish material is not required opposite wall panels that are braced in accordance with Methods GB, BV-WSP, ABW, PFH, PFG and CS-PF, unless otherwise required by Section R302.6.
 2. An approved interior finish material with an in-plane shear resistance equivalent to gypsum board shall be permitted to be substituted, unless otherwise required by Section R302.6.
 3. Except for Method LIB, gypsum wall board is permitted to be omitted provided the required length of bracing in Tables R602.10.3(1) and R602.10.3(3) is multiplied by the appropriate adjustment factor in Tables R602.10.3(2) and R602.10.3(4), respectively, unless otherwise required by Section R302.6.
- ❖ In the 2009 code a requirement was added that, for intermittent braced wall panels, regular gypsum wall board must be installed as an interior finish material on the side of the wall opposite the bracing material. Note that this requirement is for the use of standard gypsum wall board, not Method GB bracing. Interior finish gypsum wall board can be attached in accordance with Section R702.3.5 (7 inches (178 mm) on center attach-

ment required for Method GB does not apply). Narrow wall intermittent bracing methods (AWB, PFG, PFH and CS-PF) are exempt from this requirement because they were developed without gypsum wall board interior finish and they are typically used adjacent to garage door openings, where gypsum wall board is not commonly used. Wood structural panels with stone or masonry veneer (BV-WSP) do not require interior finish material. Additionally, there are exceptions that eliminate this requirement for gypsum wall board as an interior finish material if the wall bracing amount is increased.

Although the other bracing methods permit the gypsum board to be installed as a wall covering rather than a Method GB bracing material; when gypsum board is installed as Method GB bracing, the fasteners must be spaced 7 inches (178 mm) on center at all panel ends, edges and intermediate supports. The fastener schedule for gypsum board installed as a wall covering (see Section R702.3.5) is less stringent than when it is installed as a bracing material.

R602.10.5 Minimum length of a braced wall panel. The minimum length of a *braced wall panel* shall comply with Table R602.10.5. For Methods CS-WSP and CS-SFB, the minimum panel length shall be based on the adjacent clear opening height in accordance with Table R602.10.5 and Figure R602.10.5. Where a panel has an opening on either side of differing heights, the taller opening height shall be used to determine the panel length.

- ❖ Braced wall panel minimum lengths are placed into Table R602.10.5 for clarity. The column titled "Contributing length" gives the equivalent intermittent braced panel length for alternate intermittent braced wall panels and the continuously sheathed braced panel length for continuous sheathing methods.

This section requires that the minimum intermittent braced panel length be at least 48 inches (1219 mm), except when employing alternate braced panels. Minimum continuously sheathed braced panel length is dependent on the height of the wall and adjacent opening; therefore, the braced panels vary in required minimum length.

Minimum braced panel length varies depending upon bracing method and in some cases wall height, seismic design category or adjacent opening height.

- Minimum bracing length is 48 inches (1219 mm) for Methods DWB, WSP, SFB, PBS, GB, PCP, HPS, and BV-WSP for walls 10 feet (3048 mm) tall or less. Walls taller than 10 feet (3048 mm) require longer minimum braced panel lengths.
- Method LIB requires a minimum length of 55 inches (1397 mm) for an 8-foot-tall (2438 mm) wall. The minimum length varies depending upon the wall height.
- Minimum length of a Method ABW panel varies depending upon wall height and seismic design category.

- Methods CS-WSP and CS-SFB minimum length depend upon wall height and the size of the opening next to the braced wall panel.
- Methods PFH (supporting one story and a roof), PFG and CS-G have a minimum braced panel length of 24 inches (610 mm).
- Method PFH (supporting a roof) and Method CS-PF have a minimum panel length of 16 inches (406 mm).

Methods ABW, PFG, CS-G and CS-PF have a bracing capacity related to the ratio of their panel height to length. Note that this aspect ratio adjustment is separate from the required bracing adjustment in Table R602.10.3(4). However, any increase in length as a result of the aspect ratio adjustment in Table R602.10.5 is permitted to be counted towards the amount of bracing required. In many cases, when a number of minimum-length panels are used for bracing, the aspect ratio adjustment will completely account for the length increase from Table R602.10.3(4).

Remember that, for all bracing methods, wall length is measured along the wall line in the horizontal direction.

FIGURE R602.10.5. See below.

❖ See the commentary to Sections R602.10.5 and R602.10.5.1.

TABLE R602.10.5. See page 6-56.

❖ See the commentary to Sections R602.10.5 and R602.10.5.1.

R602.10.5.1 Contributing length. For purposes of computing the required length of bracing in Tables R602.10.3(1) and R602.10.3(3), the contributing length of each *braced wall panel* shall be as specified in Table R602.10.5.

❖ This section clarifies what length should be counted for a specific bracing method when the actual length of the panel is not used.

The following bracing methods contribute the measured length of the braced panel to the total bracing length:

- LIB, DWB, WSP, SFB, PBS, PCP, HPS, and BV-WSP for intermittent bracing.
- Double-sided GB.
- CS-PF in SDC D₀, D₁ and D₂.
- CS-WSP, CS-G and CS-SFB.

Other methods have a fixed amount of bracing per braced panel or an adjustment factor that is applied to the measured length of braced panel.

- Method ABW panel and each Method PFH panel in a portal contribute 4 feet (1219 mm) of bracing.
- Method GB is worth half its length for single-sided applications, i.e., 20 feet (6096 mm) of single-sided GB equals 10 feet (3048 mm) of wall bracing.
- Method PFG panel is worth 1½ times its physical length for wall bracing length, i.e., a 24-inch (610 mm) panel is worth 36 inches (914 mm) of wall bracing.
- Method CS-PF in SDC A, B and C is worth 1½ times its physical length for wall bracing length.

Only full-height braced wall panels are to be counted toward the minimum required length of bracing. Table R602.10.5 provides minimum length requirements for Methods CS-WSP or CS-SFB for various wall heights.

The braced panel lengths are based on the adjacent clear opening height as shown in Figure R602.10.5. Note that minimum panel lengths are aspect-ratio linked: as the wall height increases, so does the minimum bracing panel length. This is necessary to ensure that, as the wall gets taller, it remains sufficiently stiff.

FIGURE R602.10.5
BRACED WALL PANELS WITH CONTINUOUS SHEATHING

**TABLE R602.10.5
MINIMUM LENGTH OF BRACED WALL PANELS**

METHOD (See Table R602.10.4)		MINIMUM LENGTH ^a (inches)					CONTRIBUTING LENGTH (inches)

NP = Not Permitted.

- a. Linear interpolation shall be permitted.
- b. Use the actual length where it is greater than or equal to the minimum length.
- c. Maximum header height for PFH is 10 feet in accordance with Figure R602.10.6.2, but wall height shall be permitted to be increased to 12 feet with pony wall.
- d. Maximum opening height for PFG is 10 feet in accordance with Figure R602.10.6.3, but wall height shall be permitted to be increased to 12 feet with pony wall.
- e. Maximum opening height for CS-PF is 10 feet in accordance with Figure R602.10.6.4, but wall height shall be permitted to be increased to 12 feet with pony wall.

R602.10.5.2 Partial credit. For Methods DWB, WSP, SFB, PBS, PCP and HPS in Seismic Design Categories A, B and C, panels between 36 inches and 48 inches (914 mm and 1219 mm) in length shall be considered a *braced wall panel* and shall be permitted to partially contribute toward the required length of bracing in Tables R602.10.3(1) and R602.10.3(3), and the contributing length shall be determined from Table R602.10.5.2.

- ❖ Section R602.10.5.2 permits reductions in the minimum panel length for specific panel-type bracing methods (DWB, WSP, SFB, PBS, PCP and HPS) in SDC A, B and C as long as a length penalty is applied to the actual length of the wall panel in accordance with Table R602.10.5.2. For example, a 36-inch (914 mm) panel can be used in an 8-foot (2438 mm) wall instead of a full 48-inch (1219 mm) panel, but it will only count as 27 inches (686 mm) towards the required length of bracing.

TABLE R602.10.5.2. See below.

- ❖ See the commentary to Section R602.10.5.2.

R602.10.6 Construction of Methods ABW, PFH, PFG, CS-PF and BV-WSP. Methods ABW, PFH, PFG, CS-PF and BV-WSP shall be constructed as specified in Sections R602.10.6.1 through R602.10.6.5.

- ❖ This section places former intermittent and continuously sheathed alternate braced wall panel methods together. The text descriptions of the methods have been deleted with a figure replacing the text description. The figures contain the majority of the construction requirements for Methods ABW, PFH, PFG, CS-PF and BV-WSP.

Allowed wall heights have been increased to 12 feet (3658 mm) with the portal header height limited to 10 feet (3048 mm) and a cripple wall built above. When a cripple wall is above the header, tension straps should be nailed to the cripple wall stud, header and the jack stud below creating a continuous load path to the story or foundation below.

The use of a cripple wall (pony wall) directly over the continuously sheathed portal frame has been included in all the portal frame alternate methods in the 2015 edition. The pony wall provisions are used often as a means of elevating the second story of the structure over the garage in a home with a split-level entry. Crip-

ple walls are meant to address a problem in which a structural hinge is created over a door or window header that can result in the header bulging in or out due to wind loads blowing directly against the wall, or even differential moisture conditions. In severe cases, it can lead to structural problems. Often in garages, these areas are braced back to the ceiling with framing to prevent such an occurrence.

When “braced back” detailing is not desired, the information provided in Table R602.10.6.4 and Figure R602.10.6.2, R602.10.6.3, or R602.10.6.4 can be used to detail the portal frame to handle various design wind loads and exposures. While not specifically permitted in the code, from an engineering perspective, interpolation of the variables in the table is appropriate.

Note that the cripple wall information in Table R602.10.6.4 may be used for pony walls over any header within the scope of the table. For conventionally framed headers, the table is slightly conservative, but it is the only prescriptive guidance available for cripple walls over headers. The use of this table will ensure that the header/pony wall assembly has sufficient stiffness to prevent a hinge from forming at the header-to-pony wall joint when subjected to wind loads acting against the wall.

R602.10.6.1 Method ABW: Alternate braced wall panels.

Method ABW *braced wall panels* shall be constructed in accordance with Figure R602.10.6.1. The hold-down force shall be in accordance with Table R602.10.6.1.

- ❖ Method ABW (see Section R602.10.6.1) has been in the IRC in one form or another since 2000 and was often referred to as the “32-inch (813 mm) alternate with hold-downs.” Method ABW panels are typically used when bracing is needed in a wall area that is not long enough to accommodate a 4-foot (1219 mm) braced wall panel.

Method ABW is grouped with the intermittent wall bracing methods because it may be substituted on a one-for-one basis for a braced wall panel from any other bracing method, and, as such, it is used intermittently. Figure R602.10.6.1 clarifies the method.

For purposes of computing the required length of bracing, a single Method ABW panel is considered to be equivalent to 4 feet (1219 mm) of bracing, regardless of its actual length.

**TABLE R602.10.5.2
PARTIAL CREDIT FOR BRACED WALL PANELS LESS THAN 48 INCHES IN ACTUAL LENGTH**

ACTUAL LENGTH OF BRACED WALL PANEL (inches)	CONTRIBUTING LENGTH OF BRACED WALL PANEL (inches) ^a	
	8-foot Wall Height	9-foot Wall Height
48	48	48
42	36	36
36	27	N/A

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

N/A = Not Applicable.

a. Linear interpolation shall be permitted.

WALL CONSTRUCTION

The maximum height and minimum length are given in Table R602.10.5 while the required hold-down force is given in Table R602.10.6.1.

TABLE R602.10.6.1. See below.

❖ See the commentary to Section R602.10.6.1.

FIGURE R602.10.6.1. See below.

❖ See the commentary to Section R602.10.6.1.

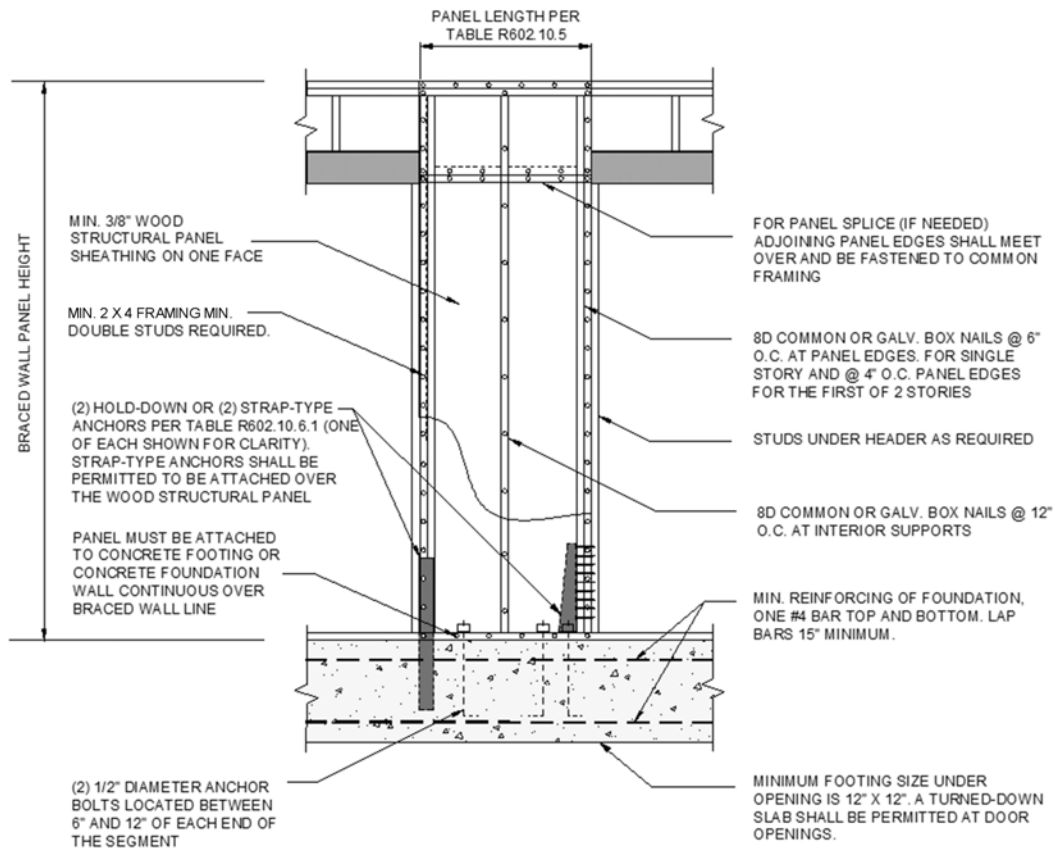

R602.10.6.2 Method PFH: Portal frame with hold-downs. Method PFH *braced wall panels* shall be constructed in accordance with Figure R602.10.6.2.

❖ Method PFH has been in the code since 2006 (where it was called “alternate braced wall panel adjacent to a door or window opening.” This method was developed primarily to maintain the traditional look of narrow wall segments on either side of garage door openings.

**TABLE R602.10.6.1
MINIMUM HOLD-DOWN FORCES FOR METHOD ABW BRACED WALL PANELS**

SEISMIC DESIGN CATEGORY AND WIND SPEED	SUPPORTING/STORY	HOLD-DOWN FORCE (pounds)				
		Height of Braced Wall Panel				
		8 feet	9 feet	10 feet	11 feet	12 feet
SDC A, B and C Ultimate design wind speed < 140 mph	One story	1,800	1,800	1,800	2,000	2,200
	First of two stories	3,000	3,000	3,000	3,300	3,600
SDC D ₀ , D ₁ and D ₂ Ultimate design wind speed < 140 mph	One story	1,800	1,800	1,800	NP	NP
	First of two stories	3,000	3,000	3,000	NP	NP

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 4.45 N, 1 mile per hour = 0.447 m/s.
NP = Not Permitted.

For SI: 1 inch = 25.4 mm.

**FIGURE R602.10.6.1
METHOD ABW—ALTERNATE BRACED WALL PANEL**

Method PFH is included in the code as an intermittent bracing method because it may be substituted on a one-for-one basis for a braced wall panel from any other bracing method and, as such, it is used intermittently.

In the 2015 code, the construction method of the intermittent portal frame with hold-downs has been updated as follows:

- Reduction of the 4,200-pound strap-type hold-downs to 3,500 pounds. The initial testing was conducted on the portal frames utilizing the 4,200 pounds per force (lbf) hold-down because that was what was readily available and in common use by the construction industry. At the time of initial testing, no attempt was made to determine the sensitivity of the system to such a reduction in tie-down capacity. As the initial prescriptive parameters of the portal frame were based on testing, there was no rationale for determining the impact of the industry-wide reduction to such tie-downs in response to the cracked-concrete provisions of ACI 318. As such, retesting of the portal frames with both 4,200 lbf and 3,500 lbf tie-downs was necessary to determine the impact on the performance of the system, if any. Portals with 24-inch-wide legs \times 8-foot height as well as 16-inch wide \times 10 feet high were tested by APA. Pairs of each size were tested with 4,200 lbf tie-downs and then retested with 3,500 lbf tie-downs. Upon consultation with Simpson Strong-Tie technical personnel, it was determined that the 3,500 lbf capacity would be simulated by using 17 nails in the 4,200-pound strap. The 4,200-pound capacity of the strap was achieved by filling all 28 holes in the strap, even though 21 nails would yield the 4,200 lbf capacities. This was done to simulate actual field-installed conditions. The results of these tests indicate that the whole portal frame system was relatively insensitive to the reduction in tie-down capacity within the over-nailed 4,200 lbf to 3,500 lbf range. The APA—The Engineered Wood Association report, APA Report T2012L-24—*Bracing Method Alternative Attachment (IBC), Portal Frame with Hold Downs (Bracing Method PFH) (IRC)—Hold-Down Strap Capacity Variations*, describes the testing in detail.
- Reduction of the number of bottom plates from three to two. The original testing was conducted with the third plate in place. The third plate causes numerous difficulties in the field, not the least of which is that the normal length threaded anchors are too short to accommodate the third plate and provide the required depth of penetration into the foundation. This results in inadequate anchor depth of embedment or the use of threaded sleeves and all-thread to extend the bolt length to accommodate the third plate. When investigating the change to the 3,500 lbf hold-

down, the tests were run with only double bottom plates. All subsequent testing was done without the third bottom plate. The results of this testing indicated that the third bottom plate has negligible impact on the performance of the portal frames.

- Clarification of the location of the panel splice edge on the portal leg.
- Added a note to clarify where a $\frac{1}{2}$ -inch spacer is used; in a built-up header it must be put on the back side of the header. This placement allows the 8d nails used in the grid pattern at the top of the portal leg to adequately penetrate the back header to provide proper load distribution. As the spacer offers no structural advantage to the header, its placement behind the built-up header is of no structural consequence.
- Added a note to fasten king studs to the header with 6-16d nails. The assembly was developed and tested with these nails present and this should be reflected in the figure.

For purposes of computing the required length of bracing, each leg of the portal frame is considered to be equivalent to 4 feet (1219 mm) of bracing. The portal frame can be built with one or two sides as required. This method can be used for wall heights up to 10 feet (3048 mm), or if a cripple wall (pony wall) is placed above the header, a total opening height may be 12 feet (3658 mm) tall. The top of the header is limited to a maximum height of 10 feet (3048 mm). Note that Method PFH is not aspect ratio based: all single-story applications are a minimum of 16 inches (406 mm) in length and all first of two-story applications are a minimum of 24 inches (610 mm) in length. If the wall height is greater than 10 feet (3048 mm) tall, then the required braced panel length increases (see Table R602.10.5).

FIGURE R602.10.6.2. See page 6-60.

- ❖ See the commentary to Section R602.10.6.2.

R602.10.6.3 Method PFG: Portal frame at garage door openings in Seismic Design Categories A, B and C. Where supporting a roof or one story and a roof, a Method PFG *braced wall panel* constructed in accordance with Figure R602.10.6.3 shall be permitted on either side of garage door openings.

- ❖ Method PFG is a “light” variation of Method PFH that is limited to areas of low and moderate seismicity (SDC A, B and C). Like Method PFH, it is a portal frame bracing method, but it does not include hold-downs and is restricted to single story and first of two-story applications. Method PFG is a 4:1 aspect ratio-based system with a 24-inch (610 mm) minimum length requirement [e.g., for an 8-foot (2438 mm) wall, the minimum length is 96 inches (2438 mm)/4 = 24 inches (610 mm); for a 10-foot (3048 mm) wall, the minimum length is 120 inches (3048 mm)/4 = 30 inches (762 mm)]. For the purposes of computing, its bracing length is equal to 1.5 times the length (horizontal dimension) of the vertical leg. Note the nailing at the sheathing-to-header overlap is the same as Method PFH but without nailing

WALL CONSTRUCTION

the interior studs of the doubled 2 by 4s at either end of the vertical legs.

In the 2015 code, the construction method of intermittent portal frames at garage door openings has been updated as follows:

- Clarification of the location of the panel splice edge on the portal leg.
- Added a note to clarify where a $\frac{1}{2}$ -inch spacer is used; in a built-up header it must be put on the back side of the header. This placement allows the 8d nails used in the grid pattern at the top of the portal leg to adequately penetrate the back header to provide proper load distribution. As the spacer offers no structural advantage to the header, its placement behind the built-up header is of no structural consequence.
- Added a note to fasten king studs to the header with 6-16d nails. The assembly was developed and tested with these nails present and this should be reflected in the figure.

FIGURE R602.10.6.3. See page 6-61.

- ❖ See the commentary to Section R602.10.6.3.

R602.10.6.4 Method CS-PF: Continuously sheathed portal frame. Continuously sheathed portal frame *braced wall panels* shall be constructed in accordance with Figure R602.10.6.4 and Table R602.10.6.4. The number of continuously sheathed portal frame panels in a single *braced wall line* shall not exceed four.

- ❖ Minimum thickness of wood structural panel sheathing for CS-PF is $\frac{7}{16}$ inch (11 mm) thickness.

The scope of this method, referred to as Method CS-PF, is for use on any floor and in any wind zone or SDC covered by the code.

For purposes of determining the length of bracing, the length of the vertical leg of the portal frame is used as the bracing length for the element. The minimum length is in Table R602.10.5. It is based on a 6:1 height-to-length ratio: for example: 16 inches (406 mm) minimum for 8-foot (2438 mm) height.

Method CS-PF can only be used with Method CS-WSP.

In the 2015 code, the construction method of the continuously sheathed portal frame has been updated as follows:

- Clarification of the location of the panel splice edge on the portal leg.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R602.10.6.2
METHOD PFH—PORTAL FRAME WITH HOLD-DOWNS

- Added a note to clarify, where a 1/2-inch spacer is used; in a built-up header it must be put on the back side of the header. This placement allows the 8d nails used in the grid pattern at the top of the portal leg to adequately penetrate the back header to provide proper load distribution. As the spacer offers no structural advantage to the header, its placement behind the built-up header is of no structural consequence.
- Added a note to fasten king studs to the header with 6-16d nails. The assembly was developed and tested with these nails present and this should be reflected in the figure.

FIGURE R602.10.6.4. See page 6-62.

❖ See the commentary to Section R602.10.6.4.

TABLE R602.10.6.4. See page 6-63.

❖ See the commentary to Section R602.10.6.

R602.10.6.5 Wall bracing for dwellings with stone and masonry veneer in Seismic Design Categories D₀, D₁ and D₂. Where stone and masonry veneer are installed in accordance with Section R703.8, wall bracing on exterior *braced wall lines* and *braced wall lines* on the interior of the build-

ing, backing or perpendicular to and laterally supporting veneered walls shall comply with this section.

Where dwellings in Seismic Design Categories D₀, D₁ and D₂ have stone or masonry veneer installed in accordance with Section R703.8, and the veneer does not exceed the first-story height, wall bracing shall be in accordance with Section R602.10.3.

Where detached one- or two-family dwellings in Seismic Design Categories D₀, D₁ and D₂ have stone or masonry veneer installed in accordance with Section R703.8, and the veneer exceeds the first-story height, wall bracing at exterior *braced wall lines* and *braced wall lines* on the interior of the building shall be constructed using Method BV-WSP in accordance with this section and Figure R602.10.6.5. Cripple walls shall not be permitted, and required interior *braced wall lines* shall be supported on continuous foundations.

Townhouses in Seismic Design Categories D₀, D₁ and D₂ with stone or masonry veneer exceeding the first-story height shall be designed in accordance with accepted engineering practice.

❖ This section includes provisions for wall bracing when stone or masonry veneer is installed as a wall covering. These provisions apply only to stone and masonry

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R602.10.6.3
METHOD PFG—PORTAL FRAME AT GARAGE DOOR OPENINGS IN SEISMIC DESIGN CATEGORIES A, B AND C

WALL CONSTRUCTION

veneer, and not other wall coverings, because stone and masonry are heavy compared to other cladding materials. When ground motion from an earthquake puts the cladding in motion, the seismic weight (mass) of a cladding material produces load on the building's lateral-load-resisting structural elements. In the code, bracing panels are the structural elements that resist the motion of the heavy cladding. The seismic lateral load on a building increases with cladding weight and ground motion intensity; therefore, the requirements for this provision are more stringent than for other bracing methods.

The intent of Section R602.10 is to permit full-height or less stone or masonry veneer on first-story walls

using the bracing requirements of Table R602.10.3(3) and R602.10.3(4). Townhouses in SDC C have additional bracing for veneer required in Table R602.10.3(4). Detached one- and two-family dwellings in SDC D₀, D₁ and D₂ with veneer one story or less in height also have additional bracing provided by Table R602.10.3(4).

One- and two-family dwellings in SDC A, B and C and townhouses in SDC A and B are exempt from seismic requirements (in accordance with Section R301.2.2). No additional bracing is required due to the use of stone or masonry veneer in these seismic design categories.

Wall veneers of one story or less are thought to

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R602.10.6.4
METHOD CS-PF—CONTINUOUSLY SHEATHED PORTAL FRAME PANEL CONSTRUCTION

resist seismic forces independently from the braced walls to which they are attached. Once these wall veneers exceed one story, however, they are subject to additional bracing requirements.

For detached one- and two-family dwellings in SDC D₀, D₁ and D₂ with stone and masonry veneer taller than the first story, Section R602.10.6.5 must be used to determine required bracing material, length and hold-down size. This is consistent with Section R301.2.2.2.5, Item 7, Exception, which permits the use of masonry veneer as permitted elsewhere in the code. This exception specifies “masonry” veneer only; however, the intent of the code is to permit the use of both stone and masonry veneer, as the two are grouped together elsewhere in the code. For example, the title of Section R703.8 is “Anchored stone and masonry veneer, general.”

Since Section R602.10.6.5 does not extend “permission” for the installation of stone and masonry veneer to townhomes in SDC D₀, D₁ and D₂, townhouses would be categorized as “irregular” under Section R301.2.2.2.5, Item 7. Townhouses in SDC D₀, D₁ and D₂ must be engineered.

The amount of bracing required for one- and two-family dwellings in SDC D₀, D₁ and D₂ that have stone and masonry veneer above the top of the first story is provided in Table R602.10.6.5. Note that Table R602.10.6.5 has bracing requirements for single-story buildings but when the veneer is one story less in height, use Tables R602.10.3(3) and R602.10.3(4).

The bracing requirements for stone and masonry veneer apply to both the interior and exterior braced wall lines. These requirements define specific bracing materials (Method BV-WSP) and mechanical hold-down devices required at the ends of each braced wall panel.

Method BV-WSP is required to be attached with 8d nails spaced 4 inches (102 mm) on center at panel ends and edges, and hold-downs are required at ends of each continuous length of wood structural panel bracing in accordance with Table R602.10.4. Requiring BV-WSP effectively prohibits the use of continuous sheathing. For walls with stone or masonry veneer above the first story in high seismic regions, BV-WSP is the only bracing method allowed.

Continuous sheathing is prohibited because the

			18	3,350	3,800	DR	DR	DR	DR

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s.

a. DR = Design Required.

b. Straps shall be installed in accordance with manufacturer’s recommendations.

capacities of Methods CS-WSP, CS-G and CS-PF are considerably lower than fully restrained, 48-inch-long (1219 mm) panels constructed with $\frac{7}{16}$ -inch-thick (11 mm) wood structural panel sheathing, attached with 8d common nails at 4 inches (1029 mm) on center and hold-downs at the end of each braced wall panel.

The hold-downs are typically required to be nailed into two full-height studs at each end of the braced wall panel element. Designers used to working with the IBC will recognize that these bracing elements are similar to shear walls.

Hold-down location and capacity requirements are provided in Table R602.10.6.5 and Figure R602.10.6.5, respectively. As illustrated in Figure R602.10.6.5, the capacity of the hold-down is determined by the relationship of the ends of braced wall panels between stories. When BV-WSP panel ends are stacked above one another, the cumulative hold-down force from Table R602.10.6.5 is required for the lower braced wall panels.

When the ends of braced wall lines are not vertically aligned, i.e., one panel ends at a different location along the wall line than the panel below; the single-story hold-down capacity given in Table R602.10.6.5 is used.

When a BV-WSP occurs above the first story, the hold-down anchorage must be continued down to the foundation. For example, if a hold-down is installed on the second or third story, each story below must have a hold-down of the same capacity that is vertically aligned with the hold down on the story above. If a braced wall panel at the story below ends at the same location along the wall line, the hold-down capacity should be greater than or equal to the cumulative hold-down force.

Note that while wood structural panel sheathing may be used over the whole wall, above and below openings, hold-downs only need to be applied to the ends of those elements that are required for intermittent bracing. This is an important consideration when bracing lengths greater than 48 inches (1219 mm) are used. For example, if a wall line has a 6-foot (1829 mm) length of BV-WSP wall bracing, consisting of one 4-foot (1219 mm) and one 2-foot (610 mm) piece attached to a common stud, the hold-downs are only required at the start and end of the 6-foot (1829 mm) length and not at 4-foot (1219 mm) intervals.

The use of stone and masonry veneer in SDC D_0 , D_1 and D_2 requires that interior braced wall lines be supported on continuous foundations regardless of plan

dimension length. In addition, cripple walls are not permitted to be used.

TABLE R602.10.6.5. See page 6-65.

❖ See the commentary to Sections R602.10.6.5 and R602.10.6.5.1.

FIGURE R602.10.6.5. See page 6-66.

❖ See the commentary to Section R602.10.6.5.

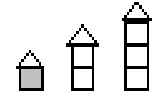

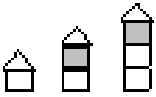

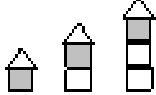

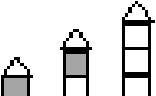

R602.10.6.5.1 Length of bracing. The length of bracing along each *braced wall line* shall be the greater of that required by the ultimate design wind speed and *braced wall line* spacing in accordance with Table R602.10.3(1) as adjusted by the factors in Table R602.10.3(2) or the seismic design category and *braced wall line* length in accordance with Table R602.10.6.5. Angled walls shall be permitted to be counted in accordance with Section R602.10.1.4, and *braced wall panel* location shall be in accordance with Section R602.10.2.2. Spacing between *braced wall lines* shall be in accordance with Table R602.10.1.3. The seismic adjustment factors in Table R602.10.3(4) shall not be applied to the length of bracing determined using Table R602.10.6.5, except that the bracing amount increase for braced wall line spacing greater than 25 feet (7620 mm) in accordance with Table R602.10.1.3 shall be required. The minimum total length of bracing in a braced wall line, after all adjustments have been taken, shall not be less than 48 inches (1219 mm) total.

❖ The minimum bracing length is determined by Table R602.10.6.5. This length is required to resist the increased loads produced by seismic forces resulting from the stone and masonry veneer. Table R602.10.6.5 supersedes the use of Tables R602.10.3(3) and R602.10.3(4) only when stone or masonry veneer exceeds the first story height. The bracing amount must be increased where the braced wall line spacing is greater than 25 feet. Note that the wind bracing requirements of Tables R602.10.3(1) and R602.10.3(2) must also be considered, although it is unlikely that the wind will control in higher seismic areas.

Braced wall panels may begin up to 10 feet (3048 mm) from the end of the braced wall line. The required minimum length of a braced wall panel used in SDC D_0 , D_1 and D_2 is 48 inches (1219 mm) with the hold-down capacity given in Table R602.10.6.5.

The intent of this bracing method is to prevent alternate braced wall panels or any method which reduces bracing length from being used for the purpose of reducing the required panel length or hold-down capacity.

**TABLE R602.10.6.5
METHOD BV-WSP WALL BRACING REQUIREMENTS**

SEISMIC DESIGN CATEGORY	STORY	BRACED WALL LINE LENGTH (FEET)					SINGLE-STORY HOLD-DOWN FORCE (pounds) ^a	CUMULATIVE HOLD-DOWN FORCE (pounds) ^b
		10	20	30	40	50		
		Minimum Total Length (feet) of Braced Wall Panels Required Along each Braced Wall Line						
D ₀		4.0	7.0	10.5	14.0	17.5	N/A	—
		4.0	7.0	10.5	14.0	17.5	1900	—
		4.5	9.0	13.5	18.0	22.5	3500	5400
		6.0	12.0	18.0	24.0	30.0	3500	8900
D ₁		4.5	9.0	13.5	18.0	22.5	2100	—
		4.5	9.0	13.5	18.0	22.5	3700	5800
		6.0	12.0	18.0	24.0	30.0	3700	9500
D ₂		5.5	11.0	16.5	22.0	27.5	2300	—
		5.5	11.0	16.5	22.0	27.5	3900	6200
		NP	NP	NP	NP	NP	N/A	N/A

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.

NP = Not Permitted.

N/A = Not Applicable.

- a. Hold-down force is minimum allowable stress design load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single-story hold-down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained.
- b. Where hold-down connectors from stories above align with stories below, use cumulative hold-down force to size middle- and bottom-story hold-down connectors.

WALL CONSTRUCTION

R602.10.7 Ends of braced wall lines with continuous sheathing. Each end of a braced wall line with continuous sheathing shall have one of the conditions shown in Figure R602.10.7.

- ❖ For continuously sheathed bracing methods, a corner as shown in Figure R602.10.7 or some other method of anchoring the wall is required at each end of the braced wall line.

For End Condition 1, a 24-inch (610 mm) corner return is required for continuously sheathed wall lines with wood structural panel in accordance with Figure R602.10.7. For wall lines with CS-SFB, the minimum corner return length is 32 inches (813 mm).

The purpose of the corner attachment for the continuously sheathed bracing methods is to connect the intersecting walls together to create a stronger, box-like structure that will perform better during high wind or seismic events. In accordance with Table R602.3(1), the corner studs require a minimum of a single row of 16d nails at 12 inches (305 mm) on center. A double row of 16d nails at 24 inches (610 mm) on

center, framing member orientation permitting, is considered equivalent. It is important to note that the intent of the nailing requirement is to provide the specified amount of nailing between the two studs, each on adjacent walls, to which the adjacent wall sheathing is attached.

An 800-pound (3560 N) hold-down device required to be attached between the stud at the edge of the braced wall panel closest to the corner and the foundation below can be used in lieu of the return corner (see End Condition 2, Figure R602.10.7). If two continuously sheathed braced wall lines meet at a corner, and the first braced panel is spaced away from the corner on one of the wall lines, then both braced wall lines lose the structural effect of the corner return; therefore, both braced wall lines must be anchored with an 800-pound (3560 N) hold-down device at the edge adjacent to the corner.

When a minimum of 4 feet (1219 mm) of braced panel is placed at a corner in a braced wall line, a corner return is not required on the perpendicular wall line (see End Condition 3, Figure R602.10.7).

(a) Braced wall panels stacked (aligned story to story). Use cumulative hold-down force.

Braced wall panels mixed stacked and not stacked. Use hold-down force as noted.

Note: Hold downs should be strap ties, tension ties, or other approved hold-down devices and shall be installed in accordance with the manufacturer's instructions.

FIGURE R602.10.6.5
METHOD BV-WSP—WALL BRACING FOR DWELLINGS WITH STONE AND MASONRY VENEER IN SEISMIC DESIGN CATEGORIES D₀, D₁ and D₂

For continuously sheathed wall panel and corner construction, the first full-height braced wall segment of the continuously sheathed braced wall line is allowed to be spaced away from the end of the braced wall line, in accordance with the exception to Section R602.10.2.2.1 and End Conditions 4 and 5, Figure R602.10.7.

Note that if two continuously sheathed wall lines meet at a corner, and along one of the two wall lines, the first bracing panel is displaced from this common corner, then both braced wall lines are denied the structural effect of the corner return. In this case, both wall lines must be anchored with an 800-pound (3560 N) hold-down device or have return panels.

- In End Condition 1 there are return panels/ braced wall panels on each side of the corner.
- In End Condition 2 there is a braced wall panel and a hold-down replacing the return panel.
- In End Condition 3, no return panel is required.
- In End Condition 4, there is a return panel and a 24 or 32 inch panel at the corner.
- In End Condition 5, there is a hold-down on the braced wall line, there is also a hold-down at the first braced wall panel on the return wall to brace that end of the wall line.

FIGURE R602.10.7. See page 6-68.

❖ See the commentary to Section R602.10.7.

R602.10.8 Braced wall panel connections. *Braced wall panels* shall be connected to floor framing or foundations as follows:

1. Where joists are perpendicular to a *braced wall panel* above or below, a rim joist, band joist or blocking shall be provided along the entire length of the *braced wall panel* in accordance with Figure R602.10.8(1). Fastening of top and bottom wall plates to framing, rim joist, band joist and/or blocking shall be in accordance with Table R602.3(1).
2. Where joists are parallel to a *braced wall panel* above or below, a rim joist, end joist or other parallel framing member shall be provided directly above and below the *braced wall panel* in accordance with Figure R602.10.8(2). Where a parallel framing member cannot be located directly above and below the panel, full-depth blocking at 16-inch (406 mm) spacing shall be provided between the parallel framing members to each side of the *braced wall panel* in accordance with Figure R602.10.8(2). Fastening of blocking and wall plates shall be in accordance with Table R602.3(1) and Figure R602.10.8(2).
3. Connections of *braced wall panels* to concrete or masonry shall be in accordance with Section R403.1.6.

❖ This section describes the code connection requirements between braced wall panels and the portions of

the structure both above and below. Without the connections required to complete the lateral load path, the purpose of wall bracing will not be realized and the structure will not be able to resist lateral loads.

Table R602.3(1) provides the basic nailing schedule for attaching braced wall panels to the floor below and the ceiling or floor above. As an example, the sole plate (or bottom plate) of the braced wall panels is required to be nailed with three 16d nails every 16 inches (406 mm) on center into the joist or blocking below the braced wall panels [see Item 16 of Table R602.3(1)].

Note that the nails do not have to be clustered every 16 inches (406 mm) on center: there just has to be three nails in every 16 inch-length (406 mm) of braced wall panel. In fact, clustering the nails may not be a good idea if, for example, they are going into a rim board. In other cases, clustering may be needed, such as an interior braced wall parallel to and situated between floor framing: clustering is necessary to attach the braced wall to the blocking.

For a braced wall panel to provide lateral load resistance to the structure, it is essential that lateral loads transfer into the panel at its top and out to the framing members below at its bottom. Correct connections are necessary to complete this lateral load path and are as shown in Figures R602.10.8(1) and R602.10.8(2).

Braced wall panel connections to foundation or floor slab must be in accordance with Section R403.1.6.

FIGURE R602.10.8(1). See page 6-69.

❖ See the commentary to Section R602.10.8.

FIGURE R602.10.8(2). See page 6-69.

❖ See the commentary to Section R602.10.8.

R602.10.8.1 Braced wall panel connections for Seismic Design Categories D₀, D₁ and D₂. *Braced wall panels* shall be fastened to required foundations in accordance with Section R602.11.1, and top plate lap splices shall be face-nailed with not less than eight 16d nails on each side of the splice.

❖ Structures in higher seismic zones need to have the capacity to withstand greater loads; therefore, additional provisions are required to ensure that these loads are transferred through the braced wall panels to the foundation. The requirements of Section R602.10.8.1 ensure the top plate lap splices and foundation connections have the needed higher load capacity.

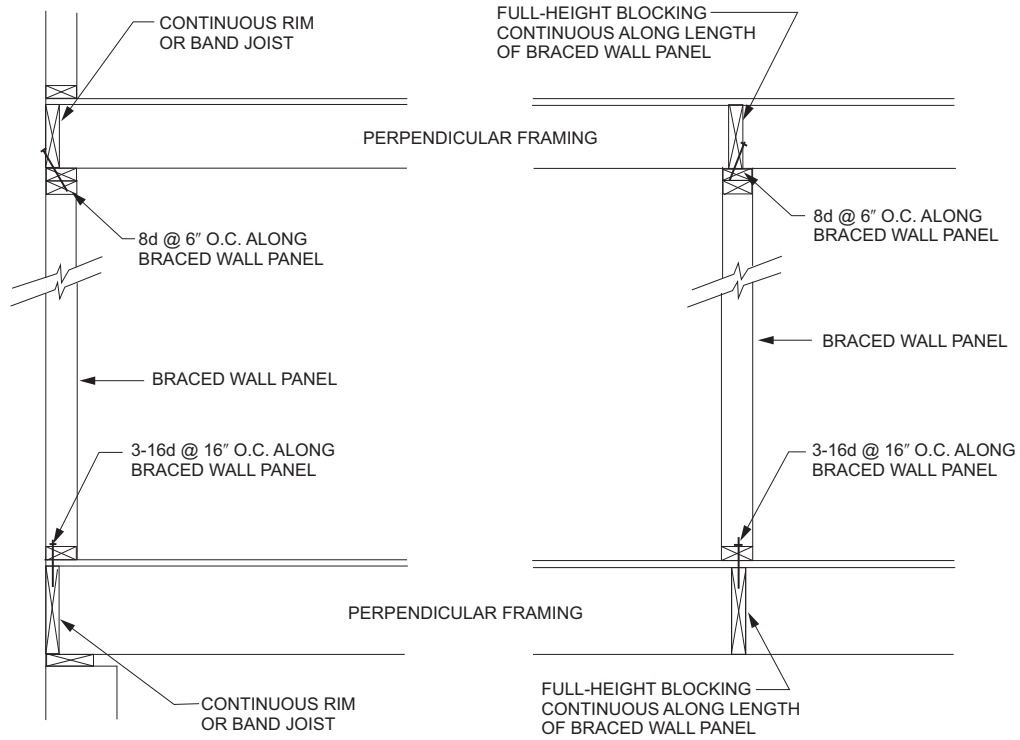

The requirement for eight 16d nails on each side of the lap splice in SDC D₀, D₁ and D₂ is reiterated in Section R602.10.8.1. Note that Table R602.3(1), Item 14, requires a 24-inch (610 mm) overlap to provide sufficient length to put in the eight 16d nails.

WALL CONSTRUCTION

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 4.45 N.

FIGURE R602.10.7
END CONDITIONS FOR BRACED WALL LINES WITH CONTINUOUS SHEATHING

For SI: 1 inch = 25.4 mm.

FIGURE R602.10.8(1)
BRACED WALL PANEL CONNECTION WHEN PERPENDICULAR TO FLOOR/CEILING FRAMING

For SI: 1 inch = 25.4 mm.

FIGURE R602.10.8(2)
BRACED WALL PANEL CONNECTION WHEN PARALLEL TO FLOOR/CEILING FRAMING

R602.10.8.2 Connections to roof framing. Top plates of exterior *braced wall panels* shall be attached to rafters or roof trusses above in accordance with Table R602.3(1) and this section. Where required by this section, blocking between rafters or roof trusses shall be attached to top plates of *braced wall panels* and to rafters and roof trusses in accordance with Table R602.3(1). A continuous band, rim or header joist or roof truss parallel to the *braced wall panels* shall be permitted to replace the blocking required by this section. Blocking shall not be required over openings in continuously sheathed *braced wall lines*. In addition to the requirements of this section, lateral support shall be provided for rafters and ceiling joists in accordance with Section R802.8 and for trusses in accordance with Section R802.10.3. Roof ventilation shall be provided in accordance with Section R806.1.

1. For Seismic Design Categories A, B and C where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is $9\frac{1}{4}$ inches (235 mm) or less, blocking between rafters or roof trusses shall not be required. Where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is between $9\frac{1}{4}$ inches (235 mm) and $15\frac{1}{4}$ inches (387 mm), blocking between rafters or roof trusses shall be provided above the braced wall panel in accordance with Figure R602.10.8.2(1).

Exception: Where the outside edge of truss vertical web members aligns with the outside face of the wall studs below, wood structural panel sheathing extending above the top plate as shown in Figure R602.10.8.2(3) shall be permitted to be fastened to each truss web with three-8d nails ($2\frac{1}{2}$ inches \times 0.131 inch) and blocking between the trusses shall not be required.

2. For Seismic Design Categories D_0 , D_1 and D_2 , where the distance from the top of the braced wall panel to the top of the rafters or roof trusses is $15\frac{1}{4}$ inches (387 mm) or less, blocking between rafters or roof trusses shall be provided above the braced wall panel in accordance with Figure R602.10.8.2(1).
3. Where the distance from the top of the braced wall panel to the top of rafters or roof trusses exceeds $15\frac{1}{4}$ inches (387 mm), the top plates of the braced wall panel shall be connected to perpendicular rafters or roof trusses above in accordance with one or more of the following methods:
 - 3.1. Soffit blocking panels constructed in accordance with Figure R602.10.8.2(2).
 - 3.2. Vertical blocking panels constructed in accordance with Figure R602.10.8.2(3).
 - 3.3. Blocking panels provided by the roof truss manufacturer and designed in accordance with Section R802.
 - 3.4. Blocking, blocking panels or other methods of lateral load transfer designed in accordance with

the AWC WFCM or accepted engineering practice.

- ❖ In the 2009 edition, new provisions were added for the connection between braced wall panels and roof framing. Although previous versions of the code did not address this connection, complex roof shapes used in modern design have necessitated prescriptive connection details to provide an effective load path.

The connection details of Section R602.10.8.2 represent a simple principle: braced wall lines extend from diaphragm to diaphragm and must be connected at both top and bottom. The roof and floor sheathing are the structural diaphragms of the building. Figures R602.10.8.2(1) through (3) illustrate the required connections and blocking between braced wall panels and roof framing, which are summarized in Commentary Figure R602.10.8.2(1).

Section R602.10.8.2, Item 1, provides what is essentially an exemption from required blocking for SDC A, B and C where the distance from the top of the rafters or roof trusses to the perpendicular top plates is 9.25 inches (235 mm) or less, provided the rafters or roof trusses are connected to the top plates of braced wall lines in accordance with Table R602.3(1).

Figure R602.10.8.2(1) illustrates the required detailing and connection for relatively low-heel trusses and rafters (less than or equal to 15.25 inches (387 mm) between the bottom of roof diaphragm sheathing and the top of double top plate). For such applications, the addition of solid lumber blocking is sufficient to prevent the trusses or conventional framing members from rolling over when subjected to wind and/or seismic loads. Attachment in accordance with Table R602.3(1), Items 1, 2 and 6—nailing at the bottom of the roof framing and blocking—is required to transfer the lateral forces (that push the roof framing along the top plate) from the roof sheathing (or diaphragm) into the braced wall line. The 2-inch (51 mm) gap at the top of the blocking permits required roof ventilation. The exception permits deleting the blocking in SDC A, B and C.

Figure R602.10.8.2(2) illustrates an alternate connection between a braced wall panel and roof sheathing (or diaphragm) that, while less direct, will provide adequate transfer of lateral forces from the roof diaphragm to the braced wall line. This detail does not provide lateral stability of the trusses at the bearing point (see truss installation diagrams) or the required roof venting. While the code permits various bracing methods for this application [see Figure R602.10.8(2), Note a], the user must be careful to specify only those methods that have sufficient weather resistance or provide a covering with an approved exterior finish. Note that the edge nailing requirement for the bracing method used at the soffit is provided in Table R602.10.4 and is not necessarily the same as the roof sheathing edge nailing, unless the same material is used for both applications.

Figure R602.10.8.2(3) illustrates a connection applicable for raised-heel trusses of up to 4 feet (1219 mm) in height. In addition to transferring the lateral load from the roof sheathing (or diaphragm) to the braced wall line, this method does address lateral stability of the trusses at the bearing point. Ventilation is provided by a gap of up to 2 inches (51 mm) at the top of braced panels between trusses. While the code permits various bracing methods for this application [see Figure R602.10.8(3), Note a], the user must be careful to specify only those methods that have sufficient weather resistance or provide a covering with an approved exterior finish. Closed soffit construction may also be used to protect bracing materials at this location. Note that the edge nailing requirement for the specific bracing method used to construct this option is provided in Table R602.10.4 and is not necessarily the same as the roof sheathing edge nailing, unless the same material is used for both applications.

R602.10.9 Braced wall panel support. *Braced wall panel support shall be provided as follows:*

1. Cantilevered floor joists complying with Section R502.3.3 shall be permitted to support *braced wall panels*.
2. Raised floor system post or pier foundations supporting *braced wall panels* shall be designed in accordance with accepted engineering practice.
3. Masonry stem walls with a length of 48 inches (1219 mm) or less supporting *braced wall panels* shall be reinforced in accordance with Figure R602.10.9. Masonry stem walls with a length greater than 48 inches (1219 mm) supporting *braced wall panels* shall

be constructed in accordance with Section R403.1 Methods ABW and PFH shall not be permitted to attach to masonry stem walls.

4. Concrete stem walls with a length of 48 inches (1219 mm) or less, greater than 12 inches (305 mm) tall and less than 6 inches (152 mm) thick shall have reinforcement sized and located in accordance with Figure R602.10.9.

❖ Section R602.10.9 contains requirements for several braced wall line special circumstances. Included are provisions for cantilevered floor joists, elevated post and pier foundations, masonry stem walls and narrow concrete stem walls.

1. Floor cantilevers. Section R502.3.3 provides the basic cantilever requirements, and Section R602.10.9 further clarifies those requirements for use with braced walls.

Section R502.3.3 restricts floor cantilevers for general use to the depth of the floor joist. Thus a 2 by 10 floor joist can cantilever out 9¹/₄ inches (235 mm) for all cases covered by the code without other considerations. Table R502.3.3(1) permits greater length cantilevers if the structure above the cantilever is limited to a single light-frame wall and roof. The length of these cantilevers can be as long as 48 inches (1219 mm) under certain circumstances. Note g of Table R502.3.3(1) requires both the blocking at the support and the continuous full-height rim board at the end of the cantilever, regardless of the basic wind speed or SDC.

2. Raised floor system post and pier foundations. Raised floor system post and pier foundations

For SI: 1 inch = 25.4 mm.

FIGURE R602.10.8.2(1)
BRACED WALL PANEL CONNECTION
TO PERPENDICULAR RAFTERS

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Methods of bracing shall be as described in Section R602.10.4.

FIGURE R602.10.8.2(2)
BRACED WALL PANEL CONNECTION OPTION TO
PERPENDICULAR RAFTERS OR ROOF TRUSSES

WALL CONSTRUCTION

generally provide little lateral support to the structure above. Lateral support instead typically comes from diagonal bracing or other elements of the foundation; however, there are ways of cantilevering the posts of the foundation by burying the ends deeply into the ground, so that they develop lateral-load-resisting characteristics.

It is difficult to accurately and fully present all of the post and pier lateral support methods in one set of prescriptive provisions. For this reason, post and pier foundations supporting braced wall panels must be engineered in accordance with the IBC or referenced documents, as stated in the Section R602.10.9, Item 2.

3. Masonry stem walls. Past field problems have made it clear that free-standing unreinforced masonry foundations adjacent to garage doors (or similar openings) may not perform well with narrow bracing options. The provisions are

intended for masonry stem walls adjacent to garage doors or similar openings.

The reinforcement details in Figure R602.10.9 are appropriate for masonry stem walls that are up to 4 feet (1219 mm) in length and not more than 4 feet (1219 mm) in height.

- If the masonry stem walls are taller than 4 feet (1219 mm), an engineered design of the reinforcement is required.
 - If the masonry stem walls are longer than 4 feet (1219 mm), this specific reinforcement is not necessary (standard construction in accordance with Section R403.1 is sufficient).
 - Masonry stem walls are not permitted to support Method ABW and PFH bracing unless specifically engineered for such applications.
4. Concrete stem walls. Narrow concrete stem walls less than 48 inches (1219 mm) in length

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Methods of bracing shall be as described in Section R602.10.4.

FIGURE R602.10.8.2(3)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES

and more than 12 inches (305 mm) tall must be reinforced using Figure R602.10.9 when supporting braced wall panels. The provisions are intended for concrete stem walls adjacent to garage doors or similar openings.

The additional reinforcement is not necessary (standard construction in accordance with Section R403.1 is sufficient) if the concrete stem walls are:

- 6 inches (152 mm) or greater in thickness.
- Less than 12 inches (305 mm) in height.
- Longer than 4 feet (1219 mm).

FIGURE R602.10.9. See page 6-74.

❖ See the commentary to Section R602.10.9.

R602.10.9.1 Braced wall panel support for Seismic Design Categories D₀, D₁ and D₂. In Seismic Design Categories D₀, D₁ and D₂, braced wall panel footings shall be as specified in Section R403.1.2.

❖ See the commentary to Section R403.1.2.

R602.10.10 Panel joints. Vertical joints of panel sheathing shall occur over, and be fastened to, common studs. Horizontal joints in *braced wall panels* shall occur over, and be fastened to, common blocking of a minimum 1½ inch (38 mm) thickness.

Exceptions:

1. Vertical joints of panel sheathing shall be permitted to occur over double studs, where adjoining panel edges are attached to separate studs with the required panel edge fastening schedule, and the adjacent studs are attached together with two rows of 10d box nails [3 inches by 0.128 inch (76.2 mm by 3.25 mm)] at 10 inches o.c. (254 mm).
2. Blocking at horizontal joints shall not be required in wall segments that are not counted as *braced wall panels*.
3. Where the bracing length provided is not less than twice the minimum length required by Tables R602.10.3(1) and R602.10.3(3), blocking at hori-

SEISMIC DESIGN CATEGORY AND WIND SPEED	DISTANCE (bottom of roof sheathing to top of top plate) [See Commentary Figure R602.10.8.2(2)]	BLOCKING ^a
SDC A, B, C	9.25" or less	Not required per Section R602.10.8.2, Item 1. Roof framing attached per Section R602.3(1)
	Greater than 9.25" to 15.25"	Required per Section R602.10.8.2, Item 1 and Figure R602.10.8.2(1)
SDC D ₀ , D ₁ , D ₂	15.25" or less	Required per Section R602.10.8.2, Item 2 and Figure R602.10.8.2(1)
All SDCs	15.25" to 48"	Required per Section R602.10.8.2(2) or Item 3 or Figures R602.10.8.2(2) or R602.10.8.2(3)

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.45 m/s.

a. Rafter or truss connection to top plate per Table R602.3(1).

Figure R602.10.8.2(1)
CONNECTION AND BLOCKING BETWEEN BRACED WALL PANELS AND ROOF FRAMING

Figure R602.10.8.2(2)
DISTANCE FROM TOP PLATE TO BOTTOM OF ROOF SHEATHING FOR PROVIDING CONNECTION REQUIREMENTS AND BLOCKING PER COMMENTARY FIGURE R602.10.8.2(1)

WALL CONSTRUCTION

zontal joints shall not be required in *braced wall panels* constructed using Methods WSP, SFB, GB, PBS or HPS.

4. Where Method GB panels are installed horizontally, blocking of horizontal joints is not required.
- ❖ Section R602.10.10 requires that all vertical and horizontal joints in panel sheathing used for bracing occur over and be attached to common framing. This is to ensure that the bracing performs as intended when subjected to lateral loads.

The requirement for vertical panel edges to be fastened to a common stud has an exception:

- The first exception in the code provision allows vertical abutting panel sheathing placed over

double studs to have each panel attached to separate studs when the studs are attached with two rows of 10d box nails spaced a maximum of 10 inches (254 mm) on center.

The requirement for horizontal joints to be blocked when they occur between the top and bottom plates has some exceptions:

- The second exception states that the horizontal joints of sheathing panels not used as braced panels do not have to be blocked. However, panel manufacturers or panel associations may recommend blocking the horizontal joints of sheathing panels regardless of whether they are used as braced panels. For example, brittle finishes (such as stucco) over panel wall sheathing

For SI: 1 inch = 25.4 mm.

FIGURE R602.10.9
MASONRY STEM WALLS SUPPORTING BRACED WALL PANELS

may require blocked horizontal panel edges to prevent cracking, even when the panels are not used for wall bracing.

- When horizontal joints of braced wall panels are not blocked, the effectiveness of the bracing is reduced and additional bracing is required. Consequently, for Methods WSP, SFB, GB, PBS and HPS, horizontal blocking of the braced wall panels may be eliminated, provided that twice the minimum required bracing length is used in the wall line. The purpose of this exception is to provide a construction alternative to installing horizontal blocking when circumstances permit.
- The required bracing length for Method GB is based on its vertical application with horizontal joints occurring over framing or blocking. Method GB bracing is considerably stronger when installed horizontally. The fourth exception permits Method GB bracing to be unblocked when it is installed horizontally.

R602.10.11 Cripple wall bracing. Cripple walls shall be constructed in accordance with Section R602.9 and braced in accordance with this section. Cripple walls shall be braced with the length and method of bracing used for the wall above in accordance with Tables R602.10.3(1) and R602.10.3(3), and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4), respectively, except that the length of cripple wall bracing shall be multiplied by a factor of 1.15. Where gypsum wall board is not used on the inside of the cripple wall bracing, the length adjustments for the elimination of the gypsum wallboard, or equivalent, shall be applied as directed in Tables R602.10.3(2) and R602.10.3(4) to the length of cripple wall bracing required. This adjustment shall be taken in addition to the 1.15 increase.

- ❖ A cripple wall is a less-than-full-height wall that is used to raise the elevation of a floor above the foundation.

Cripple walls are also often used in conjunction with a stepped foundation to maintain a common plate elevation when the foundation drops away from the plate line, accommodating a sloped building site, as shown in Figure R602.11.2. In either case, a cripple wall has the same limitations as any other stud wall in that it has no lateral load capacity without bracing.

Even though they are less than full height, cripple walls are still a part of the load path and are subject to the same vertical and horizontal loads as full-height walls. In fact, because gravity and lateral loads get larger as building height increases, cripple walls are subject to even greater loads than the walls in stories above them. Because of these greater loads, the code permits cripple walls to be braced using any method in Tables R602.10.3(1) and (3) in any SDC, as long as the length of bracing used for the cripple wall is 15 percent greater (multiplied by a factor of 1.15). The 2015 IRC has been revised to no longer require the braced wall.

R602.10.11.1 Cripple wall bracing for Seismic Design Categories D₀ and D₁ and townhouses in Seismic Design

Category C. In addition to the requirements in Section R602.10.11, the distance between adjacent edges of *braced wall panels* for cripple walls along a *braced wall line* shall be 14 feet (4267 mm) maximum.

Where *braced wall lines* at interior walls are not supported on a continuous foundation below, the adjacent parallel cripple walls, where provided, shall be braced with Method WSP or Method CS-WSP in accordance with Section R602.10.4. The length of bracing required in accordance with Table R602.10.3(3) for the cripple walls shall be multiplied by 1.5. Where the cripple walls do not have sufficient length to provide the required bracing, the spacing of panel edge fasteners shall be reduced to 4 inches (102 mm) on center and the required bracing length adjusted by 0.7. If the required length can still not be provided, the cripple wall shall be designed in accordance with accepted engineering practice.

- ❖ In SDC D₀, D₁ and townhouses in SDC C, Section R602.10.11.1 requires increased exterior cripple wall bracing when interior braced walls are not supported by a continuous foundation. (Note that this requirement is in addition to the requirements of Section R602.10.11, discussed above.) Without direct interior foundation support, these interior braced wall lines transfer the lateral forces into the floor diaphragm instead of the foundation. The floor diaphragm, in turn, transfers these lateral forces into the exterior cripple walls. Therefore, the wall bracing at the exterior cripple walls [specified in Table R602.10.3(3)] must be increased to accommodate the increased load. This is done by multiplying the length of the required exterior cripple wall bracing parallel to the unsupported interior braced wall by a factor of 1.5 and using Method WSP or CS-WSP.

If the length of wall bracing cannot be increased by a factor of 1.5 because the wall line is not long enough to accommodate the increased bracing length, the nail spacing along the perimeter wood structural panel sheathing may be reduced from 6 inches (152 mm) to 4 inches (102 mm) on center, in accordance with Section R602.10.11.1. Note that in this case it is not necessary to also increase the length of bracing by the 1.5 factor; the provision recognizes that the shear capacity of wood structural panels (Method WSP or CS-WSP) is increased sufficiently by increasing the perimeter nailing.

If there is insufficient wall line length for the required cripple wall bracing, an engineered design or other alternative bracing approved by the building official must be incorporated.

R602.10.11.2 Cripple wall bracing for Seismic Design Category D₂. In Seismic Design Category D₂, cripple walls shall be braced in accordance with Tables R602.10.3(3) and R602.10.3(4).

- ❖ Cripple wall bracing for SDC D₂ is listed in Table R602.10.3(3). Appropriate adjustment factors from Table R602.10.3(4) must also be applied. Story height is limited to two stories with a cripple wall below.

R602.10.11.3 Redesignation of cripple walls. Where all cripple wall segments along a *braced wall line* do not exceed

48 inches (1219 mm) in height, the cripple walls shall be permitted to be redesignated as a first-story wall for purposes of determining wall bracing requirements. Where any cripple wall segment in a *braced wall line* exceeds 48 inches (1219 mm) in height, the entire cripple wall shall be counted as an additional story. If the cripple walls are redesignated, the stories above the redesignated story shall be counted as the second and third stories, respectively.

❖ In all wind or seismic applications, the building designer is permitted to redesignate or redefine the cripple wall as a story, when all segments are a maximum of 48 inches (1219 mm) tall, and then use the bracing requirements of Table R602.10.3(1) or (3) without the cripple wall adjustments required by Sections R602.10.11 and R602.10.11.1. When cripple wall segments are greater than 48 inches (1219 mm) tall, the entire cripple wall must be counted as an additional story.

When redesignation is used, the cripple walls are considered the first story, while the first full-height story becomes the second story, etc. Redesignation is optional (“shall be permitted” in code language) and the builder in any SDC may choose to exercise this option.

Note that in SDC D₂, Table R602.10.3(3) only permits buildings of up to two stories, thus limiting the redesignation option to one-story buildings. With redesignation, a one story becomes a two-story, which is the maximum number of stories permitted in SDC D₂. If a two-story structure is located above a redesignated cripple wall foundation, the second story would become the third story. A three-story structure in SDC D₂ is required to be designed in accordance with the IBC.

R602.11 Wall anchorage. *Braced wall line* sills shall be anchored to concrete or masonry foundations in accordance with Sections R403.1.6 and R602.11.1.

❖ When braced wall panels are supported directly by foundations (i.e., turned-down slab edge, thickened slab, masonry or concrete foundation wall), the wood sill plate must be anchored to the foundation with anchor bolts spaced a maximum of 6 feet (1829 mm) on center. There must be a minimum of two bolts per sill plate section, with a bolt located not more than 12 inches (305 mm) and not less than 7 bolt diameters (3.5 inches) (89 mm) from each end of the plate section (see Section R403.1.6). Bolts should be at least 1/2 inch (13 mm) in diameter and should extend a minimum of 7 inches (178 mm) into the concrete or masonry foundation. A nut and washer are required on each bolt to hold the plate to the foundation.

Section R602.11 specifies how braced wall line sill plates are to be anchored to the foundation. Section R403.1.6 specifies the minimum number, size and spacing of anchor bolts.

R602.11.1 Wall anchorage for all buildings in Seismic Design Categories D₀, D₁ and D₂ and townhouses in Seismic Design Category C. Plate washers, not less than 0.229 inch by 3 inches by 3 inches (5.8 mm by 76 mm by 76 mm) in

size, shall be provided between the foundation sill plate and the nut except where *approved* anchor straps are used. The hole in the plate washer is permitted to be diagonally slotted with a width of up to 3/16 inch (5 mm) larger than the bolt diameter and a slot length not to exceed 1 3/4 inches (44 mm), provided a standard cut washer is placed between the plate washer and the nut.

❖ For one- and two-family dwellings in SDC A, B and C and townhouses in SDC A and B, braced wall lines are to be connected to the foundation with 1/2-inch (12.7 mm) bolts using a nut and washer. For higher seismic requirements (townhouses in SDC C and all structures in SDC D₀, D₁ and D₂), braced wall lines are to be connected to the foundation with 1/2-inch (12.7 mm) bolts using a 3-inch (76 mm) square plate washer and nut, in accordance with Section R602.11.1. The plate washer is permitted to have a slotted hole, which helps to locate the washer over the sill plate. If the plate washer has a slotted hole, a standard cut washer must be used between the plate washer and the nut. The slotted hole is permitted to be 3/16 inch (5 mm) wider than the bolt diameter, and the slot length is limited to a maximum of 1 3/4 inches (44 mm).

Section R602.11.1 also permits the use of “approved anchor straps” in lieu of anchor bolts, washers and nuts.

The following provisions are required in Section R602.11.1, in addition to the requirements for SDC A, B and C as previously described:

- For all buildings in SDC D₀, D₁ and D₂ and townhouses in SDC C, the plate washers are required to be 0.229 inch by 3 inches by 3 inches (5.8 mm by 76 mm by 76 mm) between the nut and the sill plate except where approved anchor straps are used.
- The use of a diagonally slotted plate washer is permitted. The slot width is required to be equal to or less than 3/16 inch (5 mm) larger than the bolt diameter and not more than 1 3/4 inches (44 mm) long. When a slotted plate washer is used, a standard cut washer must be used between the nut and plate washer.

R602.11.2 Stepped foundations in Seismic Design Categories D₀, D₁ and D₂. In all buildings located in Seismic Design Categories D₀, D₁ or D₂, where the height of a required *braced wall line* that extends from foundation to floor above varies more than 4 feet (1219 mm), the *braced wall line* shall be constructed in accordance with the following:

1. Where the lowest floor framing rests directly on a sill bolted to a foundation not less than 8 feet (2440 mm) in length along a line of bracing, the line shall be considered as braced. The double plate of the cripple stud wall beyond the segment of footing that extends to the lowest framed floor shall be spliced by extending the upper top plate not less than 4 feet (1219 mm) along the foundation. Anchor bolts shall be located not more than 1 foot and 3 feet (305 and 914 mm) from the step in the foundation. See Figure R602.11.2.

2. Where cripple walls occur between the top of the foundation and the lowest floor framing, the bracing requirements of Sections R602.10.11, R602.10.11.1 and R602.10.11.2 shall apply.
 3. Where only the bottom of the foundation is stepped and the lowest floor framing rests directly on a sill bolted to the foundations, the requirements of Sections R403.1.6 and R602.11.1 shall apply.
- ❖ When a cripple wall in SDC, D₀, D₁ and D₂ is used in a stepped foundation with a vertical step exceeding 4 feet (1219 mm), the cripple wall must be constructed as follows:

Section R602.11.2, Item 1, contains multiple requirements:

- If 8 feet (2438 mm) or more of the lowest floor is anchored directly to the foundation (the cripple wall does not run under this 8-foot (2438 mm) portion of the wall line) as shown in Commentary Figure R602.11.2(1), the foundation provides complete bracing for the cripple wall, as long as the wall above is not longer than 25 feet (7620 mm). In order to gain this benefit, the cripple wall top plate must extend over the foundation at least 4 feet (1219 mm) and be anchored with at least two bolts, as shown in Commentary Figure R602.11.2(1). Note that the first story wall must be braced in accordance with the requirements of Tables R602.10.3(1) and (3). The intent of the code provision is that, if the first story wall is anchored directly to the foundation for at least 8 feet (2438 mm) and the cripple wall top plate is extended and spliced as directed, then the first story braced wall line is sufficiently attached to the foundation to complete the load

path and no additional bracing is required.

As shown in Figure R602.11.2, a metal tie can be used as an alternative to the cripple wall top plate's 4-foot (1219 mm) overlap of the foundation, if distance "A" is greater than 8 feet (2438 mm). No additional wall bracing is required in the cripple wall if the splice is properly made.

When the distance "A" is less than 8 feet (2438 mm) in a 25-foot-long (7620 mm) wall, there is insufficient attachment directly into the foundation to complete the lateral load path for the first-story braced wall line. As such, the total required length of bracing must be applied to the cripple wall end of the wall line for it to be considered braced. In this event, neither the metal splice plate nor the overlapping upper top plate is required, although either would be considered good practice.

FIGURE R602.11.2. See below.

❖ See the commentary to Section R602.11.2.

R602.12 Simplified wall bracing. Buildings meeting all of the conditions listed below shall be permitted to be braced in accordance with this section as an alternate to the requirements of Section R602.10. The entire building shall be braced in accordance with this section; the use of other bracing provisions of Section R602.10, except as specified herein, shall not be permitted.

1. There shall be not more than three stories above the top of a concrete or masonry foundation or basement wall. Permanent wood foundations shall not be permitted.
2. Floors shall not cantilever more than 24 inches (607 mm) beyond the foundation or bearing wall below.
3. Wall height shall not be greater than 10 feet (3048 mm).

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Note: Where footing Section "A" is less than 8 feet long in a 25-foot-long wall, install bracing at cripple stud wall.

FIGURE R602.11.2
STEPPED FOUNDATION CONSTRUCTION

WALL CONSTRUCTION

4. The building shall have a roof eave-to-ridge height of 15 feet (4572 mm) or less.
 5. Exterior walls shall have gypsum board with a minimum thickness of $\frac{1}{2}$ inch (12.7 mm) installed on the interior side fastened in accordance with Table R702.3.5.
 6. The structure shall be located where the ultimate design wind speed is less than or equal to 130 mph (58 m/s), and the exposure category is B or C.
 7. The structure shall be located in Seismic Design Category A, B or C for detached one- and two-family dwellings or Seismic Design Category A or B for townhouses.
 8. Cripple walls shall not be permitted in three-story buildings.
- ❖ Section R602.12 provides a prescriptive procedure for bracing wall lines in detached one- or two-family dwellings and townhouses with the following limits:
- Seismic Design Category A, B, or C for detached one- or two-family dwellings, SDC A or B for townhouses.
 - Basic wind speeds of 130 mph (58 m/s) or less with Wind Exposure Category B or C.
 - One-, two- or three-story structure.
 - Wood structural panel or structural fiberboard sheathing is used on exterior walls with gypsum board fastened to the interior side.

When the requirements above are met, using the simplified method removes the need to check provisions for high seismic areas, to determine braced wall lines or braced wall line spacing.

A braced wall panel and its minimum length is a "bracing unit." The minimum number of bracing units is determined by drawing a rectangle around the building and then using the rectangle's dimensions to select the total bracing from Table R602.12.4.

Bracing units are required to be placed per the distribution requirements in Section R602.12.4 rather than along braced wall lines. When homes do not qualify or if the builder prefers, the traditional approach in Section R602.10 must be used.

See Section R602.10 for an explanation of lateral loads and the purpose of wall bracing. Failure of a braced wall line is evidenced by racking of the wall line. Racking occurs when a rectangular wall deforms to a parallelogram shape, in which the top and the bottom of the wall remain horizontal but the sides are no longer vertical. The purpose of wall bracing is to prevent such failures.

R602.12.1 Circumscribed rectangle. The bracing required for each building shall be determined by circumscribing a rectangle around the entire building on each floor as shown in Figure R602.12.1. The rectangle shall surround all enclosed offsets and projections such as sunrooms and attached garages. Open structures, such as carports and decks, shall be permitted to be excluded. The rectangle shall not have a side greater than 60 feet (18 288 mm), and the ratio between the long side and short side shall be not greater than 3:1.

- ❖ Required bracing length in the simplified wall bracing method is determined by drawing a rectangle around the building. Once the rectangle is drawn, all measurements for bracing are done down the length of the sides of the rectangle, not the length of the walls of the building.

Placement of braced wall lines is not necessary for

this procedure. Rather, the drawing of the rectangle determines an equivalent “braced wall line.” Note, this procedure is conservative as it assumes a rectangle side length equal to or greater than the building wall line length.

Once the rectangle is drawn, the longer side will be referred to in the provisions as the “long side.” The shorter side will be referred to as the “short side.” If the rectangle’s sides are equal in length, assign one side the label “short side” and the perpendicular walls the label “long side.”

FIGURE R602.12.1. See below.

❖ See the commentary to Section R602.12.1.

R602.12.2 Sheathing materials. The following sheathing materials installed on the exterior side of exterior walls shall be used to construct a bracing unit as defined in Section R602.12.3. Mixing materials is prohibited.

1. Wood structural panels with a minimum thickness of $\frac{3}{8}$ inch (9.5 mm) fastened in accordance with Table R602.3(3).
2. Structural fiberboard sheathing with a minimum thickness of $\frac{1}{2}$ inch (12.7 mm) fastened in accordance with Table R602.3(1).

❖ For the simplified wall bracing procedure, only wood structural panels and structural fiberboard sheathing may be used to brace the exterior walls. All exterior walls must have minimum $\frac{1}{2}$ -inch (13 mm) gypsum board on the interior side of the walls fastened in accordance with Table R702.3.5.

When using wood structural panels, narrow bracing panels may be substituted for bracing units as permitted by Section R602.12.6.

R602.12.3 Bracing unit. A bracing unit shall be a full-height sheathed segment of the exterior wall without open-

ings or vertical or horizontal offsets and a minimum length as specified herein. Interior walls shall not contribute toward the amount of required bracing. Mixing of Items 1 and 2 is prohibited on the same story.

1. Where all framed portions of all exterior walls are sheathed in accordance with Section R602.12.2, including wall areas between bracing units, above and below openings and on gable end walls, the minimum length of a bracing unit shall be 3 feet (914 mm).
2. Where the exterior walls are braced with sheathing panels in accordance with Section R602.12.2 and areas between bracing units are covered with other materials, the minimum length of a bracing unit shall be 4 feet (1219 mm).

❖ Bracing units are full-height sheathed wall segments similar to braced wall panels from Section R602.10. When buildings are continuously sheathed—sheathed over all wall areas—the minimum length of a braced unit is 3 feet (914 mm). When the bracing units are intermittent-placed along wall sections with other materials sheathing in between the bracing units—the minimum length of a braced unit is 4 feet (1219 mm).

Continuous and intermittent bracing units may be mixed from one story to another. For example, there may be intermittent sheathing on the top story and continuous sheathing on the bottom story of a building. Bracing unit methods may not be mixed within one story.

Mixing of wood structural panel and structural fiberboard sheathing in one building is not permitted in accordance with Section R602.12.2.

Commentary Figure R602.12.3 contains the two materials available and the requirements for each material and bracing unit length.

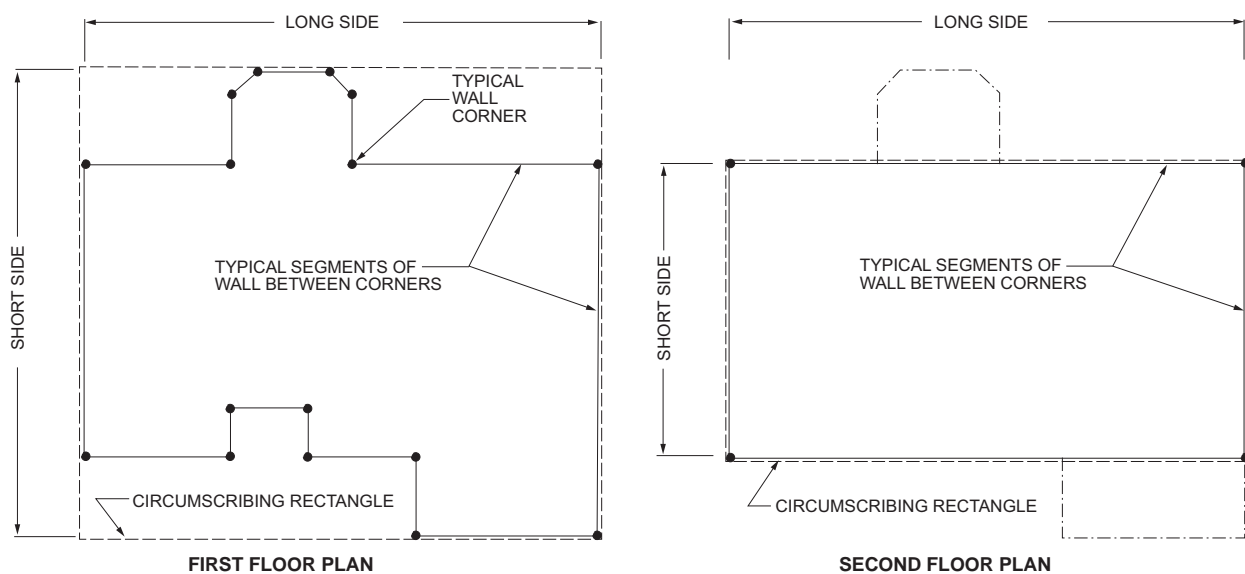

FIGURE R602.12.1
RECTANGLE CIRCUMSCRIBING AN ENCLOSED BUILDING

MATERIAL	STUD SPACING AND FASTENER CRITERIA	FASTENER SPACING CRITERIA	BRACING UNIT METHOD	MINIMUM BRACING UNIT LENGTH (feet)
Wood structural panel	Table R602.3(3)	6" edge, 12" field	Continuous	3
			Intermittent	4
Structural fiberboard sheathing	Maximum 16" spacing Table R602.3(1)	3" edge, 6" field	Continuous	3
			Intermittent	4

Figure R602.12.3
AVAILABLE BRACING METHODS FOR SIMPLIFIED WALL BRACING

R602.12.3.1 Multiple bracing units. Segments of wall compliant with Section R602.12.3 and longer than the minimum bracing unit length shall be considered as multiple bracing units. The number of bracing units shall be determined by dividing the wall segment length by the minimum bracing unit length. Full-height sheathed segments of wall narrower than the minimum bracing unit length shall not contribute toward a bracing unit except as specified in Section R602.12.6.

❖ When bracing units are longer than the minimum required length, the total length of bracing along one side of a rectangle may be added and divided by the minimum required bracing length to calculate the number of braced units on one side of the rectangle.

For example, a building has been intermittently braced with wood structural panel. There are three sections of bracing, 8, 9, and 6 feet (2438, 3048, and 1829 mm) long. Divide each wall segment length by 4 feet (1219 mm) (the minimum bracing unit length) and add the total number of bracing units together.

$$8 \text{ ft}/4 \text{ ft} + 9 \text{ ft}/4 \text{ ft} + 6 \text{ ft}/4 \text{ ft} = 2 + 2.25 + 1.5 = 5.75 \text{ full bracing units}$$

The wall line has an equivalent 5.75 bracing units. Use Section R602.12.4 to determine if that is a sufficient number of bracing units for the side of the rectangle.

R602.12.4 Number of bracing units. Each side of the circumscribed rectangle, as shown in Figure R602.12.1, shall have, at a minimum, the number of bracing units in accordance with Table R602.12.4 placed on the parallel exterior walls facing the side of the rectangle. Bracing units shall then be placed using the distribution requirements specified in Section R602.12.5.

❖ Section R602.12.4 defines the required number of bracing units for each side of the rectangle drawn around the building. Note the minimum number of bracing units for one side of the rectangle is based on the length of the perpendicular side of the rectangle. For example, to determine the number of bracing units required on the long sides of the rectangle, use the length of the short side of the rectangle.

Interpolation between rectangle side lengths is not permitted. Take the length of one side of the rectangle and round it up to the nearest 10 feet (3048 mm) of length. For example, if the side of a rectangle is 23 feet

(7010 mm), use the 30-foot (9144 mm) column in Table R602.12.4 to find the required number of bracing units.

Cripple walls are assumed to be the first story when using Table R602.12.4. Three-story buildings above a cripple wall are not permitted. If the building has three stories and a cripple wall, it is a 4-story building and outside the scope of the code.

TABLE R602.12.4. See page 6-81.

❖ See the commentary to Section R602.12.4.

R602.12.5 Distribution of bracing units. The placement of bracing units on exterior walls shall meet all of the following requirements as shown in Figure R602.12.5.

1. A bracing unit shall begin not more than 12 feet (3658 mm) from any wall corner.
2. The distance between adjacent edges of bracing units shall be not greater than 20 feet (6096 mm).
3. Segments of wall greater than 8 feet (2438 mm) in length shall have not less than one bracing unit.

❖ Bracing units shall be placed so that the first unit's edge begins within 12 feet (3658 mm) of each end of a wall line. The bracing unit edges shall be a maximum of 20 feet (6096 mm) apart. All segments of wall longer than 8 feet (2438 mm) shall have one or more bracing units.

FIGURE R602.12.5. See page 6-82.

❖ See the commentary to Section R602.12.5.

R602.12.6 Narrow panels. The bracing methods referenced in Section R602.10 and specified in Sections R602.12.6.1 through R602.12.6.3 shall be permitted when using simplified wall bracing.

❖ See Section R602.10.6 for commentary on narrow braced wall panels.

R602.12.6.1 Method CS-G. *Braced wall panels* constructed as Method CS-G in accordance with Tables R602.10.4 and R602.10.5 shall be permitted for one-story garages where all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-G panel shall be equivalent to 0.5 of a bracing unit. Segments of wall that include a Method CS-G panel shall meet the requirements of Section R602.10.4.2.

❖ See Section R602.10.4 for commentary on Method CS-G.

R602.12.6.2 Method CS-PF. Braced wall panels constructed as Method CS-PF in accordance with Section R602.10.6.4 shall be permitted where all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-PF panel shall equal 0.75 bracing units. Not more than four CS-PF panels shall be permitted on all segments of walls parallel to each side of the circumscribed rectangle. Segments of wall

that include a Method CS-PF panel shall meet the requirements of Section R602.10.4.2.

❖ See Sections R602.10.4 and R602.10.6.4 for commentary on Method CS-PF.

R602.12.6.3 Methods ABW, PFH and PFG. Braced wall panels constructed as Method ABW, PFH and PFG shall be permitted where bracing units are constructed using wood

TABLE R602.12.4
MINIMUM NUMBER OF BRACING UNITS ON EACH SIDE OF THE CIRCUMSCRIBED RECTANGLE

ULTIMATE DESIGN WIND SPEED (mph)	STORY LEVEL	EAVE-TO-RIDGE HEIGHT (feet)	MINIMUM NUMBER OF BRACING UNITS ON EACH LONG SIDE ^{a, b, d}						MINIMUM NUMBER OF BRACING UNITS ON EACH SHORT SIDE ^{a, b, d}

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

- a. Interpolation shall not be permitted.
- b. Cripple walls or wood-framed basement walls in a walk-out condition shall be designated as the first story and the stories above shall be redesignated as the second and third stories, respectively, and shall be prohibited in a three-story structure.
- c. Actual lengths of the sides of the circumscribed rectangle shall be rounded to the next highest unit of 10 when using this table.
- d. For Exposure Category C, multiply bracing units by a factor of 1.20 for a one-story building, 1.30 for a two-story building and 1.40 for a three-story building.

WALL CONSTRUCTION

structural panels applied either continuously or intermittently. Each ABW and PFH panel shall equal one bracing unit and each PFG panel shall be equal to 0.75 bracing unit.

- ❖ See Sections R602.10.4 and R602.10.6.1 for commentary on Method ABW. See Sections R602.10.4 and R602.10.6.2 for commentary on Method PFH. See Sections R602.10.4 and R602.10.6.3 for commentary on Method PFG.

R602.12.7 Lateral support. For bracing units located along the eaves, the vertical distance from the outside edge of the top wall plate to the roof sheathing above shall not exceed 9.25 inches (235 mm) at the location of a bracing unit unless lateral support is provided in accordance with Section R602.10.8.2.

- ❖ See Section R602.10.8.2 for commentary on required lateral support above braced wall panels and bracing units at the roof.

R602.12.8 Stem walls. Masonry stem walls with a height and length of 48 inches (1219 mm) or less supporting a bracing unit or a Method CS-G, CS-PF or PFG *braced wall panel* shall be constructed in accordance with Figure R602.10.9. Concrete stem walls with a length of 48 inches (1219 mm) or less, greater than 12 inches (305 mm) tall and less than 6 inches (152 mm) thick shall be reinforced sized and located in accordance with Figure R602.10.9.

- ❖ See Section R602.10.9, Items 3 and 4 for commentary on required reinforcement of stem walls less than 48 inches (1219 mm) in length. Method PFH is not permitted on masonry stem walls.

SECTION R603 COLD-FORMED STEEL WALL FRAMING

R603.1 General. Elements shall be straight and free of any defects that would significantly affect structural performance. Cold-formed steel wall framing members shall be in accordance with the requirements of this section.

- ❖ The provisions of this section apply to the construction of load-bearing wall systems using cold-formed steel framing, which is that type of construction made up in part or entirely of steel structural members cold-

formed to shape from sheet or strip steel. The framing members are generally in the form of the letter “C” (C-shape), which is described in further detail in Section R603.2.3. The use of cold-formed steel-framed designs not consistent with these provisions is beyond the scope of the code. In such cases, an analysis and design by a design professional is required.

R603.1.1 Applicability limits. The provisions of this section shall control the construction of exterior cold-formed steel wall framing and interior load-bearing cold-formed steel wall framing for buildings not more than 60 feet (18 288 mm) long perpendicular to the joist or truss span, not more than 40 feet (12 192 mm) wide parallel to the joist or truss span, and less than or equal to three stories above grade plane. Exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Cold-formed steel walls constructed in accordance with the provisions of this section shall be limited to sites where the ultimate design wind speed is less than 139 miles per hour (62 m/s), Exposure Category B or C, and the ground snow load is less than or equal to 70 pounds per square foot (3.35 kPa).

- ❖ See the commentary to Section R505.1.1.

R603.1.2 In-line framing. Load-bearing cold-formed steel studs constructed in accordance with Section R603 shall be located in-line with joists, trusses and rafters in accordance with Figure R603.1.2 and the tolerances specified as follows:

1. The maximum tolerance shall be $\frac{3}{4}$ inch (19 mm) between the centerline of the horizontal framing member and the centerline of the vertical framing member.
2. Where the centerline of the horizontal framing member and bearing stiffener is located to one side of the centerline of the vertical framing member, the maximum tolerance shall be $\frac{1}{8}$ inch (3 mm) between the web of the horizontal framing member and the edge of the vertical framing member.

- ❖ In-line framing is the preferred framing method. The advantage is that it provides a direct load path for the transfer of forces from joists to studs. The $\frac{3}{4}$ -inch (19 mm) tolerance in Item 1 is accepted industry practice, and addresses those conditions where two framing members (roof rafter and ceiling joist, for example) are

For SI: 1 foot = 304.8 mm.

**FIGURE R602.12.5
BRACING UNIT DISTRIBUTION**

to be aligned over a wall stud. The case of a bearing stiffener located on the back side of the horizontal member where the centerlines of both are to one side of the stud centerline must meet the additional limit in Item 2, as Figure R603.1.2 illustrates.

In-line framing maximizes framing alignment to minimize secondary moments on the framing members, taking into account that the prescriptive track requirements do not consider it to be a load transfer member. In the absence of in-line framing within these tolerances, a load distribution member, such as a structural track, may be required for this force transfer.

R603.2 Structural framing. Load-bearing cold-formed steel wall framing members shall be in accordance with this section.

- ❖ Stud framing must comply with the dimensional and minimum thickness requirements specified in Table R603.2.3 and as shown in Figure R603.2.3(1). Note a to Table R603.2.3 explains the meaning of the alphanumeric member designation used for all steel framing members in the code. This system replaces the varied designation approaches that had been produced by each individual manufacturer. In addition, the designation is used to identify not only a specific steel framing member but also the section properties of that same member through the use of the product technical information document.

Steel thickness is expressed in mils, which pertains to the base metal thickness measured prior to painting or the application of metallic (corrosion resistant) coatings. The base metal thickness is typically stamped or

embossed on the member by the manufacturer. Table R603.2.3 also references the equivalent thickness in inches. The use of gage numbers to define the thickness (a specific mean decimal thickness for which rolling tolerances were established) of steel sheet is a practice that has been discontinued by the steel industry.

Steel track sections are to serve in nonload-bearing applications only and are shown in Figure R603.2.3(2). They must have a minimum flange width of 1 1/4 inches (32 mm).

R603.2.1 Material. Load-bearing cold-formed steel framing members shall be cold formed to shape from structural-quality sheet steel complying with the requirements of ASTM A1003: Structural Grades 33 Type H and 50 Type H.

- ❖ Load-bearing steel framing members must be cold-formed to shape from structural-quality sheet applicable material standards. The steel grades specified have the ductility and strength to meet the intent of these provisions.

R603.2.2 Corrosion protection. Load-bearing cold-formed steel framing shall have a metallic coating complying with ASTM A1003 and one of the following:

1. A minimum of G 60 in accordance with ASTM A653.
2. A minimum of AZ 50 in accordance with ASTM A792.

- ❖ The metallic coatings specified correspond to requirements in the referenced material standards. The minimum coating designations assume normal exposure

For SI: 1 inch = 25.4 mm.

FIGURE R603.1.2
IN-LINE FRAMING

WALL CONSTRUCTION

conditions that are best defined as having the framing members enclosed within a building envelope or wall assembly within a controlled environment. While not common under the code when more severe exposure conditions are encountered, consideration should be given to specifying a heavier coating.

R603.2.3 Dimension, thickness and material grade. Load-bearing cold-formed steel wall framing members shall comply with Figure R603.2.3(1) and with the dimensional and thickness requirements specified in Table R603.2.3. Additionally, C-shaped sections shall have a minimum flange width of $1\frac{5}{8}$ inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be $\frac{1}{2}$ inch (12.7 mm). Track sections shall comply with Figure R603.2.3(2) and shall have a minimum flange width of $1\frac{1}{4}$ inches (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified.

❖ See the commentary to Section R603.2.

FIGURE R602.2.3(1). See below.

❖ See the commentary to Section R603.2.

FIGURE R602.2.3(2). See next column.

❖ See the commentary to Section R603.2.

**FIGURE R603.2.3(1)
C-SHAPED SECTION**

**FIGURE R603.2.3(2)
TRACK SECTION**

**TABLE R603.2.3
LOAD-BEARING COLD-FORMED STEEL STUD SIZES AND THICKNESSES**

MEMBER DESIGNATION ^a	WEB DEPTH (inches)	MINIMUM BASE STEEL THICKNESS mil (inches)
350S162-t	3.5	33 (0.0329), 43 (0.0428), 54 (0.0538)
550S162-t	5.5	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)

For SI: 1 inch = 25.4 mm; 1 mil = 0.0254 mm.

a. The member designation is defined by the first number representing the member depth in hundredths of an inch, "S" representing a stud or joist member, the second number representing the flange width in hundredths of an inch, and the letter "t" shall be a number representing the minimum base metal thickness in mils.

R603.2.4 Identification. Load-bearing cold-formed steel framing members shall have a legible label, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer's identification.
2. Minimum base steel thickness in inches (mm).
3. Minimum coating designation.
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

❖ Load-bearing steel framing identification provides verification that materials installed are consistent with the design and meet the intent of the code.

R603.2.5 Fastening. Screws for steel-to-steel connections shall be installed with a minimum edge distance and center-to-center spacing of $\frac{1}{2}$ inch (12.7 mm), shall be self-drilling tapping and shall conform to ASTM C1513. Structural sheathing shall be attached to cold-formed steel studs with minimum No. 8 self-drilling tapping screws that conform to ASTM C1513. Screws for attaching structural sheathing to cold-formed steel wall framing shall have a minimum head diameter of 0.292 inch (7.4 mm) with countersunk heads and shall be installed with a minimum edge distance of $\frac{3}{8}$ inch (9.5 mm). Gypsum board shall be attached to cold-formed steel wall framing with minimum No. 6 screws conforming to ASTM C954 or ASTM C1513 with a bugle-head style and

shall be installed in accordance with Section R702. For connections, screws shall extend through the steel a minimum of three exposed threads. Fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

❖ Fasteners meeting the referenced standards and installed in accordance with this section will provide a load capacity consistent with these prescriptive provisions.

R603.2.6 Web holes, web hole reinforcing and web hole patching. Web holes, web hole reinforcing and web hole patching shall be in accordance with this section.

❖ To allow for routing utilities, web holes (also referred to as “penetrations,” “utility holes” and “punchouts”) are permitted in the webs of studs. To avoid adversely affecting the strength of wall framing, web holes must meet the limits of Section R603.2.6.1.

R603.2.6.1 Web holes. Web holes in wall studs and other structural members shall comply with all of the following conditions:

1. Holes shall conform to Figure R603.2.6.1.
2. Holes shall be permitted only along the centerline of the web of the framing member.
3. Holes shall have a center-to-center spacing of not less than 24 inches (610 mm).
4. Holes shall have a web hole width not greater than 0.5 times the member depth, or 1½ inches (38 mm).
5. Holes shall have a web hole length not exceeding 4½ inches (114 mm).
6. Holes shall have a minimum distance between the edge of the bearing surface and the edge of the web hole of not less than 10 inches (254 mm).

Framing members with web holes not conforming to the above requirements shall be reinforced in accordance with

For SI: 1 inch = 25.4 mm.

**FIGURE R603.2.6.1
WALL STUD WEB HOLES**

Section R603.2.6.2, patched in accordance with Section R603.2.6.3 or designed in accordance with accepted engineering practice.

❖ Web holes are limited in size as well as to the locations along the centerline of the web of the framing member as illustrated in Figure R603.2.6.1. Otherwise, reinforcement or patching of the web hole is required.

R603.2.6.2 Web hole reinforcing. Web holes in gable end-wall studs not conforming to the requirements of Section R603.2.6.1 shall be permitted to be reinforced if the hole is located fully within the center 40 percent of the span and the depth and length of the hole does not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shape section with a hole that does not exceed the web hole size limitations of Section R603.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of ½ inch (12.7 mm).

❖ Web holes in gable endwall studs that do not meet the limitations stated in Section R603.2.6.1 may be reinforced in accordance with this section. It permits utility installations as long as the reinforcement is installed in accordance with this section and the finished opening meets the limits of Section R603.2.6.1.

R603.2.6.3 Hole patching. Web holes in wall studs and other structural members not conforming to the requirements in Section R603.2.6.1 shall be permitted to be patched in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practice where web holes exceed the following size limits:

- 1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.
- 1.2. The length of the hole measured along the web exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R603.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R603.2.6.3. The steel patch shall, as a minimum, be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25 mm) center-to-center along the edges of the patch with a minimum edge distance of ½ inch (12.7 mm).

❖ Where web holes exceed the limits of Section R603.2.6.1 but are not greater than the size limits of Item 1 in this section, they may be patched as illustrated in Figure R603.2.6.3. Otherwise the patch must be designed or the framing member should be replaced.

WALL CONSTRUCTION

For SI: 1 inch = 25.4 mm.

FIGURE R603.2.6.3
WALL STUD WEB HOLE PATCH

R603.3 Wall construction. Exterior cold-formed steel framed walls and interior load-bearing cold-formed steel framed walls shall be constructed in accordance with the provisions of this section.

❖ The balance of this section consists of the prescriptive design provisions for steel-framed walls.

R603.3.1 Wall to foundation or floor connection. Cold-formed steel framed walls shall be anchored to foundations or floors in accordance with Table R603.3.1 and Figure R603.3.1(1), R603.3.1(2), R603.3.1(3) or R603.3.1(4). Anchor bolts shall be located not more than 12 inches (305 mm) from corners or the termination of bottom tracks. Anchor bolts shall extend not less than 15 inches (381 mm) into masonry or 7 inches (178 mm) into concrete. Foundation anchor straps shall be permitted, in lieu of anchor bolts, if spaced as required to provide equivalent anchorage to the required anchor bolts and installed in accordance with manufacturer's requirements.

❖ The bottom tracks of cold-formed steel walls should be attached to the floor as illustrated in Figure R603.3.1(1) and in accordance with Table R603.3.1. Steel-framed walls anchored directly to foundations must be in accordance with Figure R603.3.1(2) with $\frac{1}{2}$ -inch diameter (12.7 mm) anchor bolts spaced as required by Table R603.3.1 based on the wind speed and the exposure category. Wall tracks connected to wood sills must be in accordance with Figure R603.3.1(3) and Table R603.3.1. Table R603.3.1 has been revised to include wind uplift connector strength and new Figure R603.3.1(4). This revision aligns the code with AISI S230-07 wind uplift connector requirements.

TABLE 603.3.1. See page 6-87.

❖ This table specifies connections for wall tracks, which will provide appropriate load capacity based on the basic wind speed and exposure category.

FIGURE R603.3.1(1). See page 6-88.

❖ This connection detail depicts the item on the first line of Table R603.3.1.

FIGURE R603.3.1(2). See page 6-88.

❖ This connection detail depicts the item on the second line of Table R603.3.1.

FIGURE R603.3.1(3). See page 6-89.

❖ This connection detail illustrates the item on the third line of Table R603.3.1.

R603.3.1.1 Gable endwalls. Gable endwalls with heights greater than 10 feet (3048 mm) shall be anchored to foundations or floors in accordance with Table R603.3.1.1(1) or R603.3.1.1(2).

❖ The connection requirements for gable endwalls that are more than 10 feet (3048 mm) in height are tabulated in Tables R603.3.1.1(1) and R603.3.1.1(2) for floors and foundations, respectively. Gable endwalls up to 10 feet (3048 mm) in height are permitted to be connected in accordance with Section R603.3.1.

TABLE R603.3.1.1(1). See page 6-90.

❖ This table specifies requirements for connecting wall tracks of gable endwalls to floors in order to provide appropriate load capacity based on the stud height as well as the basic wind speed and exposure category. Design is required for basic wind speeds exceeding 139 mph (62 m/s) in accordance with the general applicability limits of Section R603.1.1.

TABLE R603.3.1.1(2). See page 6-90.

❖ This table specifies requirements for connecting wall tracks of gable endwalls to foundations in order to provide appropriate load capacity based on the stud height as well as the basic wind speed and exposure category. Design is required for basic wind speeds exceeding 139 mph (62 m/s) in accordance with the general applicability limits of Section R603.1.1.

R603.3.2 Minimum stud sizes. Cold-formed steel walls shall be constructed in accordance with Figure R603.3.1(1), R603.3.1(2) or R603.3.1(3), as applicable. Exterior wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(16). Interior load-bearing wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(16) based upon an ultimate design wind speed of 115 miles per hour (51 m/s), Exposure Category B, and the building width, stud spacing and snow load, as appropriate. Fastening requirements shall be in accordance with Section R603.2.5 and Table R603.3.2(1). Top and bottom tracks shall have the same minimum thickness as the wall studs.

Exterior wall studs shall be permitted to be reduced to the next thinner size, as shown in Tables R603.3.2(2) through R603.3.2(16), but not less than 33 mils (0.84 mm), where both of the following conditions exist:

1. Minimum of $\frac{1}{2}$ -inch (12.7 mm) gypsum board is installed and fastened on the interior surface in accordance with Section R702.
2. Wood structural sheathing panels of minimum $\frac{7}{16}$ -inch-thick (11.1 mm) oriented strand board or $\frac{15}{32}$ -inch-thick (12 mm) plywood are installed and fastened

in accordance with Section R603.9.1 and Table R603.3.2(1) on the outside surface.

Interior load-bearing walls shall be permitted to be reduced to the next thinner size, as shown in Tables R603.3.2(2) through R603.3.2(16), but not less than 33 mils (0.84 mm), where not less than 1/2-inch (12.7 mm) gypsum board is installed and fastened in accordance with Section R702 on both sides of the wall. The tabulated stud thickness for load-bearing walls shall be used when the attic load is 10 pounds per square foot (480 Pa) or less. A limited attic storage load of 20 pounds per square foot (960 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(2) through R603.3.2(16).

For two-story buildings, the tabulated stud thickness for walls supporting one floor, roof and ceiling shall be used when the second-floor live load is 30 pounds per square foot (1440 Pa). Second-floor live loads of 40 psf (1920 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(2) through R603.3.2(11).

For three-story buildings, the tabulated stud thickness for walls supporting one or two floors, roof and ceiling shall be used when the third-floor live load is 30 pounds per square foot (1440 Pa). Third-floor live loads of 40 pounds per square foot (1920 Pa) shall be permitted provided that the next higher snow load column is used to select the stud size from Tables R603.3.2(12) through R603.3.2(16).

❖ Steel studs must comply with Tables R603.3.2(2) through R603.3.2(16). These tables specify the minimum steel stud thickness based on floor/ceilings supported, wall height, wind speed/exposure, ground snow load, building width and stud depth and spacing. These tables have been revised to combine Grade 33 ksi and 50 ksi tables into one table. This resulted in a reduction in the number of tables from 30 to 15. For tabulated thicknesses of 33 and 43 mil, Grade 33 ksi steel is to be used. For tabulated thicknesses of 54 and 68 mil, Grade 50 ksi steel is to be used. Also, 97 mil thickness has been deleted from the tables. Although the tabular values are calculated based on attic live loads of 10 psf (479 Pa) or less, values for attic live

TABLE R603.3.1

		28	NR	NR	93	227	374		
		32	NR	NR	117	268	434		
		36	NR	64	141	309	494		
40		NR	92	176	359	562			

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm, 1 pound = 4.45 N.

- a. Anchor bolts are to be located not more than 12 inches from corners or the termination of bottom tracks such as, at door openings or corners. Bolts are to extend not less than 15 inches into masonry or 7 inches into concrete.
- b. All screw sizes shown are minimum.
- c. NR = Uplift connector not required.
- d. Foundation anchor straps are permitted in place of anchor bolts, if spaced as required to provide equivalent anchorage to the required anchor bolts and installed in accordance with manufacturer's requirements.
- e. See Figure R603.3.1(4) for details.

WALL CONSTRUCTION

loads of up to 20 psf (958 Pa) may be determined by simply moving to the next higher snow load column. Similarly, although the tabular values are based on floor live loads of 30 psf (1436 Pa) or less, values for floor live loads of up to 40 psf (1915 Pa) may be determined by moving to the next higher snow load column.

In recognition of the stiffening effects of sheathing, the code allows the required stud thickness to be reduced to the next thinner size for exterior walls with minimum $\frac{1}{2}$ -inch (12.7 mm) gypsum board installed on the interior surface and wood structural panels [minimum $\frac{7}{16}$ -inch (11.1 mm) thick oriented strand board or

FIGURE R603.3.1(1)
WALL TO FLOOR CONNECTION

FIGURE R603.3.1(2)
WALL TO FOUNDATION CONNECTION

For SI: 1 inch = 25.4 mm.

$1\frac{5}{32}$ -inch (11.9 mm) thick plywood] installed on the exterior. Stud thickness must not be less than 33 mils (0.84 mm). Similarly, interior load-bearing walls with minimum $\frac{1}{2}$ -inch (12.7 mm) gypsum board installed on both sides of the wall may use the next thinner stud, but not less than 33 mils (0.84 mm).

Fastening of studs to tracks and structural sheathing to studs must be as specified in Section R603.2.4 and Table R603.3.2(1). Track thickness must be no less than that of the wall studs.

TABLE R603.3.2(1). See page 6-90.

❖ This table provides fastener size and spacing for various portions of steel stud walls. See Figure R603.9 for an illustration of sheathing fastener locations indicated as “edge” and “field.”

TABLES R603.3.2(2) through R603.3.2(16). See pages 6-91 through 6-105.

❖ See the commentary to Section R603.3.2.

For SI: 1 mil = 0.0254 mm, 1 inch = 25.4 mm.

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm.

- a. Refer to Table R603.3.1.1(2) for gable endwall bottom track to foundation connections.
- b. Where attachment is not given, special design is required.
- c. Stud height, *h*, is measured from wall bottom track to wall top track or brace connection height.

TABLE R603.3.1.1(2)
GABLE ENDWALL BOTTOM TRACK TO FOUNDATION CONNECTION REQUIREMENTS^{a, b, c}

ULTIMATE WIND SPEED (mph)		MINIMUM SPACING FOR 1/2-INCH-DIAMETER ANCHOR BOLTS ^d		
Exposure Category		Stud height, <i>h</i> (feet)		
B	C	10 < <i>h</i> ≤ 14	14 < <i>h</i> ≤ 18	18 < <i>h</i> ≤ 22
115	—	6'- 0" o.c.	5'- 7" o.c.	6'- 0" o.c.

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm.

- a. Refer to Table R603.3.1.1(1) for gable endwall bottom track to floor joist or track connection connections.
- b. Where attachment is not given, special design is required.
- c. Stud height, *h*, is measured from wall bottom track to wall top track or brace connection height.
- d. Foundation anchor straps are permitted in place of anchor bolts if spaced as required to provide equivalent anchorage to the required anchor bolts and installed in accordance with manufacturer's requirements.

TABLE R603.3.2(1)
WALL FASTENING SCHEDULE^a

DESCRIPTION OF BUILDING ELEMENT	NUMBER AND SIZE OF FASTENERS ^a	SPACING OF FASTENERS
Wall stud to top or bottom track	2-No. 8 screws	Each end of stud, one per flange
Structural sheathing to wall studs	No. 8 screws ^b	6" o.c. on edges and 12" o.c. at intermediate supports
1/2" gypsum board to framing	No. 6 screws	12" o.c.

For SI: 1 inch = 25.4 mm.

- a. All screw sizes shown are minimum.
- b. Screws for attachment of structural sheathing panels are to be bugle-head, flat-head, or similar head styles with a minimum head diameter of 0.29 inch.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mil = 0.0254 mm, 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa, 1 ksi = 1,000 psi = 6.895 MPa.

- a. Deflection criterion: $L/240$.
- b. Design load assumptions:
 - Second-floor dead load is 10 psf.
 - Second-floor live load is 30 psf.
 - Roof/ceiling dead load is 12 psf.
 - Attic live load is 10 psf.
- c. Building width is in the direction of horizontal framing members supported by the wall studs.
- d. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

WALL CONSTRUCTION

R603.3.2.1 Gable endwalls. The size and thickness of gable endwall studs with heights less than or equal to 10 feet (3048 mm) shall be permitted in accordance with the limits set forth in Table R603.3.2.1(1). The size and thickness of gable endwall studs with heights greater than 10 feet (3048 mm) shall be determined in accordance with the limits set forth in Table R603.3.2.1(2).

❖ The stud size for gable endwalls that are tabulated does not vary with the building width since the gable endwall is assumed to not provide support for the horizontal framing members. The tables provide requirements based on the stud spacing and height and they cover ultimate design wind speeds to less than 139 mph (62 m/s) for Exposure B or C. For stud heights up to 10 feet (3048 mm), the stud size is provided in Table

R603.3.2.1(1). For stud heights greater than 10 feet (3048 mm) and up to 22 feet (6706 mm), the stud size is provided in Table R603.3.2.1(2). These tables have been revised to combine Grade 33 ksi and 50 ksi tables into one table. This resulted in a reduction in the number of tables from four to two. For tabulated thicknesses of 33 and 43 mil, Grade 33 ksi steel is to be used. For tabulated thicknesses of 54 and 68 mil, Grade 50 ksi steel is to be used. Also, 97 mil thickness has been deleted from the tables.

TABLE R603.3.2.1(1). See below.

❖ See the commentary to Section R603.3.2.1.

TABLE R603.3.2.1(2). See page 6-107.

❖ See the commentary to Section R603.3.2.1.

			24	33	33	43

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mil = 0.0254 mm, 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa, 1 ksi = 1,000 psi = 6.895 MPa.

a. Deflection criterion $L/240$.

b. Design load assumptions:

Ground snow load is 70 psf.

Roof/ceiling dead load is 12 psf.

Floor dead load is 10 psf.

Floor live load is 40 psf.

Attic dead load is 10 psf.

c. Building width is in the direction of horizontal framing members supported by the wall studs.

d. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

R603.3.3 Stud bracing. The flanges of cold-formed steel studs shall be laterally braced in accordance with one of the following:

1. Gypsum board on both sides, structural sheathing on both sides, or gypsum board on one side and structural sheathing on the other side of load-bearing walls with gypsum board installed with minimum No. 6 screws in accordance with Section R702 and structural sheathing installed in accordance with Section R603.9 and Table R603.3.2(1).
2. Horizontal steel straps fastened in accordance with Figure R603.3.3(1) on both sides at mid-height for 8-foot (2438 mm) walls, and at one-third points for 9-foot and 10-foot (2743 mm and 3048 mm) walls. Horizontal steel straps shall be not less than 1½ inches in width and 33 mils in thickness (38 mm by 0.84 mm). Straps

shall be attached to the flanges of studs with one No. 8 screw. In-line blocking shall be installed between studs at the termination of straps and at 12-foot (3658 mm) intervals along the strap. Straps shall be fastened to the blocking with two No. 8 screws.

3. Sheathing on one side and strapping on the other side fastened in accordance with Figure R603.3.3(2). Sheathing shall be installed in accordance with Item 1. Steel straps shall be installed in accordance with Item 2.
- ❖ To provide resistance against buckling, lateral bracing of steel-stud flanges must be provided by gypsum board installed according to Section R702, structural sheathing installed in accordance with Table R603.3.2(1), horizontal steel strapping as indicated in Figure R603.3.3(1) or sheathing in accordance with Item 1 on one side and steel straps in accordance with

Floor live load is 40 psf.

Attic dead load is 10 psf.

c. Building width is in the direction of horizontal framing members supported by the wall studs.

d. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

WALL CONSTRUCTION

Item 2 on the other side [see Figure R603.3.3(2)]. Steel strap bracing must be installed at mid-height for 8-foot (2438 mm) walls and at one-third points for 9-foot (2743 mm) and 10-foot (3048 mm) walls (two rows of bracing). These straps must be attached to stud flanges with at least one No. 8 screw. In-line blocking must be installed between studs at the termination of all straps. Straps must be fastened to this blocking with at least two No. 8 screws.

R603.3.4 Cutting and notching. Flanges and lips of cold-formed steel studs and headers shall not be cut or notched.

- ❖ Flanges and lips of load-bearing wall framing, to retain standard integrity, must not be cut or notched. The only holes permitted in steel wall framing are those conforming to Section R603.2.5.

For SI: 1 mil = 0.0254 mm, 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R603.3.3(1)
STUD BRACING WITH STRAPPING ONLY

For SI: 1 mil = 0.0254 mm, 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R603.3.3(2)
STUD BRACING WITH STRAPPING AND SHEATHING MATERIAL

R603.3.5 Splicing. Steel studs and other structural members shall not be spliced. Tracks shall be spliced in accordance with Figure R603.3.5.

❖ Splicing of structural members, such as studs, is not permitted. Splicing of tracks is allowed since they do not serve as gravity load-carrying members. The splice shown in Figure R603.3.5 provides nominal load-carrying capability; however, it is necessary to resist the lateral loads produced by moderate wind and earthquake loads. In these cases, the floor system must act as a diaphragm with the tracks serving as the diaphragm chords.

R603.4 Corner framing. In exterior walls, corner studs and the top tracks shall be installed in accordance with Figure R603.4.

❖ Figure R603.4 illustrates the required configurations of corner studs and overlapping of tracks at corners of exterior walls.

R603.5 Exterior wall covering. The method of attachment of exterior wall covering materials to cold-formed steel stud wall framing shall conform to the manufacturer's installation instructions.

❖ Attachment of exterior wall coverings must be according to the manufacturer's instructions.

For SI: 1 inch = 25.4 mm.

**FIGURE R603.3.5
TRACK SPLICE**

For SI: 1 inch = 25.4 mm.

**FIGURE R603.4
CORNER FRAMING**

WALL CONSTRUCTION

R603.6 Headers. Headers shall be installed above all wall openings in exterior walls and interior load-bearing walls. Box beam headers and back-to-back headers each shall be formed from two equal sized C-shaped members in accordance with Figures R603.6(1) and R603.6(2), respectively, and Tables R603.6(1) through R603.6(6). L-shaped headers shall be permitted to be constructed in accordance with AISI

S230. Alternately, headers shall be permitted to be designed and constructed in accordance with AISI S100, Section D4.

- ❖ Headers must be located immediately below the ceiling or roof framing (at the top track, for example) above wall openings in all exterior walls and interior load-bearing walls in accordance with Figures R603.6(1) and R603.6(2), which illustrate the two types of pre-

For SI: 1 inch = 25.4 mm.

**FIGURE R603.6(1)
BOX BEAM HEADER**

For SI: 1 inch = 25.4 mm.

**FIGURE R603.6(2)
BACK-TO-BACK HEADER**

scriptive header options—either a box beam or back-to-back. Tables R603.6(1) through R603.6(6) specify allowable header spans for various combinations of loading and header sizes. These tables have been revised to combine Grade 33 ksi and 50 ksi tables into one table and the back-to-back header tables have been deleted. This resulted in a reduction in the number of tables from 24 to six. For tabulated thicknesses of 33 and 43 mil, Grade 33 ksi steel is to be used. For tabulated thicknesses of 54 and 68 mil, Grade 50 ksi steel is to be used. Also, 97 mil thickness has been deleted from the tables. The back-to-back header tables did not provide significant improvement over the

box header tables. The box beam header tables are now applicable to the back-to-back headers since the box beam header yields a conservative solution. Since these tables provide a somewhat limited range of design options, the code provides the option to design headers in accordance with AISI S100 or use AISI S230 for L-shaped headers.

TABLE R603.6(1). See below.

❖ See the commentary to Section R603.6.

TABLES R603.6(2) through TABLE R603.6(6). See pages 6-112 through 6-116.

❖ See the commentary to Section R603.6.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

a. Deflection criteria: $L/360$ for live loads, $L/240$ for total loads.

b. Design load assumptions:

Second-floor dead load is 10 psf.

Roof/ceiling dead load is 12 psf.

Second-floor live load is 40 psf

Third-floor live load is 30 psf.

Attic live load is 10 psf.

c. Building width is in the direction of horizontal framing members supported by the header.

d. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

R603.6.1 Headers in gable endwalls. Box beam and back-to-back headers in gable endwalls shall be permitted to be constructed in accordance with Section R603.6 or with the header directly above the opening in accordance with Figures R603.6.1(1) and R603.6.1(2) and the following provisions:

1. Two 362S162-33 for openings less than or equal to 4 feet (1219 mm).
2. Two 600S162-43 for openings greater than 4 feet (1219 mm) but less than or equal to 6 feet (1830 mm).
3. Two 800S162-54 for openings greater than 6 feet (1829 mm) but less than or equal to 9 feet (2743 mm).

❖ This section specifies the minimum size of box-beam and back-to-back headers in gable endwalls. Figures R603.6.1(1) and R603.6.1(2) illustrate these configurations and unlike Section R603.6 they may be installed directly above the opening. The required header size varies with the span and if the span

exceeds 9 feet (2743 mm), the requirements of Section R603.6 should be applied.

FIGURE R603.6.1(1). See below.

❖ See the commentary to Section R603.6.1.

FIGURE R603.6.1(2). See below.

❖ See the commentary to Section R603.6.1.

R603.7 Jack and king studs. The number of jack and king studs installed on each side of a header shall comply with Table R603.7(1). King, jack and cripple studs shall be of the same dimension and thickness as the adjacent wall studs. Headers shall be connected to king studs in accordance with Table R603.7(2) and the following provisions:

1. For box beam headers, one-half of the total number of required screws shall be applied to the header and one-half to the king stud by use of C-shaped or track member in accordance with Figure R603.6(1). The track or

FIGURE R603.6.1(1)
BOX BEAM HEADER IN GABLE ENDWALL

FIGURE R603.6.1(2)
BACK-TO-BACK HEADER IN GABLE ENDWALL

For SI: 1 inch = 25.4 mm.

WALL CONSTRUCTION

C-shaped sections shall extend the depth of the header minus 1/2 inch (12.7 mm) and shall have a minimum thickness not less than that of the wall studs.

2. For back-to-back headers, one-half the total number of screws shall be applied to the header and one-half to the king stud by use of a minimum 2-inch by 2-inch (51 mm by 51 mm) clip angle in accordance with Figure R603.6(2). The clip angle shall extend the depth of the header minus 1/2 inch (12.7 mm) and shall have a minimum thickness not less than that of the wall studs. Jack and king studs shall be interconnected with structural sheathing in accordance with Figures R603.6(1) and R603.6(2).
- ❖ Table R603.7(1) specifies the number of jack and king studs based on the header span. King and jack studs must be the same dimension as adjacent wall studs, with a steel thickness not less than that of the adjacent wall studs. The size and number of screws required for the header-to-king-stud connection are listed in Table R603.7(2). One-half of the screws are to be applied to the box-beam header and one-half to the king stud with a clip angle as shown in Figure R603.6.1(2). The clip angle must be a minimum 2-inch by 2-inch (51 mm by

51 mm) angle with a minimum steel thickness not less than the header members and the wall studs.

TABLE R603.7(1). See below.

- ❖ See the commentary to Section R603.7.

TABLE R603.7(2). See below.

- ❖ See the commentary to Section R603.7.

R603.8 Head and sill track. Head track spans above door and window openings and sill track spans beneath window openings shall comply with Table R603.8. For openings less than 4 feet (1219 mm) in height that have both a head track and a sill track, multiplying the spans by 1.75 shall be permitted in Table R603.8. For openings less than or equal to 6 feet (1829 mm) in height that have both a head track and a sill track, multiplying the spans in Table R603.8 by 1.50 shall be permitted.

- ❖ Head track spans must comply with Table R603.8 [see Figures R603.6.1(1) and R603.6.1(2) for illustrations]. Where both a top and a bottom track are provided, the tabular head track spans may be increased by the multipliers indicated.

TABLE R603.8. See page 6-119.

- ❖ See the commentary to Section R603.8.

**TABLE R603.7(1)
TOTAL NUMBER OF JACK AND KING STUDS REQUIRED AT EACH END OF AN OPENING**

SIZE OF OPENING (feet-inches)	24-INCH O.C. STUD SPACING		16-INCH O.C. STUD SPACING	
	No. of jack studs	No. of king studs	No. of jack studs	No. of king studs
Up to 3'-6"	1	1	1	1
> 3'-6" to 5'-0"	1	2	1	2
> 5'-0" to 5'-6"	1	2	2	2
> 5'-6" to 8'-0"	1	2	2	2
> 8'-0" to 10'-6"	2	2	2	3
> 10'-6" to 12'-0"	2	2	3	3
> 12'-0" to 13'-0"	2	3	3	3

> 14'-0" to 16'-0"	2	3	3	4
> 16'-0" to 18'-0"	3	3	4	4

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**TABLE R603.7(2)
HEADER TO KING STUD CONNECTION REQUIREMENTS^{a, b, c, d}**

HEADER SPAN (feet)	ULTIMATE WIND SPEED (mph), EXPOSURE CATEGORY	
	110, Exposure Category C or less than 139, Exposure Category B	Less than 139, Exposure Category C
≤ 4'	4-No. 8 screws	6-No. 8 screws
> 4' to 8'	4-No. 8 screws	8-No. 8 screws
> 8' to 12'	6-No. 8 screws	10-No. 8 screws
> 12' to 16'	8-No. 8 screws	12-No. 8 screws

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound = 4.448 N.

- a. All screw sizes shown are minimum.
- b. For headers located on the first floor of a two-story building or the first or second floor of a three-story building, the total number of screws is permitted to be reduced by 2 screws, but the total number of screws shall not be less than four.
- c. For roof slopes of 6:12 or greater, the required number of screws shall be permitted to be reduced by half, but the total number of screws shall not be less than four.
- d. Screws can be replaced by an uplift connector that has a capacity of the number of screws multiplied by 164 pounds.

R603.9 Structural sheathing. Structural sheathing shall be installed in accordance with Figure R603.9 and this section on all sheathable exterior wall surfaces, including areas above and below openings.

- ❖ Wood structural panel sheathing must be installed on all exterior wall surfaces as shown in Figure R603.9.

FIGURE R603.9
STRUCTURAL SHEATHING FASTENING PATTERN

- ❖ This illustrates the sheathing fastening and locations that are specified in Table R603.3.2(1) for structural sheathing (see the commentary to Section R603.9.3).

R603.9.1 Sheathing materials. Structural sheathing panels shall consist of minimum 7/16-inch-thick (11 mm) oriented strand board or 15/32-inch-thick (12 mm) plywood.

- ❖ Wood structural-panel sheathing must be a minimum 7/16-inch-thick (11.1 mm) oriented strand board or 15/32-inch-thick (11.9 mm) plywood fastened to studs and tracks in accordance with Table R603.3.2(1).

R603.9.2 Determination of minimum length of full-height sheathing. The minimum length of full-height sheathing on each braced wall line shall be determined by multiplying the length of the braced wall line by the percentage obtained from Table R603.9.2(1) and by the plan aspect-ratio adjustment factors obtained from Table R603.9.2(2). The minimum length of full-height sheathing shall be not less than 20 percent of the braced wall line length.

To be considered full-height sheathing, structural sheathing shall extend from the bottom to the top of the wall without interruption by openings. Only sheathed, full-height wall sections, uninterrupted by openings, which are not less than 48 inches (1219 mm) wide, shall be counted toward meeting the minimum percentages in Table R603.9.2(1). In addition, structural sheathing shall comply with all of the following requirements:

1. Be installed with the long dimension parallel to the stud framing and shall cover the full vertical height of wall from the bottom of the bottom track to the top of the top track of each story. Installing the long dimension perpendicular to the stud framing or using shorter segments shall be permitted provided that the horizontal joint is blocked as described in Item 2.
2. Be blocked where the long dimension is installed perpendicular to the stud framing. Blocking shall be not less than 33 mil (0.84 mm) thickness. Each horizontal structural sheathing panel shall be fastened with No. 8 screws spaced at 6 inches (152 mm) on center to the blocking at the joint.
3. Be applied to each end (corners) of each of the exterior walls with a minimum 48-inch-wide (1219 mm) panel.

Exception: Where stone or masonry veneer is installed, the required length of full-height sheathing and overturning anchorage required shall be determined in accordance with Section R603.9.5.

- ❖ The minimum length of full-height sheathing required on exterior walls is determined from Table R603.9.2(1). The minimum tabulated lengths are expressed as a percentage of the wall length. Because the table is

TABLE R603.8
HEAD AND SILL TRACK SPAN

ULTIMATE WIND SPEED AND EXPOSURE CATEGORY (mph)		ALLOWABLE HEAD AND SILL TRACK SPAN ^{a, b, c} (feet-inches)					
		TRACK DESIGNATION ^d					
B	C	350T125-33	350T125-43	350T125-54	550T125-33	550T125-43	550T125-54
115	—	4'-10"	5'-5"	6'-0"	5'-8"	6'-3"	6'-10"
126	110	4'-6"	5'-1"	5'-8"	5'-4"	5'-11"	6'-5"
< 139	115	4'-2"	4'-9"	5'-4"	5'-1"	5'-7"	6'-1"
—	126	3'-11"	4'-6"	5'-0"	4'-10"	5'-4"	5'-10"
—	< 139	3'-8"	4'-2"	4'-9"	4'-1"	5'-1"	5'-7"

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s.

a. Deflection limit: L/240.

b. Head and sill track spans are based on components and cladding wind pressures and 48-inch tributary span.

c. For openings less than 4 feet in height that have both a head track and sill track, the spans are permitted to be multiplied by 1.75. For openings less than or equal to 6 feet in height that have both a head track and a sill track, the spans are permitted to be multiplied by a factor of 1.5.

d. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

WALL CONSTRUCTION

based on an 8-foot (2438 mm) wall height, the lengths must be increased by the appropriate multiplier in Section R603.9.2.1 for 9-foot- (2743 mm) and 10-foot-high (3048 mm) walls as well as the building aspect ratio found in Table R603.9.2(2). An additional adjustment is permitted for buildings where hold-down anchors are provided in accordance with Section R603.9.2.2. After all adjustments are applied to these tabulated values, the resulting minimum percentage of full-height sheathing must not be less than 20 percent of the wall length.

Only sheathed wall sections that are a minimum of 48 inches (1219 mm) wide and uninterrupted by openings may be considered in meeting the minimum length requirement. This structural sheathing must be installed with the long dimension parallel to the stud framing, and it must cover the full vertical height of studs, from the bottom of the bottom track to the top of the top track of each story. Additionally, structural sheathing must be applied to each end (corners) of all exterior walls with a minimum 48-inch-wide (1219 mm) panel.

The exception requires that where stone and

masonry veneer is installed, full-height sheathing and overturn anchorage must be in accordance with Section R603.9.5.

TABLE R603.9.2(1). See below.

❖ See the commentary to Section R603.9.2.

TABLE R603.9.2(2). See below.

❖ See the commentary to Section R603.9.2.

R603.9.2.1 Full height sheathing. The minimum percentage of full-height structural sheathing shall be multiplied by 1.10 for 9-foot-high (2743 mm) walls and multiplied by 1.20 for 10-foot-high (3048 mm) walls.

❖ See the commentary to Section R603.9.2.

R603.9.2.2 Full-height sheathing in lowest story. In the lowest story of a dwelling, multiplying the percentage of full-height sheathing required in Table R603.9.2(1) by 0.6 shall be permitted provided hold-down anchors are provided in accordance with Section R603.9.4.2.

❖ See the commentary to Section R603.9.2.

**TABLE R603.9.2(1)
MINIMUM PERCENTAGE OF FULL-HEIGHT STRUCTURAL SHEATHING ON EXTERIOR WALLS^{a, b}**

WALL SUPPORTING	ROOF SLOPE	ULTIMATE WIND SPEED AND EXPOSURE (mph)					
		115 B	126 B	< 139 B		126 C	< 139 C
			110 C	115 C			
Roof and ceiling only (one story or top floor of two- or three-story building).	3:12	9	9	12	16	20	
	6:12	13	15	20	26	35	
	9:12	23	25	30	50	58	
	12:12	33	35	40	66	75	
One story, roof and ceiling (first floor of a two-story building or second floor of a three-story building).	3:12	27	30	35	50	66	
	6:12	28	30	40	58	74	
	9:12	38	40	55	74	91	
	12:12	45	50	65	100	115	
Two stories, roof and ceiling (first floor of a three-story building).	3:12	45	51	58	84	112	
	6:12	43	45	60	90	113	
	9:12	53	55	80	98	124	
	12:12	57	65	90	134	155	

For SI: 1 mph = 0.447 m/s.

a. Linear interpolation is permitted.

b. For hip-roofed homes the minimum percentage of full-height sheathing, based upon wind, is permitted to be multiplied by a factor of 0.95 for roof slopes not exceeding 7:12 and a factor of 0.9 for roof slopes greater than 7:12.

**TABLE R603.9.2(2)
FULL-HEIGHT SHEATHING LENGTH ADJUSTMENT FACTORS**

PLAN ASPECT RATIO	LENGTH ADJUSTMENT FACTORS	
	Short wall	Long wall
1:1	1.0	1.0
1.5:1	1.5	0.67
2:1	2.0	0.50
3:1	3.0	0.33
4:1	4.0	0.25

R603.9.3 Structural sheathing fastening. Edges and interior areas of structural sheathing panels shall be fastened to framing members and tracks in accordance with Figure R603.9 and Table R603.3.2(1). Screws for attachment of structural sheathing panels shall be bugle-head, flat-head, or similar head style with a minimum head diameter of 0.29 inch (8 mm).

For continuously sheathed *braced wall lines* using wood structural panels installed with No. 8 screws spaced 4 inches (102 mm) on center at all panel edges and 12 inches (304.8 mm) on center on intermediate framing members, the following shall apply:

1. Multiplying the percentages of full-height sheathing in Table R603.9.2(1) by 0.72 shall be permitted.
 2. For bottom track attached to foundations or framing below, the bottom track anchor or screw connection spacing in Tables R505.3.1(1) and R603.3.1 shall be multiplied by two-thirds
- ❖ The wall-fastening schedule [see Table R603.3.2(1)] specifies edge and field spacing requirements (see Figure R603.9). This section specifies the required type and size of screws for attaching structural sheathing to wall framing. A reduction in sheathing requirements is allowed where a reduced edge fastener spacing is utilized.

R603.9.4 Uplift connection requirements. Uplift connections shall be provided in accordance with this section.

- ❖ Uplift connections are required based on wind criteria in Section R603.9.4.1. When the optional sheathing reduction permitted by Section R603.9.2.2 is taken, a hold down must be provided in accordance with Section R603.9.4.2.

R603.9.4.1 Ultimate design wind speeds greater than 126 mph. Where ultimate design wind speeds exceed 126 miles per hour (56 m/s), Exposure Category C walls shall be pro-

vided with direct uplift connections in accordance with AISI S230, Section E13.3, and AISI S230, Section F7.2, as required for 139 miles per hour (62 m/s), Exposure Category C.

- ❖ Where the ultimate design wind speed is greater than 126 mph (56 m/s) and the exposure is C, the user is referred to AISI S230 in order to determine the uplift connection requirements.

R603.9.4.2 Hold-down anchor. Where the percentage of full-height sheathing is adjusted in accordance with Section R603.9.2.2, a hold-down anchor, with a strength of 4,300 pounds (19 kN), shall be provided at each end of each full-height sheathed wall section used to meet the minimum percent sheathing requirements of Section R603.9.2. Hold-down anchors shall be attached to back-to-back studs; structural sheathing panels shall have edge fastening to the studs, in accordance with Section R603.9.3 and AISI S230, Table E11-1.

A single hold-down anchor, installed in accordance with Figure R603.9.4.2, shall be permitted at the corners of buildings.

- ❖ Section R603.9.2.2 affords the option of using shorter braced-wall lengths and providing hold-down anchorage at the ends of the braced walls to resist uplift. The length of wall may be reduced by up to 40 percent where the hold-downs specified in this section are installed.

R603.9.5 Structural sheathing for stone and masonry veneer. Where stone and masonry veneer are installed in accordance with Section R703.8, the length of full-height sheathing for exterior and interior wall lines backing or perpendicular to and laterally supporting walls with veneer shall comply with this section.

- ❖ This section provides the required bracing for cold-formed steel framing to resist the lateral loads associ-

For SI: 1 inch = 25.4 mm.

FIGURE R603.9.4.2
CORNER STUD HOLD-DOWN DETAIL

WALL CONSTRUCTION

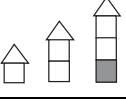

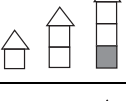

ated with the use of masonry veneer in SDC C, D₀, D₁ and D₂. Where masonry veneer is used in SDC C, Section R603.9.5.1 requires greater of the amounts of bracing specified in Section R603.9.2, except the reduction specified in Section R603.9.2.2 is permitted.

The original provisions for anchoring masonry veneer to residential buildings were developed with the concept of anchoring to wood framing. Section R603.9.5 has been revised to include provisions for cold-formed steel framing to be used to support masonry veneer in high-seismic regions. Where masonry veneer is used in SDC D₀, D₁ or D₂, Section R603.9.5.2 requires the amount of bracing and over-

turning anchorage to be in accordance with Tables R603.9.5(1) through R603.9.5(4).

Values in the four tables are based on allowable design values provided in AISI S213-07, *North American Standard for Cold-Formed Steel Framing—Lateral Design*, including Supplement No. 1. The values are located in Table C2.1-3 for 33-mil and 43-mil stud thicknesses and 6-inch and 4-inch screw spacing around the perimeter. It is assumed that in-line framing concept of cold-formed steel light-frame construction provides the continuous load path required to transfer overturning loads to the foundation. Walls from one story to another must be aligned.

**TABLE R603.9.5(1)
REQUIRED LENGTH OF FULL-HEIGHT SHEATHING AND ASSOCIATED OVERTURNING ANCHORAGE FOR WALLS SUPPORTING WALLS WITH STONE OR MASONRY VENEER AND USING 33-MIL COLD-FORMED STEEL FRAMING AND 6-INCH SCREW SPACING ON THE PERIMETER OF EACH PANEL OF STRUCTURAL SHEATHING**

SEISMIC DESIGN CATEGORY	STORY	BRACED WALL LINE LENGTH (feet)						SINGLE-STORY HOLD-DOWN FORCE (pounds)	CUMULATIVE HOLD-DOWN FORCE (pounds)
		10	20	30	40	50	60		
		Minimum total length of braced wall panels required along each braced wall line (feet)							
D ₀		3.3	4.7	6.1	7.4	8.8	10.2	3,360	—
		5.3	8.7	12.1	15.4	18.8	22.2	3,360	6,720
		7.3	12.7	18.0	23.4	28.8	34.2	3,360	10,080
D ₁		4.1	5.8	7.5	9.2	10.9	12.7	3,360	—
		6.6	10.7	14.9	19.1	23.3	27.5	3,360	6,720
		9.0	15.7	22.4	29.0	35.7	42.2	3,360	10,080
D ₂		5.7	8.2	10.6	13.0	15.4	17.8	3,360	—
		9.2	15.1	21.1	27.0	32.9	38.8	3,360	6,720
		12.7	22.1	31.5	40.9	50.3	59.7	3,360	10,080

Assumptions for building configuration for the tables include:

1. 20 percent of the wall area has door and window openings.
2. Wall veneer seismic weight perpendicular to the direction of analysis contributes to lateral forces. The masonry veneer in-plane, on walls resisting the lateral load, supports its own seismic weight.
3. Maximum story height for each floor is 10 feet.
4. Masonry is 4-inch-thick clay masonry with 40 pounds per square foot (psf) dead load.

R603.9.5.1 Seismic Design Category C. In Seismic Design Category C, the length of structural sheathing for walls sup-

porting one *story*, roof and ceiling shall be the greater of the amounts required by Section R603.9.2, except Section R603.9.2.2 shall be permitted.

❖ See the commentary to Section R603.9.5.

R603.9.5.2 Seismic Design Categories D₀, D₁ and D₂. In Seismic Design Categories D₀, D₁ and D₂, the required length of structural sheathing and overturning anchorage shall be determined in accordance with Tables R603.9.5(1), R603.9.5(2), R603.9.5(3), and R603.9.5(4). Overturning anchorage shall be installed on the doubled studs at the end of each full-height wall segment.

❖ See the commentary to Section R603.9.5.

TABLE R603.9.5(2)
REQUIRED LENGTH OF FULL-HEIGHT SHEATHING AND ASSOCIATED OVERTURNING ANCHORAGE FOR WALLS SUPPORTING WALLS WITH STONE OR MASONRY VENEER AND USING 43-MIL COLD-FORMED STEEL FRAMING AND 6-INCH SCREW SPACING ON THE PERIMETER OF EACH PANEL OF STRUCTURAL SHEATHING

SEISMIC DESIGN CATEGORY	STORY	BRACED WALL LINE LENGTH (feet)						SINGLE-STORY HOLD-DOWN FORCE (pounds)	CUMULATIVE HOLD-DOWN FORCE (pounds)

**SECTION R604
WOOD STRUCTURAL PANELS**

R604.1 Identification and grade. Wood structural panels shall conform to DOC PS 1, DOC PS 2 or ANSI/APA PRP 210, CSA O437 or CSA O325. Panels shall be identified by a grade mark or certificate of inspection issued by an *approved* agency.

- ❖ To verify the acceptability of wood structural panel products, this section requires labeling in accordance with the referenced standards. The purpose is the same as the purpose of Section R602.1 for dimension

lumber. This label provides the inspector with the necessary information to determine the acceptability of the wood structural panel (see commentary, Sections R503.2 and R503.2.1).

R604.2 Allowable spans. The maximum allowable spans for wood structural panel wall sheathing shall not exceed the values set forth in Table R602.3(3).

- ❖ The allowable span for wood structural panel sheathing is a function of its thickness and grade. Table R602.3(3) in the code provides allowable spans based on the thickness and the panel index.

**TABLE R603.9.5(3)
REQUIRED LENGTH OF FULL-HEIGHT SHEATHING AND ASSOCIATED OVERTURNING ANCHORAGE FOR WALLS SUPPORTING WALLS WITH STONE OR MASONRY VENEER AND USING 33-MIL COLD-FORMED STEEL FRAMING AND 4-INCH SCREW SPACING ON THE PERIMETER OF EACH PANEL OF STRUCTURAL SHEATHING**

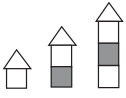

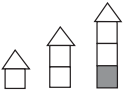

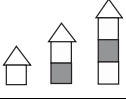

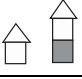

SEISMIC DESIGN CATEGORY	STORY	BRACED WALL LINE LENGTH (feet)						SINGLE-STORY HOLD-DOWN FORCE (pounds)	CUMULATIVE HOLD-DOWN FORCE (pounds)

R604.3 Installation. Wood structural panel wall sheathing shall be attached to framing in accordance with Table R602.3(1) or R602.3(3).

- ❖ Table R602.3(1) of the code contains the fastening requirements for proper wood structural panel installation for interior walls. Table R602.3(3) contains the fastening requirements for proper wood structural panel installation for exterior walls.

SECTION R605 PARTICLEBOARD

R605.1 Identification and grade. Particleboard shall conform to ANSI A208.1 and shall be so identified by a grade mark or certificate of inspection issued by an *approved* agency. Particleboard shall comply with the grades specified in Table R602.3(4).

- ❖ As with wood structural panels, particleboard must be labeled in accordance with the referenced standard. Table R602.3(4) provides prescriptive requirements relative to allowable spans. As with wood structural panel spans, these spans are a function of the thickness and grade (see commentary, Section R503.3).

SECTION R606 GENERAL MASONRY CONSTRUCTION

R606.1 General. Masonry construction shall be designed and constructed in accordance with the provisions of this section,

TMS 403 or in accordance with the provisions of TMS 402/ACI 530/ASCE 5.

- ❖ Masonry wall construction under the code must comply with Section R606 or TMS 402/ACI 530/ASCE 5, *Building Code Requirements for Masonry Structures*.

The 2012 code provided masonry design and construction requirements throughout Section R606, R607, R608 and R609. For the 2015 code, Section R606 has been revised and reorganized to include the provisions of Sections R607, R608 and R609, providing requirements for masonry construction of one- and two-family dwellings and townhouses. Commentary Figure R606.1 summarizes the relocation of sections in the 2015 code and lists new sections.

R606.1.1 Professional registration not required. When the empirical design provisions of Appendix A of TMS 402/ACI 530/ASCE 5, the provisions of TMS 403, or the provisions of this section are used to design masonry, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the *jurisdiction* having authority.

- ❖ These empirical provisions are meant for use without the services of a professional engineer or architect. State law, however, may dictate otherwise and would take precedence.

R606.2 Masonry construction materials.

- ❖ Section R606.2 has been added to the 2015 code to specify the minimum requirements for masonry mate-

WALL CONSTRUCTION

rials. While the 2012 code addressed some materials, such as masonry and grout, others were not, such as masonry units. Sections R606.2.1 through R606.2.12 define the materials to be used for masonry wall construction. The provisions are consistent with the IBC

requirements for masonry materials. Provisions for autoclaved aerated concrete (AAC) masonry units have been added to Section R606.2.3. Requirements for re-use of masonry units have been added to Section R606.2.6.

Figure R606.1—continued
CROSS REFERENCE OF 2015 IRC MASONRY CONSTRUCTION TO 2012 IRC

R606.2.1 Concrete masonry units. Concrete masonry units shall conform to the following standards: ASTM C55 for concrete brick; ASTM C73 for calcium silicate face brick; ASTM C90 for load-bearing concrete masonry units; ASTM C744 for prefaced concrete and calcium silicate masonry units; or ASTM C1634 for concrete facing brick.

❖ Concrete masonry refers to solid and hollow concrete units, including concrete brick, concrete block, split-face block, slump block and other special units. This section requires conformance to ASTM International (ASTM) standards for each specific type of concrete masonry unit. The standards include requirements for materials; manufacture; physical properties; strength; absorption; minimum dimensions and permissible variations; inspection; testing and rejection.

Concrete masonry units are selected based on the desired use and appearance. Units are typically specified by density class and compressive strength.

Hollow load-bearing concrete masonry units are manufactured in accordance with the requirements of ASTM C90 using Portland cement, water and mineral aggregates. Other suitable materials, such as approved admixtures, are permitted in accordance with ASTM C90.

Hollow load-bearing concrete masonry units have three weight classifications: normal-weight units of 125 pounds per cubic foot (pcf) (2000 kg/m³) or more; medium-weight units of between 105 pcf and 125 pcf (1680 and 2000 kg/m³) and lightweight units of less than 105 pcf (1680 kg/m³). Lightweight aggregates generally are expanded blast-furnace slag or similar suitable materials. Normal-weight units are made from sand, gravel, crushed stone or air-cooled, blast-furnace-slag aggregates.

Concrete brick is required to comply with ASTM C55. Concrete building brick and other solid concrete veneer and facing units are typically smaller than concrete masonry units conforming to ASTM C90. They are made from Portland cement, water and mineral aggregates, with or without inclusion of other approved materials.

Concrete brick is manufactured as lightweight, medium-weight and normal-weight units as described above for hollow concrete masonry units. Concrete brick is manufactured in two grades: Grade N and Grade S. Grade N units are used as architectural veneer and facing units in exterior walls, where high strength and resistance to moisture penetration and freeze-thaw cycling are required. Grade S units are used when moderate strength and resistance to freeze-thaw action and moisture penetration are required.

Calcium silicate face brick is a solid masonry unit complying with ASTM C73. These units are manufactured principally from silica sand, hydrated lime and water.

Calcium silicate face brick is manufactured in two grades: Grade SW and Grade MW. Grade SW is required where exposure to moisture in the presence

of freezing temperatures is anticipated. Grade MW is permitted where the anticipated exposure has freezing temperatures, but without water saturation.

Grade SW units have a minimum permitted compressive strength on the gross area of 4,500 psi (31.0 MPa) (average of three units), but not less than 3,500 psi (24.1 MPa) for any individual unit. Grade MW units have a minimum permitted compressive strength on the gross area of 2,500 psi (17.2 MPa) (average of three units), but not less than 2,000 psi (13.8 MPa) for any individual unit.

ASTM C744 is referenced for the manufacture of prefaced concrete and calcium silicate masonry units, commonly referred to as “glazed” concrete masonry units. The specified exposed surfaces of these units are covered during their manufacture with resin, resin and inert filler, or cement and inert filler to produce a smooth, resinous, tile-like facing.

Facing requirements of that standard address resistance to chemicals; failure of adhesion of the facing material; abrasion surface-burning characteristics, color and color change; soiling and cleansability. The standard also covers dimensional tolerances, including face dimensions and distortions.

R606.2.2 Clay or shale masonry units. Clay or shale masonry units shall conform to the following standards: ASTM C34 for structural clay *load-bearing wall* tile; ASTM C56 for structural clay nonload-bearing wall tile; ASTM C62 for building brick (solid masonry units made from clay or shale); ASTM C1088 for solid units of thin veneer brick; ASTM C126 for ceramic-glazed structural clay facing tile, facing brick and solid masonry units; ASTM C212 for structural clay facing tile; ASTM C216 for facing brick (solid masonry units made from clay or shale); ASTM C652 for hollow brick (hollow masonry units made from clay or shale); or ASTM C1405 for glazed brick (single-fired solid brick units).

Exception: Structural clay tile for nonstructural use in fireproofing of structural members and in wall furring shall not be required to meet the compressive strength specifications. The fire-resistance rating shall be determined in accordance with ASTM E119 or UL 263 and shall comply with the requirements of Section R302.

❖ Section R606.2.2 requires conformance to ASTM standards for masonry units manufactured from clay or shale. The various standards also include requirements for materials; manufacture; physical properties; minimum dimensions and permissible variations; inspections and testing.

Clay or shale masonry units are manufactured from clay and shale, which are compounds of silica or alumina. Shale is simply a hardened clay. The raw materials are formed into the desired shape by extrusion and cutting, molding or pressing while in the plastic state. The units are then fired in a kiln. The raw materials and the manufacturing process influence the physical properties of the manufactured unit.

Clay or shale masonry units are selected for their intended use from a variety of shapes, sizes and strengths. Units are specified based on grades and type.

Solid face brick units are required to conform to ASTM C216. This standard covers clay brick intended to be used in masonry and supplying structural or facing components, or both, to the structure. These units are available in a variety of sizes, textures, colors and shapes.

ASTM C216 contains requirements for two grades of durability: Grade SW and Grade MW. Grade SW brick is intended for use where high and uniform resistance to damage caused by freeze-thaw cycling is desired and where the brick may be subjected to such cycling while saturated with water. Grade MW brick is intended for use where moderate resistance to cyclic freeze-thaw damage is permissible or where the brick may be damp, but not saturated with water, when such cycling occurs. ASTM C216 further classifies face brick into three types of appearance: Types FBS, FBX and FBA. Type FBS (face brick standard) units are permitted for general use in masonry. Type FBX (face brick select) units are also for general use, but have a higher degree of precision and lower permissible variation in size than Type FBS units. Type FBA (face brick architectural) units are also for general use, but are intentionally manufactured to produce characteristic architectural effects resulting from nonuniformity in size and texture of the units.

Solid units of building brick are required to conform to ASTM C62. This specification covers brick intended for use in both structural and nonstructural masonry where external appearance is not critical. This brick was formerly called "common brick," and the standard does not contain appearance requirements.

ASTM C62 contains requirements for three grades of durability: Grade SW, Grade MW and Grade NW. Grade SW brick is intended for use where high and uniform resistance to freeze-thaw damage is desired and where the brick may be subjected to such cycling while saturated with water. Grade MW brick is intended for use where moderate resistance to cyclic freeze-thaw damage is permissible or where the brick may be damp but not saturated with water when such cycling occurs. Grade NW is used where little resistance to cyclic freeze-thaw damage is required and is acceptable for applications protected from water absorption and freezing.

Hollow brick is required to conform to ASTM C652, which regulates hollow building and hollow facing brick. Hollow brick differs from structural clay tile in that it has more stringent physical property requirements, such as thicker shell and web dimensions, and higher minimum compressive strengths.

Hollow brick has two grades of durability: Grade SW and Grade MW. Grade SW is used where a high and uniform degree of resistance to freeze-thaw degradation and disintegration by weathering is desired and when the brick may be saturated while frozen. Grade MW is intended for use where a moderate and somewhat nonuniform degree of resistance to freeze-thaw degradation is permissible.

ASTM C652 also classifies hollow brick into four

types of appearance: Types HBS, HBX, HBA and HBB. Type HBS (hollow brick standard) units are permitted for general use. Type HBX (hollow brick select) units are also for general use, but have a higher degree of dimensional precision than Type HBS units. Type HBA (hollow brick architectural) units are also for general use, but are intentionally manufactured to produce characteristic architectural effects resulting from nonuniformity in size and texture of the units. Type HBB (hollow building brick) units are for general use in masonry where a particular color, texture, finish, uniformity or limits on cracks, warpage or other imperfections detracting from their appearance are not a consideration.

ASTM C1088 regulates thin brick used in adhered veneer having a maximum actual thickness of $1\frac{3}{4}$ inches (44 mm). Thin veneer brick units are specified in three types of appearance and two grades of durability.

Exterior-grade units are for exposure to weather; interior-grade units are not. Type TBS (standard) units are permitted for general use. Type TBX (select) units are also for general use, but have a higher degree of precision and lower permissible variation in size than Type TBS units. Type TBA (architectural) units are also for general use, but are intentionally manufactured to produce characteristic effects in variations of size, color and texture.

ASTM C34 is referenced for the manufacture of structural clay load-bearing wall tile. This type of tile has two grades: Grade LBX and LB. Grade LBX is suitable for general use in masonry construction and can be used in masonry exposed to weathering, provided that the units meet durability requirements for Grade SW of ASTM C216 for solid units of face brick. This tile grade is also suitable for the direct application of stucco.

Grade LB is suitable for general use in masonry not exposed to freeze-thaw action, or for exposed masonry where protected with a minimum 3-inch (76 mm) facing of stone, brick or other masonry materials.

Fire-resistant tile intended for use in load-bearing masonry is required to conform to ASTM C34. Tile intended for use in fireproofing structural members is required to be of such sizes and shapes as to cover completely the exposed surfaces of the members.

ASTM C212, the referenced standard regulating structural clay facing tile, covers two types of structural clay load-bearing facing tile: Types FTX and FTS.

Type FTX clay facing tile is a smooth-face tile suitable for use in exposed exterior and interior masonry walls, and partitions where low absorption, easy cleaning and resistance to staining are required. The physical characteristics of this tile require a high degree of mechanical perfection, narrow color range and minimum variation in face dimensions.

Type FTS clay facing tile is a smooth- or rough-textured face tile suitable for general use in exposed exterior and interior masonry walls and partitions where moderate absorption, variation in face dimensions, minor defects in surface finish and moderate color variations are permissible.

There are two classes of tile for the types stated above: standard (for general use) and special duty (having superior resistance to impact and moisture transmission and supporting greater lateral and vertical loads).

ASTM C56 is the standard regulating the manufacture of nonload-bearing tile, which is made from the same materials as other types of tile previously mentioned and is used for partitions, fireproofing and furring.

ASTM C126 prescribes requirements for ceramic-glazed structural clay load-bearing facing tile and brick and other solid masonry units made from clay, shale, fire clay or combinations thereof. The standard specifies two grades and two types of ceramic-glazed masonry: Grade S is used with comparatively narrow mortar joints, while Grade SS is used where variations in face dimensions are very small; Type I units are used where only one finished face is to be exposed, while Type II units are used where both finished faces are to be exposed.

The finish of glazed units is important. Requirements and test methods are prescribed for imperviousness, opacity, resistance to fading and crazing, hardness, abrasion resistance and flame spread smoke density. Compressive strength requirements, dimensional tolerances and permissible distortions are also prescribed by the standard.

The exception to this section allows structural clay tile that does not meet the compressive strength specifications to be used as nonstructural fireproofing for structural members. The fire-resistance rating must be determined in accordance with ASTM E119.

R606.2.3 AAC masonry. AAC masonry units shall conform to ASTM C1386 for the strength class specified.

- ❖ AAC masonry units are a low-density cementitious product first introduced into the 2005 edition of the MSJC Code and MSJC Specification, although its use has been prevalent in other countries for several decades. AAC masonry units must comply with ASTM C1386 for the strength class specified.

R606.2.4 Stone masonry units. Stone masonry units shall conform to the following standards: ASTM C503 for marble building stone (exterior); ASTM C568 for limestone building stone; ASTM C615 for granite building stone; ASTM C 616 for sandstone building stone; or ASTM C629 for slate building stone.

- ❖ Many types of natural stone, including marble, granite, slate, limestone and sandstone, are used in building construction. This section covers natural stones that are sawed, cut, split or otherwise shaped for masonry purposes. Natural stones for building purposes are specified in various grades, textures and finishes, and are required to have physical properties appropriate to their intended use.

Where applicable to specific kinds of natural stone, the finished units are required to be sound and free from spalls, cracks, open seams, pits and other defects that would impair structural strength and durability and, when applicable, fire resistance.

This section requires conformance to the following

ASTM standards for natural stone masonry: ASTM C503 for marble building stone (exterior); ASTM C568 for limestone building stone; ASTM C615 for granite building stone; ASTM C616 for sandstone building stone or ASTM C629 for slate building stone. The standards contain requirements for absorption, density (except for slate), compressive strength (except for slate), modulus of rupture, abrasion resistance (except for granite) and acid resistance (slate only).

R606.2.5 Architectural cast stone. Architectural cast stone shall conform to ASTM C1364.

- ❖ Architectural cast stone is a masonry product that provides ornamental or functional features to buildings and other structures. Cast stone is made from fine and coarse aggregates, Portland cement, mineral oxide color pigments, chemical admixtures and water. The products are available in virtually any color and can give the appearance of a variety of natural building stones, such as limestone, granite, slate, travertine or marble. Applications range from simple window sills to the most complicated architectural elements and features. When properly manufactured and installed, cast stone has similar strength and physical properties as most dimensional building stone. ASTM C1364 establishes the physical requirements, sampling, testing and visual inspection of architectural cast stone that may be made from facing and backup mixtures or from a homogeneous mixture, produced either by wet or dry casting. The standard requires the raw materials, such as Portland cement, aggregates, coloring pigment, reinforcement, chemical admixtures, air-entraining admixtures, water-reducing and accelerating admixtures, ground slag, fly ash or natural pozzolan, and other constituents to be precisely observed. The product must also conform to specified physical and performance requirements such as compressive strength, cold water absorption, boiling water absorption, air content, field testing, resistance to freezing and thawing and linear drying shrinkage.

R606.2.6 Second hand units. Second hand masonry units shall not be reused unless they conform to the requirements of new units. The units shall be of whole, sound materials and free from cracks and other defects that will interfere with proper laying or use. Old mortar shall be cleaned from the unit before reuse.

- ❖ This section allows for the use of salvaged brick and other second-hand masonry units, provided that their quality and condition meet the requirements for new masonry units. Second-hand units must be whole, of sound material, clean and free from defects that would interfere with proper laying or use.

Most second-hand masonry units are salvaged from the demolition of old buildings. Masonry units manufactured in the past do not generally compare with the quality of masonry made by modern manufacturing methods under controlled conditions. Therefore, designers should expect salvaged masonry units to have lower strength and durability than new units.

Generally, the difference between walls laid up with new masonry units and second-hand units of the same

WALL CONSTRUCTION

type is the adhesion of the mortar to the masonry surfaces. When new masonry units are laid in fresh mortar, water and fine cementitious particles are absorbed into the masonry, thereby improving bond strength. In contrast, pores in the bed faces of second-hand masonry units, regardless of cleaning, are filled with particles of cement, lime and deleterious substances that impede adequate absorption, thereby adversely affecting bond between the mortar and the masonry.

R606.2.7 Mortar. Except for mortars listed in Sections R606.2.8, R606.2.9 and R606.2.10, mortar for use in masonry construction shall meet the proportion specifications of Table R606.2.7 or the property specifications of ASTM C270. The type of mortar shall be in accordance with Sections R606.2.7.1, R606.2.7.2 and R606.2.7.3.

❖ This section specifies the requirements for mortar used in masonry construction. Mortar is the bonding agent that separates masonry units while bonding them together. It is an integral part of any masonry wall and must be strong, durable and capable of keeping the wall intact. In addition, it should help to create a moisture-resistant barrier.

Mortar makes up approximately 25 percent of a standard modular brick wall and about 10 percent of a block wall. It is therefore a significant part of the structure. ASTM C270 discusses the materials and methods for mixing mortar. For purposes of economy, a good rule of thumb is to specify the lowest strength mortar that will satisfy the structural requirements of the project. Mortar consists of cementitious materials and well-graded

sand with sufficient fines. Mortar is used for the following purposes:

- It is a bedding or seating material for the masonry unit. It allows the unit to be leveled and properly placed.
- It bonds the units together.
- It provides compressive strength.
- It provides shear strength, particularly parallel to the wall.
- It allows some movement and elasticity between units.
- It seals irregularities of the masonry unit and provides a weather-tight wall, preventing penetration of wind and water into and through the wall. It can provide color to the wall when a mineral color additive is used.
- It can provide an architectural appearance by using various types of joints.

TABLE R606.2.7. See below.

❖ The mortar required by Sections R606.2.7.1 through R606.2.7.3 must be proportioned as shown in this table or ASTM C270. Type M mortar is suited for structures below or against grade such as retaining walls. It is also suited for masonry construction subject to high compressive loads, severe frost action or high lateral loads from earth pressures, hurricane winds or earthquakes. Type S mortar is appropriate for use in structures requiring high flexural bond strength that are subject to

TABLE R606.2.7
MORTAR PROPORTIONS^{a, b}

MORTAR	TYPE	PROPORTIONS BY VOLUME (cementitious materials)							Hydrated lime ^c or lime putty	Aggregate ratio (measured in damp, loose conditions)
		Portland cement or blended cement	Mortar cement			Masonry cement				
			M	S	N	M	S	N		
Cement-lime	M	1	—	—	—	—	—	—	over 1/4 to 1/2 over 1/2 to 1 1/4 over 1 1/4 to 2 1/2	Not less than 2 1/4 and not more than 3 times the sum of separate volumes of lime, if used, and cement
	S	1	—	—	—	—	—			
	N	1	—	—	—	—	—			
	O	1	—	—	—	—	—			
Mortar cement	M	1	—	—	1	—	—	—		
	M	—	1	—	—	—	—			
	S	1/2	—	—	1	—	—			
	S	—	—	1	—	—	—			
	O	—	—	—	1	—	—			
Masonry cement	M	1	—	—	—	—	1	—		
	M	—	—	—	1	—	—			
	S	1/2	—	—	—	—	1			
	S	—	—	—	—	1	—			
	O	—	—	—	—	—	1			

For SI: 1 cubic foot = 0.0283 m³, 1 pound = 0.454 kg.

a. For the purpose of these specifications, the weight of 1 cubic foot of the respective materials shall be considered to be as follows:

Portland Cement	94 pounds	Masonry Cement	Weight printed on bag
Mortar Cement	Weight printed on bag	Hydrated Lime	40 pounds
Lime Putty (Quicklime)	80 pounds	Sand, damp and loose	80 pounds of dry sand

b. Two air-entraining materials shall not be combined in mortar.

c. Hydrated lime conforming to the requirements of ASTM C207.

compressive and lateral loads. Type N mortar is meant for general use in above-grade masonry, residential basement construction, interior walls and partitions, masonry veneer and nonstructural masonry partitions.

R606.2.7.1 Foundation walls. Mortar for masonry foundation walls constructed as set forth in Tables R404.1.1(1) through R404.1.1(4) shall be Type M or S mortar.

- ❖ This section specifies the applicable tables in Chapter 4 that apply to masonry foundation walls.

R606.2.7.2 Masonry in Seismic Design Categories A, B and C. Mortar for masonry serving as the lateral-force-resisting system in Seismic Design Categories A, B and C shall be Type M, S or N mortar.

- ❖ Masonry construction in buildings classified as SDC A, B or C must use Type M, S or N mortar.

R606.2.7.3 Masonry in Seismic Design Categories D₀, D₁ and D₂. Mortar for masonry serving as the lateral-force-resisting system in Seismic Design Categories D₀, D₁ and D₂ shall be Type M or S Portland cement-lime or mortar cement mortar.

- ❖ In buildings classified as Seismic Design Category D₀, D₁ or D₂, in walls which are intended to resist lateral forces, and in foundation walls in any building, only Type M or S mortar is acceptable.

R606.2.8 Surface-bonding mortar. Surface-bonding mortar shall comply with ASTM C887. Surface bonding of concrete masonry units shall comply with ASTM C946.

- ❖ Specifications for materials to be used in premixed surface-bonding mortar and for the properties of the mortar are contained in ASTM C887. Requirements for masonry units and other materials used in constructing dry-stacked, surface-bonded masonry for walls and for the construction itself are contained in ASTM C946.

In addition to its primary function of bonding masonry units, surface-bonding mortar can provide resistance to penetration by wind-driven rain.

R606.2.9 Mortar for AAC masonry. Thin-bed mortar for AAC masonry shall comply with Article 2.1 C.1 of TMS 602/ACI 530.1/ASCE 6. Mortar used for the leveling courses of AAC masonry shall comply with Article 2.1 C.2 of TMS 602/ACI 530.1/ASCE 6.

- ❖ Except for the initial leveling courses of AAC masonry, which uses Type M or S masonry mortar, a special thin-bed mortar is used to bind AAC masonry units.

R606.2.10 Mortar for adhered masonry veneer. Mortar for use with adhered masonry veneer shall conform to ASTM C270 Type S or Type N or shall comply with ANSI A118.4 for latex-modified portland cement mortar.

- ❖ This section lists the types of mortars that can be used for adhered masonry veneer. The general requirements for adhered masonry veneer can be found in Chapter 7.

R606.2.11 Grout. Grout shall consist of cementitious material and aggregate in accordance with ASTM C476 or the proportion specifications of Table R606.2.11. Type M or Type S mortar to which sufficient water has been added to produce pouring consistency shall be permitted to be used as grout.

- ❖ ASTM C476 contains the requirements for grout. The code identifies two types of grout for masonry construction: fine grout and coarse grout. They differ primarily in the maximum allowable size of aggregates. The proportions in Table R606.2.11 provide a minimum compressive strength of 2,000 psi (13 789 kPa). Type M or Type S mortar (see Section R607.1) may also be used as grout if sufficient water is added to produce a pouring consistency.

R606.2.12 Metal reinforcement and accessories. Metal reinforcement and accessories shall conform to Article 2.4 of TMS 602/ACI 530.1/ASCE 6.

- ❖ The material requirements for metal reinforcement and accessories, such as joint reinforcement, anchor ties and wire fabric, must comply with Article 2.4 of the *Specification for Masonry Structures*.

R606.3 Construction requirements.

- ❖ Sections R606.3.1 through R606.3.7 provide the detail requirements of construction for masonry such as placement and joints of masonry units, wall tie installation, protection of metal reinforcement grouting and bonding patterns.

R606.3.1 Bed and head joints. Unless otherwise required or indicated on the project drawings, head and bed joints shall be ³/₈ inch (9.5 mm) thick, except that the thickness of the bed joint of the starting course placed over foundations shall be not less than ¹/₄ inch (6.4 mm) and not more than ³/₄ inch (19.1 mm). Mortar joint thickness for load-bearing masonry shall be within the following tolerances from the specified dimensions:

1. Bed joint: + ¹/₈ inch (3.2 mm).

**TABLE R606.2.11
GROUT PROPORTIONS BY VOLUME FOR MASONRY CONSTRUCTION**

TYPE	PORTLAND CEMENT OR BLENDED CEMENT SLAG CEMENT	HYDRATED LIME OR LIME PUTTY	AGGREGATE MEASURED IN A DAMP, LOOSE CONDITION	
			Fine	Coarse
Fine	1	0 to 1/10	2 ¹ / ₄ to 3 times the sum of the volume of the cementitious materials	—
Coarse	1	0 to 1/10	2 ¹ / ₄ to 3 times the sum of the volume of the cementitious materials	1 to 2 times the sum of the volumes of the cementitious materials

WALL CONSTRUCTION

2. Head joint: $-\frac{1}{4}$ inch (6.4 mm), $+\frac{3}{8}$ inch (9.5 mm).
3. Collar joints: $-\frac{1}{4}$ inch (6.4 mm), $+\frac{3}{8}$ inch (9.5 mm).

❖ The provisions of this section set forth specific requirements that are unique to construction using masonry units. Masonry units are to be laid and set in mortar. The properties of masonry walls, including strength and appearance, vary significantly depending on the thickness of the mortar joints. The initial bed joint, which is the bed joint between the first course of masonry and the foundation wall, is limited to a thickness of not less than $\frac{1}{4}$ inch (6.4 mm) and not greater than $\frac{3}{4}$ inch (19 mm). This larger variation is to allow for the inherent unevenness of concrete or concrete masonry foundation walls. The remainders of bed joints, which can be controlled by the mason, are limited to $\frac{3}{8}$ inch (9.5 mm), unless specified otherwise on the project drawings. Joint-thickness tolerances limit the eccentricity of applied loads and reflect typical industry practice. They also provide a more uniform appearance for exposed masonry. The bed joint is a horizontal joint; the head joint is a vertical joint.

R606.3.2 Masonry unit placement. The mortar shall be sufficiently plastic and units shall be placed with sufficient pressure to extrude mortar from the joint and produce a tight joint. Deep furrowing of bed joints that produces voids shall not be permitted. Any units disturbed to the extent that initial bond is broken after initial placement shall be removed and relaid in fresh mortar. Surfaces to be in contact with mortar shall be clean and free of deleterious materials.

❖ This section gives placement requirements meant to provide adequate bonding between mortar and masonry units. Mortar is the bonding agent that integrates masonry units into a wall; it is used to bind masonry units into a single element by developing a complete, strong, and durable bond. Mortar is usually placed between absorbent masonry units and loses water upon contact with the units. Mortars have a high water-cement ratio when mixed, but the ratio decreases when the mortar comes into contact with the absorbent unit.

Once the mortar has begun to set or harden, tapping or attempting to otherwise move masonry units can be detrimental to the bond. Movement at this time will break the bond between the masonry unit and mortar. The partially dried mortar will not have sufficient plasticity to re-adhere sufficiently to the masonry units. After the initial bond has been broken, the masonry units should be removed and replaced in fresh mortar.

R606.3.2.1 Solid masonry. *Solid masonry* units shall be laid with full head and bed joints and all interior vertical joints that are designed to receive mortar shall be filled.

❖ This section applies to solid masonry construction (see the definition in Section 202).

R606.3.2.2 Hollow masonry. For hollow masonry units, head and bed joints shall be filled solidly with mortar for a distance in from the face of the unit not less than the thickness of the face shell.

❖ See the definition for “Masonry unit, hollow” in Section R202. Normally, cross webs are not mortared. When individual cells are to be grouted, mortar should be placed on the webs on both sides of the cell to be grouted to prevent leakage of the grout.

R606.3.3 Installation of wall ties. The installation of wall ties shall be as follows:

1. The ends of wall ties shall be embedded in mortar joints. Wall ties shall have not less than $\frac{5}{8}$ -inch (15.9 mm) mortar coverage from the exposed face.
2. Wall ties shall not be bent after being embedded in grout or mortar.
3. For solid masonry units, solid grouted hollow units, or hollow units in anchored masonry veneer, wall ties shall be embedded in mortar bed not less than $1\frac{1}{2}$ inches (38 mm).
4. For hollow masonry units in other than anchored masonry veneer, wall ties shall engage outer face shells by not less than $\frac{1}{2}$ inch (13 mm).

❖ Proper installation of masonry wall ties is necessary to achieve bonding of multiple wythes (also see Section R608.1.2.1). In addition, wall ties should not be bent after placement in the mortar joints. This can break the initial bond between the masonry unit and mortar and possibly lead to an increased amount of moisture infiltration into the wall assembly. Bending the wall ties after initial placement can also be detrimental to the strength of the wall system because the ties lose their ability to transfer lateral loads to the backing wall assembly.

Wall ties used with solid masonry units, solid grouted units and hollow units in anchored masonry veneer are embedded in the mortar bed at least $1\frac{1}{2}$ inches (38 mm) to ensure that there is adequate bond of the mortar to the veneer ties. Hollow units in anchored masonry veneer have been added to this provision. In the 2009 edition, hollow units in anchored masonry veneer were not separated from other hollow unit applications.

Wall ties for hollow units used in applications other than anchored masonry veneer continue to require embedment of the face shell by no less than $\frac{1}{2}$ inch (13 mm). This allows the cells of the unit to be later filled with grout.

R606.3.4 Protection for reinforcement. Bars shall be completely embedded in mortar or grout. Joint reinforcement embedded in horizontal mortar joints shall not have less than $\frac{5}{8}$ -inch (15.9 mm) mortar coverage from the exposed face.

Other reinforcement shall have a minimum coverage of one bar diameter over all bars, but not less than 3/4 inch (19 mm), except where exposed to weather or soil, in which case the minimum coverage shall be 2 inches (51 mm).

❖ Commentary Figure R606.3.4 shows placement restrictions for reinforcement relative to exposed faces and coverage.

R606.3.4.1 Corrosion protection. Minimum corrosion protection of joint reinforcement, anchor ties and wire fabric for use in masonry wall construction shall conform to Table R606.3.4.1.

❖ Table R606.3.4.1 contains reference standards for protecting metal accessories used in masonry wall construction.

The corrosion protection requirements are dependent on type of steel and exposure. Because of its high resistance to corrosion, stainless steel need not be coated. Joint reinforcement, anchors, ties and accessories of other than stainless steel must be protected by zinc coatings (galvanizing). The protective value of the zinc coating increases with increasing coating thickness; therefore, the amount of galvanizing required increases with the potential severity of exposure.

**TABLE R606.3.4.1
MINIMUM CORROSION PROTECTION**

MASONRY METAL ACCESSORY	STANDARD
Joint reinforcement, interior walls	ASTM A641, Class 1
Wire ties or anchors in exterior walls completely embedded in mortar or grout	ASTM A641, Class 3
Wire ties or anchors in exterior walls not completely embedded in mortar or grout	ASTM A153, Class B-2
Joint reinforcement in exterior walls or interior walls exposed to moist environment	ASTM A153, Class B-2
Sheet metal ties or anchors exposed to weather	ASTM A153, Class B-2
Sheet metal ties or anchors completely embedded in mortar or grout	ASTM A653, Coating Designation G60
Stainless steel hardware for any exposure	ASTM A167, Type 304

R606.3.5 Grouting requirements.

❖ With reorganization of the masonry wall provisions in the 2015 code, Section R606.3.5 covering provisions for grouting above-ground masonry walls now combines all the requirements for single-wythe, multiwythe and reinforced grouted masonry construction in one

section. Sections R606.3.5.1 through R606.3.5.3 address grout placement, cleanouts and construction for all three types of grouted masonry construction.

Section R606.3.5 provides the grouting requirements for single-wythe and multiwythe masonry. Grouted single-wythe and grouted multiwythe masonry are illustrated in Commentary Figure R606.3.5. To provide for an adequate bond between the masonry units and the grout, the units must be free of excessive dust or dirt. Grouted multiwythe masonry is a form of construction in which the space between the wythes is solidly filled with grout. It is not necessary for the cores of masonry units to be filled with grout. Grouted single-wythe masonry is a form of construction in which certain cells of hollow units are continuously filled with grout.

In the 2012 code there were several conflicts in the grouting requirements. Grout pour height triggering cleanouts varied depending on whether the masonry construction was single wythe, multiwythe or reinforced. Section R606.3.5.2 specifies the grout lift height triggering cleanouts as 64 inches for all masonry construction. This height is also consistent with IBC requirements. Similarly, Section R606.3.5.1 has increased grout lift requirements triggering special inspection from 60 to 64 inches for consistency.

In Section R606.3.5.1, grout placement, maximum grouting height and grout lift height are all addressed. Construction requirements for different masonry construction types are combined into Section R606.3.5.3

with four total requirements. Alignment of units, minimum reinforcement and minimum grout thickness are all addressed in Section R606.3.5.3.

R606.3.5.1 Grout placement. Grout shall be a plastic mix suitable for pumping without segregation of the constituents and shall be mixed thoroughly. Grout shall be placed by pumping or by an approved alternate method and shall be placed before any initial set occurs and not more than 1½ hours after water has been added. Grout shall be consolidated by puddling or mechanical vibrating during placing and reconsolidated after excess moisture has been absorbed but before plasticity is lost. Grout shall not be pumped through aluminum pipes.

Maximum pour heights and the minimum dimensions of spaces provided for grout placement shall conform to Table R606.3.5.1. Grout shall be poured in lifts of 8-foot (2438 mm) maximum height. Where a total grout pour exceeds 8 feet (2438 mm) in height, the grout shall be placed in lifts not exceeding 64 inches (1626 mm) and special inspection during grouting shall be required. If the work is stopped for 1 hour or longer, the horizontal construction joints shall be formed by stopping all tiers at the same elevation and with the grout 1 inch (25 mm) below the top.

❖ The selection of fine or coarse grout is made based on the size of grout space and the height of grout pour. Table R606.3.5.1 covers requirements for selection of grout type. Fine grout is required where grout space is small, narrow or too congested with reinforcing steel. Fine grout also can be used where coarse grout is per-

mitted. It is preferable, however, to use coarse grout, because it reduces shrinkage and is less expensive. See Commentary Figure R606.3.5.1 for an illustration of grout placement for multiple-wythe masonry (see also the commentary to Section R606.3.5).

The use of aluminum pipe for pumping grout is prohibited. Aluminum can adversely affect grout and unprotected reinforcing steel through galvanic action. This restriction protects against possible contamination during grout placement.

TABLE R606.3.5.1
GROUT SPACE DIMENSIONS AND POUR HEIGHTS

GROUT TYPE	GROUT POUR MAXIMUM HEIGHT (feet)	MINIMUM WIDTH OF GROUT SPACES ^{a, b} (inches)	MINIMUM GROUT ^{b, c} SPACE DIMENSIONS FOR GROUTING CELLS OF HOLLOW UNITS (inches × inches)
Fine	1	0.75	1.5 × 2
	5	2	2 × 3
	12	2.5	2.5 × 3
	24	3	3 × 3
Coarse	1	1.5	1.5 × 3
	5	2	2.5 × 3
	12	2.5	3 × 3
	24	3	3 × 4

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

- a. For grouting between masonry wythes.
- b. Grout space dimension is the clear dimension between any masonry protrusion and shall be increased by the horizontal projection of the diameters of the horizontal bars within the cross section of the grout space.
- c. Area of vertical reinforcement shall not exceed 6 percent of the area of the grout space.

WALL CONSTRUCTION

R606.3.5.2 Cleanouts. Provisions shall be made for cleaning the space to be grouted. Mortar that projects more than $\frac{1}{2}$ inch (12.7 mm) into the grout space and any other foreign matter shall be removed from the grout space prior to inspection and grouting. Where required by the building official, cleanouts shall be provided in the bottom course of masonry for each grout pour where the grout pour height exceeds 64 inches (1626 mm). In solid grouted masonry, cleanouts shall be spaced horizontally not more than 32 inches (813 mm) on center. The cleanouts shall be sealed before grouting and after inspection.

❖ This section specifies the requirements for cleanouts where required to aid in cleaning the grout spaces. Cleanouts should be furnished as described in this section (see the commentary to Section R606.3.5 and Commentary Figure R606.3.5.2).

R606.3.5.3 Construction. Requirements for grouted masonry construction shall be as follows:

1. Masonry shall be built to preserve the unobstructed vertical continuity of the cells or spaces to be filled. In partially grouted construction, cross webs forming cells to be filled shall be full-bedded in mortar to prevent leakage of grout. Head and end joints shall be solidly filled with mortar for a distance in from the face of the wall or unit not less than the thickness of the longitudinal face shells.
2. Vertical reinforcement shall be held in position at top and bottom and at intervals not exceeding 200 diameters of the reinforcement.
3. Cells containing reinforcement shall be filled solidly with grout.
4. The thickness of grout or mortar between masonry units and reinforcement shall be not less than $\frac{1}{4}$ inch (6.4

mm), except that $\frac{1}{4}$ -inch (6.4 mm) bars shall be permitted to be laid in horizontal mortar joints not less than $\frac{1}{2}$ inch (12.7 mm) thick, and steel wire reinforcement shall be permitted to be laid in horizontal mortar joints not less than twice the thickness of the wire diameter.

❖ The general purpose of the four requirements contained in Section R606.3.5.3 is to provide for the proper placement of reinforcing steel and the grouting of cells so that the construction will act structurally as a unit.

Item 1 provides for proper laying of hollow masonry units with appropriate mortar beds, which contain the grout (prevents leakage). The item also contains requirements for the grout space in which reinforcement may be placed [see Commentary Figure R606.3.5.3(1)]. The vertical continuity of the cells must be maintained to provide for sufficient space in which to place the grout [see Commentary Figure R606.3.5.3(2)].

Following the provision in Item 2 is necessary in order to maintain the vertical alignment of reinforcing steel during the grout pour. Also, the reinforcement will be maintained in a proper position relative to the block thickness as required by the design if the vertical reinforcement is secured at the top, bottom, and intervening points so that the distance between such anchorage does not exceed 200 bar diameters. Commentary Figure R606.3.5.3(3) illustrates methods of securing the reinforcement.

Items 3 and 4 provide limitations on the method of grouting the cells containing reinforcement so that the cells to be grouted will be filled solidly and the grout will be reasonably consolidated around the reinforcing steel. When reinforcing is used in grouted masonry, the dimensional constraints given in Item 4 provide clear-

ances necessary for the adequate placement of the grout within the cavity as well as the proper bond between the reinforcement and the grout [refer to Commentary Figures R606.3.5.3(4) and R606.3.5.3(5) for illustrations of the provisions].

R606.3.6 Grouted multiple-wythe masonry. Grouted multiple-wythe masonry shall conform to all the requirements specified in Section R606.3.5 and the requirements of this section.

❖ Grouted multiple-wythe masonry walls must comply with this section.

R606.3.6.1 Bonding of backup wythe. Where all interior vertical spaces are filled with grout in multiple-wythe construction,

masonry headers shall not be permitted. Metal wall ties shall be used in accordance with Section R606.13.2 to prevent spreading of the wythes and to maintain the vertical alignment of the wall. Wall ties shall be installed in accordance with Section R606.13.2 where the backup wythe in multiple-wythe construction is fully grouted.

❖ Masonry headers are not permitted in double-wythe grouted masonry construction because they span across the wythes and would interfere with the placement of the grout. Metal ties in accordance with Section R606.13.2 of the code prevent the spreading of wythes and maintain alignment during the grouting process.

**Figure R606.3.5.3(1)
REINFORCEMENT PLACEMENT LIMITATIONS**

**Figure R606.3.5.3(2)
REINFORCED HOLLOW UNIT MASONRY VERTICAL CELL ALIGNMENT**

WALL CONSTRUCTION

R606.3.6.2 Grout barriers. Vertical grout barriers or dams shall be built of *solid masonry* across the grout space the entire height of the wall to control the flow of the grout horizontally. Grout barriers shall be not more than 25 feet (7620 mm) apart. The grouting of any section of a wall between control barriers shall be completed in one day without interruptions greater than 1 hour.

- ❖ Grout barriers allow large walls to be properly grouted in sections.

R606.3.7 Masonry bonding pattern. Masonry laid in running and stack bond shall conform to Sections R606.3.7.1 and R606.3.7.2.

- ❖ Masonry must be laid in running bond (see the definition in Chapter 2) or be reinforced horizontally as specified in this section.

R606.3.7.1 Masonry laid in running bond. In each wythe of masonry laid in running bond, head joints in successive courses shall be offset by not less than one-fourth the unit length, or the masonry walls shall be reinforced longitudinally as required in Section R606.3.7.2.

- ❖ When masonry block is placed with an offset, it is called running bond [see Commentary Figure R606.13.2.1(1)]. Running bond is the most commonly used bonding pattern for masonry wall construction.

R606.3.7.2 Masonry laid in stack bond. Where unit masonry is laid with less head joint offset than in Section R606.3.7.1, the minimum area of horizontal reinforcement

placed in mortar bed joints or in bond beams spaced not more than 48 inches (1219 mm) apart shall be 0.0007 times the vertical cross-sectional area of the wall.

- ❖ Blocks stacked vertically are in the stack bond pattern [Refer to the definition in Section R202 of the code and Commentary Figure R606.3.7.2(1)]. The amount of steel in this section is an arbitrary amount to provide continuity across the head joints. To control cracking where masonry units are placed in a stack bond and where the wall is of unreinforced masonry construction, longitudinal reinforcement must be used in the horizontal bed joints as shown in Commentary Figure R606.3.7.2(1). Premanufactured ladder or truss-type reinforcement as shown in Commentary Figure R606.3.7.2(2) is generally used to meet the requirements for longitudinal steel.

R606.4 Thickness of masonry. The nominal thickness of masonry walls shall conform to the requirements of Sections R606.4.1 through R606.4.4.

- ❖ This section establishes minimum thicknesses for various masonry wall constructions.

R606.4.1 Minimum thickness. The minimum thickness of masonry bearing walls more than one story high shall be 8 inches (203 mm). *Solid masonry* walls of one-story dwellings and garages shall be not less than 6 inches (152 mm) in thickness where not greater than 9 feet (2743 mm) in height, provided that where gable construction is used, an additional 6 feet (1829 mm) is permitted to the peak of the gable. Masonry walls shall be laterally supported in either the horizontal or vertical direction at intervals as required by Section R606.6.4.

- ❖ The minimum thickness of bearing walls and exterior nonbearing walls of masonry construction more than

WALL CONSTRUCTION

one story high is limited to a nominal 8 inches (203 mm), which means a net thickness of not less than $7\frac{1}{2}$ inches (191 mm). A lesser thickness of 6-inch (152 mm) nominal or $5\frac{1}{2}$ -inch (140 mm) net of solid masonry is permitted if the wall does not exceed 9 feet (2743 mm) in height other than at the peak of a gable, where such height may extend to 15 feet (4572 mm) as shown in Commentary Figure R606.4.1.

R606.4.2 Rubble stone masonry wall. The minimum thickness of rough, random or coursed rubble stone masonry walls shall be 16 inches (406 mm).

- ❖ Rubble stone walls must be at least 16 inches (406 mm) thick (see commentary, Section R404.1.8).

R606.4.3 Change in thickness. Where walls of masonry of hollow units or masonry-bonded hollow walls are decreased in thickness, a course of solid masonry or masonry units filled with mortar or grout shall be constructed between the wall below and the thinner wall above, or special units or construction shall be used to transmit the loads from face shells or wythes above to those below.

- ❖ Where the thickness of hollow masonry wall construction is decreased, a solid masonry course or masonry units filled with mortar or grout provides bearing for the face shells of the thinner hollow unit above.

R606.4.4 Parapet walls. Unreinforced solid masonry parapet walls shall be not less than 8 inches (203 mm) thick and their height shall not exceed four times their thickness. Unreinforced hollow unit masonry parapet walls shall be not less than 8 inches (203 mm) thick, and their height shall not exceed three times their thickness. Masonry parapet walls in areas subject to wind loads of 30 pounds per square foot (1.44 kPa) located in Seismic Design Category D_0 , D_1 or D_2 , or on townhouses in Seismic Design Category C shall be reinforced in accordance with Section R606.12.

- ❖ A parapet is an extension of a wall that extends above the roof line. Generally, parapet walls are required to

comply only with fire-resistance requirements of the code. Parapet walls are required to have a certain minimum thickness with height limitations based on the thickness and reinforcement in the wall.

R606.5 Corbeled masonry. Corbeled masonry shall be in accordance with Sections R606.5.1 through R606.5.3.

- ❖ This section prescribes the units, projection and conditions for supporting floor or roof framing for corbeled masonry.

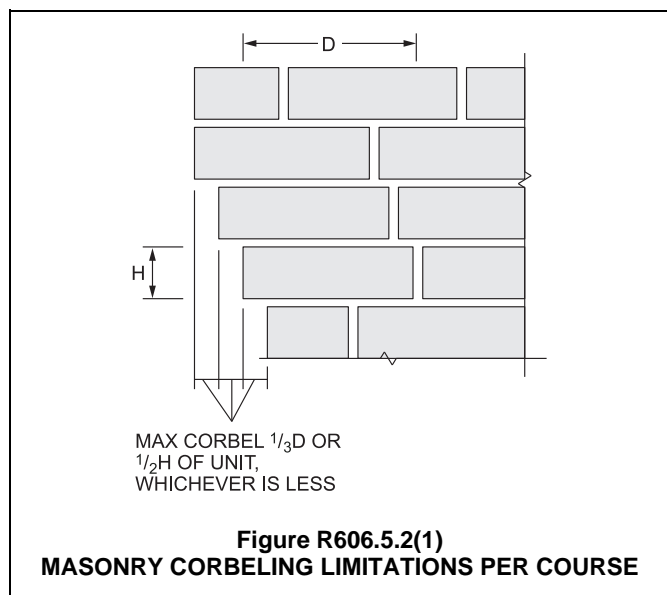

R606.5.1 Units. Solid masonry units or masonry units filled with mortar or grout shall be used for corbeling.

- ❖ Units to be used for corbeling should include solid units or units filled with mortar or grout. Units filled solid with mortar or grout will enable the unit to act as a solid unit in supporting the corbel above. Solid units and units filled solid with mortar or grout will distribute the load adequately to the masonry wall or wythe below. Further, there are many instances where solid units are not available while units filled solid with mortar or grout can be readily made on the job site as they are needed.

R606.5.2 Corbel projection. The maximum projection of one unit shall not exceed one-half the height of the unit or one-third the thickness at right angles to the wall. The maximum corbeled projection beyond the face of the wall shall not exceed:

1. One-half of the wall thickness for multiwythe walls bonded by mortar or grout and wall ties or masonry headers.
2. One-half the wythe thickness for single wythe walls, masonry-bonded hollow walls, multiwythe walls with open collar joints and veneer walls.

- ❖ Corbeling of masonry walls is permitted within certain limitations. The maximum projection for each unit is limited to one-third the unit bed depth (D) or one-half the unit height (H), whichever is less, as shown in Commentary Figure R606.5.2(1). The total horizontal projection of the corbeled courses is limited to one-half

the thickness of a solid wall or one-half the thickness of a wythe of a cavity wall as shown in Commentary Figure R606.5.2(2).

R606.5.3 Corbeled masonry supporting floor or roof-framing members. Where corbeled masonry is used to support floor or roof-framing members, the top course of the corbel shall be a header course or the top course bed joint shall have ties to the vertical wall.

- ❖ The top course of the corbel must be a header course or the bed joints must have ties to the wall where a corbel is used to support floor or roof framing.

R606.6 Support conditions. Bearing and support conditions shall be in accordance with Sections R606.6.1 through R606.6.4.

- ❖ Masonry bearing and support conditions must be in accordance with the subsections of Section R606.6.

R606.6.1 Bearing on support. Each masonry wythe shall be supported by at least two-thirds of the wythe thickness.

- ❖ At least two-thirds the thickness of the bottom course of all masonry wythes must bear directly on the supporting construction (i.e., bear on the supporting foundation wall, lintel or header, etc.).

R606.6.2 Support at foundation. Cavity wall or masonry veneer construction shall be permitted to be supported on an 8-inch (203 mm) foundation wall, provided the 8-inch (203 mm) wall is corbeled to the width of the wall system above with masonry constructed of solid masonry units or masonry units filled with mortar or grout. The total horizontal projection of the corbel shall not exceed 2 inches (51 mm) with individual corbels projecting not more than one-third the thickness of the unit or one-half the height of the unit. The hollow space behind the corbeled masonry shall be filled with mortar or grout.

- ❖ Foundations supporting masonry cavity walls must be at least 8 inches (203 mm) thick, and where the wall supported is thicker, the foundation wall must be corbeled to attain a thickness at least equal to that of the

wall supported. Corbeling limitations of this section are shown in Commentary Figure R606.6.2(1).

R606.6.3 Beam supports. Beams, girders or other concentrated loads supported by a wall or column shall have a bearing of not less than 3 inches (76 mm) in length measured parallel to the beam upon *solid masonry* not less than 4 inches (102 mm) in thickness, or upon a metal bearing plate of adequate design and dimensions to distribute the load safely, or upon a continuous reinforced masonry member projecting not less than 4 inches (102 mm) from the face of the wall.

- ❖ To provide for the transfer of vertical loads from beams, girders or other elements to the masonry wall or column, a minimum bearing as shown in Commentary Figure R606.6.3 is required. An alternative to the minimum bearing is the use of metal bearing plates that are based on structural design.

R606.6.3.1 Joist bearing. Joists shall have a bearing of not less than 1½ inches (38 mm), except as provided in Section R606.6.3, and shall be supported in accordance with Figure R606.11(1).

- ❖ Where joists bear on masonry wall or column elements, the minimum bearings as shown in Figure R606.11(1) and Commentary Figure R606.6.3.1 are considered to be adequate. The code does not provide guidance distinguishing whether a member is a joist or a beam; however, joists are generally considered to be members that are a nominal 2 inches (51 mm) maximum in thickness and placed not more than 24 inches (610 mm) on center.

R606.6.4 Lateral support. Masonry walls shall be laterally supported in either the horizontal or the vertical direction. The maximum spacing between lateral supports shall not exceed the distances in Table R606.6.4. Lateral support shall be provided by cross walls, pilasters, buttresses or structural frame members where the limiting distance is taken horizontally, or by floors or roofs where the limiting distance is taken vertically.

- ❖ The limitations on the maximum unsupported height or length of masonry walls specified in Table R606.6.4

WALL CONSTRUCTION

provides reasonable performance. For purposes of applying the unsupported height limitations, Figures R606.11(1), R606.11(2) and R606.11(3) provide details recognized as appropriate methods of anchorage. At the base of the wall, footings are a lateral support point. Thus, the unsupported height from the footing to the anchorage point at the floor or roof is the unsupported height, which must be limited to the values in Table R606.6.4.

Instead of unsupported height limitations being measured vertically from footing to supporting floor or roof, the span limitations in Table R606.6.4 of the code may be met with the use of pilasters, columns, piers, cross walls or similar elements whose relative stiffness is

greater than that of the wall. These elements are anchored to the roof or floor structural elements in a manner that transmits imposed lateral forces.

Commentary Figure R606.6.4 illustrates the lateral support limitations specified in the table.

Example:

The height or length limitation between lateral supports (see Commentary Figure R606.6.4) for a solid-gouted masonry bearing wall of 8-inch (203 mm) nominal units would be $8 \times 20 = 160$ inches (4064 mm). For a nonbearing interior wall using two wythes of 4-inch (102 mm) brick, the allowable limitation would be $(4 + 4) \times 36 = 288$ inches (7315 mm).

For SI: 1 inch = 25.4 mm.

Figure R606.6.2(1)
MASONRY CORBELING LIMITATIONS PER COURSE

For SI: 1 inch = 25.4 mm.

Figure R606.6.3
BEAM OR GIRDER BEARING ON MASONRY

**TABLE R606.6.4
SPACING OF LATERAL SUPPORT FOR MASONRY WALLS**

CONSTRUCTION	MAXIMUM WALL LENGTH TO THICKNESS OR WALL HEIGHT TO THICKNESS ^{a, b}
Bearing walls: Solid or solid grouted	20
All other	18
Nonbearing walls: Exterior	18
Interior	36

For SI: 1 foot = 304.8 mm.

- a. Except for cavity walls and cantilevered walls, the thickness of a wall shall be its nominal thickness measured perpendicular to the face of the wall. For cavity walls, the thickness shall be determined as the sum of the nominal thicknesses of the individual wythes. For cantilever walls, except for parapets, the ratio of height to nominal thickness shall not exceed 6 for solid masonry, or 4 for hollow masonry. For parapets, see Section R606.4.4.
- b. An additional unsupported height of 6 feet is permitted for gable end walls.

❖ Limitations on ratios of distance between lateral supports to wall thickness listed in this table are primarily

traditional ratios based on successful performance. The thickness in this table is based on the nominal thickness of the wall for other than cavity wall construction and the sum of the nominal thickness of the wythes not including the cavity for cavity walls; see Note a. To allow for additional height at gable-end walls, Note b permits an additional 6 feet (1829 mm). This is similar to the allowance discussed in Commentary Figure R606.4.1.

R606.6.4.1 Horizontal lateral support. Lateral support in the horizontal direction provided by intersecting masonry walls shall be provided by one of the methods in Section R606.6.4.1.1 or R606.6.4.1.2.

❖ When masonry walls span horizontally between intersecting walls, anchorage is achieved using the method in either of the following sections.

R606.6.4.1.1 Bonding pattern. Fifty percent of the units at the intersection shall be laid in an overlapping masonry bond-

WALL CONSTRUCTION

ing pattern, with alternate units having a bearing of not less than 3 inches (76 mm) on the unit below.

- ❖ Using this method, anchorage is accomplished by off setting (overlapping) alternating courses of masonry.

R606.6.4.1.2 Metal reinforcement. Interior nonload-bearing walls shall be anchored at their intersections, at vertical intervals of not more than 16 inches (406 mm) with joint reinforcement of not less than 9 gage [0.148 inch (4mm)], or 1/4-inch (6 mm) galvanized mesh hardware cloth. Intersecting masonry walls, other than interior nonloadbearing walls, shall be anchored at vertical intervals of not more than 8 inches (203 mm) with joint reinforcement of not less than 9 gage and shall extend not less than 30 inches (762 mm) in each direction at the intersection. Other metal ties, joint reinforcement or anchors, if used, shall be spaced to provide equivalent area of anchorage to that required by this section.

- ❖ See Commentary Figure R606.6.4.1.2.

R606.6.4.2 Vertical lateral support. Vertical lateral support of masonry walls in Seismic Design Category A, B or C shall be provided in accordance with one of the methods in Section R606.6.4.2.1 or R606.6.4.2.2.

- ❖ Where walls span vertically in buildings classified as SDC A, B or C, masonry walls must be anchored to the floor and roof diaphragms to transmit the anticipated lateral forces. The unsupported height from the footing to the floor or roof must be within the limits of Table R606.6.4.

R606.6.4.2.1 Roof structures. Masonry walls shall be anchored to roof structures with metal strap anchors spaced in accordance with the manufacturer's instructions, 1/2-inch (13 mm) bolts spaced not more than 6 feet (1829 mm) on center, or other *approved* anchors. Anchors shall be embedded not less than 16 inches (406 mm) into the masonry, or be hooked

or welded to bond beam reinforcement placed not less than 6 inches (152 mm) from the top of the wall.

- ❖ If 1/2-inch (12.7 mm) diameter anchor bolts are used, they must be spaced no farther apart than 6 feet (1829 mm) on center. Where approved metal strap anchors are used, the spacing must be in accordance with the manufacturer's recommendations. Anchors are embedded in the masonry wall and connected to the wooden ledger as illustrated in Commentary Figures R606.6.4.2.1(1) and R606.6.4.2.1(2).

Figure R606.6.4.2.1(2)
ANCHORAGE OF ROOF STRUCTURES

R606.6.4.2.2 Floor diaphragms. Masonry walls shall be anchored to floor *diaphragm* framing by metal strap anchors spaced in accordance with the manufacturer's instructions, $\frac{1}{2}$ -inch-diameter (13 mm) bolts spaced at intervals not to exceed 6 feet (1829 mm) and installed as shown in Figure R606.11(1), or by other *approved* methods.

- ❖ Masonry walls must be anchored to the floor diaphragm with bolts spaced no farther apart than 6 feet (1829 mm) on center. Fasteners may be either metal strap anchors installed per the manufacturer's recommendations or bolts that are embedded in the masonry walls and connected to the wooden ledger. Ledger fasteners transfer shear forces when loading is in the plane of the wall; when forces are out of plane, ledge fasteners prevent the wall and flooring system from separating.

R606.7 Piers. The unsupported height of masonry piers shall not exceed 10 times their least dimension. Where structural clay tile or hollow concrete masonry units are used for isolated piers to support beams and girders, the cellular spaces shall be filled solidly with grout or Type M or S mortar, except that unfilled hollow piers shall be permitted to be used if their unsupported height is not more than four times their least dimension. Where hollow masonry units are solidly filled with grout or Type M, S or N mortar, the allowable compressive stress shall be permitted to be increased as provided in Table R606.9.

- ❖ Isolated masonry piers conforming to this section may be used to support beams and girders. The minimum pier area should be based on the design load sup-

ported and the allowable stress of the construction in accordance with Table R606.9.

R606.7.1 Pier cap. Hollow piers shall be capped with 4 inches (102 mm) of *solid masonry* or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout.

- ❖ Beams and girders must be directly supported on a sill plate or the masonry piers to provide a complete load path to the foundation.

R606.8 Chases. Chases and recesses in masonry walls shall not be deeper than one-third the wall thickness, and the maximum length of a horizontal chase or horizontal projection shall not exceed 4 feet (1219 mm), and shall have not less than 8 inches (203 mm) of masonry in back of the chases and recesses and between adjacent chases or recesses and the jambs of openings. Chases and recesses in masonry walls shall be designed and constructed so as not to reduce the required strength or required fire resistance of the wall and in no case shall a chase or recess be permitted within the required area of a pier. Masonry directly above chases or recesses wider than 12 inches (305 mm) shall be supported on noncombustible lintels.

- ❖ A chase is a continuous recess in a masonry wall that receives a pipe, conduit, etc. Generally, chases are vertical. It is best to construct chases as the masonry wall is built so the strength of the wall is not reduced.

R606.9 Allowable stresses. Allowable compressive stresses in masonry shall not exceed the values prescribed in Table R606.9. In determining the stresses in masonry, the effects of all loads and conditions of loading and the influence of all forces affecting the design and strength of the several parts shall be taken into account.

- ❖ Masonry compressive stresses are determined from the type and compressive strength of the unit and the type of mortar used in construction. Table R606.9 lists the maximum permitted stresses. Stresses must be computed based on the actual dimensions of the masonry.

Example:

How does a Type S versus Type N mortar affect the allowable compressive stress in unit masonry for a wall composed of solid concrete brick having a unit compressive stress of 2,500 psi (17 237 kPa)?

Solution:

From Table R606.9, the allowable compressive strength is a function of the mortar and would be:

2,500 psi solid units (17 237 kPa): using Type S mortar = 160 psi (1103 kPa).

2,500 psi solid units (17 237 kPa): using Type N mortar = 140 psi (965 kPa).

Table R606.9. See page 6-148.

- ❖ See the commentary to Section R606.9.

TABLE R606.9
ALLOWABLE COMPRESSIVE STRESSES FOR
EMPIRICAL DESIGN OF MASONRY

CONSTRUCTION; COMPRES- SIVE STRENGTH OF UNIT, GROSS AREA	ALLOWABLE COMPRESSIVE STRESSES ^a GROSS CROSS-SECTIONAL AREA ^b	
	Type M or S mortar	Type N mortar
Solid masonry of brick and other solid units of clay or shale; sand-lime or con- crete brick: 8,000 + psi 4,500 psi 2,500 psi 1,500 psi	350 225 160 115	300 200 140 100
Grouted ^c masonry, of clay or shale; sand-lime or con- crete: 4,500 + psi 2,500 psi 1,500 psi	225 160 115	200 140 100
Solid masonry of solid con- crete masonry units: 3,000 + psi 2,000 psi 1,200 psi	225 160 115	200 140 100
Masonry of hollow load- bearing units: 2,000 + psi 1,500 psi 1,000 psi 700 psi	140 115 75 60	120 100 70 55
Hollow walls (cavity or masonry bonded ^d) solid units: 2,500 + psi 1,500 psi Hollow units	160 115 75	140 100 70
Stone ashlar masonry: Granite Limestone or marble Sandstone or cast stone	720 450 360	640 400 320
Rubble stone masonry: Coarse, rough or random	120	100

For SI: 1 pound per square inch = 6.895 kPa.

- Linear interpolation shall be used for determining allowable stresses for masonry units having compressive strengths that are intermediate between those given in the table.
- Gross cross-sectional area shall be calculated on the actual rather than nominal dimensions.
- See Section R606.13.
- Where floor and roof loads are carried upon one wythe, the gross cross-sectional area is that of the wythe under load; if both wythes are loaded, the gross cross-sectional area is that of the wall minus the area of the cavity between the wythes. Walls bonded with metal ties shall be considered as cavity walls unless the collar joints are filled with mortar or grout.

R606.9.1 Combined units. In walls or other structural members composed of different kinds or grades of units, materials or mortars, the maximum stress shall not exceed the allow-

able stress for the weakest of the combination of units, materials and mortars of which the member is composed. The net thickness of any facing unit that is used to resist stress shall be not less than 1½ inches (38 mm).

- Walls containing different grades of units, materials or mortars must be limited to the maximum compressive stresses for the weakest combination of units and mortar.

Example:

What is the allowable compressive stress in unit masonry for a wall constructed of 8,000 psi (55 152 kPa) solid brick units, 2,000 psi (13 788 kPa) hollow masonry units, and Type S mortar?

Solution:

From Table R606.9, the allowable compressive stress would be limited to the smaller of:

8,000 psi (55 158 kPa) solid brick units using Type S mortar = 350 psi (2413 kPa);

2,000 psi (13 789 kPa) hollow masonry units using Type S mortar = 140 psi (965 kPa).

The allowable unit masonry stress used in design would be the weaker of the two materials constructed with Type S mortar. Therefore, the allowable stress would be 140 psi (965 kPa).

R606.10 Lintels. Masonry over openings shall be supported by steel lintels, reinforced concrete or masonry lintels or masonry arches, designed to support load imposed.

- Masonry wall openings require a structural member designed to support the masonry above. Note that wood is not permitted for a lintel supporting a masonry wall.

R606.11 Anchorage. Masonry walls shall be anchored to floor and roof systems in accordance with the details shown in Figure R606.11(1), R606.11(2) or R606.11(3). Footings shall be permitted to be considered as points of lateral support.

- Masonry walls depend on floors and roofs for out-of-plane lateral support. Inadequate anchorage of masonry walls in areas of high, and even moderate, seismicity can be problematic. The referenced figures show anchorage requirements that vary based on seismic design category. They illustrate details that provide adequate load transfer under lateral loads.

FIGURE R606.11(1). See page 6-149.

- FIGURE R606.11(2).** See page 6-150

- See the commentary to Section R606.11.

- FIGURE R606.11(3).** See page 6-151.

- See the commentary to Section R606.11.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

Note: Where bolts are located in hollow masonry, the cells in the courses receiving the bolt shall be grouted solid.

FIGURE R606.11(1)
ANCHORAGE REQUIREMENTS FOR MASONRY WALLS LOCATED IN SEISMIC DESIGN CATEGORY A, B OR C AND WHERE WIND LOADS ARE LESS THAN 30 PSF

WALL CONSTRUCTION

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R606.11(2)
REQUIREMENTS FOR REINFORCED GROUTED MASONRY CONSTRUCTION IN SEISMIC DESIGN CATEGORY C

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Note: A full bed joint must be provided. Cells containing vertical bars are to be filled to the top of wall and provide inspection opening as shown on detail "A." Horizontal bars are to be laid as shown on detail "B." Lintel bars are to be laid as shown on Section C.

FIGURE R606.11(3)
REQUIREMENTS FOR REINFORCED MASONRY CONSTRUCTION IN SEISMIC DESIGN CATEGORY D₀, D₁ OR D₂

R606.12 Seismic requirements. The seismic requirements of this section shall apply to the design of masonry and the construction of masonry building elements located in Seismic Design Category D₀, D₁ or D₂. Townhouses in Seismic Design Category C shall comply with the requirements of Section R606.12.2. These requirements shall not apply to glass unit masonry conforming to Section R610, anchored masonry veneer conforming to Section R703.8 or adhered masonry veneer conforming to Section R703.12.

❖ Although the code generally permits unreinforced walls, this section requires reinforcement in walls of buildings classified as SDC C, D₀, D₁ or D₂.

R606.12.1 General. Masonry structures and masonry elements shall comply with the requirements of Sections R606.12.2 through R606.12.4 based on the seismic design category established in Table R301.2(1). Masonry structures and masonry elements shall comply with the requirements of Section R606.12 and Figures R606.11(1), R606.11(2) and R606.11(3) or shall be designed in accordance with TMS 402/ACI 530/ASCE 5 or TMS 403.

❖ Masonry walls must comply with this section unless a design is provided. The three cited figures show the reinforcing requirements as a function of the seismic design category and wind load.

R606.12.1.1 Floor and roof diaphragm construction. Floor and roof *diaphragms* shall be constructed of wood structural panels attached to wood framing in accordance with Table R602.3(1) or to cold-formed steel floor framing in accordance with Table R505.3.1(2) or to cold-formed steel roof framing in accordance with Table R804.3. Additionally, sheathing panel edges perpendicular to framing members shall be backed by blocking, and sheathing shall be connected to the blocking with fasteners at the edge spacing. For Seismic Design Categories C, D₀, D₁ and D₂, where the width-to-thickness dimension of the *diaphragm* exceeds 2-to-1, edge spacing of fasteners shall be 4 inches (102 mm) on center.

❖ This section reiterates the requirements of Chapters 5 and 8 for fastening structural wood sheathing to floor framing and roof framing. Additional blocking is specified for the structural wood sheathing edges perpendicular to the floor or roof framing, thus providing a blocked diaphragm. Edge fasteners as specified for panel edges must be used at this blocking. Furthermore, if a diaphragm's depth-to-span ratio is greater

than 2 in a building classified as SDC C, D₀, D₁ or D₂, the edge nail spacing must be reduced to 4 inches (102 mm) on center. These requirements result in added strength and stiffness for diaphragms that support masonry walls.

R606.12.2 Seismic Design Category C. Townhouses located in Seismic Design Category C shall comply with the requirements of this section.

❖ Townhouses classified as SDC C must conform to the requirements of this section as well as Figures R606.11(1) and R606.11(2). The requirements are based on whether or not an element is part of the lateral-force-resisting system. They are aimed at providing ductility by specifying minimum reinforcement.

R606.12.2.1 Minimum length of wall without openings. Table R606.12.2.1 shall be used to determine the minimum required solid wall length without openings at each masonry exterior wall. The provided percentage of solid wall length shall include only those wall segments that are 3 feet (914 mm) or longer. The maximum clear distance between wall segments included in determining the solid wall length shall not exceed 18 feet (5486 mm). Shear wall segments required to meet the minimum wall length shall be in accordance with Section R606.12.2.2.3.

❖ The code prescribes length of bracing for wood, steel and concrete wall systems. Previous to the 2009 edition of the code, there was no regulation of the minimum length of bracing wall to be provided in masonry wall buildings. This section corrects this situation by basing the minimum wall length requirements on those developed for concrete walls, a comparable material both in terms of load requirements and capacity. These provisions are applicable to multistory construction without engineered design in SDC C and single story in SDC D₀, D₁ and D₂. The provisions are based on concrete requirements, providing interim guidance until more specific masonry requirements are developed.

TABLE R606.12.2.1. See below.

❖ See the commentary to Section R606.12.2.1.

R606.12.2.2 Design of elements not part of the lateral force-resisting system.

R606.12.2.2.1 Load-bearing frames or columns. Elements not part of the lateral force-resisting system shall be analyzed

TABLE R606.12.2.1
MINIMUM SOLID WALL LENGTH ALONG EXTERIOR WALL LINES

SEISMIC DESIGN CATEGORY	MINIMUM SOLID WALL LENGTH (percent) ^a		
	One story or top story of two story	Wall supporting light-framed second story and roof	Wall supporting masonry second story and roof
Townhouses in C	20	25	35
D ₀ or D ₁	25	NP	NP
D ₂	30	NP	NP

NP = Not permitted, except with design in accordance with the *International Building Code*.

a. For all walls, the minimum required length of solid walls shall be based on the table percent multiplied by the dimension, parallel to the wall direction under consideration, of a rectangle inscribing the overall building plan.

to determine their effect on the response of the system. The frames or columns shall be adequate for vertical load carrying capacity and induced moment caused by the design *story* drift.

- ❖ Load-bearing elements not part of a lateral-force-resisting system must be analyzed for their effect on the response of the system and must be capable of supporting all loads in combination with drift-induced bending stresses. These empirical masonry provisions do not cover the design of elements referred to in this section. They would require an engineering design using TMS 402/ACI 530/ASCE 5 (see the commentary to Section R606.12.2).

R606.12.2.2.2 Masonry partition walls. Masonry partition walls, masonry screen walls and other masonry elements that are not designed to resist vertical or lateral loads, other than those induced by their own weight, shall be isolated from the structure so that vertical and lateral forces are not imparted to these elements. Isolation joints and connectors between these elements and the structure shall be designed to accommodate the design *story* drift.

- ❖ Nonload-bearing elements that are not designed to resist vertical or lateral loads from earthquake effects on the building lateral force system must be isolated from the structure with isolation joints and connectors that can accommodate the design drift. The design *story* drift should be taken as 1 percent of the *story* height as allowed in Section 12.14.8.5 of ASCE 7 unless an analysis is performed.

R606.12.2.2.3 Reinforcement requirements for masonry elements. Masonry elements listed in Section R606.12.2.2 shall be reinforced in either the horizontal or vertical direction as shown in Figure R606.11(2) and in accordance with the following:

1. Horizontal reinforcement. Horizontal joint reinforcement shall consist of not less than two longitudinal W1.7 wires spaced not more than 16 inches (406 mm) for walls greater than 4 inches (102 mm) in width and not less than one longitudinal W1.7 wire spaced not more than 16 inches (406 mm) for walls not exceeding 4 inches (102 mm) in width; or not less than one No. 4 bar spaced not more than 48 inches (1219 mm). Where two longitudinal wires of joint reinforcement are used, the space between these wires shall be the widest that the mortar joint will accommodate. Horizontal reinforcement shall be provided within 16 inches (406 mm) of the top and bottom of these masonry elements.
 2. Vertical reinforcement. Vertical reinforcement shall consist of not less than one No. 4 bar spaced not more than 48 inches (1219 mm). Vertical reinforcement shall be located within 16 inches (406 mm) of the ends of masonry walls.
- ❖ This section specifies reinforcement for masonry walls that are not part of the building lateral force system, as described in the previous section (see commentary, Section R606.12.2).

R606.12.2.3 Design of elements part of the lateral force-resisting system.

R606.12.2.3.1 Connections to masonry shear walls. Connectors shall be provided to transfer forces between masonry walls and horizontal elements in accordance with the requirements of Section 4.1.4 of TMS 402/ACI 530/ASCE 5. Connectors shall be designed to transfer horizontal design forces acting either perpendicular or parallel to the wall, but not less than 200 pounds per linear foot (2919 N/m) of wall. The maximum spacing between connectors shall be 4 feet (1219 mm). Such anchorage mechanisms shall not induce tension stresses perpendicular to grain in ledgers or nailers.

- ❖ The connection of horizontal elements such as diaphragms to masonry walls or columns must be designed in accordance with TMS 402/ACI 530/ASCE 5. These connections should also be in accordance with Figure R606.11(2) and meet the minimum requirements specified in this section. Because these connections have been a source of earthquake-related failures, the code does not allow diaphragm anchorage mechanisms that cause cross-grain bending. This addresses the problem of premature failure of wood ledgers (see commentary, Section R606.12.2).

R606.12.2.3.2 Connections to masonry columns. Connectors shall be provided to transfer forces between masonry columns and horizontal elements in accordance with the requirements of Section 4.1.4 of TMS 402/ACI 530/ASCE 5. Where anchor bolts are used to connect horizontal elements to the tops of columns, the bolts shall be placed within lateral ties. Lateral ties shall enclose both the vertical bars in the column and the anchor bolts. There shall be not less than two No. 4 lateral ties provided in the top 5 inches (127 mm) of the column.

- ❖ These empirical masonry provisions do not cover the design of masonry columns. A design in accordance with TMS 402/ACI 530/ASCE 5 must be provided. In that event, this section provides a reference to the appropriate section of the standard for the column-to-diaphragm connection design (see commentary, Section R606.12.2).

R606.12.2.3.3 Minimum reinforcement requirements for masonry shear walls. Vertical reinforcement of not less than one No. 4 bar shall be provided at corners, within 16 inches (406 mm) of each side of openings, within 8 inches (203 mm) of each side of movement joints, within 8 inches (203 mm) of the ends of walls, and at a maximum spacing of 10 feet (3048 mm).

Horizontal joint reinforcement shall consist of not less than two wires of W1.7 spaced not more than 16 inches (406 mm); or bond beam reinforcement of not less than one No. 4 bar spaced not more than 10 feet (3048 mm) shall be provided. Horizontal reinforcement shall be provided at the bottom and top of wall openings and shall extend not less than 24 inches (610 mm) nor less than 40 bar diameters past the opening; continuously at structurally connected roof and floor levels; and within 16 inches (406 mm) of the top of walls.

- ❖ Masonry shear walls resist the lateral loads from wind or earthquakes. This section specifies reinforcing requirements, which are illustrated in Figure R606.11(2) (see commentary, Section R606.12.2).

WALL CONSTRUCTION

R606.12.3 Seismic Design Category D₀ or D₁. Structures in Seismic Design Category D₀ or D₁ shall comply with the requirements of Seismic Design Category C and the additional requirements of this section. AAC masonry shall not be used for the design of masonry elements that are part of the lateral force-resisting system.

- ❖ Buildings classified as SDC D₀ or D₁ must conform to the requirements of this section as well as the requirements for SDC C [see Section R606.12.2 and Figure R606.11(2)]. AAC masonry is not permitted as part of the lateral force-resisting system.

R606.12.3.1 Design requirements. Masonry elements other than those covered by Section R606.12.2.2 shall be designed in accordance with the requirements of Chapters 1 through 7 and Sections 8.1 and 8.3 of TMS 402, ACI 530/ASCE 5 and shall meet the minimum reinforcement requirements contained in Sections R606.12.3.2 and R606.12.3.2.1. Otherwise, masonry shall be designed in accordance with TMS 403.

Exception: Masonry walls limited to one *story* in height and 9 feet (2743 mm) between lateral supports need not be designed provided they comply with the minimum reinforcement requirements of Sections R606.12.3.2 and R606.12.3.2.1.

- ❖ This section specifies the design criteria for masonry elements in SDC D₀ or D₁.

Except for nonload-bearing elements that are not part of the lateral-force-resisting system, masonry elements must be designed using TMS 402/ACI 530/ASCE 5. The exception allows certain one-story masonry walls to satisfy the specified prescriptive code requirements rather than being designed to other engineering standards.

R606.12.3.2 Minimum reinforcement requirements for masonry walls. Masonry walls other than those covered by Section R606.12.2.2.3 shall be reinforced in both the vertical and horizontal direction. The sum of the cross-sectional area of horizontal and vertical reinforcement shall be not less than 0.002 times the gross cross-sectional area of the wall, and the minimum cross-sectional area in each direction shall be not less than 0.0007 times the gross cross-sectional area of the wall. Reinforcement shall be uniformly distributed. Table R606.12.3.2 shows the minimum reinforcing bar sizes

required for varying thicknesses of masonry walls. The maximum spacing of reinforcement shall be 48 inches (1219 mm) provided that the walls are solid grouted and constructed of hollow open-end units, hollow units laid with full head joints or two wythes of solid units. The maximum spacing of reinforcement shall be 24 inches (610 mm) for all other masonry.

- ❖ The sum of horizontal and vertical reinforcement must be at least 0.2 percent of the cross-sectional area of the wall, and the reinforcing should be distributed as shown in Table R606.12.3.2 [see commentary, Figure R606.11(3) and Section R606.12.3].

TABLE R606.12.3.2. See below.

- ❖ This table lists the minimum reinforcement areas specified in Section R606.12.3.2. The minimum bar size shown in the far right column satisfies the requirement for 0.0007 times the gross cross-sectional area of the wall. This must be provided as a minimum in both the vertical and horizontal directions. Additional reinforcement is necessary in either direction to meet the requirement for a total of 0.002 times the gross cross-sectional area.

R606.12.3.2.1 Shear wall reinforcement requirements. The maximum spacing of vertical and horizontal reinforcement shall be the smaller of one-third the length of the shear wall, one-third the height of the shear wall, or 48 inches (1219 mm). The minimum cross-sectional area of vertical reinforcement shall be one-third of the required shear reinforcement. Shear reinforcement shall be anchored around vertical reinforcing bars with a standard hook.

- ❖ See the commentary to Section R606.12.3.

R606.12.3.3 Minimum reinforcement for masonry columns. Lateral ties in masonry columns shall be spaced not more than 8 inches (203 mm) on center and shall be not less than $\frac{3}{8}$ -inch (9.5 mm) diameter. Lateral ties shall be embedded in grout.

- ❖ See Figure R606.11(3). Also see the commentary to Sections R606.12.2.2.2 and R606.12.3.

R606.12.3.4 Material restrictions. Type N mortar or masonry cement shall not be used as part of the lateral force-resisting system.

- ❖ This restates the requirement of Section R607.1.3.

TABLE R606.12.3.2
MINIMUM DISTRIBUTED WALL REINFORCEMENT FOR BUILDINGS ASSIGNED TO SEISMIC DESIGN CATEGORY D₀ or D₁

NOMINAL WALL THICKNESS (inches)	MINIMUM SUM OF THE VERTICAL AND HORIZONTAL REINFORCE- MENT AREAS ^a (square inches per foot)	MINIMUM REINFORCEMENT AS DIS- TRIBUTED IN BOTH HORIZONTAL AND VERTICAL DIRECTIONS ^b (square inches per foot)	MINIMUM BAR SIZE FOR REINFORCEMENT SPACED AT 48 INCHES
6	0.135	0.047	#4
8	0.183	0.064	#5
10	0.231	0.081	#6
12	0.279	0.098	#6

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square inch per foot = 2064 mm²/m.

- Based on the minimum reinforcing ratio of 0.002 times the gross cross-sectional area of the wall.
- Based on the minimum reinforcing ratio each direction of 0.0007 times the gross cross-sectional area of the wall.

R606.12.3.5 Lateral tie anchorage. Standard hooks for lateral tie anchorage shall be either a 135-degree (2.4 rad) standard hook or a 180-degree (3.2 rad) standard hook.

- ❖ Lateral ties (required by Section R606.12.3.3) must be anchored as specified. Also see the commentary to Section R606.12.3.

R606.12.4 Seismic Design Category D₂. Structures in Seismic Design Category D₂ shall comply with the requirements of Seismic Design Category D₁ and to the additional requirements of this section.

- ❖ Buildings classified as SDC D₂ must conform to the requirements of this section as well as all the requirements for SDC D₀ and D₁ and Figure R606.11(3).

R606.12.4.1 Design of elements not part of the lateral force-resisting system. Stack bond masonry that is not part of the lateral force-resisting system shall have a horizontal cross-sectional area of reinforcement of not less than 0.0015 times the gross cross-sectional area of masonry. Table R606.12.4.1 shows minimum reinforcing bar sizes for masonry walls. The maximum spacing of horizontal reinforcement shall be 24 inches (610 mm). These elements shall be solidly grouted and shall be constructed of hollow open-end units or two wythes of solid units.

- ❖ For elements that are not part of the lateral-force-resisting system, horizontal reinforcement must be at least 0.0015 times the cross-sectional area of the wall as shown in Table R606.12.4.1.

**TABLE R606.12.4.1
MINIMUM REINFORCING FOR STACKED BONDED
MASONRY WALLS IN SEISMIC DESIGN CATEGORY D₂**

NOMINAL WALL THICKNESS (inches)	MINIMUM BAR SIZE SPACED AT 24 INCHES
6	#4
8	#5
10	#5
12	#6

For SI: 1 inch = 25.4 mm.

- ❖ See the commentary to Section R606.12.4.1.

R606.12.4.2 Design of elements part of the lateral force-resisting system. Stack bond masonry that is part of the lateral force-resisting system shall have a horizontal cross-sectional area of reinforcement of not less than 0.0025 times the gross cross-sectional area of masonry. Table R606.12.4.2 shows minimum reinforcing bar sizes for masonry walls. The maximum spacing of horizontal reinforcement shall be 16 inches (406 mm). These elements shall be solidly grouted and shall be constructed of hollow open-end units or two wythes of solid units.

- ❖ Elements that are part of the lateral-force-resisting system must have horizontal reinforcement of at least 0.0025 times the cross-sectional area of the wall as shown in Table R606.12.4.2. These elements may be

constructed of solid grouted hollow open-end units or of two wythes of solid units solidly grouted.

**TABLE R606.12.4.2
MINIMUM REINFORCING FOR STACKED BONDED
MASONRY WALLS IN SEISMIC DESIGN CATEGORY D₂**

NOMINAL WALL THICKNESS (inches)	MINIMUM BAR SIZE SPACED AT 16 INCHES
6	#4
8	#5
10	#5
12	#6

For SI: 1 inch = 25.4 mm.

- ❖ See the commentary to Section R606.12.4.2.

R606.13 Multiple-wythe masonry. The facing and backing of multiple-wythe masonry walls shall be bonded in accordance with Section R606.13.1, R606.13.2 or R606.13.3. In cavity walls, neither the facing nor the backing shall be less than 3 inches (76 mm) nominal in thickness and the cavity shall be not more than 4 inches (102 mm) nominal in width. The backing shall be not less than as thick as the facing.

Exception: Cavities shall be permitted to exceed the 4-inch (102 mm) nominal dimension provided tie size and tie spacing have been established by calculation.

- ❖ The provisions of Section R606.13 apply to masonry walls more than one masonry unit in thickness. In cases where a wall thickness is made up of multiple wythes of masonry units, bonding is required so that the wythes are tied together to act as a unit. Section R606.13 contains the specifics of what constitutes an acceptable bonding mechanism. Two basic types of bonding are permissible: the first involves various overlapping arrangements; the second is achieved by installation of corrosion-resistant metal ties as stipulated for cavity-wall masonry construction.

R606.13.1 Bonding with masonry headers. Bonding with solid or hollow masonry headers shall comply with Sections R606.13.1.1 and R606.13.1.2.

- ❖ There are two methods of bonding multiwythe walls through the use of headers. They can be solid or hollow unit, depending on the wall system in question.

R606.13.1.1 Solid units. Where the facing and backing (adjacent wythes) of *solid masonry* construction are bonded by means of masonry headers, not less than 4 percent of the wall surface of each face shall be composed of headers extending not less than 3 inches (76 mm) into the backing. The distance between adjacent full-length headers shall not exceed 24 inches (610 mm) either vertically or horizontally. In walls in which a single header does not extend through the wall, headers from the opposite sides shall overlap not less

WALL CONSTRUCTION

than 3 inches (76 mm), or headers from opposite sides shall be covered with another header course overlapping the header below not less than 3 inches (76 mm).

- ❖ See the commentary to Section R606.13.1 and Commentary Figure R606.13.1.1.

R606.13.1.2 Hollow units. Where two or more hollow units are used to make up the thickness of a wall, the stretcher courses shall be bonded at vertical intervals not exceeding 34 inches (864 mm) by lapping not less than 3 inches (76 mm) over the unit below, or by lapping at vertical intervals not exceeding 17 inches (432 mm) with units that are not less than 50 percent thicker than the units below.

- ❖ See the commentary to Section R606.13.1 and Commentary Figure R606.13.1.2.

R606.13.2 Bonding with wall ties or joint reinforcement. Bonding with wall ties or joint reinforcement shall comply with Section R606.13.2.3.

- ❖ See the commentary to Section R606.13.

R606.13.2.1 Bonding with wall ties. Bonding with wall ties, except as required by Section R607, where the facing and backing (adjacent wythes) of masonry walls are bonded with $\frac{3}{16}$ -inch-diameter (5 mm) wall ties embedded in the horizontal mortar joints, there shall be not less than one metal tie for each $4\frac{1}{2}$ square feet (0.418 m²) of wall area. Ties in alternate courses shall be staggered. The maximum vertical distance between ties shall not exceed 24 inches (610 mm), and the maximum horizontal distance shall not exceed 36 inches (914 mm). Rods or ties bent to rectangular shape shall be used with hollow masonry units laid with the cells vertical. In other walls, the ends of ties shall be bent to 90-degree (0.79 rad) angles to provide hooks not less than 2 inches (51 mm) long. Additional bonding ties shall be provided at all openings,

spaced not more than 3 feet (914 mm) apart around the perimeter and within 12 inches (305 mm) of the opening.

- ❖ Multiwythe walls can be bonded with wire-type ties. Generally, this type of tie consists of metal Z ties or rectangular ties. The code requires certain maximum spacing for wire ties similar to that for masonry headers. This section provides minimum wire diameters and requires spacing based on a square footage area of the wall in question. Additional bonding ties are required around wall openings, such as windows or doors. These wire ties are used to anchor wythes of masonry together to resist loads or to transfer loads across air spaces to the backing wall material [see Commentary Figures R606.13.2.1(1) and R606.13.2.1(2)].

R606.13.2.2 Bonding with adjustable wall ties. Where the facing and backing (adjacent wythes) of masonry are bonded with adjustable wall ties, there shall be not less than one tie for each 2.67 square feet (0.248 m²) of wall area. Neither the vertical nor the horizontal spacing of the adjustable wall ties shall exceed 24 inches (610 mm). The maximum vertical offset of bed joints from one wythe to the other shall be 1.25 inches (32 mm). The maximum clearance between connecting parts of the ties shall be $\frac{1}{16}$ inch (2 mm). Where pintle legs are used, ties shall have not less than two $\frac{3}{16}$ -inch-diameter (5 mm) legs.

- ❖ This section pertains to the use of adjustable ties for anchoring the facing to the backing. Reduced tie spacing is required when these types of ties are specified. Maximum vertical offsets are prescribed so that the adjustable tie will not disengage through use. Many forms of adjustable wall ties are available for masonry construction (see Commentary Figure R606.13.2.2).

WALL CONSTRUCTION

R606.13.2.3 Bonding with prefabricated joint reinforcement. Where the facing and backing (adjacent wythes) of masonry are bonded with prefabricated joint reinforcement, there shall be not less than one cross wire serving as a tie for each 2.67 square feet (0.248 m²) of wall area. The vertical spacing of the joint reinforcement shall not exceed 16 inches (406 mm). Cross wires on prefabricated joint reinforcement shall not be smaller than No. 9 gage. The longitudinal wires shall be embedded in the mortar.

❖ Adjacent wythes of masonry could also be bonded with prefabricated joint reinforcements. They can be used in these wall types when air spaces exist between two wythes of masonry, or they can be used in double-wythe grouted-wall construction. Cross wires must be

of minimum size to provide proper load transfer. This reinforcement is placed in the bed joints. Commentary Figure R606.13.2.3 illustrates two of the more common types available.

R606.13.3 Bonding with natural or cast stone. Bonding with natural and cast stone shall conform to Sections R606.13.3.1 and R606.13.3.2.

❖ Ashlar masonry and rubble stone masonry require bonding through masonry headers. Although quite different from the usual masonry headers for clay or concrete masonry walls, bonder stones are required based on the square footage of wall area. Bonder stones must be embedded in mortar and have the proper extension into the wall surfaces on both sides.

For SI: 1 inch = 25.4 mm.

Each masonry type has separate bonding stone spacing requirements based on the construction. The bonding requirements in this section are primarily drawn from TMS 402/ACI 530/ASCE 5.

R606.13.3.1 Ashlar masonry. In ashlar masonry, bonder units, uniformly distributed, shall be provided to the extent of not less than 10 percent of the wall area. Such bonder units shall extend not less than 4 inches (102 mm) into the backing wall.

❖ When one or both of the wythes in a multiwythe masonry wall system are laid in an ashlar pattern, the wythes must be tied together with masonry bonder units spaced as prescribed in this section.

R606.13.3.2 Rubble stone masonry. Rubble stone masonry 24 inches (610 mm) or less in thickness shall have bonder units with a maximum spacing of 3 feet (914 mm) vertically and 3 feet (914 mm) horizontally, and if the masonry is of greater thickness than 24 inches (610 mm), shall have one bonder unit for each 6 square feet (0.557 m²) of wall surface on both sides.

❖ See the commentary to Section R606.13.3.

R606.14 Anchored and adhered masonry veneer.

❖ Section R606 does not contain provisions for anchored or adhered veneer, which is located in Chapter 7.

Sections R606.14.1 and R606.14.4 provide a pointer to the anchored and adhered veneer provisions of Chapter 7.

R606.14.1 Anchored veneer. Anchored masonry veneer installed over a backing of wood or cold-formed steel shall meet the requirements of Section R703.8.

❖ See the commentary to Section R606.14.

R606.14.2 Adhered veneer. Adhered masonry veneer shall be installed in accordance with the requirements of Section R703.12.

❖ See the commentary to Section R606.14.

SECTION R607 GLASS UNIT MASONRY

R607.1 General. Panels of glass unit masonry located in load-bearing and nonload-bearing exterior and interior walls shall be constructed in accordance with this section.

❖ Code provisions for glass unit masonry are empirical. By definition (see the definition for “Masonry unit, glass” in Section R202) these units are nonload-bearing. Therefore, when they are used in a wall opening, a properly designed header or lintel must be installed. Furthermore, panels of glass unit masonry must be isolated from the structure so that in-plane loads are not transferred to the glass.

R607.2 Materials. Hollow glass units shall be partially evacuated and have a minimum average glass face thickness of $3/16$ inch (5 mm). The surface of units in contact with mortar shall

be treated with a polyvinyl butyral coating or latex-based paint. The use of reclaimed units is prohibited.

❖ Glass masonry units may be hollow or solid. Hollow units must have the required minimum face thickness. The materials specified for treating edges in contact with mortar improve the bonding between glass blocks and mortar.

R607.3 Units. Hollow or solid glass block units shall be standard or thin units.

❖ Hollow or solid-glass units are classified as either standard units or thin units.

R607.3.1 Standard units. The specified thickness of standard units shall be not less than $3\frac{7}{8}$ inches (98 mm).

❖ See the commentary to Section R607.3.

R607.3.2 Thin units. The specified thickness of thin units shall be not less than $3\frac{1}{8}$ inches (79 mm) for hollow units and not less than 3 inches (76 mm) for solid units.

❖ See the commentary to Section R607.3.

R607.4 Isolated panels. Isolated panels of glass unit masonry shall conform to the requirements of this section.

❖ The code limits hollow glass unit masonry panel sizes based on structural and performance considerations. Height limits are more restrictive than length limits, primarily as a result of historical requirements rather than actual field experience or engineering principles. Exterior panels constructed of standard units may be up to 144 square feet (13.4 m²). Exterior panels constructed of thin units are limited to 85 square feet (7.9 m²). Interior panels are limited to 250 square feet (23.2 m²) for standard units and 150 square feet (13.9 m²) for thin units. These limitations are derived from TMS 402/ACI 530/ASCE 5.

R607.4.1 Exterior standard-unit panels. The maximum area of each individual standard-unit panel shall be 144 square feet (13.4 m²) where the design wind pressure is 20 pounds per square foot (958 Pa). The maximum area of such panels subjected to design wind pressures other than 20 pounds per square foot (958 Pa) shall be in accordance with Figure R607.4.1. The maximum panel dimension between structural supports shall be 25 feet (7620 mm) in width or 20 feet (6096 mm) in height.

❖ The area limit specified in this section corresponds to a wind pressure of 20 psf (958 Pa). The area should be adjusted using Figure R607.4.1 for other values of wind pressure (see commentary, Section R607.4).

R607.4.2 Exterior thin-unit panels. The maximum area of each individual thin-unit panel shall be 85 square feet (7.9 m²). The maximum dimension between structural supports shall be 15 feet (4572 mm) in width or 10 feet (3048 mm) in height. Thin units shall not be used in applications where the design wind pressure as stated in Table R301.2(1) exceeds 20 pounds per square foot (958 Pa).

❖ See the commentary to Section R607.4.

R607.4.3 Interior panels. The maximum area of each individual standard-unit panel shall be 250 square feet (23.2 m²). The maximum area of each thin-unit panel shall be 150 square feet (13.9 m²). The maximum dimension between structural supports shall be 25 feet (7620 mm) in width or 20 feet (6096 mm) in height.

❖ See the commentary to Section R607.4.

R607.4.4 Curved panels. The width of curved panels shall conform to the requirements of Sections R607.4.1, R607.4.2 and R607.4.3, except additional structural supports shall be provided at locations where a curved section joins a straight section, and at inflection points in multicurved walls.

❖ Support is required for standard and thin units, exterior and interior panels, at locations where a curved panel joins a straight section, and at inflection points (see the commentary to Section R607.4).

R607.5 Panel support. Glass unit masonry panels shall conform to the support requirements of this section.

❖ Structural members supporting glass-unit masonry panels must meet the deflection limit of this section to minimize the potential for cracking in the glass panels. Lateral support is required for the top and sides of panels and may be accomplished by anchors or channel-type restraints.

R607.5.1 Deflection. The maximum total deflection of structural members that support glass unit masonry shall not exceed $1/600$.

❖ See the commentary to Section R607.5.

R607.5.2 Lateral support. Glass unit masonry panels shall be laterally supported along the top and sides of the panel. Lateral supports for glass unit masonry panels shall be designed to resist not less than 200 pounds per lineal feet (2918 N/m) of panel, or the actual applied loads, whichever is greater. Except for single unit panels, lateral support shall be provided by panel anchors along the top and sides spaced not greater than 16 inches (406 mm) on center or by channel-type restraints. Single unit panels shall be supported by channel-type restraints.

Exceptions:

1. Lateral support is not required at the top of panels that are one unit wide.
2. Lateral support is not required at the sides of panels that are one unit high.

❖ See the commentary to Section R607.5.

R607.5.2.1 Panel anchor restraints. Panel anchors shall be spaced not greater than 16 inches (406 mm) on center in both jambs and across the head. Panel anchors shall be embedded not less than 12 inches (305 mm) and shall be provided with

For SI: 1 square foot = 0.0929 m², 1 pound per square foot = 0.0479 kPa.

FIGURE R607.4.1
GLASS UNIT MASONRY DESIGN WIND LOAD RESISTANCE

two fasteners so as to resist the loads specified in Section R607.5.2.

❖ See Commentary Figure R607.5.2.1.

R607.5.2.2 Channel-type restraints. Glass unit masonry panels shall be recessed not less than 1 inch (25 mm) within channels and chases. Channel-type restraints shall be oversized to accommodate expansion material in the opening, packing and sealant between the framing restraints, and the glass unit masonry perimeter units.

❖ This type of lateral support is an option to the anchors described in the previous section. No specific material is specified for the channel, which means that any channel-type restraint providing the lateral support specified by Section R607.5.2 is acceptable.

R607.6 Sills. Before bedding of glass units, the sill area shall be covered with a water base asphaltic emulsion coating. The coating shall be not less than $\frac{1}{8}$ inch (3 mm) thick.

❖ Application of asphaltic emulsion is recommended by glass block manufacturers. See Commentary Figure R607.5.2.1.

R607.7 Expansion joints. Glass unit masonry panels shall be provided with expansion joints along the top and sides at all structural supports. Expansion joints shall be not less than $\frac{3}{8}$ inch (10 mm) in thickness and shall have sufficient thickness to accommodate displacements of the supporting structure. Expansion joints shall be entirely free of mortar and other debris and shall be filled with resilient material.

❖ See Commentary Figure R607.5.2.1.

R607.8 Mortar. Glass unit masonry shall be laid with Type S or N mortar. Mortar shall not be retempered after initial set.

Mortar unused within $1\frac{1}{2}$ hours after initial mixing shall be discarded.

❖ See the commentary to Section R606.2.7.

R607.9 Reinforcement. Glass unit masonry panels shall have horizontal joint reinforcement spaced not greater than 16 inches (406 mm) on center located in the mortar bed joint. Horizontal joint reinforcement shall extend the entire length of the panel but shall not extend across expansion joints. Longitudinal wires shall be lapped not less than 6 inches (152 mm) at splices. Joint reinforcement shall be placed in the bed joint immediately below and above openings in the panel. The reinforcement shall have not less than two parallel longitudinal wires of size W1.7 or greater, and have welded cross wires of size W1.7 or greater.

❖ See Commentary Figure R607.5.2.1.

R607.10 Placement. Glass units shall be placed so head and bed joints are filled solidly. Mortar shall not be furrowed. Head and bed joints of glass unit masonry shall be $\frac{1}{4}$ inch (6.4 mm) thick, except that vertical joint thickness of radial panels shall be not less than $\frac{1}{8}$ inch (3 mm) or greater than $\frac{5}{8}$ inch (16 mm). The bed joint thickness tolerance shall be minus $\frac{1}{16}$ inch (1.6 mm) and plus $\frac{1}{8}$ inch (3 mm). The head joint thickness tolerance shall be plus or minus $\frac{1}{8}$ inch (3 mm).

❖ This section specifies the joint thicknesses and tolerances consistent with TMS 402/ACI 530/ASCE 5.

SECTION R608 EXTERIOR CONCRETE WALL CONSTRUCTION

R608.1 General. Exterior concrete walls shall be designed and constructed in accordance with the provisions of this section or

WALL CONSTRUCTION

in accordance with the provisions of PCA 100 or ACI 318. Where PCA 100, ACI 318 or the provisions of this section are used to design concrete walls, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the jurisdiction having authority.

- ❖ These provisions are for exterior concrete walls which should be designed in accordance with this section or under one of the following design documents:

ACI 318: *Building Code Requirements for Structural Concrete*

PCA100: *Prescriptive Design of Exterior Concrete Walls for One- and Two-family Dwellings*

Exterior concrete walls are usually designed and constructed to carry the vertical loads from the structure above and to resist wind and seismic lateral forces. Walls must be cast-in-place using either removable or stay-in-place forming systems. This section provides requirements, primarily in tables and figures, that will permit the exterior wall of typical homes to be constructed of concrete without the added expense of hiring a registered design professional.

Most states do not require the seal of an architect or engineer for small residential buildings. Check with the state authorities in the location of the project for local regulations.

R608.1.1 Interior construction. These provisions are based on the assumption that interior walls and partitions, both load-bearing and nonload-bearing, floors and roof/ceiling assemblies are constructed of *light-framed construction* complying with the limitations of this code and the additional limitations of Section R608.2. Design and construction of light-framed assemblies shall be in accordance with the applicable provisions of this code. Where second-story exterior walls are of *light-framed construction*, they shall be designed and constructed as required by this code.

Aspects of concrete construction not specifically addressed by this code, including interior concrete walls, shall comply with ACI 318.

- ❖ The provisions of Section R608 are based on the assumption that the exterior concrete walls would be used in combination with floors, roofs and interior walls of light-framed construction complying with the prescriptive requirements of the code. Light-framed construction includes members of wood or cold-formed steel.

While Section R608 does not address the use of interior walls of concrete construction, in some cases such walls can be used without adversely affecting the performance of buildings designed in accordance with this section. Interior concrete walls must be designed in accordance with the code or ACI 318.

R608.1.2 Other concrete walls. Exterior concrete walls constructed in accordance with this code shall comply with the shapes and minimum concrete cross-sectional dimensions of Table R608.3. Other types of forming systems resulting in

concrete walls not in compliance with this section shall be designed in accordance with ACI 318.

- ❖ It is intended that portions of the building and aspects of concrete construction not specifically addressed by Section R608 be designed and constructed in accordance with ACI 318.

R608.2 Applicability limits. The provisions of this section shall apply to the construction of exterior concrete walls for buildings not greater than 60 feet (18 288 mm) in plan dimensions, floors with clear spans not greater than 32 feet (9754 mm) and roofs with clear spans not greater than 40 feet (12 192 mm). Buildings shall not exceed 35 feet (10 668 mm) in mean roof height or two stories in height above grade. Floor/ceiling dead loads shall not exceed 10 pounds per square foot (479 Pa), roof/ceiling dead loads shall not exceed 15 pounds per square foot (718 Pa) and *attic* live loads shall not exceed 20 pounds per square foot (958 Pa). Roof overhangs shall not exceed 2 feet (610 mm) of horizontal projection beyond the exterior wall and the dead load of the overhangs shall not exceed 8 pounds per square foot (383 Pa).

Walls constructed in accordance with the provisions of this section shall be limited to buildings subjected to a maximum design wind speed of 160 mph (72 m/s) Exposure B, 136 mph (61 m/s) Exposure C and 125 mph (56 m/s) Exposure D. Walls constructed in accordance with the provisions of this section shall be limited to detached one- and two-family *dwellings* and townhouses assigned to Seismic Design Category A or B, and detached one- and two-family *dwellings* assigned to Seismic Design Category C.

Buildings that are not within the scope of this section shall be designed in accordance with PCA 100 or ACI 318.

- ❖ The requirements set forth in Section R608 apply only to the construction of houses that meet the limits set forth in Section R608.2 (see Commentary Figure R608.2). The applicability limits are necessary for defining reasonable boundaries to the conditions that must be considered in developing prescriptive construction requirements. This section, however, does not limit the application of alternative methods or materials through engineering design by a registered design professional.

The applicability limits are based on industry convention and experience. Detailed applicability limits were documented in the process of developing prescriptive design requirements for various elements of the structure. In some cases, engineering sensitivity analyses were performed to help define appropriate limits.

The applicability limits strike a reasonable balance among engineering theory, available test data and proven field practices for typical residential construction applications. They are intended to prevent misapplication while at the same time addressing a reasonably large percentage of new housing conditions.

The limits of Section R608.2 apply to detached one- or two-family dwellings, and townhouses, with maximum building plan dimensions of 60 feet (18 288 mm), that are not more than two stories in height above grade, excluding a basement that is not considered a story above grade plane.

The provisions for above-grade exterior concrete walls are limited to buildings where the maximum design wind speed is 160 miles per hour (72 m/s) Exposure B, 136 miles per hour (61 m/s) Exposure C and 125 miles per hour (56 m/s) Exposure D. Also, the provisions are limited to detached one- and two-family dwellings and townhouses in SDC A or B, and detached one- and two-family dwellings in SDC C. One- and two-family dwellings located in higher design wind speed regions and requiring seismic design will be required to be designed in accordance with PCA 100 or ACI 318. Townhouses in SDC C and all buildings in SDC D must meet the requirements in PCA Standard 100 or be designed in accordance with ACI 318.

R608.3 Concrete wall systems. Concrete walls constructed in accordance with these provisions shall comply with the shapes and minimum concrete cross-sectional dimensions of Table R608.3.

❖ The minimum thickness and cross-section dimension of concrete walls must comply with Table R608.3. This section prescribes the dimensional requirements of exterior concrete walls. The requirements for flat, waffle-grid and screen-grid wall systems are prescribed.

For flat wall systems refer to Figure R608.3(1). Unlike masonry units, which must be manufactured in accordance with an ASTM standard, there is no standard to require the minimum thickness of nominal 6-, 8-, 10-, or 12-inch (152, 203, 254 or 305 mm) flat concrete walls. The actual as-built minimum thickness is permitted to be no more than 1/2 inch (12.7 mm) less than the nominal

thickness (see Note d of Table R611.3).

The design strength of flat concrete walls is based on thicknesses of 5.5, 7.5, 9.5 and 11.5 inches (140, 191, 241 and 292 mm).

For waffle-grid and screen-grid systems, refer to Figures R608.3(2) and R608.3(3). For waffle-grid and screen-grid minimum thickness, see Notes e, f and g of Table R608.3.

R608.3.1 Flat wall systems. Flat concrete wall systems shall comply with Table R608.3 and Figure R608.3(1) and have a minimum nominal thickness of 4 inches (102 mm).

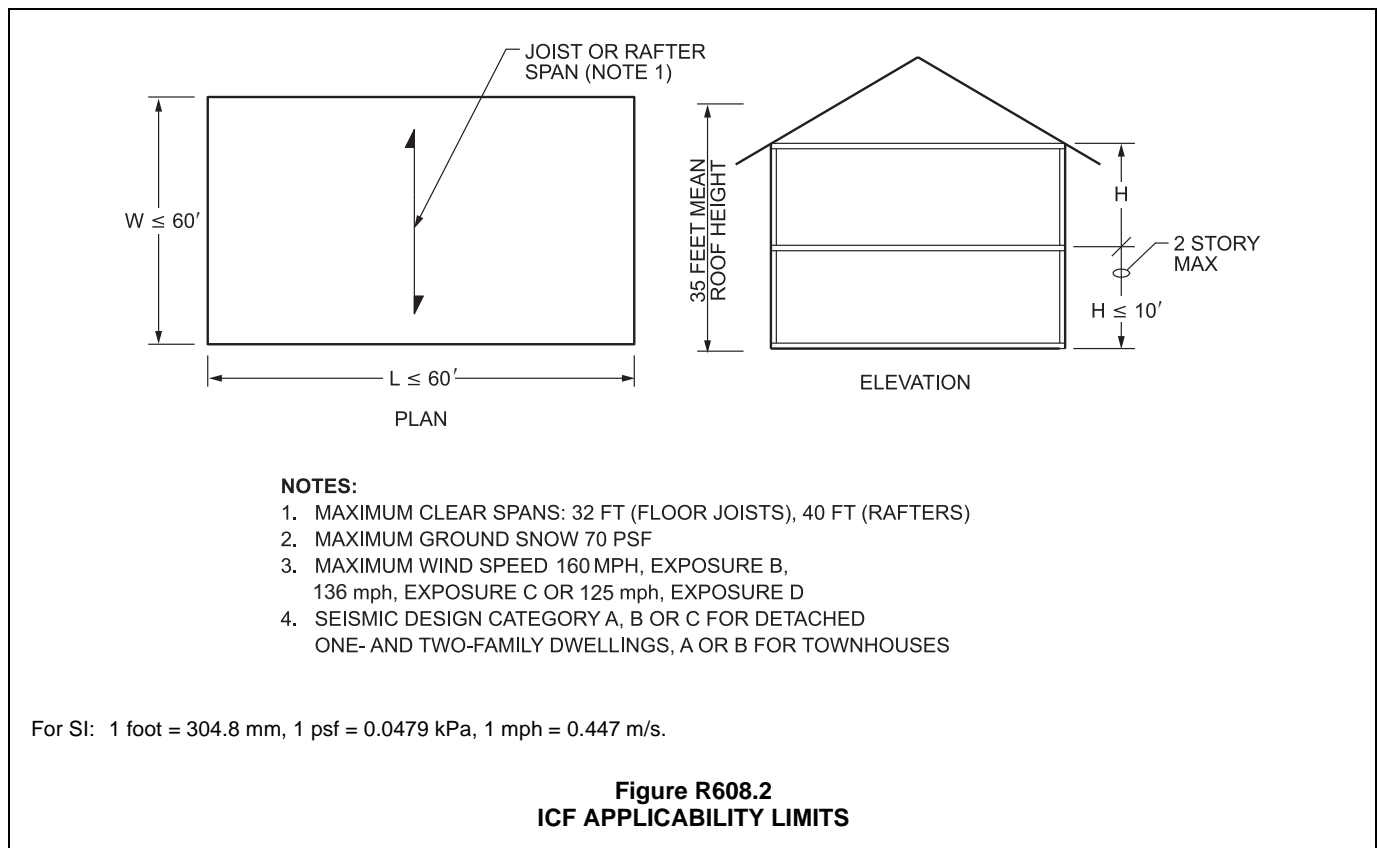

❖ See the commentary to Section R608.3.

R608.3.2 Waffle-grid wall systems. Waffle-grid wall systems shall comply with Table R608.3 and Figure R608.3(2) and shall have a minimum nominal thickness of 6 inches (152 mm) for the horizontal and vertical concrete members (cores). The core and web dimensions shall comply with Table R608.3. The maximum weight of waffle-grid walls shall comply with Table R608.3.

❖ See the commentary to Section R608.3.

R608.3.3 Screen-grid wall systems. Screen-grid wall systems shall comply with Table R608.3 and Figure R608.3(3) and shall have a minimum nominal thickness of 6 inches (152 mm) for the horizontal and vertical concrete members (cores). The core dimensions shall comply with Table R608.3. The maximum weight of screen-grid walls shall comply with Table R608.3.

❖ See the commentary to Section R608.3.

WALL CONSTRUCTION

TABLE R608.3
DIMENSIONAL REQUIREMENTS FOR WALLS^{a, b}

WALL TYPE AND NOMINAL THICKNESS	MAXIMUM WALL WEIGHT ^c (psf)	MINIMUM WIDTH, W, OF VERTICAL CORES (inches)	MINIMUM THICKNESS, T, OF VERTICAL CORES (inches)	MAXIMUM SPACING OF VERTICAL CORES (inches)	MAXIMUM SPACING OF HORIZONTAL CORES (inches)	MINIMUM WEB THICKNESS (inches)
4" Flat ^d	50	N/A	N/A	N/A	N/A	N/A
6" Flat ^d	75	N/A	N/A	N/A	N/A	N/A
8" Flat ^d	100	N/A	N/A	N/A	N/A	N/A
10" Flat ^d	125	N/A	N/A	N/A	N/A	N/A
6" Waffle-grid	56	8 ^e	5.5 ^e	12	16	2
8" Waffle-grid	76	8 ^f	8 ^f	12	16	2
6" Screen-grid	53	6.25 ^g	6.25 ^g	12	12	N/A

For SI: 1 inch = 25.4 mm; 1 pound per square foot = 0.0479 kPa, 1 pound per cubic foot = 2402.77 kg/m³, 1 square inch = 645.16 mm², 1 inch⁴ = 42 cm⁴.

- a. Width "W," thickness "T," spacing and web thickness, refer to Figures R608.3(2) and R608.3(3).
- b. N/A indicates not applicable.
- c. Wall weight is based on a unit weight of concrete of 150 pcf. For flat walls the weight is based on the nominal thickness. The tabulated values do not include any allowance for interior and exterior finishes.
- d. Nominal wall thickness. The actual as-built thickness of a flat wall shall not be more than 1/2 inch less or more than 1/4 inch more than the nominal dimension indicated.
- e. Vertical core is assumed to be elliptical-shaped. Another shape core is permitted provided the minimum thickness is 5 inches, the moment of inertia, *I*, about the centerline of the wall (ignoring the web) is not less than 65 inch⁴, and the area, *A*, is not less than 31.25 square inches. The width used to calculate *A* and *I* shall not exceed 8 inches.
- f. Vertical core is assumed to be circular. Another shape core is permitted provided the minimum thickness is 7 inches, the moment of inertia, *I*, about the centerline of the wall (ignoring the web) is not less than 200 inch⁴, and the area, *A*, is not less than 49 square inches. The width used to calculate *A* and *I* shall not exceed 8 inches.
- g. Vertical core is assumed to be circular. Another shape core is permitted provided the minimum thickness is 5.5 inches, the moment of inertia, *I*, about the centerline of the wall is not less than 76 inch⁴, and the area, *A*, is not less than 30.25 square inches. The width used to calculate *A* and *I* shall not exceed 6.25 inches.

For SI: 1 inch = 25.4 mm.

**FIGURE R608.3(3)
SCREEN-GRID WALL SYSTEM**

R608.4 Stay-in-place forms. Stay-in-place concrete forms shall comply with this section.

❖ Materials that stay in place after concrete cures must be able to withstand the rigors of the environment. From a thermal standpoint, most stay-in-place form systems and some removable form systems that incorporate insulation into the wall before the concrete is placed provide enough insulating value to meet code requirements. However, some forming systems will require the addition of insulation to the interior or exterior of the concrete wall to meet code requirements for insulating value. The form material, except foam plastic, can be anything that meets the flame spread and smoke-developed indexes of Section R302.9. Foam plastic must comply with Section R316.3. Covering foam plastic that would otherwise be exposed to the interior of the building must comply with Sections R316.4 and R702.3.4. Adhesively attaching the gypsum board to the foam plastic as the only means of fastening is not permitted out of concern that when the adhesive is exposed to higher temperature expected in a fire, it may soften and allow the gypsum board to delaminate from the foam plastic.

It is generally accepted that a monolithic concrete wall is a solid wall through which water and air cannot readily flow; however, there is a possibility that the concrete wall may have drying shrinkage cracks through which water may enter. Small gaps between stay-in-place form blocks are inherent in current screen-grid stay-in-place form walls and may allow water to enter the structure. As a result, a moisture barrier on the exterior face of the stay-in-place form wall is generally required and should be considered minimum acceptable practice.

Flat wall insulating concrete form (ICF) systems must comply with ASTM E2634.

R608.4.1 Surface burning characteristics. The flame spread index and smoke-developed index of forming material, other than foam plastic, left exposed on the interior shall comply with Section R302.9. The surface burning characteristics of foam plastic used in insulating concrete forms shall comply with Section R316.3.

❖ See the commentary to Section R608.4.

R608.4.2 Interior covering. Stay-in-place forms constructed of rigid foam plastic shall be protected on the interior of the building as required by Sections R316.4 and R702.3.4. Where gypsum board is used to protect the foam plastic, it shall be installed with a mechanical fastening system. Use of adhesives is permitted in addition to mechanical fasteners.

❖ See the commentary to Section R608.4.

R608.4.3 Exterior wall covering. Stay-in-place forms constructed of rigid foam plastics shall be protected from sunlight and physical damage by the application of an *approved* exterior wall covering complying with this code. Exterior surfaces of other stay-in-place forming systems shall be protected in accordance with this code.

Requirements for installation of masonry veneer, stucco and other finishes on the exterior of concrete walls and other

construction details not covered in this section shall comply with the requirements of this code.

❖ See the commentary to Section R608.4.

R608.4.4 Flat ICF wall systems. Flat ICF wall system forms shall conform to ASTM E2634.

❖ See the commentary to Section R608.4.

R608.5 Materials. Materials used in the construction of concrete walls shall comply with this section.

❖ Concrete walls are composed of three basic materials: concrete, reinforcing steel for concrete and form materials. These materials must comply with this section or ACI 318.

R608.5.1 Concrete and materials for concrete. Materials used in concrete, and the concrete itself, shall conform to requirements of this section, PCA 100 or ACI 318.

❖ Concrete and materials for concrete must comply with this section, PCA 100 or ACI 318.

R608.5.1.1 Cements. The following standards as referenced in Chapter 44 shall be permitted to be used.

1. ASTM C150
2. ASTM C595
3. ASTM C1157

❖ This section lists the standards for cements that are permitted to be used for concrete specified in Section R608.5. The three types listed are for Portland cement, blended hydraulic cement and hydraulic cement (refer to Chapter 44 for the latest edition to use).

R608.5.1.2 Concrete mixing and delivery. Mixing and delivery of concrete shall comply with ASTM C94 or ASTM C685.

❖ Concrete must be mixed and delivered in accordance with requirements of *Specification for Ready-mixed Concrete*, ASTM C94 or ASTM C685, *Specification for Concrete Made by Volumetric Batching and Continuous Mixing*. Test methods for uniformity of mixing are given in ASTM C94.

R608.5.1.3 Maximum aggregate size. The nominal maximum size of coarse aggregate shall not exceed one-fifth the narrowest distance between sides of forms, or three-fourths the clear spacing between reinforcing bars or between a bar and the side of the form.

Exception: When *approved*, these limitations shall not apply where removable forms are used and workability and methods of consolidation permit concrete to be placed without honeycombs or voids.

❖ The maximum aggregate size is based on requirements in ACI 318. These limitations on aggregate size are intended to result in concrete that can be placed such that it properly encases reinforcement and minimizes honeycombing and voids. The exception, which is also based on ACI 318, is limited to use with removable forms because proper placement and encasement of reinforcement can be verified through visual inspection after removal of forms.

R608.5.1.4 Proportioning and slump of concrete. Proportions of materials for concrete shall be established to provide workability and consistency to permit concrete to be worked readily into forms and around reinforcement under conditions of placement to be employed, without segregation or excessive bleeding. Slump of concrete placed in removable forms shall not exceed 6 inches (152 mm).

Exception: When *approved*, the slump is permitted to exceed 6 inches (152 mm) for concrete mixtures that are resistant to segregation, and are in accordance with the form manufacturer's recommendations.

Slump of concrete placed in stay-in-place forms shall exceed 6 inches (152 mm). Slump of concrete shall be determined in accordance with ASTM C143.

- ❖ The maximum slump requirements are based on current practice. Considerations included in the prescribed maximums are ease of placement, ability to fill cavities thoroughly and limiting the pressures exerted on the form by fresh concrete.

Where removable wall forms are used, maximum slump of concrete is 6 inches (152 mm). The maximum slump is based on experience with ease of placement, ability to fill cavities thoroughly, and limiting the pressures exerted on the form by fresh concrete. The 6-inch (152 mm) maximum slump refers to the characteristics of the specified mixture proportions based on water/cementitious materials ratio only. The exception envisions the use of mid-range or high-range water-reducing admixtures to increase the slump above 6 inches (152 mm), since their use does not adversely affect the tendency of the aggregate to segregate.

The minimum slump requirement for walls cast in stay-in-place forms must be greater than 6 inches (152 mm). It is important that the concrete mix design utilize proper materials in the proper proportions so that the specified strength is achieved at the specified slump [i.e., greater than 6 inches (152 mm)]. Ordering a concrete mix at a lower slump (e.g., 4 inches [102 mm]) and adding water at the job site to increase the slump to more than 6 inches (152 mm) will adversely affect the strength of the concrete, and possibly jeopardize the safety of the structure. Normally it would be expected that a concrete mixture with a specified slump in excess of 6 inches (152 mm) would contain mid-range or high-range water-reducing admixtures so as to mitigate the possibility of segregation of the aggregate.

R608.5.1.5 Compressive strength. The minimum specified compressive strength of concrete, f'_c , shall comply with Section R402.2 and shall be not less than 2,500 pounds per square inch (17.2 MPa) at 28 days.

- ❖ The minimum specified compressive strength of concrete of 2,500 psi (17.2 MPa) is based on the minimum current practice, which corresponds to minimum compressive strength permitted by ACI 318 and Section R402.2 of the code (see commentary, Section R402.2).

R608.5.1.6 Consolidation of concrete. Concrete shall be consolidated by suitable means during placement and shall be worked around embedded items and reinforcement and into corners of forms. Where stay-in-place forms are used, concrete shall be consolidated by internal vibration.

Exception: When *approved*, self-consolidating concrete mixtures with slumps equal to or greater than 8 inches (203 mm) that are specifically designed for placement without internal vibration need not be internally vibrated.

- ❖ Where stay-in-place forms are used, concrete must be consolidated by internal vibration. A study by Portland Cement Association (PCA) determined that internal vibration is required. The study showed that with standard mix design with a slump between 4 inches (102 mm) and 8 inches (203 mm) that internal vibration is required. Two of the mixtures were intended to be used without internal vibration and good results were obtained with both. One mixture utilized a high-range water-reducing admixture to achieve a slump between 8 inches (203 mm) and 10 inches (254 mm). The other contained a high-range water-reducing admixture and a viscosity-modifying admixture to achieve a self-consolidating concrete (SCC) with a slump in excess of 8 inches (203 mm). Slumps in excess of 8 inches (203 mm) should not be obtained by the use of water alone since segregation is likely.

R608.5.2 Steel reinforcement and anchor bolts.

- ❖ This section prescribes the requirements for the steel reinforcement for concrete walls. Also, this section contains the requirements for anchor bolts and tension straps for connection details.

R608.5.2.1 Steel reinforcement. Steel reinforcement shall comply with ASTM A615, ASTM A706, or ASTM A996. ASTM A996 bars produced from rail steel shall be Type R.

- ❖ The types of steel reinforcement permitted by this section are consistent with ACI 318. The wall reinforcement tables, in Section R608.6.2, are based on Grade 60 [minimum yield strength of 60,000 psi (414 mPa)]. However, Section R608.5.4.7 has provisions for use of alternate grades. Type R is specified for ASTM A996 (rail steel) because the ASTM standard permits two designations. The type designated R is specified because it is the only one of the two that complies with the more stringent bend requirements of ACI 318.

R608.5.2.2 Anchor bolts. Anchor bolts for use with connection details in accordance with Figures R608.9(1) through R608.9(12) shall be bolts with heads complying with ASTM A307 or ASTM F1554. ASTM A307 bolts shall be Grade A with heads. ASTM F1554 bolts shall be Grade 36 minimum. Instead of bolts with heads, it is permissible to use rods with threads on both ends fabricated from steel complying with ASTM A36. The threaded end of the rod to be embedded in the concrete shall be provided with a hex or square nut.

- ❖ All bolts in the prescriptive details of Figures R608.9(1) through R608.9(12) may be subject to tensile loading. Since the concrete breakout strength in tension is con-

siderably greater for a headed bolt versus a hooked bolt of the same size and embedment depth, the prescriptive designs are based on the use of bolts with heads. In lieu of bolts with heads, the provisions permit the use of rods with threads on both ends with the end embedded in the concrete having a hex or square nut. ACI 318 requires that connections subjected to seismic forces be designed to fail in a ductile manner. Therefore, it is imperative that bolts with a higher yield strength or bolts larger than specified in the figures not be used in these connections since it is likely that in the event of a load being applied that is greater than that assumed in design, the concrete may fail prior to the bolt yielding.

R608.5.2.3 Sheet steel angles and tension tie straps. Angles and tension tie straps for use with connection details in accordance with Figures R608.9(1) through R608.9(12) shall be fabricated from sheet steel complying with ASTM A653 SS, ASTM A792 SS, or ASTM A875 SS. The steel shall be minimum Grade 33 unless a higher grade is required by the applicable figure.

- ❖ Grade 33 is the minimum grade of sheet steel specified for components of connections in Figures R608.9(1) through R608.9(12) because it is the lowest strength recognized under the standards for structural steel (Type SS). The requirement applies to angles and other components of connections that are field fabricated and is not intended to apply to proprietary clip angles and other proprietary connectors that are available.

R608.5.3 Form materials and form ties. Forms shall be made of wood, steel, aluminum, plastic, a composite of cement and foam insulation, a composite of cement and wood chips, or other *approved* material suitable for supporting and containing concrete. Forms shall provide sufficient strength to contain concrete during the concrete placement operation.

Form ties shall be steel, solid plastic, foam plastic, a composite of cement and wood chips, a composite of cement and foam plastic, or other suitable material capable of resisting the forces created by fluid pressure of fresh concrete.

- ❖ The materials listed are based on currently available removable and stay-in-place forming systems. From a structural design standpoint, the material can be anything that has sufficient strength and durability to contain the concrete during pouring and curing.

R608.5.4 Reinforcement installation details.

- ❖ This section contains the requirements for concrete wall reinforcement support and cover, location, lap splices, development lengths, hooks and alternate grade.

R608.5.4.1 Support and cover. Reinforcement shall be secured in the proper location in the forms with tie wire or other bar support system such that displacement will not occur during the concrete placement operation. Steel reinforcement in concrete cast against the earth shall have a minimum cover of 3 inches (76 mm). Minimum cover for reinforcement in concrete cast in removable forms that will be exposed to the

earth or weather shall be 1½ inches (38 mm) for No. 5 bars and smaller, and 2 inches (50 mm) for No. 6 bars and larger. For concrete cast in removable forms that will not be exposed to the earth or weather, and for concrete cast in stay-in-place forms, minimum cover shall be ¾ inch (19 mm). The minus tolerance for cover shall not exceed the smaller of one-third the required cover and ¾ inch (10 mm). See Section R608.5.4.4 for cover requirements for hooks of bars developed in tension.

- ❖ Reinforcement should be adequately supported in the forms to prevent displacement by concrete placement or workers. Concrete cover as protection of reinforcement against weather and other effects is measured from the concrete surface to the outermost surface of the steel to which the cover requirement applies. The condition “concrete surfaces exposed to earth or weather” refers to direct exposure to moisture changes and not just to temperature changes. Stay-in-place forms provide an alternative method of protecting from earth or weather and the minimum cover for concrete not exposed to weather or earth is allowed. The tolerance for cover is based on ACI 318 requirements.

R608.5.4.2 Location of reinforcement in walls. For location of reinforcement in foundation walls and above-grade walls, see Sections R404.1.3.3.7.2 and R608.6.5, respectively.

- ❖ See the commentary to Section R608.6.5 for exterior concrete above-grade walls.
See the commentary to Section R404.1.3.3.7.2 for foundation walls.

R608.5.4.3 Lap splices. Vertical and horizontal wall reinforcement required by Sections R608.6 and R608.7 shall be the longest lengths practical. Where splices are necessary in reinforcement, the length of lap splices shall be in accordance with Table R608.5.4(1) and Figure R608.5.4(1). The maximum gap between noncontact parallel bars at a lap splice shall not exceed the smaller of one-fifth the required lap length and 6 inches (152 mm). See Figure R608.5.4(1).

- ❖ Where continuous bars are not provided, lap splices are necessary to allow forces to be transferred between sections of rebar. The length of lap splices in Table R608.5.4(1) is based on ACI 318 requirements. Noncontact lap splices are permitted provided the spacing of lapped bars does not exceed the smaller of one fifth the required lap length or 6 inches (152 mm). If individual bars in noncontact lap splices are too widely spaced, an unreinforced section is created. Forcing a potential crack to follow a zigzag line (5:1 slope) is considered a minimum precaution. These requirements are based on ACI 318. Figure R608.5.4(1) illustrates the code text requirements.

TABLE R608.5.4(1). See page 6-169.

- ❖ See the commentary to Sections R608.5.4.3 and R608.5.4.4.

FIGURE R608.5.4(1). See page 6-169.

- ❖ This figure illustrates the requirements of Section R608.5.4.3.

R608.5.4.4 Development of bars in tension. Where bars are required to be developed in tension by other provisions of this code, development lengths and cover for hooks and bar extensions shall comply with Table R608.5.4(1) and Figure R608.5.4(2). The development lengths shown in Table R608.5.4(1) shall apply to bundled bars in lintels installed in accordance with Section R608.8.2.2.

❖ Development lengths and cover for hooks and bar extensions must comply with Table R608.5.4(1) and Figure R608.5.4(2). These requirements are based on ACI 318.

FIGURE R608.5.4(2). See page 6-170.

❖ See the commentary to Section R608.5.4.4.

R608.5.4.5 Standard hooks. Where reinforcement is required by this code to terminate with a standard hook, the hook shall comply with Figure R608.5.4(3).

❖ The hook requirements shown in Figure R608.5.4(3) are consistent with ACI 318 requirements.

FIGURE R608.5.4(3). See page 6-170.

❖ See the commentary to Section R608.5.4.5.

R608.5.4.6 Webs of waffle-grid walls. Reinforcement, including stirrups, shall not be placed in webs of waffle-grid walls, including lintels. Webs are permitted to have form ties.

❖ Reinforcement must not be placed in the web of waffle-grid walls and lintels.

**TABLE R608.5.4(1)

WALL CONSTRUCTION

R608.5.4.7 Alternate grade of reinforcement and spacing. Where tables in Sections R404.1.3 and R608.6 specify vertical wall reinforcement based on minimum bar size and maximum spacing, which are based on Grade 60 (420 MPa) steel reinforcement, different size bars or bars made from a different grade of steel are permitted provided an equivalent area of steel per linear foot of wall is provided. Use of Table R608.5.4(2) is permitted to determine the maximum bar spac-

ing for different bar sizes than specified in the tables and/or bars made from a different grade of steel. Bars shall not be spaced less than one-half the wall thickness, or more than 48 inches (1219 mm) on center.

❖ See the commentary to Section R608.5.2.1.

TABLE R608.5.4(2). See page 6-171.

❖ See the commentary to Section R608.5.2.1.

48	48	48	32	48	48	31	48	21	32	45	22	34	15	23	32

For SI: 1 inch = 25.4 mm.

- a. This table is for use with tables in Section R608.6 that specify the minimum bar size and maximum spacing of vertical wall reinforcement for foundation walls and above-grade walls. Reinforcement specified in tables in Section R608.6 is based on Grade 60 (420 MPa) steel reinforcement.
- b. Bar spacing shall not exceed 48 inches on center and shall be not less than one-half the nominal wall thickness.
- c. For Grade 50 (350 MPa) steel bars (ASTM A996, Type R), use spacing for Grade 40 (280 MPa) bars or interpolate between Grade 40 (280 MPa) and Grade 60 (420 MPa).

R608.5.5 Construction joints in walls. Construction joints shall be made and located to not impair the strength of the wall. Construction joints in plain concrete walls, including walls required to have not less than No. 4 bars at 48 inches (1219 mm) on center by Section R608.6, shall be located at points of lateral support, and not less than one No. 4 bar shall extend across the construction joint at a spacing not to exceed 24 inches (610 mm) on center. Construction joint reinforcement shall have not less than 12 inches (305 mm) embedment on both sides of the joint. Construction joints in reinforced concrete walls shall be located in the middle third of the span between lateral supports, or located and constructed as required for joints in plain concrete walls.

Exception: Vertical wall reinforcement required by this code is permitted to be used in lieu of construction joint reinforcement, provided the spacing does not exceed 24 inches (610 mm), or the combination of wall reinforcement and No. 4 bars described in Section R608.5.5 does not exceed 24 inches (610 mm).

- ❖ Construction joints must be located where they will cause the least weakness in the structure. The reinforcement required by this section is required to provide for transfer of shear and other forces through the construction joint. These provisions are consistent with ACI 318.

R608.6 Above-grade wall requirements.

- ❖ This section provides the following requirements for above-grade concrete walls:
 - General requirements
 - Wall reinforcement
 - Continuity of vertical reinforcement between stories
 - Termination of vertical reinforcement in the top-most story
 - Location of reinforcement in the wall

R608.6.1 General. The minimum thickness of load-bearing and nonload-bearing above-grade walls and reinforcement shall be as set forth in the appropriate table in this section based on the type of wall form to be used. The wall shall be designed in accordance with ACI 318 where the wall or building is not within the limitations of Section R608.2, where design is required by the tables in this section or where the wall is not within the scope of the tables in this section.

Above-grade concrete walls shall be constructed in accordance with this section and Figure R608.6(1), R608.6(2), R608.6(3) or R608.6(4). Above-grade concrete walls that are continuous with stem walls and not laterally supported by the slab-on-ground shall be designed and constructed in accordance with this section. Concrete walls shall be supported on continuous foundation walls or slabs-on-ground that are monolithic with the footing in accordance with Section R403. The minimum length of solid wall without openings shall be in accordance with Section R608.7. Reinforcement around openings, including lintels, shall be in accordance with Section R608.8. Lateral support for above-grade walls in the out-

of-plane direction shall be provided by connections to the floor framing system, if applicable, and to ceiling and roof framing systems in accordance with Section R608.9. The wall thickness shall be equal to or greater than the thickness of the wall in the *story* above.

- ❖ Section R608.6 provides reinforcement tables for load-bearing and nonload-bearing above-grade walls constructed within the applicability limits of Section R608.2. Section R608.6.2 provides the minimum required vertical and horizontal wall reinforcement for different design wind pressures and three wall heights. Vertical wall reinforcement tables are limited to one- and two-story buildings for nonload-bearing and load-bearing walls, in accordance with Figure R608.6(1), R608.6(2), R608.6(3) or R608.6(4).

Section R608.6 completely replaces the prescriptive technical provisions for exterior concrete walls from the 2006 edition of the code. The new provisions reflect changes made to ACI 318 and ASCE 7 since the provisions in the previous code were developed. The new provisions cover horizontal and vertical reinforcement in Section R608.6, reinforcement and shear wall (solid walls) requirements for wind loads in Section R608.7 and revised reinforcement requirements around openings and lintels over openings in Section R608.8. Additionally, the provisions providing revised details for connecting wood frame assemblies (floors, ceilings and roofs) to exterior concrete walls and added details for connecting cold-formed steel framing assemblies to the exterior concrete walls are contained in Section R608.9.

FIGURE R608.6(1). See page 6-173.

FIGURE R608.6(2). See page 6-173.

- ❖ See the commentary to Section R608.6.1.

FIGURE R608.6(3). See page 6-174.

- ❖ See the commentary to Section R608.6.1.

FIGURE R608.6(4). See page 6-174.

- ❖ See the commentary to Section R608.6.1.

R608.6.2 Wall reinforcement for wind. Vertical wall reinforcement for resistance to out-of-plane wind forces shall be determined from Table R608.6(1), R608.6(2), R608.6(3) or R608.6(4). For the design of nonload-bearing walls, in Tables R608.6(1), R608.6(2) and R608.6(3) use the appropriate column labeled “Top.” (see Sections R608.7.2.2.2 and R608.7.2.2.3). There shall be a vertical bar at corners of exterior walls. Unless more horizontal reinforcement is required by Section R608.7.2.2.1, the minimum horizontal reinforcement shall be four No. 4 bars [Grade 40 (280 MPa)] placed as follows: top bar within 12 inches (305 mm) of the top of the wall, bottom bar within 12 inches (305 mm) of the finish floor and one bar each at approximately one-third and two-thirds of the wall height.

- ❖ The wall reinforcement must be in accordance with this section and Tables R608.6(1), R608.6(2), R608.6(3)

and R608.6(4). The following design assumptions were used in developing these tables.

1. Walls are simply supported at each floor and roof that provides lateral support, or by the exterior finish ground level in the case where walls are continuous with stem walls.
2. Lateral support is provided for the wall by the floors and roof, and by the slab-on-ground where the wall is monolithic with or anchored to the slab.
3. Allowable deflection criterion is the laterally unsupported height of the wall, in inches (mm), divided by 240.
4. The minimum possible axial load is considered for each case. For “top” bearing walls, no axial load was considered. For “side” bearing walls, the moment induced by the eccentricity of the dead and live load of the floor construction supported by the ledger board or cold-formed steel track bolted to the side of the wall was considered since it is additive with the moment induced by the outward-acting wind load. The axial load on the wall due to the floor construction supported by the ledger board or cold-formed steel track was not considered.
5. Wind loads were calculated in accordance with ASCE 7 for enclosed buildings using components and cladding pressure coefficients for the wall interior zone (designated number 4 in Figure 30.4-1 of ASCE 7), effective wind area of 10

square feet (0.929 m²) and mean roof height of 35 feet (10.7 m).

TABLE R608.6(1). See page 6-175.

- ❖ See the commentary to Section R608.6.2. For flat walls, design strength (i.e., capacity) was based on thicknesses of 3.5, 5.5, 7.5 and 9.5 inches (89, 140, 196 and 241 mm). This approach will provide adequate strength regardless of whether the forms used are 1/2-inch (12.7 mm) less than the stated nominal thickness of 4, 6, 8 or 10 inches (102, 152, 203 or 254 mm) or 1/4-inch (6.4 mm) more than the stated nominal thickness.

TABLE R608.6(2). See page 6-176.

- ❖ See the commentary to Section R608.6.2. For 6-inch (152 mm) and 8-inch (203 mm) waffle-grid walls, rectangular cross sections with through-the-wall thicknesses of 5 inches (127 mm) and 7 inch (178 mm) respectively, were used. The lengths of the rectangles for 6-inch (152 mm) and 8-inch (203 mm) walls were 6.25 and 7 inches (159 and 178 mm), respectively. The web was ignored for computing section proportions and resisting out-of-plane shear.

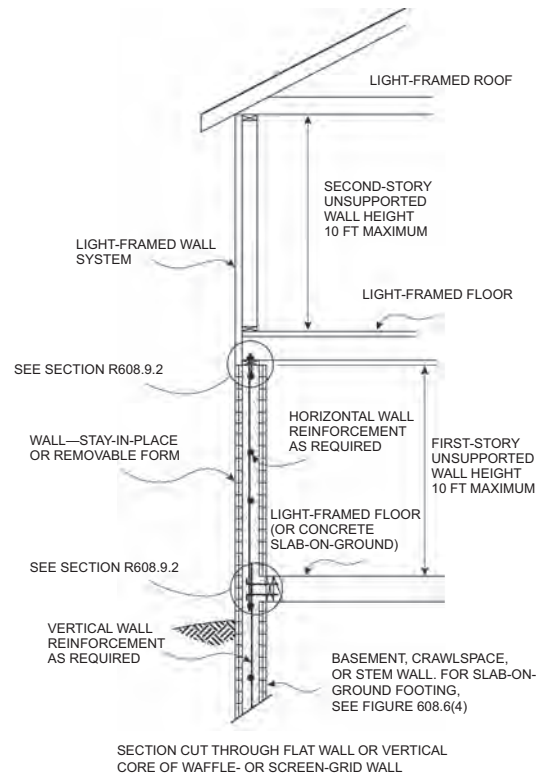

TABLE R608.6(3). See page 6-177.

- ❖ See the commentary to Section R608.6.2. For 6-inch (152 mm) screen-grid walls, a square cross section with 5.5-inch (140 mm) sides was used. The spacing of

For SI: 1 foot = 304.8 mm.

FIGURE R608.6(1)
ABOVE-GRADE CONCRETE WALL CONSTRUCTION ONE STORY

For SI: 1 foot = 304.8 mm.

FIGURE R608.6(2)
ABOVE-GRADE CONCRETE WALL CONSTRUCTION CONCRETE FIRST STORY AND LIGHT-FRAMED SECOND STORY

WALL CONSTRUCTION

the rectangular resisting elements was 12 inches (305 mm) in all cases since this is the maximum spacing of vertical cores permitted by Table R608.3.

TABLE R608.6(4). See page 6-178 and 6-179.

❖ See the commentary to Section R608.6.2. In addition to the load combinations for dead, live and wind loads, also included is the lateral soil load [i.e., 30 and 60 psf/ft (4.7 and 9.4 kPa/m) of depth]. In addition, the floor live load, L , on the slab-on-ground [40 psf (1.9 kPa)] was included as a surcharge load. The surcharge load is the product of the floor live load and the coefficient of earth pressure, K , implied by the lateral soil load used in the design of the stem wall. Since lateral soil load is the product of K and the density of the soil, by assuming a soil density of 110 pcf (1762 kg/m³), a value of K was computed for each soil class.

R608.6.3 Continuity of wall reinforcement between stories.

Vertical reinforcement required by this section shall be continuous between elements providing lateral support for the wall. Reinforcement in the wall of the *story* above shall be continuous with the reinforcement in the wall of the *story* below, or the foundation wall, if applicable. Lap splices, where required, shall comply with Section R608.5.4.3 and Figure R608.5.4(1). Where the above-grade wall is supported by a monolithic slab-on-ground and footing, dowel bars with a size and spacing to match the vertical above-grade concrete wall reinforcement shall be embedded in the monolithic slab-on-ground and footing the distance required to develop the dowel bar in tension in accordance with Section R608.5.4.4 and Figure R608.5.4(2)

For SI: 1 foot = 304.8 mm.

FIGURE R608.6(3)
ABOVE-GRADE CONCRETE WALL
CONSTRUCTION TWO-STORY

and lap-spliced with the above-grade wall reinforcement in accordance with Section R608.5.4.3 and Figure R608.5.4(1).

Exception: Where reinforcement in the wall above cannot be made continuous with the reinforcement in the wall below, the bottom of the reinforcement in the wall above shall be terminated in accordance with one of the following:

1. Extend below the top of the floor the distance required to develop the bar in tension in accordance with Section R608.5.4.4 and Figure R608.5.4(2).
2. Lap-spliced in accordance with Section R608.5.4.3 and Figure R608.5.4(1) with a dowel bar that extends into the wall below the distance required to develop the bar in tension in accordance with Section R608.5.4.4 and Figure R608.5.4(2).

Where a construction joint in the wall is located below the level of the floor and less than the distance required to develop the bar in tension, the distance required to develop the bar in tension shall be measured from the top of the concrete below the joint. See Section R608.5.5.

❖ The wall vertical reinforcement must be continuous through the basement, crawl space or stem wall and must be continuous through the stories above and terminate at the top of the top-most story.

Where there is no basement, crawl space or stem wall, the continuous vertical reinforcement must be doweled into a monolithic slab-on-ground footing in accordance with Section R608.5.4.4.

Where continuity cannot be made, the exception permits extending the wall reinforcing below the top of the floor to the required development length or lap-splice with a dowel bar in the wall below.

For SI: 1 inch = 25.4 mm.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound per square inch = 1.895 kPa, 1 square foot = 0.0929 m².

- a. Table is based on ASCE 7 components and cladding wind pressures for an enclosed building using a mean roof height of 35 feet, interior wall area 4, an effective wind area of 10 square feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II.
- b. Table is based on concrete with a minimum specified compressive strength of 2,500 psi.
- c. See Section R608.6.5 for location of reinforcement in wall.
- d. Deflection criterion is $L/240$, where L is the unsupported height of the wall in inches.
- e. Interpolation is not permitted.
- f. Where No. 4 reinforcing bars at a spacing of 48 inches are specified in the table as indicated by shaded cells, use of bars with a minimum yield strength of 40,000 psi or 60,000 psi is permitted.
- g. Other than for No. 4 bars spaced at 48 inches on center, table values are based on reinforcing bars with a minimum yield strength of 60,000 psi. Vertical reinforcement with a yield strength of less than 60,000 psi or bars of a different size than specified in the table are permitted in accordance with Section R608.5.4.7 and Table R608.5.4(2).
- h. See Table R608.3 for tolerances on nominal thicknesses.
- i. "Top" means gravity load from roof or floor construction bears on top of wall. "Side" means gravity load from floor construction is transferred to wall from a wood ledger or cold-formed steel track bolted to side of wall. For nonload-bearing walls where floor framing members span parallel to the wall, use of the "Top" bearing condition is permitted.

TABLE R608.6(2)
MINIMUM VERTICAL REINFORCEMENT FOR WAFFLE-GRID ABOVE-GRADE WALLS^{a, b, c, d, e}

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound per square inch = 6.895 kPa, 1 square foot = 0.0929 m².

- a. Table is based on ASCE 7 components and cladding wind pressures for an enclosed building using a mean roof height of 35 feet, interior wall area 4, an effective wind area of 10 square feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II.
- b. Table is based on concrete with a minimum specified compressive strength of 2,500 psi.
- c. See Section R608.6.5 for location of reinforcement in wall.
- d. Deflection criterion is $L/240$, where L is the unsupported height of the wall in inches.
- e. Interpolation is not permitted.
- f. Where No. 4 reinforcing bars at a spacing of 48 inches are specified in the table as indicated by shaded cells, use of bars with a minimum yield strength of 40,000 psi or 60,000 psi is permitted.
- g. Other than for No. 4 bars spaced at 48 inches on center, table values are based on reinforcing bars with a minimum yield strength of 60,000 psi. Maximum spacings shown are the values calculated for the specified bar size. Where the bar used is Grade 60 and the size specified in the table, the actual spacing in the wall shall not exceed a whole-number multiple of 12 inches such as, 12, 24, 36 and 48, that is less than or equal to the tabulated spacing. Vertical reinforcement with a yield strength of less than 60,000 psi or bars of a different size than specified in the table are permitted in accordance with Section R608.5.4.7 and Table R608.5.4(2).
- h. See Table R608.3 for minimum core dimensions and maximum spacing of horizontal and vertical cores.
- i. "Top" means gravity load from roof or floor construction bears on top of wall. "Side" means gravity load from floor construction is transferred to wall from a wood ledger or cold-formed steel track bolted to side of wall. For nonload-bearing walls and where floor framing members span parallel to the wall, the "top" bearing condition is permitted to be used.

				60	DR	DR	6@21	6@27	DR	DR	DR	

- For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound per square inch = 6.895 kPa, 1 square foot = 0.0929 m².
- Table is based on ASCE 7 components and cladding wind pressures for an enclosed building using a mean roof height of 35 feet, interior wall area 4, an effective wind area of 10 square feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II.
 - Table is based on concrete with a minimum specified compressive strength of 2,500 psi.
 - See Section R608.6.5 for location of reinforcement in wall.
 - Deflection criterion is $L/240$, where L is the height of the wall in inches from the exterior finish ground level to the top of the above-grade wall.
 - Interpolation is not permitted. For intermediate values of basic wind speed, heights of stem wall and above-grade wall, and design lateral soil load, use next higher value.
 - Where No. 4 reinforcing bars at a spacing of 48 inches are specified in the table as indicated by shaded cells, use of bars with a minimum yield strength of 40,000 psi or 60,000 psi is permitted.
 - Other than for No. 4 bars spaced at 48 inches on center, table values are based on reinforcing bars with a minimum yield strength of 60,000 psi. Maximum spacings shown are the values calculated for the specified bar size. In waffle and screen-grid walls where the bar used is Grade 60 and the size specified in the table, the actual spacing in the wall shall not exceed a whole-number multiple of 12 inches such as, 12, 24, 36 and 48, that is less than or equal to the tabulated spacing. Vertical reinforcement with a yield strength of less than 60,000 psi and/or bars of a different size than specified in the table are permitted in accordance with Section R608.5.4.7 and Table R608.5.4(2).
 - Height of stem wall is the distance from the exterior finish ground level to the top of the slab-on-ground.
 - Where the distance from the exterior finish ground level to the top of the slab-on-ground is equal to or greater than 4 feet, the stem wall shall be laterally supported at the top and bottom before backfilling. Where the wall is designed and constructed to be continuous with the above-grade wall, temporary supports bracing the top of the stem wall shall remain in place until the above-grade wall is laterally supported at the top by floor or roof construction.
 - See Table R608.3 for tolerances on nominal thicknesses, and minimum core dimensions and maximum spacing of horizontal and vertical cores for waffle- and screen-grid walls.

(continued)

TABLE R608.6(4)—continued
MINIMUM VERTICAL REINFORCEMENT FOR FLAT, WAFFLE- AND SCREEN-GRID
ABOVE-GRADE WALLS DESIGNED CONTINUOUS WITH FOUNDATION STEM WALLS^{a, b, c, d, e, k, l}

- k. Tabulated values are applicable to construction where gravity loads bear on top of wall, and conditions where gravity loads from floor construction are transferred to wall from a wood ledger or cold-formed steel track bolted to side of wall. See Tables R608.6(1), R608.6(2) and R608.6(3).
- l. DR = Design Required.

R608.6.4 Termination of reinforcement. Where indicated in Items 1 through 3, vertical wall reinforcement in the top-most *story* with concrete walls shall be terminated with a 90-degree (1.57 rad) standard hook complying with Section R608.5.4.5 and Figure R608.5.4(3).

1. Vertical bars adjacent to door and window openings required by Section R608.8.1.2.
2. Vertical bars at the ends of required solid wall segments (see Section R608.7.2.2.2).
3. Vertical bars (other than end bars, see Item 2) used as shear reinforcement in required solid wall segments where the reduction factor for design strength, R_3 , used is based on the wall having horizontal and vertical shear reinforcement (see Section R608.7.2.2.3).

The bar extension of the hook shall be oriented parallel to the horizontal wall reinforcement and be within 4 inches (102 mm) of the top of the wall.

Horizontal reinforcement shall be continuous around the building corners by bending one of the bars and lap-splicing it with the bar in the other wall in accordance with Section R608.5.4.3 and Figure R608.5.4(1).

Exception: In lieu of bending horizontal reinforcement at corners, separate bent reinforcing bars shall be permitted provided that the bent bar is lap-spliced with the horizontal reinforcement in both walls in accordance with Section R608.5.4.3 and Figure R608.5.4(1).

In required solid wall segments where the reduction factor for design strength, R_3 , is based on the wall having horizontal and vertical shear reinforcement in accordance with Section R608.7.2.2.1, horizontal wall reinforcement shall be terminated with a standard hook complying with Section R608.5.4.5 and Figure R608.5.4(3) or in a lap-splice, except at corners where the reinforcement shall be continuous as required.

- ❖ This section prescribes the required termination of the vertical reinforcement at the top of the top-most story and the termination of the horizontal reinforcement at the building corners.

The vertical wall reinforcement in the top-most story must terminate with a 90-degree (1.57 rad) standard hook oriented parallel to the horizontal wall reinforcement and within 4 inches (102 mm) of the top of the wall. This applies to the following vertical bars:

1. The required minimum vertical wall reinforcement.
2. Vertical bars adjacent to door and window openings.
3. Vertical bars at the ends of required solid wall segments.

4. Vertical shear reinforcing bars (except other than end bars for solid wall segments) in accordance with Section R608.7.2.2.3.

The requirement that vertical wall reinforcement be terminated with a standard hook is based on current standards for conventional masonry construction. The requirement has proven very effective in masonry construction conditions with wind speeds of 110 mph (49 m/s) or greater where the wind speed is based on the previous edition of ASCE 7. In the 2006 code the requirement for hooks was triggered at a design wind pressure greater than 40 pounds per square foot (psf). The requirement for hooks in the 2015 code provides for a factored roof uplift force greater than 1000 plf. The hook allows the full tensile strength of the reinforcing bar to be developed and therefore provides additional tensile strength in the concrete wall to resist the large roof uplift forces in high wind areas.

The horizontal reinforcing must be continuous at the building corners. The continuity is achieved by bending the horizontal bar in one wall around the corner with sufficient length to lap splice with the horizontal bar in the other wall. The lap splice is to be in accordance with Section R608.5.4.3. The exception permits the use of a bent corner bar with sufficient length of each leg to lap splice with the horizontal bars in both walls.

R608.6.5 Location of reinforcement in wall. Except for vertical reinforcement at the ends of required solid wall segments, which shall be located as required by Section R608.7.2.2.2, the location of the vertical reinforcement shall not vary from the center of the wall by more than the greater of 10 percent of the wall thickness and $\frac{3}{8}$ -inch (10 mm). Horizontal and vertical reinforcement shall be located to provide not less than the minimum cover required by Section R608.5.4.1.

- ❖ The amount of reinforcement required by the tables in Section R608.6 for a given condition of wall type, height, thickness and eccentricity of loads supported was computed based on the centroid of the vertical reinforcement being at the center of the wall. In engineering terms, the effective depth, d , was one-half the wall thickness. The 2006 code required the reinforcement to be located within the center one-third of the wall thickness. Depending on how this was interpreted, this allowed the centroid of the vertical reinforcement to vary by up to one-sixth the wall thickness from the location assumed in the calculations. This meant that the effective depth for a 6-inch (152 mm) wall was reduced 1 inch (25 mm) if the reinforcement was positioned toward the flexural compression side of the wall.

This amounted to a reduction in d of approximately 33 percent. Since design moment strength is approximately proportional to the effective depth, this misplacement of the reinforcement from where it was assumed in the design resulted in an approximately 33-percent reduction in design moment strength.

Section R608.6.5 requires that the vertical reinforcement be placed at the center of the wall with a tolerance of the larger of 10 percent of the wall thickness and $\frac{3}{8}$ -inch (9.5 mm). The latter criterion is based on the tolerance on d in ACI 318 for members with effective depth, d , less than or equal to 8 inches. The ACI 318 tolerance of $\frac{3}{8}$ -inch (9.5 mm) is approximately 10 percent of the wall thickness of a $3\frac{1}{2}$ -inch (89 mm) wall. Based on this, it was decided that if 10-percent tolerance was permitted for a very thin wall, then it should also be acceptable for thicker walls.

The location for vertical reinforcement at the ends of solid wall segments must be in accordance with Section R608.7.2.2.2.

R608.7 Solid walls for resistance to lateral forces.

❖ The tables in Section R608.6 are based on concrete walls without door or window openings. This simplified approach rarely arises in residential construction since walls generally contain windows and doors to meet functional needs. The amount of openings affects the lateral (racking) strength of the building parallel to the wall, which resists wind and seismic forces. Section R608.7 addresses the minimum amount of solid wall required to resist in-plane shear loads from wind and seismic forces.

This section prescribes the required length of solid wall, the solid wall segments, minimum length of solid wall segments, maximum spacing of segments, required reinforcement in solid wall segments and required solid wall segments at the ends (corners) of all exterior walls.

R608.7.1 Length of solid wall. Each exterior wall line in each *story* shall have a total length of solid wall required by Section R608.7.1.1. A solid wall is a section of flat, waffle-grid or screen-grid wall, extending the full *story height* without openings or penetrations, except those permitted by Section R608.7.2. Solid wall segments that contribute to the total length of solid wall shall comply with Section R608.7.2.

❖ This section defines a solid wall. A solid wall is permitted to have only openings or penetrations as allowed by Section R608.7.2.

R608.7.1.1 Length of solid wall for wind. Buildings shall have solid walls in each exterior endwall line (the side of a building that is parallel to the span of the roof or floor framing) and sidewall line (the side of a building that is perpendicular to the span of the roof or floor framing) to resist lateral in-plane wind forces. The site-appropriate basic wind speed and exposure category shall be used in Tables R608.7(1A) through (1C) to determine the unreduced total length, UR , of solid wall required in each exterior endwall line and sidewall line. For buildings with a mean roof height of less than 35 feet (10 668 mm), the unreduced values determined from Tables

R608.7(1A) through (1C) are permitted to be reduced by multiplying by the applicable factor, R_1 , from Table R608.7(2); however, reduced values shall be not less than the minimum values in Tables R608.7(1A) through (1C). Where the floor-to-ceiling height of a *story* is less than 10 feet (3048 mm), the unreduced values determined from Tables R608.7(1A) through (C), including minimum values, are permitted to be reduced by multiplying by the applicable factor, R_2 , from Table R608.7(3). To account for different design strengths than assumed in determining the values in Tables R608.7(1A) through (1C), the unreduced lengths determined from Tables R608.7(1A) through (1C), including minimum values, are permitted to be reduced by multiplying by the applicable factor, R_3 , from Table R608.7(4). The reductions permitted by Tables R608.7(2), R608.7(3) and R608.7(4) are cumulative.

The total length of solid wall segments, TL , in a wall line that comply with the minimum length requirements of Section R608.7.2.1 [see Figure R608.7(1)] shall be equal to or greater than the product of the unreduced length of solid wall from Tables R608.7(1A) through (1C), UR and the applicable reduction factors, if any, from Tables R608.7(2), R608.7(3) and R608.7(4) as indicated by Equation R6-1.

$$TL \geq R_1 \cdot R_2 \cdot R_3 \cdot UR \quad \text{(Equation R6-1)}$$

where:

TL = Total length of solid wall segments in a wall line that comply with Section R608.7.2.1 [see Figure R608.7(1)].

R_1 = 1.0 or reduction factor for mean roof height from Table R608.7(2).

R_2 = 1.0 or reduction factor for floor-to-ceiling wall height from Table R608.7(3).

R_3 = 1.0 or reduction factor for design strength from Table R608.7(4).

UR = Unreduced length of solid wall from Tables R608.7(1A) through (1C).

The total length of solid wall in a wall line, TL , shall be not less than that provided by two solid wall segments complying with the minimum length requirements of Section R608.7.2.1.

To facilitate determining the required wall thickness, wall type, number and *grade* of vertical bars at each end of each solid wall segment, and whether shear reinforcement is required, use of Equation R6-2 is permitted.

$$R \leq \frac{TL}{R_1 \cdot R_2 \cdot UR} \quad \text{(Equation R6-2)}$$

After determining the maximum permitted value of the reduction factor for design strength, R_3 , in accordance with Equation R6-2, select a wall type from Table R608.7(4) with R_3 less than or equal to the value calculated.

❖ All buildings must have minimum solid wall length as described in Figure R608.7(1).

Each endwall and sidewall [as shown in Figure R608.7(1)] must have solid walls to resist the lateral in-plane wind forces.

The unreduced length (UR) of solid wall is determined from Tables R608.7(1A), R608.7(1B) and R608.7(1C) and then reduced by the appropriate reduction factors from Tables R608.7(2), R608.7(3) and R608.7(4). The minimum length cannot be less than that required by Section R608.7.2.1. The minimum length must have two solid wall segments complying with Section R608.7.2.1.

Table R608.7(4) provides reduction factors for increased design strength of solid wall segments. Previous prescriptive methods do not recognize that different lengths of solid wall segments and different amounts of vertical reinforcement near the end of a segment of the same length generally increase the design strength with regard to the in-plane force the segment is capable of resisting. In order to recognize these benefits, solid wall segments of different lengths, thicknesses, number and size of bars at the ends of the segments, and presence or absence of horizontal shear reinforcement were evaluated. Segments were evaluated as cantilevered flexural elements fixed at the base with a height of 8 feet (2438 mm). It was felt that 8 feet (2438 mm) was a reasonable height to use for this calculation, even where the floor-to-ceiling wall height may be 10 feet (3048 mm), because the tops of most wall openings are 8 feet (2438 mm) or less above the floor. Design moment strengths for solid wall segments in flat walls were computed based on the parameters listed below:

1. Solid wall segment length
2. Segment thickness (i.e., nominal thickness minus 1/2 inch)
3. Number of reinforcing bars at end of segment and their location
4. Size of reinforcing bars at end of segment
5. Yield strength of reinforcement
6. Specified compressive strength of concrete

Using these parameters, design moment strengths were computed for each unique solid wall segment combination shown in Table R608.7(4).

For waffle and screen-grid walls, design moment strengths of solid wall segments were computed based on the assumption of a flanged section. The flange width in the through-the-wall dimension was assumed to be 5.5 inches (140 mm) for 6-inch (152 mm) waffle- and screen-grid walls, and 7.5 inches (191 mm) for 8-inch (203 mm) waffle-grid walls. The depth of the concrete compression zone, *a*, was computed to ensure that a sufficient depth of concrete (in the in-plane direction) is provided in the area of the segment under compression. Sufficient depth is ensured in the field by complying with Note e of Table R608.7(4). In the 2006 code, the design shear strength (based on concrete alone) of solid wall segments was computed based on the area of the vertical core of concrete. In Table R608.7(4), the design shear strength (based on concrete alone) of solid wall segments was computed based on an assumed web thickness of 2.6 inches (66

mm) for 6-inch and 8-inch (152 mm and 203 mm) nominal waffle-grid walls and 2.2 inches (56 mm) for 6-inch (152 mm) nominal screen-grid walls. These values, which are based on recommendations contained in *Testing and Design of Lintels Using Insulating Concrete Forms*, give some credit to the flanges for their contribution in resisting shear stresses that is not accounted for in the provisions of ACI 318.

Tables R608.7(1A), R608.7(1B) and R608.7(1C) are based on the Envelope Procedure (Part 2) Chapter 28 of the wind load provisions of ASCE 7 for low-rise buildings. ASCE 7 defines a low-rise building as an enclosed or partially enclosed building with a mean roof height of less than or equal to 60 feet (18 288 mm) in which the mean roof height does not exceed the least horizontal dimension. Commentary Figure R608.7.1.1 shows the velocity pressures for the various basic wind speeds and exposure categories and how they were grouped for purposes of designs in the table. The velocity pressures are based on a building with a mean roof height of 35 feet (10 668 mm). The basic wind speeds in the shaded cells were used to compute the velocity pressures to be resisted by solid walls in each of the two exterior wall lines parallel to the direction of the wind.

To compute the forces, external pressure coefficients, *G_{Cpf}*, from Figure 28.4-1 of ASCE 7 were used to calculate the design wind pressures for various building surfaces and these pressures were applied to the building as shown in Figure 28.4-1. The following assumptions were used to calculate the forces.

1. Floor-to-ceiling wall heights (all stories)—10 feet (3048 mm)
2. Thickness of second-floor assembly, if applicable—16 inches (406 mm)

BASIC WIND SPEED (mph)			VELOCITY PRESSURE (psf)
Exposure Category			
B	C	D	
115			21.07
120			22.94
130	110		26.92
140	119	110	31.23
150	127	117	35.85
160	136	125	40.78
170	144	133	46.04
180	153	141	51.62
194	165	152	60.11
212	180	166	71.54
230	195	180	84.17

For SI: 1 mph = 0.4470 m/s, 1 psf = 0.0479 kN/m².

Figure R608.7.1.1
VELOCITY PRESSURES

3. Thickness of attic floor/ceiling assembly above the top story ceiling—12 inches (305 mm)
4. Width of roof overhang (when computing wind forces perpendicular to ridge)—24 inches (610 mm)

ASCE 7 requires that the main windforce-resisting system be designed for the larger of the forces computed as described above, and a force of 16 psf multiplied by the wall area of the building and 8 psf multiplied by the roof area of the building projected onto a vertical plane normal to the assumed wind direction. The minimum force generally governs for the design of buildings having lower sloped roofs [i.e., approximately 5 in 12 (23 degrees) or less] sited in areas with lower basic wind speeds, as illustrated by the shaded cells in Tables R608.7(1A), R608.7(1B) and R608.7(1C).

The unadjusted solid wall lengths are based on a design strength of 840 pounds per foot (132 kPa/m) of length of solid wall segment and the forces computed as described above were divided by 840 plf to obtain the unadjusted lengths of solid wall tabulated in Tables R608.7(1A), R608.7(1B) and R608.7(1C).

TABLE R608.7(1A). See page 6-181 and 6-182.

R608.7.2 Solid wall segments. Solid wall segments that contribute to the required length of solid wall shall comply with this section. Reinforcement shall be provided in accordance with Section R608.7.2.2 and Table R608.7(4). Solid wall segments shall extend the full story-height without openings, other than openings for the utilities and other building services passing through the wall. In flat walls and waffle-grid walls, such openings shall have an area of less than 30 square inches (19 355 mm²) without any dimension exceeding 6¹/₄ inches (159 mm), and shall not be located within 6 inches (152 mm) of the side edges of the solid wall segment. In screen-grid walls, such openings shall be located in the portion of the solid wall segment between horizontal and vertical cores of concrete and opening size and location are not restricted provided there is not any concrete removed.

❖ Provisions for limited openings in solid wall segments recognize the reality that mandating a segment with no openings is not practical. Prohibiting the opening

within 6 inches (152 mm) of the edge of a solid wall segment is intended to prevent holes from reducing the area of concrete in the compression zone.

R608.7.2.1 Minimum length of solid wall segment and maximum spacing. Only solid wall segments equal to or greater than 24 inches (610 mm) in length shall be included in the total length of solid wall required by Section R608.7.1. In addition, not more than two solid wall segments equal to or greater than 24 inches (610 mm) in length and less than 48 inches (1219 mm) in length shall be included in the required total length of solid wall. The maximum clear opening width shall be 18 feet (5486 mm). See Figure R608.7(1).

❖ A minimum of two solid wall segments is required for each solid wall line, as shown in Figure R608.7(1). Only solid wall segments that are a minimum of 24 inches (610 mm) in length are to be counted in the total required length of solid wall. No more than two solid wall segments are permitted to be less than 48 inches (1219 mm). The maximum spacing (clear opening width) between segments is 18 feet (5486 mm).

FIGURE R608.7(1). See page 6-191.

❖ See the commentary to Sections R608.7.1.1, R608.7.2.1 and R608.7.2.3.

R608.7.2.2 Reinforcement in solid wall segments.

❖ This section contains the provisions for horizontal and vertical shear reinforcement in solid wall segments where the option to provide the shear reinforcement from Table R608.7(4) is chosen.

Also, this section prescribes the location and termination of the required vertical bars at the ends of the solid wall segments.

This section also contains the provisions for solid wall segments at corners.

R608.7.2.2.1 Horizontal shear reinforcement. Where reduction factors for design strength, R_3 , from Table R608.7(4) based on horizontal and vertical shear reinforcement being provided are used, solid wall segments shall have horizontal reinforcement consisting of minimum No. 4 bars. Horizontal shear reinforcement shall be the same grade of steel required for the vertical reinforcement at the ends of solid wall segments by Section R608.7.2.2.2.

The spacing of horizontal reinforcement shall not exceed the smaller of one-half the length of the solid wall segment, minus 2 inches (51 mm), and 18 inches (457 mm). Horizontal shear reinforcement shall terminate in accordance with Section R608.6.4.

❖ There are two options with respect to horizontal shear reinforcement. If the option to use no horizontal and vertical shear reinforcement is assumed in selecting the reduction factor (R_3) for design strength from Table R608.7(4), horizontal reinforcement must be provided in accordance with Section R608.6.2. On the other hand, if the option to use horizontal and vertical shear reinforcement is assumed in selecting the reduction factor (R_3) for design strength from Table R608.7(4), horizontal reinforcement must be installed in accordance with Section R608.7.2.2.1.

		5:12	4.94	5.37	6.31	7.31	8.40	9.55	6.34	
		7:12	11.71	12.75	14.97	17.36	19.93	22.67	7.39	
		12:12	22.70	24.71	29.00	33.64	38.62	43.94	10.29	
	60	< 1:12	3.68	4.01	4.71	5.46	6.27	7.13	4.23	
		5:12	5.11	5.57	6.54	7.58	8.70	9.90	7.31	
		7:12	14.38	15.66	18.37	21.31	24.46	27.83	8.71	
		12:12	29.30	31.90	37.44	43.42	49.85	56.72	12.57	

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound-force per linear foot = 0.146 kN/m, 1 pound per square foot = 47.88 Pa.

- a. Tabulated lengths were derived by calculating design wind pressures in accordance with Figure 28.4-1 of ASCE 7 for a building with a mean roof height of 35 feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II. For wind perpendicular to the ridge, the effects of a 2-foot overhang on each endwall are included. The design pressures were used to calculate forces to be resisted by solid wall segments in each. The forces to be resisted by each wall line were then divided by the default design strength of 840 pounds per linear foot of length to determine the unreduced length, *UR*, of solid wall length required in each endwall. The actual mean roof height of the building shall not exceed the least horizontal dimension of the building.
- b. Tabulated lengths in the “minimum” column are based on the requirement of Section 28.4.4 of ASCE 7 that the main windforce-resisting system be designed for a minimum pressure of 16 psf multiplied by the wall area of the building and 8 psf multiplied by the roof area of the building projected onto a vertical plane normal to the assumed wind direction. Tabulated lengths in shaded cells are less than the “minimum” value. Where the minimum controls, it is permitted to be reduced in accordance with Notes c, d and e. See Section R608.7.1.1.
- c. For buildings with a mean roof height of less than 35 feet, tabulated lengths are permitted to be reduced by multiplying by the appropriate factor, R_1 , from Table R608.7(2). The reduced length shall be not less than the “minimum” value shown in the table.
- d. Tabulated lengths for “one story or top story of two story” are based on a floor-to-ceiling height of 10 feet. Tabulated lengths for “first story of two story” are based on floor-to-ceiling heights of 10 feet each for the first and second story. For floor-to-ceiling heights less than assumed, use the lengths in this table or Table R608.7 (1B) or (1C), or multiply the value in the table by the reduction factor, R_2 , from Table R608.7(3).
- e. Tabulated lengths are based on the default design shear strength of 840 pounds per linear foot of solid wall segment. The tabulated lengths are permitted to be reduced by multiplying by the applicable reduction factor for design strength, R_3 , from Table R608.7(4).
- f. The reduction factors, R_1 , R_2 and R_3 , in Tables R608.7(2), R608.7(3), and R608.7(4), respectively, are permitted to be compounded, subject to the limitations of Note b. However, the minimum number and minimum length of solid wall segments in each wall line shall comply with Sections R608.7.1 and R608.7.2.1, respectively.
- g. For intermediate values of sidewall length, endwall length, roof slope and basic wind speed, use the next higher value, or determine by interpolation.

	45	< 1:12	10.27	11.18	13.12	15.21	17.47	19.87	10.50	
		5:12	14.26	15.52	18.22	21.13	24.26	27.60	12.82	
		7:12	20.21	22.01	25.83	29.95	34.39	39.12	13.86	
		12:12	31.20	33.97	39.87	46.23	53.07	60.39	16.76	
	60	< 1:12	10.64	11.59	13.60	15.77	18.11	20.60	10.70	
		5:12	14.77	16.09	18.88	21.90	25.14	28.60	13.79	
		7:12	23.05	25.09	29.45	34.15	39.21	44.61	15.18	
		12:12	37.97	41.34	48.52	56.27	64.60	73.49	19.05	

- For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound force per linear foot = 0.146 kN/m, 1 pound per square foot = 47.88 Pa.
- Tabulated lengths were derived by calculating design wind pressures in accordance with Figure 28.4-1 of ASCE 7 for a building with a mean roof height of 35 feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II. For wind perpendicular to the ridge, the effects of a 2-foot overhang on each endwall are included. The design pressures were used to calculate forces to be resisted by solid wall segments in each endwall. The forces to be resisted by each wall line were then divided by the default design strength of 840 pounds per linear foot of length to determine the unreduced length, UR , of solid wall length required in each endwall. The actual mean roof height of the building shall not exceed the least horizontal dimension of the building.
 - Tabulated lengths in the “minimum” column are based on the requirement of Section 28.4.4 of ASCE 7 that the main windforce-resisting system be designed for a minimum pressure of 1016 psf multiplied by the wall area of the building and 8 psf multiplied by the roof area of the building projected onto a vertical plane normal to the assumed wind direction. Tabulated lengths in shaded cells are less than the “minimum” value. Where the minimum controls, it is permitted to be reduced in accordance with Notes c, d and e. See Section R608.7.1.1.
 - For buildings with a mean roof height of less than 35 feet, tabulated lengths are permitted to be reduced by multiplying by the appropriate factor, R_1 , from Table R608.7(2). The reduced length shall be not less than the “minimum” value shown in the table.
 - Tabulated lengths for “one story or top story of two story” are based on a floor-to-ceiling height of 10 feet. Tabulated lengths for “first story of two story” are based on floor-to-ceiling heights of 10 feet each for the first and second story. For floor-to-ceiling heights less than assumed, use the lengths in this table or Table R608.7(1A) or (1C), or multiply the value in the table by the reduction factor, R_2 , from Table R608.7(3).
 - Tabulated lengths are based on the default design shear strength of 840 pounds per linear foot of solid wall segment. The tabulated lengths are permitted to be reduced by multiplying by the applicable reduction factor for design strength, R_3 , from Table R608.7(4).
 - The reduction factors, R_1 , R_2 and R_3 , in Tables R608.7(2), R608.7(3), and R608.7(4), respectively, are permitted to be compounded, subject to the limitations of Note b. However, the minimum number and minimum length of solid wall segments in each wall line shall comply with Sections R608.7.1 and R608.7.2.1, respectively.
 - For intermediate values of sidewall length, endwall length, roof slope and basic wind speed, use the next higher value, or determine by interpolation.

		5:12	9.97	10.86	12.74	14.78	16.97	19.30	9.48
		7:12	10.69	11.64	13.66	15.84	18.19	20.69	10.21
		12:12	12.67	13.80	16.19	18.78	21.56	24.53	12.25
	60	< 1:12	11.37	12.38	14.53	16.85	19.35	22.01	10.65
		5:12	14.18	15.44	18.12	21.02	24.13	27.45	13.54
		7:12	15.46	16.83	19.75	22.91	26.29	29.92	14.85
		12:12	18.98	20.66	24.25	28.13	32.29	36.74	18.48

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound force per linear foot = 0.146 kN/m, 1 pound per square foot = 47.88 Pa.

- Tabulated lengths were derived by calculating design wind pressures in accordance with Figure 28.4-1 of ASCE 7 for a building with a mean roof height of 35 feet, topographic factor, K_{zt} , equal to 1.0, and Risk Category II. The design pressures were used to calculate forces to be resisted by solid wall segments in each sidewall. The forces to be resisted by each wall line were then divided by the default design strength of 840 pounds per linear foot of length to determine the unreduced length, U_R , of solid wall length required in each sidewall. The actual mean roof height of the building shall not exceed the least horizontal dimension of the building.
- Tabulated lengths in the “minimum” column are based on the requirement of Section 28.4.4 of ASCE 7 that the main windforce-resisting system be designed for a minimum pressure of 16 psf multiplied by the wall area of the building and 8 psf multiplied by the roof area of the building projected onto a vertical plane normal to the assumed wind direction. Tabulated lengths in shaded cells are less than the “minimum” value. Where the minimum controls, it is permitted to be reduced in accordance with Notes c, d and e. See Section R608.7.1.1.
- For buildings with a mean roof height of less than 35 feet, tabulated lengths are permitted to be reduced by multiplying by the appropriate factor, R_1 , from Table R608.7(2). The reduced length shall be not less than the “minimum” value shown in the table.
- Tabulated lengths for “one story or top story of two story” are based on a floor-to-ceiling height of 10 feet. Tabulated lengths for “first story of two story” are based on floor-to-ceiling heights of 10 feet each for the first and second story. For floor-to-ceiling heights less than assumed, use the lengths in this table or Table R608.7(1A) or (1B), or multiply the value in the table by the reduction factor, R_2 , from Table R608.7(3).
- Tabulated lengths are based on the default design shear strength of 840 pounds per linear foot of solid wall segment. The tabulated lengths are permitted to be reduced by multiplying by the applicable reduction factor for design strength, R_3 , from Table R608.7(4).
- The reduction factors, R_1 , R_2 and R_3 , in Tables R608.7(2), R608.7(3), and R608.7(4), respectively, are permitted to be compounded, subject to the limitations of Note b. However, the minimum number and minimum length of solid walls segments in each wall line shall comply with Sections R608.7.1 and R608.7.2.1, respectively.
- For intermediate values of sidewall length, endwall length, roof slope and basic wind speed, use the next higher value, or determine by interpolation.

TABLE R608.7(2)
REDUCTION FACTOR, R_1 , FOR BUILDINGS WITH MEAN ROOF HEIGHT LESS THAN 35 FEET^a

MEAN ROOF HEIGHT ^{b, c} (feet)	REDUCTION FACTOR R_1 , FOR MEAN ROOF HEIGHT		
	Exposure category		
	B	C	D
< 15	0.96	0.84	0.87
20	0.96	0.89	0.91
25	0.96	0.93	0.94
30	0.96	0.97	0.98
35	1.00	1.00	1.00

For SI: 1 foot = 304.8 mm, 1 degree = 0.0175 rad.

- a. See Section R608.7.1.1 and Note c to Table R608.7(1A) for application of reduction factors in this table. This reduction is not permitted for “minimum” values.
 b. For intermediate values of mean roof height, use the factor for the next greater height, or determine by interpolation.
 c. Mean roof height is the average of the roof eave height and height of the highest point on the roof surface, except that for roof slopes of less than or equal to $2\frac{1}{8}$:12 (10 degrees), the mean roof height is permitted to be taken as the roof eave height.

TABLE R608.7(3)
REDUCTION FACTOR, R_2 , FOR FLOOR-TO-CEILING WALL HEIGHTS LESS THAN 10 FEET^{a, b}

STORY UNDER CONSIDERATION	FLOOR-TO-CEILING HEIGHT ^c (feet)	ENDWALL LENGTH (feet)	ROOF SLOPE	REDUCTION FACTOR, R_2
Endwalls—for wind perpendicular to ridge				
One story or top story of two story	8	15	< 5:12	0.83
			7:12	0.90
			12:12	0.94
		60	< 5:12	0.83
			7:12	0.95
			12:12	0.98
First story of two story	16 combined first and second story	15	< 5:12	0.83
			7:12	0.86
			12:12	0.89
		60	< 5:12	0.83
			7:12	0.91
			12:12	0.95
Sidewalls—for wind parallel to ridge				
One story or top story of two story	8	15	< 1:12	0.84
			5:12	0.87
			7:12	0.88
			12:12	0.89
		60	< 1:12	0.86
			5:12	0.92
			7:12	0.93
			12:12	0.95
First story of two story	16 combined first and second story	15	< 1:12	0.83
			5:12	0.84
			7:12	0.85
			12:12	0.86
		60	< 1:12	0.84
			5:12	0.87
			7:12	0.88
			12:12	0.90

For SI: 1 foot = 304.8 mm.

- a. See Section R608.7.1.1 and Note d to Table R608.7(1A) for application of reduction factors in this table.
 b. For intermediate values of endwall length, and/or roof slope, use the next higher value, or determine by interpolation.
 c. Tabulated values in Table R608.7(1A) and (1C) for “one story or top story of two story” are based on a floor-to-ceiling height of 10 feet. Tabulated values in Table R608.7(1B) and (1C) for “first story of two story” are based on floor-to-ceiling heights of 10 feet each for the first and second story. For floor to ceiling heights between those shown in this table and those assumed in Table R608.7(1A), (1B) or (1C), use the solid wall lengths in Table R608.7(1A), (1B) or (1C), or determine the reduction factor by interpolating between 1.0 and the factor shown in this table.

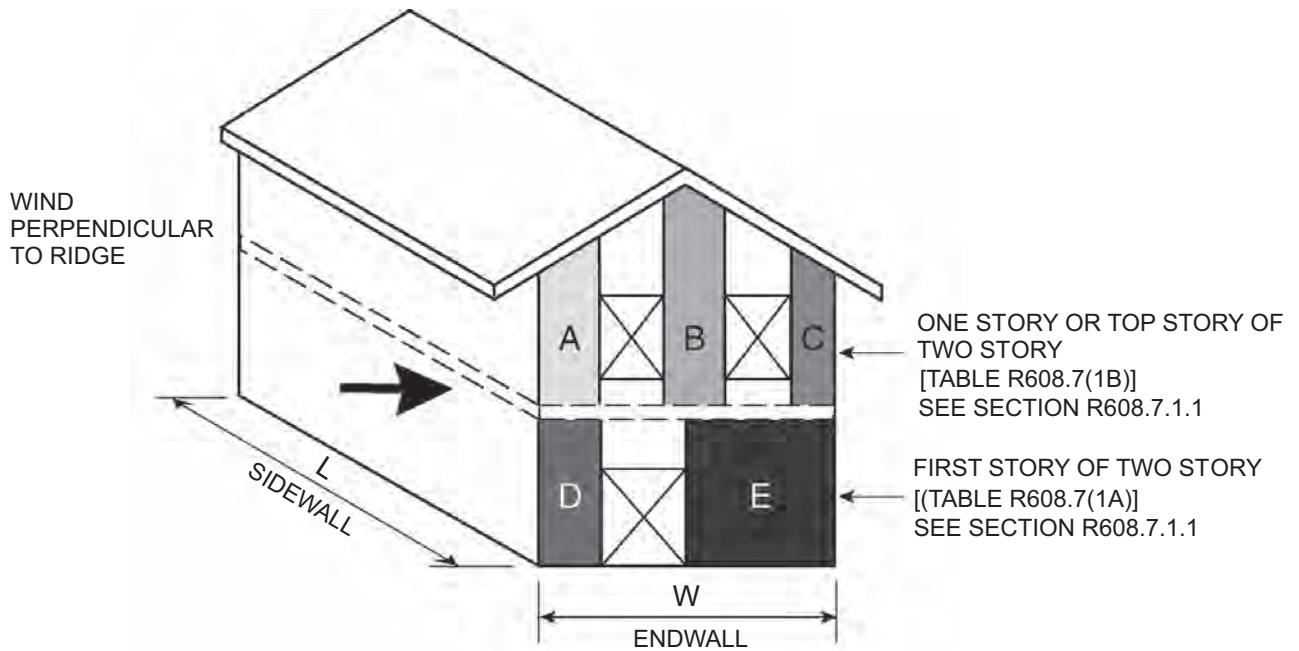

WALL CONSTRUCTION

TABLE R608.7(4)
REDUCTION FACTOR FOR DESIGN STRENGTH, R_3 , FOR FLAT, WAFFLE- AND SCREEN-GRID WALLS^{a, c}

NOMINAL THICKNESS OF WALL (inches)	VERTICAL BARS AT EACH END OF SOLID WALL SEGMENT		VERTICAL REINFORCEMENT LAYOUT DETAIL [see Figure R608.7(2)]	REDUCTION FACTOR, R_3 , FOR LENGTH OF SOLID WALL

	2	5	3	0.93	0.93	0.46	0.23
	3	5	4	0.93	0.93	0.24	0.16

For SI: 1 inch = 25.4 mm, 1,000 pounds per square inch = 6.895 MPa.

- See Note e to Table R608.7(1A) for application of adjustment factors in this table.
- Yield strength in pounds per square inch of vertical wall reinforcement at ends of solid wall segments.
- Values are based on concrete with a specified compressive strength, f'_c , of 2,500 psi. Where concrete with f'_c of not less than 3,000 psi is used, values in shaded cells are permitted to be decreased by multiplying by 0.91.
- Horizontal and vertical shear reinforcement shall be provided in accordance with Section R608.7.2.2.
- Each end of each solid wall segment shall have rectangular flanges. In the through-the-wall dimension, the flange shall be not less than 5½ inches for 6-inch-nominal waffle- and screen-grid walls, and not less than 7½ inches for 8-inch-nominal waffle-grid walls. In the in-plane dimension, flanges shall be long enough to accommodate the vertical reinforcement required by the layout detail selected from Figure R608.7(2) and provide the cover required by Section R608.5.4.1. If necessary to achieve the required dimensions, form material shall be removed or use of flat wall forms is permitted.

NOTE: EACH SOLID WALL SEGMENT (A, B, C, D, E, AND F) SHALL COMPLY WITH THE MINIMUM SOLID WALL SEGMENT LENGTH IN ORDER TO BE APPLICABLE TO THE MINIMUM SOLID WALL LENGTH EQUATIONS IN SECTION R608.7.1.1. SEE SECTION R608.7.2

FIGURE R608.7(1)
MINIMUM SOLID WALL LENGTH

R608.7.2.2.2 Vertical reinforcement. Vertical reinforcement applicable to the reduction factor(s) for design strength, R_s , from Table R608.7(4) that is used, shall be located at each end of each solid wall segment in accordance with the applicable detail in Figure R608.7(2). The No. 4 vertical bar required on each side of an opening by Section R608.8.1.2 is permitted to be used as reinforcement at the ends of solid wall segments where installed in accordance with the applicable detail in Figure R608.7(2). There shall be not less than two No. 4 bars at each end of solid wall segments located as required by the applicable detail in Figure R608.7(2). One of the bars at each end of solid wall segments shall be deemed to meet the requirements for vertical wall reinforcement required by Section R608.6.

The vertical wall reinforcement at each end of each solid wall segment shall be developed below the bottom of the adjacent wall opening [see Figure R608.7(3)] by one of the following methods:

1. Where the wall height below the bottom of the adjacent opening is equal to or greater than 22 inches (559 mm) for No. 4 or 28 inches (711 mm) for No. 5 vertical wall reinforcement, reinforcement around openings in accordance with Section R608.8.1 shall be sufficient.
 2. Where the wall height below the bottom of the adjacent opening is less than required by Item 1 above, the vertical wall reinforcement adjacent to the opening shall extend into the footing far enough to develop the bar in tension in accordance with Section R608.5.4.4 and Figure R608.5.4(2), or shall be lap-spliced with a dowel that is embedded in the footing far enough to develop the dowel-bar in tension.
- ❖ Solid wall segments must have vertical rebars at each end of the segment. The location is to be in accordance with this section and Figure R608.7(2). The vertical rebars at each end of the segment must be developed below the adjacent opening in accordance with this section and Figure R608.7(3).

FIGURE R608.7(2). See page 6-193.

❖ See the commentary to Section R608.7.2.2.2.

❖ section and Figure R608.7(3).

FIGURE R608.7(3). See page 6-194.

❖ See the commentary to Section R608.7.2.2.2.

R608.7.2.2.3 Vertical shear reinforcement. Where reduction factors for design strength, R_s , from Table R608.7(4) based on horizontal and vertical shear reinforcement being provided are used, solid wall segments shall have vertical reinforcement consisting of minimum No. 4 bars. Vertical shear reinforcement shall be the same grade of steel required by Section R608.7.2.2.2 for the vertical reinforcement at the ends of solid wall segments. The spacing of vertical reinforcement

throughout the length of the segment shall not exceed the smaller of one third the length of the segment, and 18 inches (457 mm). Vertical shear reinforcement shall be continuous between stories in accordance with Section R608.6.3, and shall terminate in accordance with Section R608.6.4. Vertical shear reinforcement required by this section is permitted to be used for vertical reinforcement required by Table R608.6(1), R608.6(2), R608.6(3) or R608.6(4), whichever is applicable.

❖ There are two options with respect to vertical shear reinforcement. If the option to use no horizontal and vertical shear reinforcement is assumed in selecting the reduction factor (R_s) for design strength from Table R608.7(4), vertical reinforcement must be provided in accordance with Sections R608.6.2 and R608.7.2.2.2. On the other hand, if the option to use horizontal and vertical shear reinforcement is assumed in selecting the reduction factor (R_s) for design strength from Table R608.7(4), vertical reinforcement must be installed in accordance with Sections R608.7.2.2.2 and R608.7.2.2.3.

R608.7.2.3 Solid wall segments at corners. At all interior and exterior corners of exterior walls, a solid wall segment shall extend the full height of each wall *story*. The segment shall have the length required to develop the horizontal reinforcement above and below the adjacent opening in tension in accordance with Section R608.5.4.4. For an exterior corner, the limiting dimension is measured on the outside of the wall, and for an interior corner the limiting dimension is measured on the inside of the wall. See Section R608.8.1. The length of a segment contributing to the required length of solid wall shall comply with Section R608.7.2.1.

The end of a solid wall segment complying with the minimum length requirements of Section R608.7.2.1 shall be located not more than 6 feet (1829 mm) from each corner.

❖ A full-height (story height) solid wall segment must be located at each corner (end) of an endwall line and each corner (end) of a sidewall line as shown in Figure R608.7(1).

The minimum length must be sufficient for the development length of the horizontal rebar above and below the adjacent opening and comply with Section R608.7.2.1.

The code permits the corner (end) segments, as shown in Figure R608.7(1), that comply with the minimum length requirements to be located no more than 6 feet (1829 mm) from each corner.

R608.8 Requirements for lintels and reinforcement around openings.

❖ This section contains the requirements for reinforcement around openings and lintels above openings as prescribed in Sections R608.8.1 and R608.8.2.

DETAIL NO.	NOM. WALL THICKNESS, IN.	REINFORCEMENT LAYOUT AT ENDS OF SOLID WALL SEGMENTS	NOTES
1	4		<p>For SI: 1 inch = 25.4 mm.</p> <p>1. See Table R608.7(4) for use of details.</p>
2	4		<p>2. Minimum length of solid wall segment and size and grade of reinforcement in each end of each solid wall segment shall be determined from Table R608.7(4).</p>
3	6 8 10		<p>3.. For minimum cover requirements, see Section R608.5.4.1.</p>
4	6		<p>4.. For details 3 - 8 where two or more bars are in the same row parallel to the end of the segment, place bars so that corner bars are as close to the sides of the wall segments as minimum cover requirements of Section R608.5.4.1 will permit.</p>
5	8		<p>5.. For waffle- and screen-grid walls, each end of each solid wall segment shall have rectangular flanges. In the through-the-wall dimension, the flange shall be not less than 5½ inches for 6-inch nominal waffle- and screen-grid forms, and not less than 7½ inches for 8-inch nominal waffle-grid forms. In the in-plane dimension, flanges shall be long enough to accommodate the vertical reinforcement required by the layout detail selected and provide the cover required by Section R608.5.4.1. If necessary to achieve the required dimensions, form material shall be removed or flat wall forms are permitted. See Table R608.7(4), Note e.</p>

7	10		
8	10	<p>* For minimum cover see Section R608.5.4.1</p>	

FIGURE R608.7(2)
VERTICAL REINFORCEMENT LAYOUT DETAIL

WALL CONSTRUCTION

FIGURE R608.7(3)
VERTICAL WALL REINFORCEMENT ADJACENT TO WALL OPENINGS

R608.8.1 Reinforcement around openings. Reinforcement shall be provided around openings in walls equal to or greater than 2 feet (610 mm) in width in accordance with this section and Figure R608.8(1), in addition to the minimum wall reinforcement required by Sections R404.1.3, R608.6 and R608.7. Vertical wall reinforcement required by this section is permitted to be used as reinforcement at the ends of solid wall segments required by Section R608.7.2.2.2 provided it is located in accordance with Section R608.8.1.2. Wall openings shall have a minimum depth of concrete over the width of the opening of 8 inches (203 mm) in flat walls and waffle-grid walls, and 12 inches (305 mm) in screen-grid walls. Wall openings in waffle-grid and screen-grid walls shall be located such that not less than one-half of a vertical core occurs along each side of the opening.

- ❖ Reinforcement of openings less than 2 feet (610 mm) in width is not required. Only openings equal to or greater than 2 feet (610 mm) in width require reinforcement. The required opening reinforcement is in addition to the minimum wall reinforcement required for concrete foundation walls, above-grade walls and solid wall segments. See Figure R608.8(1) for the minimum reinforcement required at wall openings.

FIGURE R608.8(1). See page 6-195.

- ❖ See the commentary to Sections R608.8.1, R608.8.1.1 and R608.8.1.2.

R608.8.1.1 Horizontal reinforcement. Lintels complying with Section R608.8.2 shall be provided above wall openings equal to or greater than 2 feet (610 mm) in width.

Exception: Continuous horizontal wall reinforcement placed within 12 inches (305 mm) of the top of the wall story as required in Sections R404.1.2.2 and R608.6.2 is permitted in lieu of top or bottom lintel reinforcement required by Section R608.8.2 provided that the continuous horizontal wall reinforcement meets the location require-

ments specified in Figures R608.8(2), R608.8(3), and R608.8(4) and the size requirements specified in Tables R608.8(2) through R608.8(10).

Openings equal to or greater than 2 feet (610 mm) in width shall have not less than one No. 4 bar placed within 12 inches (305 mm) of the bottom of the opening. See Figure R608.8(1).

Horizontal reinforcement placed above and below an opening shall extend beyond the edges of the opening the dimension required to develop the bar in tension in accordance with Section R608.5.4.4.

- ❖ Horizontal reinforcement is required both above and below all openings equal to or greater than 2 feet (610 mm) in width.

The reinforcement above the opening must be a lintel complying with Section R608.8.2. Lintels are horizontal members used to transfer wall, floor, roof, and attic dead loads, snow and live loads above opening in walls to the sides of the opening. The exception permits the continuous horizontal wall reinforcement required for foundation walls and above-grade walls to serve as the top or bottom lintel reinforcement provided it meets the requirement of Section R608.8.2. The reinforcement below the opening must be a No. 4 bar placed within 12 inches (305 mm) of the bottom of the opening [see Figure R608.8(1)].

R608.8.1.2 Vertical reinforcement. Not less than one No. 4 bar [Grade 40 (280 MPa)] shall be provided on each side of openings equal to or greater than 2 feet (610 mm) in width. The vertical reinforcement required by this section shall extend the full height of the wall story and shall be located within 12 inches (305 mm) of each side of the opening. The vertical reinforcement required on each side of an opening by this section is permitted to serve as reinforcement at the ends of solid wall segments in accordance with Section R608.7.2.2.2, provided it is located as required by the applicable detail in Figure

R608.7(2). Where the vertical reinforcement required by this section is used to satisfy the requirements of Section R608.7.2.2.2 in waffle- and screen-grid walls, a concrete flange shall be created at the ends of the solid wall segments in accordance with Table R608.7(4), Note e. In the top-most story, the reinforcement shall terminate in accordance with Section R608.6.4.

❖ The minimum vertical reinforcement required on each side of the opening is to provide resistance to roof uplift loads. One No. 4 bar on each side of the opening is required and will resist roof uplift load based on the design wind speeds defined in Section R608.2. The vertical reinforcement must extend the full height of the wall story and be within 12 inches (305 mm) of each side of the opening as shown in Figure R608.8(1).

This minimum vertical reinforcement is permitted to serve as reinforcement at the ends of solid wall segments (see Section R608.7.2.2.2).

R608.8.2 Lintels. Lintels shall be provided over all openings equal to or greater than 2 feet (610 mm) in width. Lintels with uniform loading shall conform to Sections R608.8.2.1 and R608.8.2.2, or Section R608.8.2.3. Lintels supporting concentrated loads, such as from roof or floor beams or girders, shall be designed in accordance with ACI 318.

❖ To support the loads from above, any wall opening of 2 feet (610 mm) or more requires a lintel in accordance

with Section R608.8.2. Figures R608.8(2) through R608.8(4) illustrate these requirements. Openings smaller than 2 feet (610 mm) can be installed without the use of a lintel to transfer loads from above as a beam. The referenced figures indicate the need for horizontal reinforcement and stirrups for transverse reinforcement depending on the type of wall being constructed and the size of the opening. Commentary Figure R608.8.2 provides a summary of the referenced figures and tables in Sections R608.8.2.1 through R608.8.2.3.

The requirements of Section R608.8.2 are for lintels subjected to uniform loading. Lintels are either load

TYPE OF WALL	APPLICABLE FIGURES	APPLICABLE TABLES
Flat	R608.8(2)	Load bearing: R608.8(2) through R608.8(5) Nonload bearing: R608.8(5)
Waffle-grid	R608.8(3)	Load bearing: R608.8(6) and R608.8(7) Nonload bearing: R608.8(10)
Screen-grid	R608.8(4)	Load bearing: R608.8(8) Nonload bearing: R608.8(10)

**Figure R608.8.2
APPLICABLE REQUIREMENTS FOR LINTELS**

**FIGURE R608.8(1)
REINFORCEMENT OF OPENINGS**

bearing (LB) or nonload bearing (NLB). Lintels subjected to concentrated loads must be designed in accordance with ACI 318.

FIGURE R608.8(2). See below.

❖ See the commentary to Sections R608.8.2 and R608.8.2.1.

FIGURE R608.8(3). See page 6-197.

❖ See the commentary to Sections R608.8.2 and R608.8.2.1.

FIGURE R608.8(4). See page 6-198.

❖ See the commentary to Sections R608.8.2 and R608.8.2.1.

R608.8.2.1 Lintels designed for gravity load-bearing conditions. Where a lintel will be subjected to gravity load condition 1 through 5 of Table R608.8(1), the clear span of the lintel shall not exceed that permitted by Tables R608.8(2) through R608.8(8). The maximum clear span of lintels with and without stirrups in flat walls shall be determined in accordance with Tables R608.8(2) through R608.8(5), and constructed in accordance with Figure R608.8(2). The maximum clear span of lintels with and without stirrups in waffle-grid walls shall be determined in accordance with Tables R608.8(6) and R608.8(7), and constructed in accordance with Figure R608.8(3). The maximum clear span of lintels with and without stirrups in screen-grid walls shall be determined in accordance with Table R608.8(8), and constructed in accordance with Figure R608.8(4).

Where required by the applicable table, No. 3 stirrups shall be installed in lintels at a maximum spacing of $d/2$ where d equals the depth of the lintel, D , less the cover of the concrete as shown in Figures R608.8(2) through R608.8(4). The smaller value of d computed for the top and bottom bar shall be used to determine the maximum stirrup spacing. Where stirrups are required in a lintel with a single bar or two bundled bars in the top and bottom, they shall be fabricated like the letter “c” or “s”

with 135-degree (2.36 rad) standard hooks at each end that comply with Section R608.5.4.5 and Figure R608.5.4(3) and installed as shown in Figures R608.8(2) through R608.8(4). Where two bars are required in the top and bottom of the lintel and the bars are not bundled, the bars shall be separated by not less than 1 inch (25 mm). The free end of the stirrups shall be fabricated with 90- or 135-degree (1.57 or 2.36 rad) standard hooks that comply with Section R608.5.4.5 and Figure R608.5.4(3) and installed as shown in Figures R608.8(2) and R608.8(3). For flat, waffle-grid and screen-grid lintels, stirrups are not required in the center distance, A , portion of spans in accordance with Figure R608.8(1) and Tables R608.8(2) through R608.8(8). See Section R608.8.2.2, Item 5, for requirement for stirrups through out lintels with bundled bars.

❖ In developing the loading conditions of Table R608.8(1), arching action above the opening was considered. Based on this concept, the lintel only supports the weight of the concrete above the lintel bounded by a triangle with its base corresponding to the clear span of the lintel, and sides which start at the top of the lintel at the edges of the opening and extend upward and inward toward the center of the opening at an angle of 45 degrees (0.79 rad). Given this geometry, the apex of the triangle is on the centerline of the opening and the height of the triangle is one-half the opening width. Therefore, in order to consider arching action, the height of the wall above the top of the lintel must be greater than one-half the opening width. Where arching action can be considered and there are no loads introduced into the triangular area, Table R608.8(1) indicates that the lintel is to be designed for a nonload-bearing condition (NLB). If loads are imposed on the wall within the triangular area beneath the arch, such as from a floor ledger board bolted to the side of the wall the lintel must be designed for load-bearing conditions (LB). Where a lintel is subjected to load-bearing conditions (LB) 1 through 5, as shown in Table

For SI: 1 inch = 25.4 mm.

FIGURE R608.8(2)
LINTEL FOR FLAT WALLS

R608.8(1), the lintel span and reinforcement must be in accordance with this section and Tables R608.8(2) through R608.8(8). The five (5) loading conditions can be summarized as follows:

1. Design for floor load only
2. Design for roof load only
3. Design for loads from roof, attic, light-framed second-story exterior wall and second floor
4. Design for loads from roof, attic, second-story exterior concrete wall and second floor, or in the case of a one-story house, design for loads from roof, attic, first-story exterior concrete wall and first floor
5. Design for loads from roof, attic, first- and second-story exterior concrete walls and first and second floor

Tables R608.8(2) through R608.8(8) provide designs for lintels with and without stirrups. Where stirrups are required, No. 3 stirrups must be installed in accordance with Section R608.8.2.1 and Figures R608.8(1) through R608.8(4). Where stirrups are required in a lintel with a single bar in the top and bottom, they are normally fabricated like the letter "c" or "s" with 135-degree (2.36 rad) standard hooks as shown in Figure R608.5.4(3) and installed as shown in Figures R608.8(2) through R608.8(4). Where two bars are required in the top and bottom of the lintel, stirrups must be fabricated with 90- or 135-degree (1.57 or 2.36 rad) standard hooks as shown in Figure R608.5.4(3) and installed as shown in Figures R608.8(2) and R608.8(3) unless the bars are bundled.

TABLES R608.8(1) through R608.8(10). See pages 6-199 through 6-214.

LINTELS FOR SCREEN-GRID WALLS

TABLE R608.8(1)
LINTEL DESIGN LOADING CONDITIONS^{a, b, d}

DESCRIPTION OF LOADS AND OPENINGS ABOVE INFLUENCING DESIGN OF LINTEL		DESIGN LOAD CONDITION ^c	
Opening in wall of top story of two-story building, or first story of one-story building			
Wall supporting loads from roof, including attic floor, if applicable, and	Top of lintel equal to or less than W/2 below top of wall	2	
	Top of lintel greater than W/2 below top of wall	NLB	
Wall not supporting loads from roof or attic floor		NLB	
Opening in wall of first story of two-story building where wall immediately above is of concrete construction, or opening in basement wall of one-story building where wall immediately above is of concrete construction			
LB ledger board mounted to side of wall with bottom of ledger less than or equal to W/2 above top of lintel, and	Top of lintel greater than W/2 below bottom of opening in story above	1	
	Top of lintel less than or equal to W/2 below bottom of opening in story above, and	Opening is entirely within the footprint of the opening in the story above	1
		Opening is partially within the footprint of the opening in the story above	4
LB ledger board mounted to side of wall with bottom of ledger more than W/2 above top of lintel		NLB	
NLB ledger board mounted to side of wall with bottom of ledger less than or equal to W/2 above top of lintel, or no ledger board, and	Top of lintel greater than W/2 below bottom of opening in story above	NLB	
	Top of lintel less than or equal to W/2 below bottom of opening in story above, and	Opening is entirely within the footprint of the opening in the story above	NLB
		Opening is partially within the footprint of the opening in the story above	1
Opening in basement wall of two-story building where walls of two stories above are of concrete construction			
LB ledger board mounted to side of wall with bottom of ledger less than or equal to W/2 above top of lintel, and	Top of lintel greater than W/2 below bottom of opening in story above	1	
	Top of lintel less than or equal to W/2 below bottom of opening in story above, and	Opening is entirely within the footprint of the opening in the story above	1
		Opening is partially within the footprint of the opening in the story above	5
LB ledger board mounted to side of wall with bottom of ledger more than W/2 above top of lintel		NLB	
NLB ledger board mounted to side of wall with bottom of ledger less than or equal to W/2 above top of lintel, or no ledger board, and	Top of lintel greater than W/2 below bottom of opening in story above	NLB	
	Top of lintel less than or equal to W/2 below bottom of opening in story above, and	Opening is entirely within the footprint of the opening in the story above	NLB
		Opening is partially within the footprint of the opening in the story above	1
Opening in wall of first story of two-story building where wall immediately above is of light-framed construction, or opening in basement wall of one-story building where wall immediately above is of light-framed construction			
Wall supporting loads from roof, second floor and top-story wall of light-framed construction, and	Top of lintel equal to or less than W/2 below top of wall	3	
	Top of lintel greater than W/2 below top of wall	NLB	
Wall not supporting loads from roof or second floor		NLB	

- a. LB means load bearing, NLB means nonload bearing, and W means width of opening.
- b. Footprint is the area of the wall below an opening in the story above, bounded by the bottom of the opening and vertical lines extending downward from the edges of the opening.
- c. For design loading condition “NLB” see Tables R608.8(9) and R608.8(10). For all other design loading conditions, see Tables R608.8(2) through R608.8(8).
- d. A NLB ledger board is a ledger attached to a wall that is parallel to the span of the floor, roof or ceiling framing that supports the edge of the floor, ceiling or roof.

	Center distance A ^{k, l}			3-3	4-1	2-5	2-7	2-1	1-11	1-7	1-2

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- a. See Table R608.3 for tolerances permitted from nominal thickness.
- b. Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Note j.
- c. Table values are based on uniform loading. See Section R608.8.2 for lintels supporting concentrated loads.
- d. Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- e. Linear interpolation is permitted between ground snow loads and between lintel depths.
- f. DR indicates design required.
- g. Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- h. Stirrups shall be fabricated from reinforcing bars with the same yield strength as that used for the main longitudinal reinforcement.
- i. Allowable clear span without stirrups applicable to all lintels of the same depth, D . Top and bottom reinforcement for lintels without stirrups shall be not less than the least amount of reinforcement required for a lintel of the same depth and loading condition with stirrups. All other spans require stirrups spaced at not more than $d/2$.
- j. Where concrete with a minimum specified compressive strength of 3,000 psi is used, clear spans for lintels without stirrups shall be permitted to be multiplied by 1.05. If the increased span exceeds the allowable clear span for a lintel of the same depth and loading condition with stirrups, the top and bottom reinforcement shall be equal to or greater than that required for a lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups that has been increased.
- k. Center distance, A , is the center portion of the clear span where stirrups are not required. This is applicable to all longitudinal bar sizes and steel yield strengths.
- l. Where concrete with a minimum specified compressive strength of 3,000 psi is used, center distance, A , shall be permitted to be multiplied by 1.10.
- m. The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel clear spans in the table greater than 18 feet are shown for interpolation and information only.
