For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, Grade 40 = 280 MPa; Grade 60 = 420 MPa.

Note: Top and bottom reinforcement for lintels without stirrups shown in shaded cells shall be equal to or greater than that required for lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups.

- a. See Table R608.3 for tolerances permitted from nominal thickness.
- b. Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Note j.
- c. Table values are based on uniform loading. See Section R608.8.2 for lintels supporting concentrated loads.
- d. Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- e. Linear interpolation is permitted between ground snow loads and between lintel depths.
- f. DR indicates design required.
- g. Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- h. Stirrups shall be fabricated from reinforcing bars with the same yield strength as that used for the main longitudinal reinforcement.
- i. Allowable clear span without stirrups applicable to all lintels of the same depth, D . Top and bottom reinforcement for lintels without stirrups shall be not less than the least amount of reinforcement required for a lintel of the same depth and loading condition with stirrups. All other spans require stirrups spaced at not more than $d/2$.
- j. Where concrete with a minimum specified compressive strength of 3,000 psi is used, clear spans for lintels without stirrups shall be permitted to be multiplied by 1.05. If the increased span exceeds the allowable clear span for a lintel of the same depth and loading condition with stirrups, the top and bottom reinforcement shall be equal to or greater than that required for a lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups that has been increased.
- k. Center distance, A , is the center portion of the clear span where stirrups are not required. This is applicable to all longitudinal bar sizes and steel yield strengths.
- l. Where concrete with a minimum specified compressive strength of 3,000 psi is used, center distance, A , shall be permitted to be multiplied by 1.10.
- m. The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel clear spans in the table greater than 18 feet are shown for interpolation and information only.

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 foot = 304.8 mm, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- Where lintels are formed with waffle-grid forms, form material shall be removed, if necessary, to create top and bottom flanges of the lintel that are not less than 3 inches in depth (in the vertical direction), are not less than 5 inches in width for 6-inch-nominal waffle-grid forms and not less than 7 inches in width for 8-inch-nominal waffle-grid forms. See Figure R608.8(3). Flat form lintels shall be permitted in place of waffle-grid lintels. See Tables R608.8(2) through R608.8(5).
- See Table R608.3 for tolerances permitted from nominal thicknesses and minimum dimensions and spacing of cores.
- Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Notes 1 and n. Table values are based on uniform loading. See Section R608.8.2 for lintels supporting concentrated loads.
- Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- Linear interpolation is permitted between ground snow loads.
- DR indicates design required. STL - stirrups required throughout lintel.
- Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- Stirrups shall be fabricated from reinforcing bars with the same yield strength as that used for the main longitudinal reinforcement.
- Lintels less than 24 inches in depth with stirrups shall be formed from flat-walls forms [see Tables R608.8(2) through R608.8(5)], or, if necessary, form material shall be removed from waffle-grid forms so as to provide the required cover for stirrups. Allowable spans for lintels formed with flat-wall forms shall be determined from Tables R608.8(2) through R608.8(5).
- Where stirrups are required for 24-inch deep lintels, the spacing shall not exceed 12 inches on center.
- Allowable clear span without stirrups applicable to all lintels of the same depth, D . Top and bottom reinforcement for lintels without stirrups shall be not less than the least amount of reinforcement required for a lintel of the same depth and loading condition with stirrups. All other spans require stirrups spaced at not more than $d/2$.
- Where concrete with a minimum specified compressive strength of 3,000 psi is used, clear spans for lintels without stirrups shall be permitted to be multiplied by 1.05. If the increased span exceeds the allowable clear span for a lintel of the same depth and loading condition with stirrups, the top and bottom reinforcement shall be equal to or greater than that required for a lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups that has been increased.
- Center distance, A , is the center portion of the span where stirrups are not required. This is applicable to all longitudinal bar sizes and steel yield strengths.
- Where concrete with a minimum specified compressive strength of 3,000 psi is used, center distance, A , shall be permitted to be multiplied by 1.10.
- The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel spans in the table greater than 18 feet are shown for interpolation and information only.

TABLE R608.8(7)
MAXIMUM ALLOWABLE CLEAR SPANS FOR 8-INCH-THICK WAFFLE-GRID LINTELS IN LOAD-BEARING WALLS^{a, b, c, d, e, f, o}

	Center distance <i>A</i> ^{m, n}		2-1	2-11	1-9	1-10	1-6	1-3	1-1	STL	STL

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 foot = 304.8 mm, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- Where lintels are formed with waffle-grid forms, form material shall be removed, if necessary, to create top and bottom flanges of the lintel that are not less than 3 inches in depth (in the vertical direction), are not less than 5 inches in width for 6-inch-nominal waffle-grid forms and not less than 7 inches in width for 8-inch-nominal waffle-grid forms. See Figure R608.8(3). Flat form lintels shall be permitted in lieu of waffle-grid lintels. See Tables R608.8(2) through R608.8(5).
- See Table R608.3 for tolerances permitted from nominal thicknesses and minimum dimensions and spacing of cores.
- Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Notes l and n. Table values are based on uniform loading. See Section R608.8.2 for lintels supporting concentrated loads.
- Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- Linear interpolation is permitted between ground snow loads.
- DR indicates design required. STL - stirrups required throughout lintel.
- Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- Stirrups shall be fabricated from reinforcing bars with the same yield strength as that used for the main longitudinal reinforcement.
- Lintels less than 24 inches in depth with stirrups shall be formed from flat-walls forms [see Tables R608.8(2) through R608.8(5)], or, if necessary, form material shall be removed from waffle-grid forms so as to provide the required cover for stirrups. Allowable spans for lintels formed with flat-wall forms shall be determined from Tables R608.8(2) through R608.8(5).
- Where stirrups are required for 24-inch deep lintels, the spacing shall not exceed 12 inches on center.
- Allowable clear span without stirrups applicable to all lintels of the same depth, D . Top and bottom reinforcement for lintels without stirrups shall be not less than the least amount of reinforcement required for a lintel of the same depth and loading condition with stirrups. All other spans require stirrups spaced at not more than $d/2$.
- Where concrete with a minimum specified compressive strength of 3,000 psi is used, clear spans for lintels without stirrups shall be permitted to be multiplied by 1.05. If the increased span exceeds the allowable clear span for a lintel of the same depth and loading condition with stirrups, the top and bottom reinforcement shall be equal to or greater than that required for a lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups that has been increased.
- Center distance, A , is the center portion of the span where stirrups are not required. This is applicable to all longitudinal bar sizes and steel yield strengths.
- Where concrete with a minimum specified compressive strength of 3,000 psi is used, center distance, A , shall be permitted to be multiplied by 1.10.
- The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel spans in the table greater than 18 feet are shown for interpolation and information only.

		60,000	DR	DR	DR	DR	DR	DR	DR	DR	DR
		Center distance <i>A</i> ^{n, o}		2-0	2-6	1-6	1-7	1-4	1-2	1-0	STL

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 foot = 304.8 mm, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- a. Where lintels are formed with screen-grid forms, form material shall be removed if necessary to create top and bottom flanges of the lintel that are not less than 5 inches in width and not less than 2.5 inches in depth (in the vertical direction). See Figure R608.8(4). Flat form lintels shall be permitted in lieu of screen-grid lintels. See Tables R608.8(2) through R608.8(5).
- b. See Table R608.3 for tolerances permitted from nominal thickness and minimum dimensions and spacings of cores.
- c. Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Notes m and o. Table values are based on uniform loading. See Section R608.7.2.1 for lintels supporting concentrated loads.
- d. Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- e. Linear interpolation is permitted between ground snow loads.
- f. DR indicates design required. STL indicates stirrups required throughout lintel.
- g. Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- h. Stirrups shall be fabricated from reinforcing bars with the same yield strength as that used for the main longitudinal reinforcement.
- i. Stirrups are not required for lintels less than 24 inches in depth fabricated from screen-grid forms. Top and bottom reinforcement shall consist of a No. 4 bar having a yield strength of 40,000 psi or 60,000 psi.
- j. Lintels between 12 and 24 inches in depth with stirrups shall be formed from flat-wall forms [see Tables R608.8(2) through R608.8(5)], or form material shall be removed from screen-grid forms to provide a concrete section comparable to that required for a flat wall. Allowable spans for flat lintels with stirrups shall be determined from Tables R608.8(2) through R608.8(5).
- k. Where stirrups are required for 24-inch deep lintels, the spacing shall not exceed 12 inches on center.
- l. Allowable clear span without stirrups applicable to all lintels of the same depth, D . Top and bottom reinforcement for lintels without stirrups shall be not less than the least amount of reinforcement required for a lintel of the same depth and loading condition with stirrups. All other spans require stirrups spaced at not more than 12 inches.
- m. Where concrete with a minimum specified compressive strength of 3,000 psi is used, clear spans for lintels without stirrups shall be permitted to be multiplied by 1.05. If the increased span exceeds the allowable clear span for a lintel of the same depth and loading condition with stirrups, the top and bottom reinforcement shall be equal to or greater than that required for a lintel of the same depth and loading condition that has an allowable clear span that is equal to or greater than that of the lintel without stirrups that has been increased.
- n. Center distance, A , is the center portion of the span where stirrups are not required. This is applicable to all longitudinal bar sizes and steel yield strengths.
- o. Where concrete with a minimum specified compressive strength of 3,000 psi is used, center distance, A , shall be permitted to be multiplied by 1.10.
- p. The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel spans in the table greater than 18 feet are shown for interpolation and information only.

TABLE R608.8(9)—continued
MAXIMUM ALLOWABLE CLEAR SPANS FOR FLAT LINTELS WITHOUT STIRRUPS IN NONLOAD-BEARING WALLS^{a, b, c, d, e, g, h}

LINTEL DEPTH, <i>D</i> ⁱ (inches)	NUMBER OF BARS AND BAR SIZE	STEEL YIELD STRENGTH, <i>f_y</i> (psi)	NOMINAL WALL THICKNESS (inches)							
			4		6		8		10	
			Lintel Supporting							
			Concrete Wall	Light- framed Gable	Concrete Wall	Light- framed Gable	Concrete Wall	Light- framed Gable	Concrete Wall	Light- framed Gable
Maximum Clear Span of Lintel (feet - inches)										
24	1-#4	40,000	16-1	17-1	13-11	15-10	12-7	14-9	11-8	13-10
		60,000	16-11	18-5	16-1	19-3	14-6	18-0	13-5	17-0
	1-#5	40,000	16-11	18-5	16-3	19-8	14-9	18-5	13-8	17-4
		60,000	16-11	18-5	17-4	—	17-0	—	15-8	—
	2-#4	40,000	16-11	18-5	17-4	—	16-1	—	14-10	—
		60,000	16-11	18-5	17-4	—	17-6	—	17-1	—
	1-#6	40,000	16-11	18-5	17-4	—	17-6	—	17-4	—
		60,000	16-11	18-5	17-4	—	17-6	—	17-8	—

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- a. See Table R608.3 for tolerances permitted from nominal thickness.
- b. Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Note e.
- c. Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ inch, whichever is less.
- d. Linear interpolation between lintels depths, D , is permitted provided the two cells being used to interpolate are shaded.
- e. Where concrete with a minimum specified compressive strength of 3,000 psi is used, spans in cells that are shaded shall be permitted to be multiplied by 1.05.
- f. Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.
- g. DR indicates design required.
- h. The maximum clear opening width between two solid wall segments shall be 18 feet. See Section R608.7.2.1. Lintel spans in the table greater than 18 feet are shown for interpolation and information purposes only.

TABLE R608.8(10)
MAXIMUM ALLOWABLE CLEAR SPANS FOR WAFFLE-GRID AND SCREEN-GRID LINTELS WITHOUT STIRRUPS IN NONLOAD-BEARING WALLS^{c, d, e, f, g}

LINTEL DEPTH ^b , <i>D</i> (inches)	FORM TYPE AND NOMINAL WALL THICKNESS (inches)					
	6-inch Waffle-grid ^a		8-inch Waffle-grid ^a		6-inch Screen-grid ^b	
	Lintel supporting					
	Concrete Wall	Light-framed Gable	Concrete Wall	Light-framed Gable	Concrete Wall	Light-framed Gable
Maximum Clear Span of Lintel (feet - inches)						
8	10-3	8-8	8-8	8-3	—	—
12	9-2	7-6	7-10	7-1	8-8	6-9
16	10-11	10-0	9-4	9-3	—	—
20	12-5	12-2	10-7	11-2	—	—
24	13-9	14-2	11-10	12-11	13-0	12-9

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, Grade 40 = 280 MPa, Grade 60 = 420 MPa.

- a. Where lintels are formed with waffle-grid forms, form material shall be removed, if necessary, to create top and bottom flanges of the lintel that are not less than 3 inches in depth (in the vertical direction), are not less than 5 inches in width for 6-inch waffle-grid forms and not less than 7 inches in width for 8-inch waffle-grid forms. See Figure R608.8(3). Flat form lintels shall be permitted in lieu of waffle-grid lintels. See Tables R608.8(2) through R608.8(5).
- b. Where lintels are formed with screen-grid forms, form material shall be removed if necessary to create top and bottom flanges of the lintel that are not less than 5 inches in width and not less than 2.5 inches in depth (in the vertical direction). See Figure R608.8(4). Flat form lintels shall be permitted in lieu of screen-grid lintels. See Tables R608.8(2) through R608.8(5).
- c. See Table R608.3 for tolerances permitted from nominal thickness and minimum dimensions and spacing of cores.
- d. Table values are based on concrete with a minimum specified compressive strength of 2,500 psi. See Note g.
- e. Deflection criterion is $L/240$, where L is the clear span of the lintel in inches, or $1/2$ -inch, whichever is less.
- f. Top and bottom reinforcement shall consist of a No. 4 bar having a minimum yield strength of 40,000 psi.
- g. Where concrete with a minimum specified compressive strength of 3,000 psi is used, spans in shaded cells shall be permitted to be multiplied by 1.05.
- h. Lintel depth, D , is permitted to include the available height of wall located directly above the lintel, provided that the increased lintel depth spans the entire length of the lintel.

R608.8.2.2 Bundled bars in lintels. It is permitted to bundle two bars in contact with each other in lintels if all of the following are observed:

1. Bars equal to or less than No. 6 are bundled.
 2. Where the wall thickness is not sufficient to provide not less than 3 inches (76 mm) of clear space beside bars (total on both sides) oriented horizontally in a bundle, the bundled bars shall be oriented in a vertical plane.
 3. Where vertically oriented bundled bars terminate with standard hooks to develop the bars in tension beyond the support (see Section R608.5.4.4), the hook extensions shall be staggered to provide not less than 1 inch (25 mm) clear spacing between the extensions.
 4. Bundled bars shall not be lap spliced within the lintel span and the length on each end of the lintel that is required to develop the bars in tension.
 5. Bundled bars shall be enclosed within stirrups throughout the length of the lintel. Stirrups and the installation thereof shall comply with Section R608.8.2.1.
- ❖ Section 7.6.6 of ACI 318 permits bars to be bundled if provisions applicable to the bundled bars are followed. The number of bars being bundled is limited to two to increase the likelihood that the bundle will be properly encased by concrete, and to avoid having to increase development lengths required by Section 12.4.1 of ACI 318 for 3 or 4 bars in a bundle. The limitation on bar size in Item 1 is based on the maximum bar size shown in the lintel tables and is consistent with residential construction practices. The requirement in Item 2 that the wall be thick enough where horizontally oriented bundled bars are used to provide a minimum of 3 inches (76 mm) of clear space beside the bars is based on the use of two No. 4 bars bundled horizontally in a 4-inch (102 mm) wall. This requirement is to ensure that the bundle is properly encased in concrete and to facilitate getting concrete to portions of the lintel below the bundle. The requirement in Item 3 that hook extensions in vertically oriented bundles be separated by at least 1 inch (25 mm) is based on recommendations in Commentary Section R7.6.6 of ACI 318. The limitation in Item 4 on location of lap splices of bundled bars is to make sure that congestion due to the laps will not occur in the critical stress areas of the lintel. Item 5 is consistent with ACI 318 requirements.

R608.8.2.3 Lintels without stirrups designed for nonload-bearing conditions. The maximum clear span of lintels without stirrups designed for nonload-bearing conditions of Table R608.8(1).1 shall be determined in accordance with this section. The maximum clear span of lintels without stirrups in flat walls shall be determined in accordance with Table R608.8(9), and the maximum clear span of lintels without

stirrups in walls of waffle-grid or screen-grid construction shall be determined in accordance with Table R608.8(10).

❖ Lintels in nonload-bearing walls are horizontal members used to transfer wall dead loads from above around openings. Lintels are divided into two categories as follows:

1. Lintels at the top of the wall in a one-story building or the second story of a two-story building where the gable portion of the endwall is light-framed construction (supporting light-framed gable); and
2. Lintels in concrete walls, including the gable (supporting concrete wall).

The following design assumptions were made in analyzing the lintels in nonload-bearing walls:

1. Lintels have fixed end restraints since the walls and lintels are cast monolithically. The negative moment at the support ($w^2/12$) is the governing moment.
2. In the case of waffle-grid and screen-grid walls, a vertical core occurs at each end of the lintel for proper bearing.
3. Lateral restraint (out-of-plane) is provided for the lintel by the floor or roof system above.
4. Allowable deflection criteria is the clear span of the lintel, in inches, divided by 240, or $1/2$ -inch (12.7 mm), whichever is smaller.
5. Lintels support only dead loads from the wall above.

R608.9 Requirements for connections—general. Concrete walls shall be connected to footings, floors, ceilings and roofs in accordance with this section.

❖ This section prescribes the required connections between concrete walls and light-framed floor, ceiling and roof systems. The concrete wall connection to the footing must be in accordance with Sections R608.6 and R608.7.

R608.9.1 Connections between concrete walls and light-framed floor, ceiling and roof systems. Connections between concrete walls and light-framed floor, ceiling and roof systems using the prescriptive details of Figures R608.9(1) through R608.9(12) shall comply with this section and Sections R608.9.2 and R608.9.3.

❖ This section prescribes the anchor bolt requirements for face-mounted wall ledger board or cold-formed steel tracks and sill plates as shown in Figures R608.9(1) through R608.9(12). The anchor bolts must be headed bolts or threaded rod with hex or square nut. J- or S-hooks are not permitted.

Stay-in-place form material at each anchor bolt for face-mounted wood ledger board and cold-formed steel tracks must be removed such that each wood ledger board or steel track is in direct contact with the concrete at each bolt location. The exception permits a vapor retarder to be installed between the concrete and the wood or cold-formed steel.

FIGURE R608.9(11) and TABLE R608.9(11). See pages 6-237 and 6-238.

❖ See the commentary to Sections R608.9.1 and R608.9.3.

FIGURE R608.9(12) and TABLE R608.9(12). See pages 6-239 and 6-240.

❖ See the commentary to Sections R608.9.1 and R608.9.3.

R608.9.1.1 Anchor bolts. Anchor bolts used to connect light-framed floor, ceiling and roof systems to concrete walls in accordance with Figures R608.9(1) through R608.9(12) shall have heads, or shall be rods with threads on both ends with a hex or square nut on the end embedded in the concrete. Bolts and threaded rods shall comply with Section R608.5.2.2. Anchor bolts with J- or L-hooks shall not be used where the connection details in these figures are used.

❖ See the commentary to Section R608.9.1.

R608.9.1.2 Removal of stay-in-place form material at bolts. Holes in stay-in-place forms for installing bolts for attaching face-mounted wood ledger boards to the wall shall be not less than 4 inches (102 mm) in diameter for forms not greater than 1½ inches (38 mm) in thickness, and increased 1 inch (25 mm) in diameter for each ½-inch (12.7 mm) increase in form thickness. Holes in stay-in-place forms for installing bolts for attaching face-mounted cold-formed steel tracks to the wall shall be not less than 4 inches (102 mm) square. The wood ledger board or steel track shall be in direct contact with the concrete at each bolt location.

Exception: A vapor retarder or other material less than or equal to 1/16 inch (1.6 mm) in thickness is permitted to be installed between the wood ledger or cold-formed track and the concrete.

❖ See the commentary to Section R608.9.1.

		115B	120B	130B	140B	150B	160B
				110C	119C	127C	136C
			110D	117D	125D		
12	12						6
12	24					6	6
16	16					6	6A
16	32				6	6	6A
19.2	19.2				6A	6A	6B
19.2	38.4			6	6A	6A	6B
24	24			6A	6B	6B	6B

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s.

- This table is for use with the detail in Figure R608.9(8). Use of this detail is permitted where a cell is not shaded.
- Wall design per other provisions of Section R608 is required.
- For wind design, minimum 4-inch-nominal wall is permitted in unshaded cells that do not contain a number.
- Number 6 indicates minimum permitted nominal wall thickness in inches necessary to develop required strength (capacity) of connection. As a minimum, this nominal thickness shall occur in the portion of the wall indicated by the cross-hatching in Figure R608.9(8). For the remainder of the wall, see Note b.
- Letter "A" indicates that a minimum nominal 3 × 6 sill plate is required. Letter "B" indicates that a 5/8-inch-diameter anchor bolt and a minimum nominal 3 × 6 sill plate are required.

For SI: 1 mil = 0.0254 mm, 1 inch = 25.4 mm, 1 pound-force = 4.448 N.

16	32					6	6
19.2	19.2					6	6
19.2	38.4				6	6	6
24	24				6	6	6B

For SI: 1 inch = 25.4 mm, 1 mile per hour = 0.447 m/s.

- a. This table is for use with the detail in Figure R608.9(12). Use of this detail is permitted where a cell is not shaded.
- b. Wall design per other provisions of Section R608 is required.
- c. For wind design, minimum 4-inch-nominal wall is permitted in cells that do not contain a number.
- d. Number 6 indicates minimum permitted nominal wall thickness in inches necessary to develop required strength (capacity) of connection. As a minimum, this nominal thickness shall occur in the portion of the wall indicated by the cross-hatching in Figure R608.9(12). For the remainder of the wall, see Note b.
- e. Letter "B" indicates that a ⁵/₈-inch-diameter anchor bolt is required.

R608.9.2 Connections between concrete walls and light-framed floor systems. Connections between concrete walls and light-framed floor systems shall be in accordance with one of the following:

1. For floor systems of wood frame construction, the provisions of Section R608.9.1 and the prescriptive details of Figures R608.9(1) through R608.9(4), where permitted by the tables accompanying those figures. Portions of connections of wood-framed floor systems not noted in the figures shall be in accordance with Section R502, or AWC WFCM, if applicable. Wood framing members shall be of a species having a specific gravity equal to or greater than 0.42.
 2. For floor systems of cold-formed steel construction, the provisions of Section R608.9.1 and the prescriptive details of Figures R608.9(5) through R608.9(8), where permitted by the tables accompanying those figures. Portions of connections of cold-formed-steel framed floor systems not noted in the figures shall be in accordance with Section R505, or AISI S230, if applicable.
 3. Proprietary connectors selected to resist loads and load combinations in accordance with Appendix A (ASD) or Appendix B (LRFD) of PCA 100.
 4. An engineered design using loads and load combinations in accordance with Appendix A (ASD) or Appendix B (LRFD) of PCA 100.
 5. An engineered design using loads and material design provisions in accordance with this code, or in accordance with ASCE 7, ACI 318, and AWC NDS for wood frame construction or AISI S100 for cold-formed steel frame construction.
- ❖ Section R608.9.2 provides four approaches for designing anchorages between concrete walls and light-framed floor construction. First, prescriptive details are provided in Figures R608.9(1) through R608.9(4) for floors of wood frame construction and in Figures R608.9(5) through R608.9(8) for cold-formed-steel framed floor systems. The wood framing members must have a specific gravity equal to or greater than 0.42. Each prescriptive detail may only be used where permitted by the table accompanying that figure. The prescriptive details are based on LRFD loads in Appendix B of PCA 100 and addresses loads in three directions occurring simultaneously (horizontal in the plane of the wall, horizontal out-of-plane and vertical). The second approach (Item 3) allows selection of proprietary connection hardware based on loads given in Appendix A or Appendix B of PCA 100. The third approach (Item 4) allows engineered anchorage design to meet the loads tabulated in Appendix A or Appendix B of PCA 100. The fourth approach (Item 5) involves an engineered design for the specific building configuration.

R608.9.3 Connections between concrete walls and light-framed ceiling and roof systems. Connections between con-

crete walls and light-framed ceiling and roof systems shall be in accordance with one of the following:

1. For ceiling and roof systems of wood frame construction, the provisions of Section R608.9.1 and the prescriptive details of Figures R608.9(9) and R608.9(10), where permitted by the tables accompanying those figures. Portions of connections of wood-framed ceiling and roof systems not noted in the figures shall be in accordance with Section R802, or AWC WFCM, if applicable. Wood framing members shall be of a species having a specific gravity equal to or greater than 0.42.
 2. For ceiling and roof systems of cold-formed-steel construction, the provisions of Section R608.9.1 and the prescriptive details of Figures R608.9(11) and R608.9(12), where permitted by the tables accompanying those figures. Portions of connections of cold-formed-steel framed ceiling and roof systems not noted in the figures shall be in accordance with Section R804, or AISI S230, if applicable.
 3. Proprietary connectors selected to resist loads and load combinations in accordance with Appendix A (ASD) or Appendix B (LRFD) of PCA 100.
 4. An engineered design using loads and load combinations in accordance with Appendix A (ASD) or Appendix B (LRFD) of PCA 100.
 5. An engineered design using loads and material design provisions in accordance with this code, or in accordance with ASCE 7, ACI 318, and AWC NDS for wood-frame construction or AISI S100 for cold-formed-steel frame construction.
- ❖ Section R611.9.3 provides four approaches for designing anchorages between concrete walls and light-framed ceiling and roof construction. First, prescriptive details are provided in Figures R608.9(9) and R608.9(10) for roofs of wood framed construction and in Figures R608.9(11) and R608.9(12) for cold-formed steel framed roof systems. The wood framing members must have a specific gravity equal to or greater than 0.42. Each prescriptive detail may only be used where permitted by the table accompanying that figure. The prescriptive details are based on the tabulated LRFD loads in Appendix B of PCA 100 and address loads in three directions occurring simultaneously (horizontal in the plane of the wall, horizontal out-of-plane and vertical). The second approach (Item 3) allows selection of proprietary connection hardware based on loads given in Appendix A or B of PCA 100. The fourth approach (Item 5) involves an engineered design for the specific building configuration.

R608.10 Floor, roof and ceiling diaphragms. Floors and roofs in buildings with exterior walls of concrete shall be designed and constructed as diaphragms. Where gable-end walls occur, ceilings shall be designed and constructed as diaphragms. The design and construction of floors, roofs and

WALL CONSTRUCTION

ceilings of wood framing or cold-formed-steel framing serving as diaphragms shall comply with the applicable requirements of this code, or AWC WFCM or AISI S230, if applicable. Wood framing members shall be of a species having a specific gravity equal to or greater than 0.42.

❖ Resistance for wind and seismic forces relies on wood structural panel diaphragms at the roof and floors. In some cases, blocked diaphragms are necessary in order to develop the shear strength required. Where gable endwalls occur, wood structural panel ceiling diaphragms are relied on to support the top of the concrete gable endwall, in addition to the support provided by the roof diaphragm. In addition to basic diaphragm construction, wood structural panel sheathing needs to be fastened at the noted edge-nail or edge-screw spacing to the framing members to which tension ties are attached.

SECTION R609 EXTERIOR WINDOWS AND DOORS

R609.1 General. This section prescribes performance and construction requirements for exterior windows and doors installed in walls. Windows and doors shall be installed and flashed in accordance with the fenestration manufacturer's written instructions. Window and door openings shall be flashed in accordance with Section R703.4. Written installation instructions shall be provided by the fenestration manufacturer for each window or door.

❖ Doors and windows are components of the exterior wall. Accordingly, this section specifies performance criteria for exterior windows and doors as well as their supporting elements to protect against high wind pressure and water intrusion.

R609.2 Performance. Exterior windows and doors shall be designed to resist the design wind loads specified in Table R301.2(2) adjusted for height and exposure in accordance with Table R301.2(3) or determined in accordance with ASCE 7 using the allowable stress design load combinations of ASCE 7. Design wind loads for exterior glazing not part of a labeled assembly shall be permitted to be determined in accordance with Chapter 24 of the *International Building Code*.

❖ Exterior windows and doors (with or without glazing) are subject to wind loading as specified in Section R301.2.1. The code requires use of the component and cladding pressures of Table R301.2(2), illustrated in Figure R301.2(7). As an alternative, the code permits design wind loads in accordance with ASCE 7 using ASD load combinations. Exterior glazing not part of a labeled assembly is allowed to have its design wind load determined in accordance with Chapter 24 of the IBC.

R609.3 Testing and labeling. Exterior windows and sliding doors shall be tested by an *approved* independent laboratory, and bear a *label* identifying manufacturer, performance characteristics and *approved* inspection agency to indicate compliance with AAMA/WDMA/CSA 101/I.S.2/A440. Exterior side-hinged doors shall be tested and *labeled* as conforming

to AAMA/WDMA/CSA 101/I.S.2/A440 or AMD 100, or comply with Section R609.5.

Exception: Decorative glazed openings.

❖ Section R609.3 requires exterior windows and sliding doors to be tested and labeled in accordance with AAMA/WDMA/CSA 101/I.S.2/A440. Section R609.3 requires exterior side-hinged doors to be tested and labeled in accordance with one of the following:

1. AAMA standard
2. AMD 100

Where side-hinged doors are not included within the scope of the standards listed in the options above, then compliance with Section R609.5 is required.

Within the AAMA standard there are additional performance levels for air leakage, water penetration resistance, forced entry resistance and operating force. Therefore, in order to be labeled in accordance with the AAMA standard, the performance levels must also be met.

AMD 100 uses ASTM E330 to obtain a full exterior door system design pressure rating. Once rated, the standard defines methods for qualifying door system components for substitution in the rated system, such as door frames, hinges, locking systems, door slabs, doorglass assemblies, sidelights, transoms, mullions, astragals and thresholds.

Compliance with Section R609.5 (ASTM E330) only determines the structural performance under uniform static air pressure differences and does not address the additional performance levels within the AAMA standard.

R609.3.1 Comparative analysis. Structural wind load design pressures for window and door units different than the size tested in accordance with Section R609.3 shall be permitted to be different than the design value of the tested unit where determined in accordance with one of the following comparative analysis methods:

1. Structural wind load design pressures for window and door units smaller than the size tested in accordance with Section R609.3 shall be permitted to be higher than the design value of the tested unit provided such higher pressures are determined by accepted engineering analysis. Components of the smaller unit shall be the same as those of the tested unit. Where such calculated design pressures are used, they shall be validated by an additional test of the window or door unit having the highest allowable design pressure.
 2. In accordance with WDMA I.S.11.
- ❖ Comparative analysis based on accepted engineering methods provides a proven, accurate and reliable means for determining design pressures (DP) of different sized products within a fenestration product line based on testing of specimen unit(s) from the respective line. This alleviates the need for costly testing of all sizes within the line, saving considerable construction costs and providing greater design flexibility, especially for specialty/custom products. Section R609.3.1

provides for two methods of comparative analysis.

Method 1 is limited only to comparative analysis for units smaller than the unit tested. Where a window or door is tested in accordance with the requirements of Section R609.3, smaller units of identical construction need not be tested. Instead, their properties may be determined by comparison to the tested unit and the application of accepted engineering analysis. However, where the analysis determines that the smaller units have a higher allowable design pressure, the unit with the highest allowable calculated design pressure must be tested to validate the findings, or the design pressure of the largest tested unit must be used.

Method 2 can be used as comparative analysis to accurately determine DP ratings for fenestration products that are larger in width and/or height than the actual tested specimen provided proper analytical methods are followed. WDMA I.S. 11—*Industry Standard for Analytical Method for Design Pressure (DP) Ratings of Fenestration Products*, provides more comprehensive alternative methods appropriate for using comparative analysis to determine the DP of units different in size, both smaller and larger, than that of the tested unit(s) within a product line. The comparative analysis methods included in WDMA I.S. 11 are based on accepted engineering analysis which must also be sealed by a licensed professional engineer (PE).

R609.4 Garage doors. Garage doors shall be tested in accordance with either ASTM E330 or ANSI/DASMA 108, and shall meet the acceptance criteria of ANSI/DASMA 108.

- ❖ Garage doors must be tested in accordance with either one of the standards indicated. In addition, they must also meet the acceptance criteria of ANSI/DASMA 108. See Section R609.5 for garage doors not within the scope of Section R609.4.

R609.5 Other exterior window and door assemblies. Exterior windows and door assemblies not included within the scope of Section R609.3 or R609.4 shall be tested in accordance with ASTM E330. Glass in assemblies covered by this exception shall comply with Section R308.5.

- ❖ Where exterior windows, sliding doors and side-hinged doors are not included within the scope of Section R609.3 and AAMA/WDMA/CSA 101/I.S.2/A440, they must be tested in accordance with ASTM E330. Excluded from the AAMA Standard are products such as, but not limited to, site-built assemblies, garage doors, sloped glazing, storm windows and doors and sunrooms. Where garage doors are not within the scope of Section R609.4 and ANSI/DASMA 108 they must be tested in accordance with ASTM E330. The user should verify whether ANSI/DASMA 108 is limited to sectional garage doors. Solid garage doors may be outside the scope of ANSI/DASMA 108.

R609.6 Wind-borne debris protection. Protection of exterior windows and glass doors in buildings located in wind-borne debris regions shall be in accordance with Section R301.2.1.2.

- ❖ See the commentary to Sections R301.2.1.2 and R609.6.1.

R609.6.1 Fenestration testing and labeling. Fenestration shall be tested by an *approved* independent laboratory, listed by an *approved* entity, and bear a *label* identifying manufacturer, performance characteristics, and *approved* inspection agency to indicate compliance with the requirements of the following specification(s):

1. ASTM E1886 and ASTM E1996; or
2. AAMA 506.

- ❖ In buildings located in wind-borne debris regions as established in accordance with Section R301.2.1, exterior windows, skylights and doors must be protected in accordance with Section R301.2.1.2, which mirrors some of the requirements of Section R609.6.1. Fenestration regulated by Section R609.6.1 includes storm shutters not in accordance with the prescriptive requirements of the exception to Section R301.2.1.2, and exterior windows, skylights and doors not equipped with storm shutters. Such fenestrations must bear a label indicating that they have been tested in accordance with AAMA 506, or both ASTM E1886 and ASTM E1996. These tests determine the ability of the fenestration to resist cyclic pressures and impact by wind-borne debris (also see commentary, Section R301.2.1.2).

R609.7 Anchorage methods. The methods cited in this section apply only to anchorage of window and glass door assemblies to the main force-resisting system.

- ❖ These requirements provide a mechanism for transferring the wind forces from the door or window to a lateral-force-resisting element. Anchorage should be according to the manufacturer's recommendations. Variations should provide equal or greater anchorage performance.

R609.7.1 Anchoring requirements. Window and glass door assemblies shall be anchored in accordance with the published manufacturer's recommendations to achieve the design pressure specified. Substitute anchoring systems used for substrates not specified by the fenestration manufacturer shall provide equal or greater anchoring performance as demonstrated by accepted engineering practice.

- ❖ See the commentary to Section R609.7.

R609.7.2 Anchorage details. Products shall be anchored in accordance with the minimum requirements illustrated in Figures R609.7.2(1), R609.7.2(2), R609.7.2(3), R609.7.2(4), R609.7.2(5), R609.7.2(6), R609.7.2(7) and R609.7.2(8).

- ❖ The code incorporates prescriptive anchorage methods that provide for transfer of wind loads to the supporting construction (see commentary, Section R609.7).

R609.7.2.1 Masonry, concrete or other structural substrate. Where the wood shim or buck thickness is less than 1½ inches (38 mm), window and glass door assemblies shall be anchored through the jamb, or by jamb clip and anchors shall be embedded directly into the masonry, concrete or

WALL CONSTRUCTION

other substantial substrate material. Anchors shall adequately transfer load from the window or door frame into the rough opening substrate [see Figures R609.7.2(1) and R609.7.2(2)].

Where the wood shim or buck thickness is 1½ inches (38 mm) or more, the buck is securely fastened to the masonry, concrete or other substantial substrate, and the buck extends beyond the interior face of the window or door frame, window and glass door assemblies shall be anchored through the jamb, or by jamb clip, or through the flange to the secured wood buck. Anchors shall be embedded into the secured wood buck to adequately transfer load from the window or door frame assembly [see Figures R609.7.2(3), R609.7.2(4) and R609.7.2(5)].

❖ When a wood member at least 1.5 inches (38 mm) thick is used as a shim, it must be anchored to the substrate. Otherwise window and door assemblies must be anchored directly to the substrate [see Figures R609.7.2(1) through R609.7.2(5)].

FIGURES R609.7.2(1) through R609.7.2(8). See pages 6-244 and 6-245.

❖ See the commentary to Sections R609.7 and R609.7.2.1.

R609.7.2.2 Wood or other approved framing material. Where the framing material is wood or other *approved* framing material, window and glass door assemblies shall be anchored through the frame, or by frame clip, or through the flange. Anchors shall be embedded into the frame construction to adequately transfer load [see Figures R609.7.2(6), R609.7.2(7) and R609.7.2(8)].

❖ Door and window assemblies must be anchored directly to wood framing [see Figures R609.7.2(6) through R609.7.2(8)].

R609.8 Mullions. Mullions shall be tested by an *approved* testing laboratory in accordance with AAMA 450, or be engineered in accordance with accepted engineering practice. Mullions tested as stand-alone units or qualified by engineering shall use performance criteria cited in Sections R609.8.1, R609.8.2 and R609.8.3. Mullions qualified by an actual test of an entire assembly shall comply with Sections R609.8.1 and R609.8.3.

❖ Mullions provide support for adjacent window and/or door assemblies. Generally, they must be tested and perform as required for windows and doors. Deflection limits and a factor of safety maintain serviceability and provide minimum strength.

R609.8.1 Load transfer. Mullions shall be designed to transfer the design pressure loads applied by the window and door assemblies to the rough opening substrate.

❖ See the commentary to Section R609.8.

R609.8.2 Deflection. Mullions shall be capable of resisting the design pressure loads applied by the window and door assemblies to be supported without deflecting more than $L/175$, where L is the span of the mullion in inches.

❖ See the commentary to Section R609.8.

R609.8.3 Structural safety factor. Mullions shall be capable of resisting a load of 1.5 times the design pressure loads applied by the window and door assemblies to be supported without exceeding the appropriate material stress levels. If tested by an *approved* laboratory, the 1.5 times the design pressure load shall be sustained for 10 seconds, and the permanent deformation shall not exceed 0.4 percent of the mullion span after the 1.5 times design pressure load is removed.

❖ See the commentary to Section R609.8.

SECTION R610 STRUCTURAL INSULATED PANEL WALL CONSTRUCTION

R610.1 General. Structural insulated panel (SIP) walls shall be designed in accordance with the provisions of this section. Where the provisions of this section are used to design structural insulated panel walls, project drawings, typical details and specifications are not required to bear the seal of the architect or engineer responsible for design, unless otherwise required by the state law of the *jurisdiction* having authority.

❖ The purpose of Section R610 is to provide a prescriptive method for the design and installation of structural insulated panel (SIP) walls, which otherwise would require an engineered design. It establishes minimum requirements for the component materials such as the facing, core and adhesive (see the typical panel illustrated in Figure R610.4). SIPs consist primarily of a foam plastic core laminated between wood structural panel facings. Structurally, SIPs can be thought of as analogous to a steel wide-flange beam, with the facing serving as the beam flanges and the core serving as the web with the composite assembly producing the desired strength and stiffness. In engineering design of such panels, axial forces are carried by the facings and bending is resisted by the internal force couple in the facings.

The benefits that can be provided by SIP construction include improved thermal efficiency and reduced air infiltration. Manufacturing SIPs in a factory-controlled environment provides improved tolerances when compared to conventional wood wall framing. SIPs also minimize the amount of wood framing required for wall construction. The less framing that is necessary, the lower the framing factor and the result is that less energy is lost due to thermal bridging.

R610.2 Applicability limits. The provisions of this section shall control the construction of exterior structural insulated panel walls and interior load-bearing structural insulated panel walls for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist or truss span, not greater than 40 feet (12 192 mm) in width parallel to the joist or truss span and not greater than two stories in height with each wall not greater than 10 feet (3048 mm) high. Exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Structural insulated panel walls constructed in accordance with the provisions of this section shall be limited to sites where the ultimate design wind speed (V_{ult}) is not greater than 155 miles per hour (69 m/s), Exposure B or 140 miles per hour (63 m/s) Exposure C, the ground snow load is not greater than 70 pounds per foot (3.35 kPa), and the seismic design category is A, B or C.

❖ This section establishes the bounds for these prescriptive SIP walls. SIP construction that exceeds these limits should be substantiated as an alternative method of design and construction in accordance with Section R104.11. These limits for snow load and wind speed as well as the building plan dimensions, wall height and number of stories are all reflected in the required wall construction that is determined under Section R610.5. Also note that for earthquake concerns these provisions are restricted to SDC A, B or C.

R610.3 Materials. SIPs shall comply with the following criteria:

❖ This section establishes minimum requirements for the component materials such as the facing, core, adhesive, lumber and fasteners. For a manufacturer's product to be covered by this section of the code, all materials used in SIP production must meet or exceed these criteria. Using these minimum material properties, the capacity of SIP walls was established by testing which was then used to develop the wall construction requirements in Section R610.5.

R610.3.1 Core. The core material shall be composed of foam plastic insulation meeting one of the following requirements:

1. ASTM C578 and have a minimum density of 0.90 pounds per cubic foot (14.4 kg/m³).
2. Polyurethane meeting the physical properties shown in Table R610.3.1.
3. An *approved* alternative.

All cores shall meet the requirements of Section R316.

❖ The middle section of the SIP is referred to as the core and it consists of light-weight foam plastic insulation. Two types of foam plastic insulation are recognized. For either type a minimum density requirement provides for a continuous, uniform layer of insulation. Item 1 refers to rigid, cellular polystyrene that complies with ASTM C578 and Item 2 allows polyurethane insulation that complies with the material criteria listed in Table R610.3.1. The cross reference to Section R316 points to the provisions governing all foam plastic insulation which provide other necessary material criteria such as flame spread and smoke-developed indexes.

TABLE R610.3.1. See page 6-247.

❖ This table contains the specific material properties that must be met in order to qualify polyurethane as a core material for SIPs.

R610.3.2 Facing. Facing materials for SIPs shall be wood structural panels conforming to DOC PS 1 or DOC PS 2, each having a minimum nominal thickness of $7/16$ inch (11 mm) and shall meet the additional minimum properties specified in Table R610.3.2. Facing shall be identified by a grade mark or certificate of inspection issued by an *approved* agency.

❖ In addition to conforming to DOC PS 1 or DOC PS 2, additional wood structural panel properties are listed in Table R610.3.2. It should be noted that these properties exceed DOC PS 1 and DOC PS 2. Thus, the wood structural panel supplier should provide verification

that their product meets these enhanced requirements for SIP facing in order to comply with this section.

TABLE R610.3.2. See below.

❖ The minimum properties for facing materials in Table R610.3.2 were established by the SIPs industry with a specific grade of wood structural panels. Panel properties for the wood structural panel facing materials in the 2009 IRC do not reflect the facing materials commonly available in the marketplace, which typically have higher properties in the along direction and lower properties in the across direction.

As a result, the Structural Insulated Panel Association (SIPA) worked with APA - The Engineered Wood Association to re-evaluate the performance of SIPs using readily available facing materials. Results of this re-evaluation are documented in APA Report T2009P-28, which shows no performance difference for SIP applications covered in IRC Section R610 when using the new facing materials with higher properties in the along direction and lower properties in the across direction, as compared to the 2009 IRC.

The facer material table has therefore been updated to reflect material properties of the wood structural panels currently used in the production of SIPs.

R610.3.3 Adhesive. Adhesives used to structurally laminate the foam plastic insulation core material to the structural wood facers shall conform to ASTM D2559 or *approved* alternative specifically intended for use as an adhesive used in the lamination of structural insulated panels. Each con-

tainer of adhesive shall bear a *label* with the adhesive manufacturer’s name, adhesive name and type and the name of the quality assurance agency.

❖ Structural adhesive bonds the foam plastic insulation to the wood structural panel facing in the lamination process and it is key to the SIP performance. This section recognizes ASTM D2559 for this purpose which provides an adhesive rated for exterior use as is appropriate for exterior walls. This section also brings up “approved alternatives.” Under Section R104.11, an alternative design may be based on ICC ES AC05 *Acceptance Criteria for Sandwich Panel Adhesives*, which would require a classification of Type II, Class 2, in order to provide high moisture resistance in a load-bearing application.

R610.3.4 Lumber. The minimum lumber framing material used for SIPs prescribed in this document is NLGA graded No. 2 Spruce-pine-fir. Substitution of other wood species/grades that meet or exceed the mechanical properties and specific gravity of No. 2 Spruce-pine-fir shall be permitted.

❖ This section establishes the minimum requirements for wood framing that is utilized in SIP wall construction.

R610.3.5 SIP screws. Screws used for the erection of SIPs as specified in Section R610.5 shall be fabricated from steel, shall be provided by the SIP manufacturer and shall be sized to penetrate the wood member to which the assembly is being attached by not less than 1 inch (25 mm). The screws shall be corrosion resistant and have a minimum shank diameter of

TABLE R610.3.1
MINIMUM PROPERTIES FOR POLYURETHANE INSULATION USED AS SIPS CORE

PHYSICAL PROPERTY	POLYURETHANE
Density, core nominal (ASTM D1622)	2.2 lb/ft ³
Compressive resistance at yield or 10% deformation, whichever occurs first (ASTM D1621)	19 psi (perpendicular to rise)
Flexural strength, min. (ASTM C203)	30 psi
Tensile strength, min. (ASTM D1623)	35 psi
Shear strength, min. (ASTM C273)	25 psi
Substrate adhesion, min. (ASTM D1623)	22 psi
Water vapor permeance of 1.00-in. thickness, max. (ASTM E96)	2.3 perm
Water absorption by total immersion, max. (ASTM C272)	4.3% (volume)
Dimensional stability (change in dimensions), max. [ASTM D2126 (7 days at 158°F/100% humidity and 7 days at -20°F)]	2%

For SI: 1 pound per cubic foot = 16.02 kg/m³, 1 pound per square inch = 6.895 kPa, °C = [(°F) - 32]1.8.

TABLE R610.3.2
MINIMUM PROPERTIES^a FOR ORIENTED STRAND BOARD FACER MATERIAL IN SIP WALLS

THICKNESS (in.)	PRODUCT	FLATWISE STIFFNESS ^b (lbf-in ² /ft)		FLATWISE STRENGTH ^c (lbf-in/ft)		TENSION ^c (lbf/ft)		DENSITY ^d (pcf)
		Along	Across	Along	Across	Along	Across	
7/16	Sheathing	55,600	16,500	1,040	460	7,450	5,800	34

For SI: 1 inch = 25.4 mm, 1 lbf-in²/ft = 9.415 × 10⁻⁶ kPa/m, 1 lbf-in/ft = 3.707 × 10⁻⁴ kN/m, 1 lbf/ft = 0.0146 N/mm, 1 pound per cubic foot = 16.018 kg/m³.

a. Values listed in Table R610.3.2 are qualification test values and are not to be used for design purposes.

b. Mean test value shall be in accordance with Section 7.6 of DOC PS 2.

c. Characteristic test value (5th percent with 75% confidence).

d. Density shall be based on oven-dry weight and oven-dry volume.

WALL CONSTRUCTION

0.188 inch (4.7 mm) and a minimum head diameter of 0.620 inch (15.5 mm).

- ❖ SIP screws must be steel and be corrosion resistant. The only required use of this fastener type is in the corner detail that is illustrated in Figure R610.9.

R610.3.6 Nails. Nails specified in Section R610 shall be common or galvanized box unless otherwise stated.

- ❖ Nailing of SIP wall assemblies is specified in Figures R610.5(3), R610.5(4), R610.5(5), R610.5.2, R610.8 and R610.9. This section clarifies the style of nail that must be used in these connections. For additional fastening requirements, see Section R610.5.

R610.4 SIP wall panels. SIPs shall comply with Figure R610.4 and shall have minimum panel thickness in accordance with Tables R610.5(1) and R610.5(2) for above-grade walls. SIPs shall be identified by grade mark or certificate of inspection issued by an *approved* agency.

- ❖ Figure R610.4 illustrates the primary components of the SIP wall panel. Manufacturing these panels in a factory-controlled environment provides improved tolerances when compared to conventional wood wall framing. SIP panels minimize the amount of wood framing required in wall construction. Also, the core may be recessed as necessary around the panel edges to accept dimension lumber, such as at the top plate connection (see Section R610.5.1). In order to verify a SIP wall panel's suitability in a particular application it must be identified by either a grade mark or certificate of inspection.

FIGURE R610.4. See next column.

- ❖ See the commentary to Section R610.4.

R610.4.1 Labeling. Panels shall be identified by grade mark or certificate of inspection issued by an *approved* agency. Each (SIP) shall bear a stamp or *label* with the following minimum information:

1. Manufacturer name/logo.
2. Identification of the assembly.
3. Quality assurance agency.

- ❖ Third-party labeling is required for the entire SIP assembly once fabrication is completed. This requirement provides the ability to verify the panel's suitability for a particular application. The label must identify the quality assurance agency. This agency provides inspections to verify adequate quality control in the manufacturing process.

R610.5 Wall construction. Exterior walls of SIP construction shall be designed and constructed in accordance with the provisions of this section and Tables R610.5(1) and R610.5(2) and Figures R610.5(1) through R610.5(5). SIP walls shall be fastened to other wood building components in accordance with Tables R602.3(1) through R602.3(4).

Framing shall be attached in accordance with Table R602.3(1) unless otherwise provided for in Section R610.

- ❖ Based on the minimum material properties established in Section R610.3, the capacity of SIP walls was estab-

lished by testing which was then used to develop the tabulated wall thickness requirements of this section. Other than the specific nailing requirements in Section R610, the fastening of wood components must be in accordance with the fastening schedule of Table R602.3(1). This section also makes it clear that the connection of the SIP wall assembly to other wood elements must be in accordance with the applicable requirements for fastening wood members. Figures R610.5(3), R610.5(4), R610.5(5), R610.8 and R610.9 indicate where SIP connections require sealant. With no particular sealant criteria given in this section, sealants should be according to the panel manufacturer's recommendations.

Because SIP walls do not contain stud framing, an adjusted fastener schedule for attaching an exterior wall covering may be necessary unless the manufacturer of the wall covering provides recommendations for attaching their product to SIP walls. A design may be required to determine the appropriate fastening requirements when a wall covering manufacturer does not provide attachment recommendations.

TABLE 610.5(1). See page 6-250.

- ❖ The tabulated SIP wall thicknesses are given based on specific values of snow load and wind criteria as well as the building plan dimensions, wall height and number of stories all of which reflect the applicability limits of Section R610.2. Additional criteria such as deflection limit, dead loads, ceiling and floor live loads are noted under the table. Typical wall heights of up to 10

FIGURE R610.4
SIP WALL PANEL

feet (305 mm) per story are provided for as this is the limit that is established in Section R610.2. Note that the story height allows an additional 16 inches (406 mm) for the depth of floor framing (see Section R301.3).

While there were no performance issues, the assumptions used in generating Tables R610.5(1) and R610.5(2) were also reviewed by the SIPA Technical Advisory Committee, which suggested more stringent criteria by not allowing any load duration increase, including wind load, for SIPs.

TABLE 610.5(2). See page 6-251.

❖ See the commentary to Table R610.5(1).

FIGURES R610.5(1) and R610.5(2). See page 6-252.

❖ See the commentary to Table R610.5(1).

FIGURE R610.5(3). See page 6-253.

❖ See the commentary to Sections R610.3.6 and R610.5.

FIGURE R610.5(4). See page 6-253.

❖ As the note cautions, only the fastening for the SIP installation is illustrated, and other applicable fastening requirements for wood framing must be satisfied. Also see the commentary to Sections R610.3.6 and R610.5.

FIGURE R610.5(5). See page 6-254.

❖ As the note cautions, only the fastening for the SIP installation is illustrated, and other applicable fastening requirements for wood framing must be satisfied. Also see the commentary to Sections R610.3.6 and R610.5.

R610.5.1 Top plate connection. SIP walls shall be capped with a double top plate installed to provide overlapping at corner, intersections and splines in accordance with Figure R610.5.1. The double top plates shall be made up of a single 2 by top plate having a width equal to the width of the panel core, and shall be recessed into the SIP below. Over this top plate a cap plate shall be placed. The cap plate width shall match the SIP thickness and overlap the facers on both sides of the panel. End joints in top plates shall be offset not less than 24 inches (610 mm).

❖ The double top plate consists of a cap plate which is sized to match the width of the SIP and a lower plate which is sized to match the width of the core allowing it to be recessed into the top edge of the panel. By matching the width of the panel, the cap plate delivers loads to the panel facings rather than the core of the panel. This double top plate configuration is depicted in Figures R610.5(3) and R610.5(4).

FIGURE R610.5.1. See page 6-254.

❖ Note 2 clarifies that the cap plate is placed over the recessed lower top plate. This figure also illustrates the requirements for headers (see Section R610.10).

R610.5.2 Bottom (sole) plate connection. SIP walls shall have full bearing on a sole plate having a width equal to the nominal width of the foam core. Where SIP walls are supported directly on continuous foundations, the wall wood sill plate shall be anchored to the foundation in accordance with Figure R610.5.2 and Section R403.1.

❖ Like the lower top plate, the bottom (sole) plate must match the width of the core so that it can be recessed within the panel as shown in Figures R610.5(4) and R610.5(5). Figure R610.5.2 illustrates a bottom plate connection to a foundation.

FIGURE R610.5.2. See page 6-255.

❖ See the commentary to Section R610.5.2.

R610.5.3 Wall bracing. SIP walls shall be braced in accordance with Section R602.10. SIP walls shall be considered continuous wood structural panel sheathing for purposes of computing required bracing. SIP walls shall meet the requirements of Section R602.10.4.2 except that SIP corners shall be fabricated as shown in Figure R610.9. Where SIP walls are used for wall bracing, the SIP bottom plate shall be attached to wood framing below in accordance with Table R602.3(1).

❖ This section clarifies that the wood frame wall bracing requirements apply and where the SIP wall construction is used as wall bracing, it must be evaluated as a continuously sheathed braced wall line. When the SIP wall is required to serve as wall bracing, this section also makes it clear that the connection of the bottom (sole) plate must be in accordance with braced wall panel requirements in the general fastening schedule for wood construction.

R610.6 Interior load-bearing walls. Interior load-bearing walls shall be constructed as specified for exterior walls.

❖ This section directs the reader to exterior wall construction (see Section R610.5) for determining requirements for interior load-bearing walls.

R610.7 Drilling and notching. The maximum vertical chase penetration in SIPs shall have a maximum side dimension of 2 inches (51 mm) centered in the panel. Vertical chases shall have a minimum spacing of 24 inches (610 mm) on center. A maximum of two horizontal chases shall be permitted in each wall panel—one at 14 inches (360 mm) plus or minus 2 inches (51 mm) from the bottom of the panel and one at 48 inches (1220 mm) plus or minus 2 inches (51 mm) from the bottom edge of the SIPs panel. Additional penetrations are permitted where justified by analysis.

❖ This section permits SIP manufacturers to form chases in the panel core both horizontally and vertically within the stated location and dimensional limits. Doing so during the fabrication process enables utilities to be installed in the finished walls without compressing insulation or having to field-drill through framing members.

WALL CONSTRUCTION

FIGURE R610.5.2
SIP WALL TO CONCRETE SLAB FOR FOUNDATION WALL ATTACHMENT

R610.8 Connection. SIPs shall be connected at vertical in-plane joints in accordance with Figure R610.8 or by other *approved* methods.

- ❖ Prescriptive details for joining adjacent panels are provided in Figure R610.8. This connection is required for serviceability purposes and it is not intended to provide load transfer between the panels.

FIGURE R610.8. See page 6-256.

- ❖ Two types of connection details for joining adjacent panels are furnished in the figure. These connections are intended primarily for serviceability purposes and are not designed to transfer stresses between the panels.

R610.9 Corner framing. Corner framing of SIP walls shall be constructed in accordance with Figure R610.9.

- ❖ The corner connection of SIP wall panels requires the use of SIP screws (see Section R610.3.5) as illustrated in Figure R610.9. Where SIP walls are used as wall bracing (see Section R610.5.3) this connection supersedes the corner details for continuously sheathed wall bracing in Table R602.3(1) and Figure R602.10.7.

FIGURE R610.9. See page 6-257.

- ❖ See the commentary to Section R610.9.

R610.10 Headers. SIP headers shall be designed and constructed in accordance with Table R610.10 and Figure R610.5.1. SIP headers shall be continuous sections without splines. Headers shall be not less than $11\frac{7}{8}$ inches (302 mm) deep. Headers longer than 4 feet (1219 mm) shall be constructed in accordance with Section R602.7.

- ❖ The minimum depth of SIP headers is given and the permitted spans are tabulated. Where greater header spans are desired, the general requirements for wood headers are applicable, including those for wood structural panel box headers.

TABLE R610.10. See page 6-257.

- ❖ See the commentary to Section R610.10.

R610.10.1 Wood structural panel box headers. Wood structural panel box headers shall be allowed where SIP headers are not applicable. Wood structural panel box headers shall be constructed in accordance with Figure R602.7.3 and Table R602.7.3.

- ❖ See the commentary to Sections R602.7.3 and R610.10.

Chapter 7: Wall Covering

General Comments

Interior wall coverings are used for a variety of purposes. Often designed simply as an aesthetic element to finish the interior of the building, these wall coverings may also protect structural elements from impact or moisture damage. Exterior wall coverings, in great part, provide the weather-resistant exterior envelope that protects the building's interior from the elements. As evidenced by the common use of exterior insulation and finish systems (EIFS) in various regions of the country, new methods and materials are constantly introduced to provide different appearances, improved insulating quality, sound transmission control and fire resistance. The code has developed prescriptive and performance regulations to control these aspects and the types and thickness of exterior wall coverings.

This chapter contains provisions for the design and construction of interior and exterior wall coverings. In addition to identifying the various types of wall coverings regulated by the code, Chapter 7 references a number of material standards related to the specific types of wall covering materials. Of primary consideration are the application methods prescribed by the code for those wall covering materials conforming to their applicable referenced standard.

Section R701 establishes the scope of the chapter and a general requirement dealing with weather protection

for wall covering materials sensitive to adverse weather conditions. Section R702 establishes the various types of materials—including interior plaster, gypsum board, ceramic tile, wood veneer paneling, hardboard paneling, wood shakes and wood shingles— material standards and methods of application permitted when installing interior coverings. The requirements for the use of vapor retarders for wall moisture control are included in this section. Section R703 addresses exterior wall coverings as well as the water-resistive barrier required beneath the exterior materials. Exterior wall coverings regulated by this section include aluminum, stone and masonry veneer, wood, hardboard, particleboard, wood structural panel siding, wood shakes and shingles, exterior plaster, steel, vinyl, fiber cement, exterior insulation finish, insulated vinyl siding and polypropylene siding.

Purpose

This chapter provides the minimum requirements applicable to wall covering materials used both in exterior and interior applications. It specifies the types of wall coverings addressed by the code, including such common materials as gypsum board and ceramic tile used on a building's interior, as well as horizontal siding and wood structural panel siding installed as the exterior membrane.

SECTION R701 GENERAL

R701.1 Application. The provisions of this chapter shall control the design and construction of the interior and exterior wall covering for buildings.

❖ Chapter 7 deals with both interior and exterior wall coverings. A variety of interior coverings are regulated, including interior plaster, gypsum board, ceramic tile, wood veneer paneling, hardboard paneling, wood shakes and wood shingles. Aluminum, stone and masonry veneer, wood, hardboard, particleboard, wood structural panel siding, wood shakes and shingles, exterior plaster, steel, vinyl, fiber cement, exterior insulation finish, insulated vinyl siding and polypropylene siding are addressed where used as exterior wall coverings.

R701.2 Installation. Products sensitive to adverse weather shall not be installed until adequate weather protection for the installation is provided. Exterior sheathing shall be dry before applying exterior cover.

❖ Because many materials are subject to deterioration from the effects of moisture or other adverse weather

conditions, the code limits the installation of such materials until proper weather protection is in place. Gypsum plaster systems, gypsum board and interior-grade plywood are particularly sensitive to moisture. It is also critical that exterior sheathing be dry prior to installation of the surface cover materials. Entrapment of moisture in the exterior wall assembly can result in reduced effectiveness of the wall over time.

To assist in the application of the provisions of this chapter, it is important to understand the terminology that is used. Commentary Figures R701.2(1) and R701.2(2) provide pictorial descriptions of several of these terms.

SECTION R702 INTERIOR COVERING

R702.1 General. Interior coverings or wall finishes shall be installed in accordance with this chapter and Table R702.1(1), Table R702.1(2), Table R702.1(3) and Table R702.3.5. Interior masonry veneer shall comply with the requirements of Section R703.7.1 for support and Section R703.7.4 for anchorage, except an airspace is not required. Interior finishes

and materials shall conform to the flame spread and smoke-development requirements of Section R302.9.

- ❖ This section contains the installation requirements for interior wall coverings. Interior wall coverings of plaster and gypsum board must be installed in accordance with the applicable tables. The installation requirements include material orientation, backing support, spacing and size as well as method of attachment to supports. These requirements can result in wall coverings that will perform as intended in regard to durability and appearance. Interior wall coverings of masonry veneer must be supported in accordance with Section R703.8.1 and anchored in accordance with Section R703.8.4. No airspace is required for interior masonry veneer since it is not required to be weather resistant. All interior finishes must meet the flame spread and smoke-development provisions of Section R302.9.

TABLE R702.1(1). See page 7-3.

- ❖ Based on several variables, this table sets forth the required plaster thickness measured from the face of the lath, masonry or concrete to the plaster surface. Both gypsum plaster and Portland cement mortar are addressed, with the option of the plaster application occurring over a variety of plaster bases. In most cases, the minimum plaster thickness is mandated; however, the maximum thickness is regulated where plaster is applied over a monolithic concrete wall or ceiling.

TABLE R702.1(2). See page 7-4.

- ❖ This table covers the maximum permitted amount of aggregate for gypsum plaster, measured in cubic feet per 100 pounds (16 oz kg/m). Applicable for damp, loose sand, perlite and vermiculite, the limits vary based on the type of plaster base or lath. The maximum proportions for each coat of both two-coat and three-coat plaster systems are identified.

TABLE R702.1(3). See page 7-4.

- ❖ Where cement plaster is used rather than gypsum plaster, this table is applicable for determining the maximum permitted volume of Portland, blended, plastic or masonry cement, lime and aggregate. In addition, the minimum period for moist curing of interior cement plaster and the minimum required interval between coats are established.

R702.2 Interior plaster.

- ❖ Multicoat plastering has been commonplace for the past century. The industry generally views multicoat work as necessary for control of plaster thickness and density, particularly when applied by hand. Because of the uniformity created where plaster is applied in thin, successive layers, the code requires three-coat plastering over metal lath and two-coat work over other plaster bases approved for use by the code. Reducing the requirement for plaster bases other than metal lath depends on the rigidity of the plaster base itself. More-

rigid plaster bases are not as susceptible to variations in thickness and flatness of the surface. In fact, the first coat applied in three-coat work on a flexible base, such as metal lath, is used to stiffen that base to provide the rigidity necessary to attain uniform thickness and surface flatness.

Both a gypsum plaster and a cement plaster interior wall covering system are shown in Commentary Fig-

ure R702.2(1). The finished thicknesses for both plastering methods, determined by the type of base materials, are set forth in Table R702.1(1). Commentary Figure R702.2(2) illustrates the veneer plaster interior wall covering system. This section also cites the material standards to which gypsum plaster and cement plaster must conform.

TABLE R702.1(1)
THICKNESS OF PLASTER

PLASTER BASE	FINISHED THICKNESS OF PLASTER FROM FACE OF LATH, MASONRY, CONCRETE (inches)	
	Gypsum Plaster	Cement Plaster
Expanded metal lath	$\frac{5}{8}$, minimum ^a	$\frac{5}{8}$, minimum ^a
Wire lath	$\frac{5}{8}$, minimum ^a	$\frac{3}{4}$, minimum (interior) ^b $\frac{7}{8}$, minimum (exterior) ^b
Gypsum lath ^g	$\frac{1}{2}$, minimum	$\frac{3}{4}$, minimum (interior) ^b
Masonry walls ^c	$\frac{1}{2}$, minimum	$\frac{1}{2}$, minimum
Monolithic concrete walls ^{c, d}	$\frac{5}{8}$, maximum	$\frac{7}{8}$, maximum
Monolithic concrete ceilings ^{c, d}	$\frac{3}{8}$, maximum ^e	$\frac{1}{2}$, maximum
Gypsum veneer base ^{f, g}	$\frac{1}{16}$, minimum	$\frac{3}{4}$, minimum (interior) ^b
Gypsum sheathing ^g	—	$\frac{3}{4}$, minimum (interior) ^b $\frac{7}{8}$, minimum (exterior) ^b

For SI: 1 inch = 25.4 mm.

- a. Where measured from back plane of expanded metal lath, exclusive of ribs, or self-furring lath, plaster thickness shall be $\frac{3}{4}$ inch minimum.
- b. Where measured from face of support or backing.
- c. Because masonry and concrete surfaces vary in plane, thickness of plaster need not be uniform.
- d. Where applied over a liquid bonding agent, finish coat shall be permitted to be applied directly to concrete surface.
- e. Approved acoustical plaster shall be permitted to be applied directly to concrete or over base coat plaster, beyond the maximum plaster thickness shown.
- f. Attachment shall be in accordance with Table R702.3.5.
- g. Where gypsum board is used as a base for cement plaster, a water-resistive barrier complying with Section R703.2 shall be provided.

**TABLE R702.1(2)
GYPSUM PLASTER PROPORTIONS^a**

NUMBER	COAT	PLASTER BASE OR LATH	MAXIMUM VOLUME AGGREGATE PER 100 POUNDS NEAT PLASTER ^b (cubic feet)	
			Damp Loose Sand ^a	Perlite or Vermiculite ^c
Two-coat work	Base coat	Gypsum lath	2.5	2
	Base coat	Masonry	3	3
Three-coat work	First coat	Lath	2 ^d	2
	Second coat	Lath	3 ^d	2 ^e
	First and second coats	Masonry	3	3

For SI: 1 inch = 25.4 mm, 1 cubic foot = 0.0283 m³, 1 pound = 0.454 kg.

- Wood-fibered gypsum plaster shall be mixed in the proportions of 100 pounds of gypsum to not more than 1 cubic foot of sand where applied on masonry or concrete.
- Where determining the amount of aggregate in set plaster, a tolerance of 10 percent shall be allowed.
- Combinations of sand and lightweight aggregate shall be permitted to be used, provided the volume and weight relationship of the combined aggregate to gypsum plaster is maintained.
- If used for both first and second coats, the volume of aggregate shall be permitted to be 2.5 cubic feet.
- Where plaster is 1 inch or more in total thickness, the proportions for the second coat may be increased to 3 cubic feet.

**TABLE R702.1(3)
CEMENT PLASTER PROPORTIONS, PARTS BY VOLUME**

COAT	CEMENT PLASTER TYPE	CEMENTITIOUS MATERIALS				VOLUME OF AGGREGATE PER SUM OF SEPARATE VOLUMES OF CEMENTITIOUS MATERIALS ^b
		Portland Cement Type I, II or III or Blended Cement Type IP, I (PM), IS or I (SM)	Plastic Cement	Masonry Cement Type M, S or N	Lime	
First	Portland or blended	1			$\frac{3}{4} - 1\frac{1}{2}$ ^a	2 $\frac{1}{2}$ - 4
	Masonry			1		2 $\frac{1}{2}$ - 4
	Plastic		1			2 $\frac{1}{2}$ - 4
Second	Portland or blended	1			$\frac{3}{4} - 1\frac{1}{2}$	3 - 5
	Masonry			1		3 - 5
	Plastic		1			3 - 5
Finish	Portland or blended	1			$\frac{3}{4} - 2$	1 $\frac{1}{2}$ - 3
	Masonry			1		1 $\frac{1}{2}$ - 3
	Plastic		1			1 $\frac{1}{2}$ - 3

For SI: 1 inch = 25.4 mm, 1 pound = 0.454 kg.

- Lime by volume of 0 to $\frac{3}{4}$ shall be used where the plaster will be placed over low-absorption surfaces such as dense clay tile or brick.
- The same or greater sand proportion shall be used in the second coat than used in the first coat.

R702.2.1 Gypsum plaster. Gypsum plaster materials shall conform to ASTM C5, C22, C28, C35, C59, C61, C587, C631, C847, C933, C1032 and C1047, and shall be installed or applied in compliance with ASTM C843 and C844. Gypsum lath or gypsum base for veneer plaster shall conform to ASTM C1396. Plaster shall be not less than three coats where applied over metal lath and not less than two coats where applied over other bases permitted by this section, except that veneer plaster shall be applied in one coat not to exceed $\frac{3}{16}$ inch (4.76 mm) thickness, provided the total thickness is in accordance with Table R702.1(1).

- ❖ This section sets forth the standards applicable to gypsum plaster materials. These materials are to be installed according to ASTM C843 and C844. The minimum number of coats of gypsum plaster is established according to the type of base upon which they are installed.

R702.2.2 Cement plaster. Cement plaster materials shall conform to ASTM C91 (Type M, S or N), C150 (Type I, II and III), C595 [Type IP, I (PM), IS and I (SM)], C847, C897, C926, C933, C1032, C1047 and C1328, and shall be installed or applied in compliance with ASTM C1063. Gypsum lath shall conform to ASTM C1396. Plaster shall be not less than three coats where applied over metal lath and not less than two coats where applied over other bases permitted by this section, except that veneer plaster shall be applied in one coat not to exceed $\frac{3}{16}$ inch (4.76 mm) thickness, provided the total thickness is in accordance with Table R702.1(1).

- ❖ This section sets forth the standards applicable to cement plaster materials. These materials are to be installed according to ASTM C1063. The minimum number of coats of cement plaster is established according to the type of base upon which they are installed.

R702.2.2.1 Application. Each coat shall be kept in a moist condition for not less than 24 hours prior to application of the next coat.

Exception: Applications installed in accordance with ASTM C926.

- ❖ This section establishes the minimum amount of time the previous coat of plaster must remain moist before applying another coat.

R702.2.2.2 Curing. The finish coat for two-coat cement plaster shall not be applied sooner than 48 hours after application of the first coat. For three-coat cement plaster, the second coat shall not be applied sooner than 24 hours after application of the first coat. The finish coat for three-coat cement plaster shall not be applied sooner than 48 hours after application of the second coat.

- ❖ This section establishes the minimum amount of time the previous coat of plaster must cure before applying another coat.

R702.2.3 Support. Support spacing for gypsum or metal lath on walls or ceilings shall not exceed 16 inches (406 mm) for $\frac{3}{8}$ -inch-thick (9.5 mm) or 24 inches (610 mm) for $\frac{1}{2}$ -inch-thick (12.7 mm) plain gypsum lath. Gypsum lath shall be installed at right angles to support framing with end joints in

adjacent courses staggered by not less than one framing space.

- ❖ To provide a relatively firm base for the first layer of plaster, the code mandates a maximum span between supporting elements of the lath. Applicable to both gypsum and metal lath for either wall or ceiling installations, the maximum spacing of supports is based on the lath thickness. Gypsum lath must be installed perpendicular to the direction of the support framing, with the end joints staggered in adjacent courses.

R702.3 Gypsum board and gypsum panel products.

- ❖ Gypsum board and gypsum panel products are by far the most commonly used interior coverings and are available in a variety of types and sizes. This section sets forth the criteria for the application of gypsum board and gypsum panel products in wall and ceiling applications.

R702.3.1 Materials. Gypsum board and gypsum panel product materials and accessories shall conform to ASTM C22, C475, C514, C1002, C1047, C1177, C1178, C1278, C1396 or C1658 and shall be installed in accordance with the provisions of this section. Adhesives for the installation of gypsum board and gypsum panel products shall conform to ASTM C557.

- ❖ This section sets forth the standards applicable to gypsum board materials and accessories. Included in the list of standards is ASTM C557, which deals with the use of adhesives to attach gypsum board to wood framing members.

R702.3.2 Wood framing. Wood framing supporting gypsum board and gypsum panel products shall be not less than 2 inches (51 mm) nominal thickness in the least dimension except that wood furring strips not less than 1-inch by 2-inch (25 mm by 51 mm) nominal dimension shall be permitted to be used over solid backing or framing spaced not more than 24 inches (610 mm) on center.

- ❖ For adequate structural backing, vertical support for gypsum board or gypsum panel products used as an interior wall covering is required to be no less than 2 inches (51 mm) nominal thickness. Dimensional lumber meeting this 2-inch (51 mm) nominal dimension would have an actual thickness of approximately $1\frac{1}{2}$ inches (38 mm).

Wood stripping used as furring over vertical supports on which the interior wall covering is to be applied is also required to meet the 2-inch (51 mm) nominal dimension in any direction unless the framing members are spaced at 24 inches (610 mm) on center or less. Where the spacing of the framing does not exceed 24 inches (610 mm) or where the furring strips are placed on solid backing, the minimum size requirements are reduced to 1 inch by 2 inches (25.4 mm by 51 mm).

Commentary Figures R702.3.2(1), R702.3.2(2) and R702.3.2(3) illustrate the dimensional constraints.

R702.3.3 Cold-formed steel framing. Cold-formed steel framing supporting gypsum board and gypsum panel products shall be not less than $1\frac{1}{4}$ inches (32 mm) wide in the least dimension. Nonload-bearing cold-formed steel framing

shall comply with AISI S220 and ASTM C645, Section 10. Load-bearing cold-formed steel framing shall comply with AISI S200 and ASTM C 955, Section 8.

- ❖ In the same manner as wood framing, cold-formed steel framing must be of a minimum cross-sectional dimension where used to support gypsum board or gypsum panel products. For cold-formed steel members, the minimum dimension must be 1¼ inches (32 mm).

This section also references two standards covering cold-formed steel framing members. ASTM C645 addresses nonstructural cold-formed steel framing members, while ASTM C955 addresses load-bearing cold-formed steel studs, tracks and bracing for gypsum panels.

R702.3.4 Insulating concrete form walls. Foam plastics for insulating concrete form walls constructed in accordance with Sections R404.1.2 and R608 on the interior of *habitable*

spaces shall be protected in accordance with Section R316.4. Use of adhesives in conjunction with mechanical fasteners is permitted. Adhesives used for interior and exterior finishes shall be compatible with the insulating form materials.

- ❖ Reinforcing the provisions of Section R316.4 regarding the thermal barrier requirement for foam plastic insulation, this section references the requirements in Chapters 4 and 6 regulating foundation walls and insulating concrete form (ICF) wall systems. Foam plastic insulation used in these wall applications must be separated from the interior of the building by a minimum $\frac{1}{2}$ -inch (12.7 mm) gypsum board or equivalent material.

Adhesives may be used to fasten the protective membrane (typically gypsum board) over the ICF wall. In all cases, however, mechanical fasteners must supplement the adhesive. Total reliance on the adhesive to provide the continued protection afforded by the gypsum board during a fire is misguided. Where used in conjunction with mechanical fasteners, adhesives must also be compatible with the insulating form materials.

R702.3.5 Application. Supports and fasteners used to attach gypsum board and gypsum panel products shall comply with Table R702.3.5. Gypsum sheathing shall be attached to exterior walls in accordance with Table R602.3(1). Gypsum board and gypsum panel products shall be applied at right angles or parallel to framing members. All edges and ends of gypsum board and gypsum panel products shall occur on the framing members, except those edges and ends that are perpendicular to the framing members. Interior gypsum board shall not be installed where it is directly exposed to the weather or to water.

- ❖ To provide adequate backing for nailing the gypsum board or gypsum panel products to the support framing, all edges and ends, except those that are perpendicular to framing support members, must occur on framing members. Gypsum board may be installed in either a perpendicular or parallel manner. This is illustrated in Commentary Figure R702.3.5(1). Already addressed in a general sense in Section R701.2, the installation of interior gypsum board and gypsum panel products must not be done while the interior of the building is exposed to weather. Direct exposure of interior gypsum board and gypsum panel products to weather or water is not permitted.

TABLE R702.3.5. See page 7-9.

- ❖ Table R702.3.5 is a comprehensive table identifying the minimum thickness and fastening requirements for gypsum board. The gypsum board thickness [$\frac{3}{8}$ -inch, $\frac{1}{2}$ -inch or $\frac{5}{8}$ -inch (10 mm, 12.7 mm or 16 mm)], loca-

tion of the gypsum board (wall or ceiling), orientation of the gypsum board to the framing members (parallel or perpendicular), spacing of framing members [16 inches or 24 inches (406 mm or 610 mm)] on center and type of fasteners (nails or screws) are all set forth in the table. Where gypsum sheathing is to be attached to exterior walls, the provisions of Table R602.3(1) apply. Commentary Figure R702.3.5(2) shows a single-nailing method of attachment; however, Note a of Table R702.3.5 permits a double-nailing method as illustrated in Commentary Figure 702.3.5(3).

R702.3.5.1 Screw fastening. Screws for attaching gypsum board and gypsum panel products to wood framing shall be Type W or Type S in accordance with ASTM C1002 and shall penetrate the wood not less than $\frac{5}{8}$ inch (15.9 mm). Gypsum board and gypsum panel products shall be attached to cold-formed steel framing with minimum No. 6 screws. Screws for attaching gypsum board and gypsum panel products to cold-formed steel framing less than 0.033 inch (1 mm) thick shall be Type S in accordance with ASTM C1002 or bugle head style in accordance with ASTM C1513 and shall penetrate the steel not less than $\frac{3}{8}$ inch (9.5 mm). Screws for attaching gypsum board and gypsum panel products to cold-formed steel framing 0.033 inch to 0.112 inch (1 mm to 3 mm) thick shall be in accordance with ASTM C954 or bugle head style in accordance with ASTM C1513. Screws for attaching gypsum board and gypsum panel products to structural insulated panels shall penetrate the wood structural panel facing not less than $\frac{7}{16}$ inch (11.1 mm).

- ❖ Screws may be used in place of nails in the application of gypsum board and gypsum panel products. This section restates the provisions of Table R702.3.5 regarding the use of screws. Where gypsum board is attached to wood framing members, screws complying with ASTM C1002 Type S or W are to be spaced in accordance with the table and must penetrate wood framing members a minimum of $\frac{5}{8}$ inch (15.9 mm). Where attaching gypsum board or gypsum panel products to cold-formed steel framing members, a minimum No. 6 screw is required. For cold-formed steel framing members less than 0.033 inch (1 mm) thick, screws must comply with either ASTM C1002 Type S or ASTM C1513 bugle-head style and must penetrate a minimum of $\frac{3}{8}$ inch (9.5 mm) into the framing. For cold-formed steel framing members 0.033 inch to 0.112 inch (1 mm to 3 mm) thick, screws must comply with either ASTM C1002 Type S or ASTM C1513 bugle-head style. Where attaching gypsum board or gypsum panel products to wood structural panels, the screws must penetrate a minimum of $\frac{7}{16}$ inch (11 mm) into the panel.

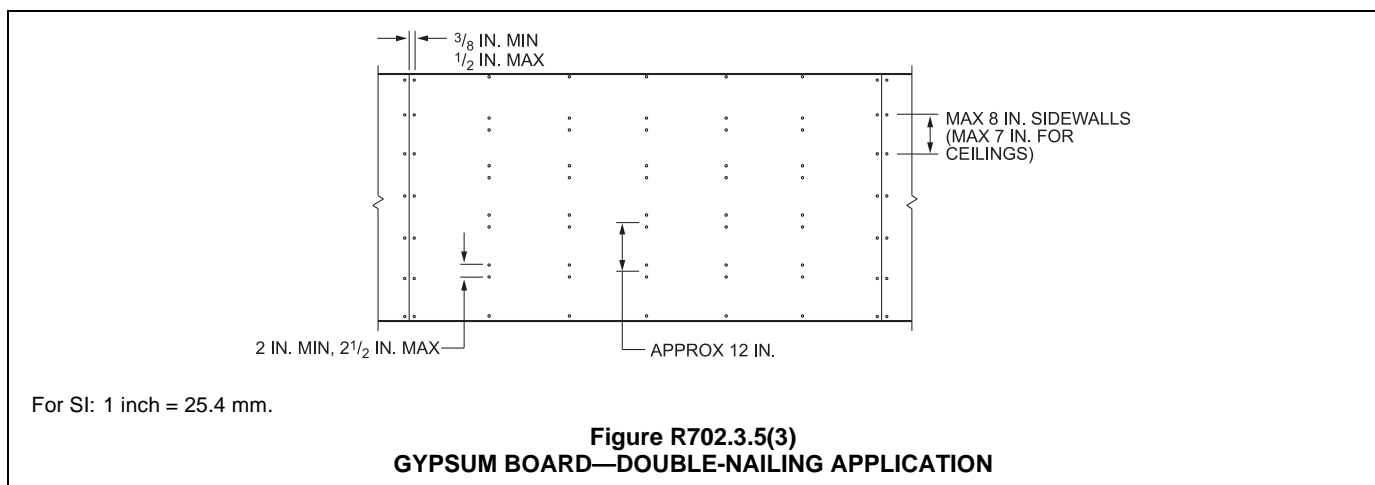

**TABLE R702.3.5
MINIMUM THICKNESS AND APPLICATION OF GYPSUM BOARD AND GYPSUM PANEL PRODUCTS**

THICKNESS OF GYPSUM BOARD OR GYPSUM PANEL PRODUCTS (inches)	APPLICATION	ORIENTATION OF GYPSUM BOARD OR GYPSUM PANEL PRODUCTS TO FRAMING	MAXIMUM SPACING OF FRAMING MEMBERS (inches o.c.)	MAXIMUM SPACING OF FASTENERS (inches)		SIZE OF NAILS FOR APPLICATION TO WOOD FRAMING ^c
				Nails ^a	Screws ^b	
Application without adhesive						
$\frac{3}{8}$	Ceiling ^d	Perpendicular	16	7	12	13 gage, $1\frac{1}{4}$ " long, $\frac{19}{64}$ " head; 0.098" diameter, $1\frac{1}{4}$ " long, annular-ringed; or 4d cooler nail, 0.080" diameter, $1\frac{3}{8}$ " long, $\frac{7}{32}$ " head.
	Wall	Either direction	16	8	16	
$\frac{1}{2}$	Ceiling	Either direction	16	7	12	13 gage, $1\frac{3}{8}$ " long, $\frac{19}{64}$ " head; 0.098" diameter, $1\frac{1}{4}$ " long, annular-ringed; 5d cooler nail, 0.086" diameter, $1\frac{3}{8}$ " long, $\frac{15}{64}$ " head; or gypsum board nail, 0.086" diameter, $1\frac{5}{8}$ " long, $\frac{9}{32}$ " head.
	Ceiling ^d	Perpendicular	24	7	12	
	Wall	Either direction	24	8	12	
	Wall	Either direction	16	8	16	
$\frac{5}{8}$	Ceiling	Either direction	16	7	12	13 gage, $1\frac{5}{8}$ " long, $\frac{19}{64}$ " head; 0.098" diameter, $1\frac{3}{8}$ " long, annular-ringed; 6d cooler nail, 0.092" diameter, $1\frac{7}{8}$ " long, $\frac{1}{4}$ " head; or gypsum board nail, 0.0915" diameter, $1\frac{7}{8}$ " long, $\frac{19}{64}$ " head.
	Ceiling	Perpendicular	24	7	12	
	Type X at garage ceiling beneath habitable rooms	Perpendicular	24	6	6	$1\frac{7}{8}$ " long 6d coated nails or equivalent drywall screws. Screws shall comply with Section R702.3.5.1
	Wall	Either direction	24	8	12	13 gage, $1\frac{5}{8}$ " long, $\frac{19}{64}$ " head; 0.098" diameter, $1\frac{3}{8}$ " long, annular-ringed; 6d cooler nail, 0.092" diameter, $1\frac{7}{8}$ " long, $\frac{1}{4}$ " head; or gypsum board nail, 0.0915" diameter, $1\frac{7}{8}$ " long, $\frac{19}{64}$ " head.
	Wall	Either direction	16	8	16	
Application with adhesive						
$\frac{3}{8}$	Ceiling ^d	Perpendicular	16	16	16	Same as above for $\frac{3}{8}$ " gypsum board and gypsum panel products.
	Wall	Either direction	16	16	24	
$\frac{1}{2}$ or $\frac{5}{8}$	Ceiling	Either direction	16	16	16	Same as above for $\frac{1}{2}$ " and $\frac{5}{8}$ " gypsum board and gypsum panel products, respectively.
	Ceiling ^d	Perpendicular	24	12	16	
	Wall	Either direction	24	16	24	
Two $\frac{3}{8}$ layers	Ceiling	Perpendicular	16	16	16	Base ply nailed as above for $\frac{1}{2}$ " gypsum board and gypsum panel products; face ply installed with adhesive.
	Wall	Either direction	24	24	24	

For SI: 1 inch = 25.4 mm.

- For application without adhesive, a pair of nails spaced not less than 2 inches apart or more than $2\frac{1}{2}$ inches apart shall be permitted to be used with the pair of nails spaced 12 inches on center.
- Screws shall be in accordance with Section R702.3.6. Screws for attaching gypsum board or gypsum panel products to structural insulated panels shall penetrate the wood structural panel facing not less than $\frac{7}{16}$ inch.
- Where cold-formed steel framing is used with a clinching design to receive nails by two edges of metal, the nails shall be not less than $\frac{5}{8}$ inch longer than the gypsum board or gypsum panel product thickness and shall have ringed shanks. Where the cold-formed steel framing has a nailing groove formed to receive the nails, the nails shall have barbed shanks or be 5d, 13 $\frac{1}{2}$ gage, $1\frac{5}{8}$ inches long, $\frac{15}{64}$ -inch head for $\frac{1}{2}$ -inch gypsum board or gypsum panel product; and 6d, 13 gage, $1\frac{7}{8}$ inches long, $\frac{15}{64}$ -inch head for $\frac{5}{8}$ -inch gypsum board or gypsum panel product.
- Three-eighths-inch-thick single-ply gypsum board or gypsum panel product shall not be used on a ceiling where a water-based textured finish is to be applied, or where it will be required to support insulation above a ceiling. On ceiling applications to receive a water-based texture material, either hand or spray applied, the gypsum board or gypsum panel product shall be applied perpendicular to framing. Where applying a water-based texture material, the minimum gypsum board thickness shall be increased from $\frac{3}{8}$ inch to $\frac{1}{2}$ inch for 16-inch on center framing, and from $\frac{1}{2}$ inch to $\frac{5}{8}$ inch for 24-inch on center framing or $\frac{1}{2}$ -inch sag-resistant gypsum ceiling board shall be used.

WALL COVERING

For SI: 1 inch = 25.4 mm.

R702.3.6 Horizontal gypsum board diaphragm ceilings.

Gypsum board and gypsum panel products shall be permitted on wood joists to create a horizontal *diaphragm* in accordance with Table R702.3.6. Gypsum board and gypsum panel products shall be installed perpendicular to ceiling framing members. End joints of adjacent courses of board and panels shall not occur on the same joist. The maximum allowable *diaphragm* proportions shall be 1 $\frac{1}{2}$:1 between shear resisting elements. Rotation or cantilever conditions shall not be permitted. Gypsum board or gypsum panel products shall not be used in *diaphragm* ceilings to resist lateral forces imposed by masonry or concrete construction. Perimeter edges shall be blocked using wood members not less than 2-inch by 6-inch (51 mm by 152 mm) nominal dimension. Blocking material shall be installed flat over the top plate of the wall to provide a nailing surface not less than 2 inches (51 mm) in width for the attachment of the gypsum board or gypsum panel product.

❖ Generally a gypsum board or gypsum panel product ceiling does not serve as a load-carrying structural element for other than its own weight. This section provides installation requirements [refer to Commentary Figure R702.3.7(1)] that allow gypsum board and gypsum panel products to be used as membranes in horizontal diaphragm ceilings. When installed according to this section, it provides an economical and aesthetically pleasing finished surface that can also resist horizontal shear and wind forces.

Table R702.3.6 provides the shear capacity, maximum fastener spacing and minimum edge distance that is to be used in designing a horizontal gypsum board or gypsum panel product ceiling diaphragm. Because the material thickness and fastener size do not vary, the capacity is strictly a function of the framing member spacing. Further qualifications on the tabulated shear capacities that are stated in the footnotes include: ceiling diaphragm capacities are not cumulative with other diaphragm capacities; the capacities given are only for “short-term” loads due to wind and earthquakes; in structures classified as Seismic Design Category D₀, D₁, D₂, or E the capacities must be reduced by 50 percent.

Limiting diaphragm proportions and prohibiting cantilevers and rotation control the deflection and distor-

tion of the ceiling diaphragm [see Commentary Figure R702.3.6(1)].

The use of a gypsum board or gypsum panel product ceiling diaphragm to resist lateral loads from masonry or concrete is prohibited.

All perimeter edges must be blocked [see Commentary Figure R702.3.6(2)].

R702.3.7 Water-resistant gypsum backing board. Gypsum board used as the base or backer for adhesive application of ceramic tile or other required nonabsorbent finish material shall conform to ASTM C1396, C1178 or C1278. Use of water-resistant gypsum backing board shall be permitted on ceilings. Water-resistant gypsum board shall not be installed over a Class I or II vapor retarder in a shower or tub compartment. Cut or exposed edges, including those at wall intersections, shall be sealed as recommended by the manufacturer.

❖ Water-resistant gypsum backing board must be used as a base for ceramic tile or other required nonabsorbent finish materials where attached with an adhesive. It must be used in conjunction with the tile or wall panels because of its moisture-resistant qualities.

Gypsum board installed on the walls and ceilings at shower and bathtub areas must be finished to prevent moisture from penetrating the wall or ceiling finish and contacting the gypsum board. The finish applied to the exposed face of the gypsum board must create a water-resistant barrier that not only stops water from getting to the gypsum board but also prevents the release of moisture from within the wall or the gypsum board itself. For this reason, gypsum board must not be installed over the outboard side of any vapor barrier or retarder. This will create a waterproof membrane on both faces of the gypsum board, causing moisture to be trapped in the gypsum board that will ultimately cause it to decompose and fail.

R702.3.7.1 Limitations. Water-resistant gypsum backing board shall not be used where there will be direct exposure to water, or in areas subject to continuous high humidity.

❖ Although many gypsum board sheet products are manufactured and approved for use in wet areas or areas exposed to moisture or humidity, there are still some extreme conditions where even water-resistant

TABLE R702.3.6
SHEAR CAPACITY FOR HORIZONTAL WOOD-FRAMED GYPSUM BOARD DIAPHRAGM CEILING ASSEMBLIES

MATERIAL	THICKNESS OF MATERIAL (min.) (inch)	SPACING OF FRAMING MEMBERS (max.) (inch)	SHEAR VALUE ^{a, b} (plf of ceiling)	MINIMUM FASTENER SIZE ^{c, d}
Gypsum board or gypsum panel product	$\frac{1}{2}$	16 o.c.	90	5d cooler or wallboard nail; $1\frac{5}{8}$ -inch long; 0.086-inch shank; $1\frac{5}{64}$ -inch head
Gypsum board or gypsum panel product	$\frac{1}{2}$	24 o.c.	70	5d cooler or wallboard nail; $1\frac{5}{8}$ -inch long; 0.086-inch shank; $1\frac{5}{64}$ -inch head

For SI: 1 inch = 25.4 mm, 1 pound per linear foot = 1.488 kg/m.

a. Values are not cumulative with other horizontal diaphragm values and are for short-term loading caused by wind or seismic loading. Values shall be reduced 25 percent for normal loading.

b. Values shall be reduced 50 percent in Seismic Design Categories D₀, D₁, D₂ and E.

c. $1\frac{1}{2}$ -inch, No. 6 Type S or W screws shall be permitted to be substituted for the listed nails.

d. Fasteners shall be spaced not more than 7 inches on center at all supports, including perimeter blocking, and not less than $\frac{3}{8}$ inch from the edges and ends of the gypsum board.

WALL COVERING

gypsum board will not provide the level of moisture protection necessary.

Water-resistant gypsum board is not to be used in areas that will be subject to a continuous exposure to moisture or humidity at locations such as saunas, steam rooms, gang showers or indoor pools. Gypsum board products, including the water-resistant type, are not intended for these extreme conditions and will not perform satisfactorily. Nongypsum wall and ceiling materials such as concrete masonry, ceramic tile on cement backer board, cement plaster (stucco) or other materials designed and recommended for high-moisture exposure must be used in these locations.

R702.4 Ceramic tile.

❖ Based on the code's requirement for nonabsorbent surfaces in bathtub and shower areas, ceramic tile is one of several materials used in such areas subject to water splash. Ceramic tile is regulated wherever installed, particularly when gypsum board is used as a base or backer board. This section regulates the installation of ceramic tile in residential construction.

R702.4.1 General. Ceramic tile surfaces shall be installed in accordance with ANSI A108.1, A108.4, A108.5, A108.6, A108.11, A118.1, A118.3, A136.1 and A137.1.

❖ This section references a number of ANSI standards that apply to the installation of ceramic tile. Commentary Figure R702.4.1 illustrates two possible methods of ceramic tile application.

R702.4.2 Backer boards. Materials used as backers for wall tile in tub and shower areas and wall panels in shower areas shall be of materials listed in Table R702.4.2, and installed in accordance with the manufacturer's recommendations.

❖ Tile can be installed in a wet area with one of the backing materials as listed in Table 702.4.2 and as illustrated in Commentary Figure R702.4.2. Paper-faced gypsum board (i.e. green board) must not be used in

WALL COVERING

areas that are in direct contact with water. When this material gets wet through cracks in the grout joints, deteriorated caulking between the tile and tub assembly or improper flashing between the tub and tile interface, the water is absorbed into the material and can

cause the paper facing to delaminate. The delamination can cause damage to the tile surface. In addition, water trapped in paper-faced gypsum board can create mold problems.

Figure R702.4.1
INTERIOR WALL TILE INSTALLATION

Figure R702.4.2
EXAMPLE OF WALL TILE INSTALLATION TUB AND SHOWER AREA

**TABLE R702.4.2
BACKER BOARD MATERIALS**

MATERIAL	STANDARD
Glass mat gypsum backing panel	ASTM C1178
Fiber-reinforced gypsum panels	ASTM C1278
Nonasbestos fiber-cement backer board	ASTM C1288 or ISO 8336, Category C
Nonasbestos fiber mat reinforced cementitious backer units	ASTM C1325

R702.5 Other finishes. Wood veneer paneling and hardboard paneling shall be placed on wood or cold-formed steel framing spaced not more than 16 inches (406 mm) on center. Wood veneer and hard board paneling less than $\frac{1}{4}$ -inch (6 mm) nominal thickness shall not have less than a $\frac{3}{8}$ -inch (10 mm) gypsum board or gypsum panel product backer. Wood veneer paneling not less than $\frac{1}{4}$ -inch (6 mm) nominal thickness shall conform to ANSI/HPVA HP-1. Hardboard paneling shall conform to CPA/ANSI A135.5.

❖ This section contains requirements for wood veneer and hardboard paneling that are not addressed in previous sections. Modular home construction will generally use hardboard paneling applied directly to the studs. For this reason, there are specific provisions for wood veneer and hardboard siding. Wall finishes with adequate thickness will resist excessive bending and possible failure.

R702.6 Wood shakes and shingles. Wood shakes and shingles shall conform to CSSB *Grading Rules for Wood Shakes and Shingles* and shall be permitted to be installed directly to the studs with maximum 24 inches (610 mm) on-center spacing.

❖ Complying wood shakes and shingles may be attached directly to the studs in an interior application provided the studs are spaced at no more than 24 inches (610 mm) on center. The shakes and shingles must conform to the appropriate grading rules set forth by the Cedar Shake and Shingle Bureau.

R702.6.1 Attachment. Nails, staples or glue are permitted for attaching shakes or shingles to the wall, and attachment of the shakes or shingles directly to the surface shall be permitted provided the fasteners are appropriate for the type of wall surface material. Where nails or staples are used, two fasteners shall be provided and shall be placed so that they are covered by the course above.

❖ Because there is no concern for weather protection, the shakes or shingles may be attached directly to the surface with nails, staples or glue. At least two fasteners are required per shake or shingle where nails or staples are used, located so that the course above will cover the fasteners.

R702.6.2 Furring strips. Where furring strips are used, they shall be 1 inch by 2 inches or 1 inch by 3 inches (25 mm by 51 mm or 25 mm by 76 mm), spaced a distance on center

equal to the desired exposure, and shall be attached to the wall by nailing through other wall material into the studs.

❖ In addition to direct attachment of wood shakes and shingles to studs or a wall surface, the use of furring strips is permitted under specific conditions. Furring strips should be either 1 inch by 2 inches (25 mm by 51 mm) or 1 inch by 3 inches (25 mm by 76 mm). The spacing of the strips is determined by the desired exposure of the shake or shingle, attached by nailing through other wall surface materials into the studs.

R702.7 Vapor retarders. Class I or II vapor retarders are required on the interior side of frame walls in Climate Zones 5, 6, 7, 8 and Marine 4.

Exceptions:

1. Basement walls.
2. Below-grade portion of any wall.
3. Construction where moisture or its freezing will not damage the materials.

❖ The purpose of this section is to provide prescriptive methods for moisture control. The code contains three different vapor retarder classes, based upon the vapor permeability of the material. These are defined in Chapter 2 of the code. The basic requirement is for Class I or II vapor retarders to be installed on the interior side of framed walls in Climate Zones 5, 6, 7 and 8 and Marine 4. These climate zones are defined in Chapter 11 of the code. Figure N1101.7 and Table N1101.7 of Chapter 11 provide information regarding the climate zones for all geographic locations in the United States.

In cold climates, warm, moist air inside the building can migrate through the building envelope and condense on building surfaces or within building component cavities as the migrating air is cooled. Vapor retarders can help protect insulation and building materials from moisture damage, degradation and decay by preventing water vapor from entering the external building envelope component cavities.

As can be seen by studying Figure N1101.7, Climate Zones 5, 6, 7 and 8 and Marine 4 are in the middle to northern portions of the continental United States and Alaska. These are areas where colder winter temperatures cause moisture from the interior of the building to form condensate in the exterior walls of the building. A Class I or II vapor retarder is therefore called for on the interior side of the exterior wall. See the example as shown in Commentary Figure R702.7. A portion of the southern United States (along the Gulf of Mexico and the lower Atlantic coast) is a humid climate. In these locations, identified as Climate Zones 1 through 4 in Table N1101.7, no vapor retarder is required, as the exterior weather/water-resistant barrier provides the necessary protection.

R702.7.1 Class III vapor retarders. Class III vapor retarders shall be permitted where any one of the conditions in Table R702.7.1 is met.

❖ Wall assemblies can be designed and constructed to dry inward, outward and to both sides in all climate zones. This section allows more flexibility in the design and construction of moisture-forgiving wall systems. These requirements recognize that many common materials function to various degrees to slow the passage of moisture. In many situations, common materials such as the kraft facing on a fiberglass batt or latex paint may serve to retard moisture sufficiently. In particular, the “standard” sheet of polyethylene is usually not required as a vapor retarder in walls. This section therefore allows the use of Class III vapor retarders in lieu of the Class I or II otherwise specified in Section R702.7. Classes of vapor retarders are defined in Chapter 2.

The Class III vapor retarders allow more moisture vapor to pass through them. These are allowed to be used with exterior wall assemblies described in Table R702.7.1 because those assemblies can be expected to dry. Section R702.7.2 describes materials that are deemed to be Class III vapor retarders, and Section R702.7.3 describes the attributes of cladding that make it “vented” as called out in Table R702.7.1.

TABLE R702.7.1
CLASS III VAPOR RETARDERS

CLIMATE ZONE	CLASS III VAPOR RETARDERS PERMITTED FOR: ^a
Marine 4	Vented cladding over wood structural panels. Vented cladding over fiberboard. Vented cladding over gypsum. Continuous insulation with R -value ≥ 2.5 over 2×4 wall. Continuous insulation with R -value ≥ 3.75 over 2×6 wall.
5	Vented cladding over wood structural panels. Vented cladding over fiberboard. Vented cladding over gypsum. Continuous insulation with R -value ≥ 5 over 2×4 wall. Continuous insulation with R -value ≥ 7.5 over 2×6 wall.
6	Vented cladding over fiberboard. Vented cladding over gypsum. Continuous insulation with R -value ≥ 7.5 over 2×4 wall. Continuous insulation with R -value ≥ 11.25 over 2×6 wall.
7 and 8	Continuous insulation with R -value ≥ 10 over 2×4 wall. Continuous insulation with R -value ≥ 15 over 2×6 wall.

For SI: 1 pound per cubic foot = 16 kg/m³.

a. Spray foam with a maximum permeance of 1.5 perms at the installed thickness, applied to the interior cavity side of wood structural panels, fiberboard, insulating sheathing or gypsum is deemed to meet the continuous insulation requirement where the spray foam R -value meets or exceeds the specified continuous insulation R -value.

❖ This table describes the situations where it is permissible to use Class III vapor retarders instead of Class I or II. Class III vapor retarders allow more moisture vapor to pass through them. These are allowed to be used with exterior wall assemblies described in Table R702.7.1 because those assemblies can be expected to dry. The table provides types of wall assemblies that can be used with Class III vapor retarders in different climate zones. The climate zones are determined from Chapter 11 of the code.

R702.7.2 Material vapor retarder class. The vapor retarder class shall be based on the manufacturer’s certified testing or a tested assembly.

The following shall be deemed to meet the class specified:

Class I: Sheet polyethylene, unperforated aluminum foil.

Class II: Kraft-faced fiberglass batts.

Class III: Latex or enamel paint.

❖ The vapor retarder class is defined in Section 202 of the code in terms of vapor permeability. The test method called out for determination of the perm value is ASTM E96. However, this section provides a list of materials that can be used for each class of vapor retarder and are deemed to comply with the test standard. No testing is required for these materials. All other materials are required to be tested.

WALL COVERING

R702.7.3 Minimum clear airspaces and vented openings for vented cladding. For the purposes of this section, vented cladding shall include the following minimum clear airspaces. Other openings with the equivalent vent area shall be permitted.

1. Vinyl lap or horizontal aluminum siding applied over a weather-resistive barrier as specified in Table R703.3(1).
 2. Brick veneer with a clear airspace as specified in Table R703.8.4.
 3. Other approved vented claddings.
- ❖ The purpose of this section is to define what is intended by “vented cladding” as called out in Table R702.7.1. As can be seen, vented cladding is material commonly used in the code, including vinyl siding, aluminum siding, and brick with a clear airspace. By “other approved vented claddings,” the code intends materials that can be shown to allow drying of the components behind them in the same manner and at the same rate that the specific items in No. 1 or 2 would allow drying.

SECTION R703 EXTERIOR COVERING

R703.1 General. Exterior walls shall provide the building with a weather-resistant exterior wall envelope. The exterior wall envelope shall include flashing as described in Section R703.4.

Exception: Log walls designed and constructed in accordance with the provisions of ICC 400.

- ❖ Exterior walls of buildings must be protected against damage caused by precipitation, wind and other weather conditions. This section requires that flashing be installed in the exterior wall at penetrations and terminations of the exterior wall covering. Section R703.4 is referenced for flashing requirements (see commentary, Section R703.4).

R703.1.1 Water resistance. The exterior wall envelope shall be designed and constructed in a manner that prevents the accumulation of water within the wall assembly by providing a water-resistant barrier behind the exterior veneer as required by Section R703.2 and a means of draining to the exterior water that enters the assembly. Protection against condensation in the exterior wall assembly shall be provided in accordance with Section R702.7 of this code.

Exceptions:

1. A weather-resistant exterior wall envelope shall not be required over concrete or masonry walls designed in accordance with Chapter 6 and flashed in accordance with Section R703.4 or R703.8.
2. Compliance with the requirements for a means of drainage, and the requirements of Sections R703.2 and R703.4, shall not be required for an exterior wall envelope that has been demonstrated to resist wind-driven rain through testing of the exterior wall

envelope, including joints, penetrations and intersections with dissimilar materials, in accordance with ASTM E331 under the following conditions:

- 2.1. Exterior wall envelope test assemblies shall include at least one opening, one control joint, one wall/eave interface and one wall sill. All tested openings and penetrations shall be representative of the intended end-use configuration.
- 2.2. Exterior wall envelope test assemblies shall be at least 4 feet by 8 feet (1219 mm by 2438 mm) in size.
- 2.3. Exterior wall assemblies shall be tested at a minimum differential pressure of 6.24 pounds per square foot (299 Pa).
- 2.4. Exterior wall envelope assemblies shall be subjected to the minimum test exposure for a minimum of 2 hours.

The exterior wall envelope design shall be considered to resist wind-driven rain where the results of testing indicate that water did not penetrate control joints in the exterior wall envelope, joints at the perimeter of openings penetration or intersections of terminations with dissimilar materials.

- ❖ As part of providing a weather-resistant exterior envelope, exterior walls are required to provide water resistance. This section prescribes two basic components of providing water resistance for an exterior wall assembly: a water-resistive barrier installed between the covering and substrate of the exterior wall, and a means of draining moisture that may penetrate behind the exterior wall assembly back to the exterior. Section R703.2 is referenced for the requirements of the water-resistive barrier (see commentary, Section R703.2). This section does not, however, contain a prescriptive requirement for the means of drainage. The method to provide the means of drainage is a performance criterion and must be evaluated based on the ability to allow moisture that may penetrate behind the exterior wall covering to effectively drain back to the exterior. This can be achieved in many ways, including, but not limited to, providing a rain-screen pressure-equalized type of exterior assembly, or providing discontinuities or gaps between the surface of the substrate and the back side of the finish, such as through the use of noncorrodible furring or two layers of Grade D paper.

For common types of construction, such as vinyl siding or brick veneer, the typical practice of installing building paper, flashing and weeps will comply with the intent of this section. For stucco or adhered masonry veneer, installing two layers of Grade D paper and flashing will comply with the intent of this section. Discontinuities between the exterior wall covering and substrate must be such that they encourage the flow of moisture via gravity or capillary action to a location where the water may exit, such as at

flashings and weeps. The absence of a means of drainage may result in the accumulation of moisture that becomes trapped between the wall covering and the substrate. Over time, extended exposure to moisture may contribute to the degradation of the wall covering, building substrate or even the structural elements of the exterior wall.

Exception 1 states that where the exterior wall envelope is designed and constructed of concrete or masonry materials in accordance with the requirements of Chapter 6 and flashed in accordance with Section R703.4 or R703.8, the water-resistive barrier and a means of drainage may be omitted. This is because the penetration of moisture behind the exterior wall covering is not detrimental to concrete and masonry substrates.

Exception 2 permits the use of exterior wall coverings that do not have a means of draining water or meet the prescriptive requirements of Sections R703.2 and R703.4 provided that the exterior wall envelope, with penetration details, demonstrates wind-driven rain resistance when tested. The test specimen(s) must incorporate the penetration and termination details intended for use. Only details that have not allowed water to penetrate will be permitted to be used in the exterior wall envelope. The minimum panel size specified represents that which is commonly used in testing to ASTM E331; however, this does not preclude the testing of larger panels if desired. The modifications to the test pressure differential and test duration are intended to represent more closely conditions that will be encountered in service. The pass/fail criterion is based on the visual observation of moisture on the interior side of the wall assembly. For frame-type wall assemblies, such as stud walls, this requires the observation of locations such as the interior face of the exterior wall sheathing and wall framing members for the presence of moisture during the test. The test method is intended to assess the performance of the method(s) and material(s) used to seal the interface between the termination of the exterior wall covering and the penetrating item(s) or abutting construction. The test is not necessarily intended to test the performance of the penetrating item.

Walls designed and constructed in accordance with this chapter must also comply with the requirements of Section R702.7 of the code. This requires that frame-type wall assemblies be protected from moisture infiltration from the building interior through the use of a vapor retarder (see Commentary Figure R702.7) or by the ventilation of the wall cavity within a frame-type wall assembly.

R703.1.2 Wind resistance. Wall coverings, backing materials and their attachments shall be capable of resisting wind loads in accordance with Tables R301.2(2) and R301.2(3). Wind-pressure resistance of the siding and backing materials shall be determined by ASTM E330 or other applicable standard test methods. Where wind-pressure resistance is determined by design analysis, data from approved design

standards and analysis conforming to generally accepted engineering practice shall be used to evaluate the siding and backing material and its fastening. All applicable failure modes including bending rupture of siding, fastener withdrawal and fastener head pull-through shall be considered in the testing or design analysis. Where the wall covering and the backing material resist wind load as an assembly, use of the design capacity of the assembly shall be permitted.

❖ All components in an exterior wall assembly must be able to resist wind loads. This includes the exterior wall covering as well as the substrate backing portion of the wall assembly. This section references component and cladding wind loads and height and exposure adjustment factors for those loads given in Tables R301.2(2) and R301.2(3), respectively. The resistance of the exterior wall assembly can be determined by testing or design analysis. Testing should conform with ASTM E330 or other applicable standard test methods. Design analysis should be conducted in accordance with design standards and generally accepted engineering principles. Testing or design analysis should consider all failure modes including flexural failure of wall covering, fastener withdrawal and head pull-through. When the entire exterior wall assembly, consisting of the wall covering and the substrate, contributes to its ability to resist wind loads, the structural design capacity of the assembly is permitted to be taken into account.

R703.2 Water-resistive barrier. One layer of No. 15 asphalt felt, free from holes and breaks, complying with ASTM D226 for Type 1 felt or other approved water-resistive barrier shall be applied over studs or sheathing of all exterior walls. Such felt or material shall be applied horizontally, with the upper layer lapped over the lower layer not less than 2 inches (51 mm). Where joints occur, felt shall be lapped not less than 6 inches (152 mm). The felt or other approved material shall be continuous to the top of walls and terminated at penetrations and building appendages in a manner to meet the requirements of the exterior wall envelope as described in Section R703.1. The water-resistive barrier is not required for detached accessory buildings.

❖ Asphalt-saturated felt or any other approved water-resistive material is required behind all types of materials used as exterior wall coverings because of the possibility of moisture penetrating the substrate behind it. This felt or other material protects the wall construction from potential rotting.

The water-resistive membrane may be omitted for detached accessory buildings.

R703.3 Nominal thickness and attachments. The nominal thickness and attachment of exterior wall coverings shall be in accordance with Table R703.3(1), the wall covering material requirements of this section, and the wall covering manufacturer's installation instructions. Cladding attachment over foam sheathing shall comply with the additional requirements and limitations of Sections R703.15 through R703.17. Nominal material thicknesses in Table R703.3(1) are based on a maximum stud spacing of 16 inches (406 mm) on center. Where specified by the siding manufacturer's instructions and

supported by a test report or other documentation, attachment to studs with greater spacing is permitted. Fasteners for exterior wall coverings attached to wood framing shall be in accordance with Section R703.3.2 and Table R703.3(1). Exterior wall coverings shall be attached to cold-formed steel light frame construction in accordance with the cladding manufacturer's installation instructions, the requirements of Table R703.3(1) using screw fasteners substituted for the nails specified in accordance with Table R703.3(2), or an approved design.

❖ New Section R703.3 replaces the 2012 *International Residential Code*® (IRC®) Table R703.4 with Table R703.3(1). Table R703.3(1) is simplified and former notes and column text are moved to Sections R703.3, R703.3.1, R703.3.2 and R703.3.3.

Section R703.3 covers nominal thickness and attachment of siding. Nominal thickness is based on 16-inch on-center stud spacing. Table R703.3(1) is referenced for nail specifications that have been reformatted to match Table R602.3(1). Minimum fastener size and penetration requirements, along with other installation details, are in Table R703.3(1) and mirror current Western Wood Products Association (WWPA) and Western Red Cedar Lumber Association (WRCLA) installation guides. Screws must be used for attachment to cold-formed steel framing. Where screw fasteners are used, the requirements of Table R703.3(1) are modified by the screw fastener substitution Table R703.3(2). The *water-resistive barrier required* column is deleted in Table R703.3(1). All products in Table R703.3(1) require a water-resistive barrier except for detached accessory buildings as prescribed in Section R703.2.

Section R703.3.1 prescribes the wind limitations for wall covering attachment in accordance with Table R703.3(1). Table R703.3.1 simplifies the determination of whether prescriptive fastening provisions of Table R703.3(1) apply to a specific building. Fasteners are limited to a maximum design pressure of 30 psf. The limits in Table R703.3.1 indicate where component and cladding pressures exceed 30 psf as a function of wind speed exposure and mean roof height. In most cases, especially in areas with lower wind speeds, the prescriptive fastening requirements in Table R703.3(1) will be applicable. According to Table R301.2(2), for Zone 5 and an effective wind area of 10 square feet, the maximum negative pressure for an ultimate design wind speed of 140 mph is 28.0 psf (this is approximately equal to the old 110 mph basic wind speed). This value—less than 30 psf—correlates directly with the 140-mph limitation in Table R703.3.1. However, the tabulated pressures in Table R301.2(2) are for an assumed Exposure B site condition and a mean roof height of 30 feet. For residential buildings with a ultimate design wind speed of

140 mph and Exposure C or D, or a mean roof height greater than 30 feet, the maximum negative pressure is substantially higher than 30 psf. While mean roof heights of 50 feet and 60 feet are listed in the table as upper limits for the wind pressures, the IRC limit of three stories (Section R102.1) also applies.

Where the prescribed wind limitations are exceeded, the wall covering attachment must be designed to resist the component and cladding loads of Table R301.2(2). The design wind pressures must be determined using an effective wind area of 10 square feet. For wall cladding, the effective wind area will be governed by the effective wind area of an individual fastener, which is less than 10 square feet.

Notes b, c, d, g and r from the 2012 IRC Table R703.4 have been combined to form the text of Section R703.3.2. Due to the exterior wall covering fasteners being exposed to moisture in the atmosphere, Section R703.3.2 requires the exterior wall covering to be fastened with approved corrosion-resistant fasteners such as aluminum, galvanized, stainless steel, or rust-preventative coated. This section requires all nails and staples to comply with ASTM F1667. Where sheathing is used as backing for exterior wall covering, the wall covering fasteners must be driven into the studs. However, where wood or wood structural panel is used as the backing, the exterior wall covering fasteners are permitted to be driven into the backing in accordance with Table R703.3.2.

Section R703.3.3 prescribes the minimum length and penetration of fasteners for attaching the exterior wall covering. The penetration requirements of Notes m, o, v, y and z from 2012 IRC Table R703.4 have been moved to the items in this section.

TABLE R703.3(2)
SCREW FASTENER SUBSTITUTION FOR SIDING
ATTACHMENT TO COLD-FORMED STEEL LIGHT FRAME
CONSTRUCTION^{a, b, c, d, e}

NAIL DIAMETER PER TABLE R703.3(1)	MINIMUM SCREW FASTENER SIZE
0.099"	No. 6
0.113"	No. 7
0.120"	No. 8

For SI: 1 inch = 25.4 mm

- a. Screws shall comply with ASTM C1513 and shall penetrate a minimum of three threads through minimum 33 mil (20 gage) cold-formed steel frame construction.
- b. Screw head diameter shall be not less than the nail head diameter required by Table R703.3(1).
- c. Number and spacing of screw fasteners shall comply with Table R703.3(1).
- d. Pan head, hex washer head, modified truss head or other screw head types with a flat attachment surface under the head shall be used for vinyl siding attachment.

TABLE R703.3(1)
SIDING MINIMUM ATTACHMENT AND MINIMUM THICKNESS

SIDING MATERIAL	NOMINAL THICKNESS (inches)	JOINT TREATMENT	TYPE OF SUPPORTS FOR THE SIDING MATERIAL AND FASTENERS						Number or spacing of fasteners

For SI: 1 inch = 25.4 mm.

- a. Aluminum nails shall be used to attach aluminum siding.
- b. Aluminum (0.019 inch) shall be unbacked only where the maximum panel width is 10 inches and the maximum flat area is 8 inches. The tolerance for aluminum siding shall be +0.002 inch of the nominal dimension.
- c. Shall be of approved type.
- d. Where used to resist shear forces, the spacing must be 4 inches at panel edges and 8 inches on interior supports.
- e. Vertical end joints shall occur at studs and shall be covered with a joint cover or shall be caulked.
- f. Face nailing: one 6d common nail through the overlapping planks at each stud. Concealed nailing: one 11-gage 1¹/₂-inch-long galv. roofing nail through the top edge of each plank at each stud in accordance with the manufacturer's installation instructions.
- g. Vertical joints, if staggered, shall be permitted to be away from studs if applied over wood structural panel sheathing.
- h. Minimum fastener length must be sufficient to penetrate sheathing other nailable substrate and framing a total of a minimum of 1¹/₄ inches or in accordance with the manufacturer's installation instructions.
- i. Where specified by the manufacturer's instructions and supported by a test report, fasteners are permitted to penetrate into or fully through nailable sheathing or other nailable substrate of minimum thickness specified by the instructions or test report, without penetrating into framing.
- j. Insulated vinyl siding shall comply with ASTM D7793.
- k. Polypropylene siding shall comply with ASTM D7254.
- l. Cladding attachment over foam sheathing shall comply with the additional requirements and limitations of Sections R703.15, R703.16 and R703.17.

R703.3.1 Wind limitations. Where the design wind pressure exceeds 30 psf or where the limits of Table R703.3.1 are exceeded, the attachment of wall coverings shall be designed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3). For the determination of wall covering attachment, component and cladding loads shall be determined using an effective wind area of 10 square feet (0.93 m²).

❖ See the commentary to Section R703.3.

**TABLE R703.3.1
LIMITS FOR ATTACHMENT PER TABLE R703.3(1)**

MAXIMUM MEAN ROOF HEIGHT			
Ultimate Wind Speed (mph 3-second gust)	Exposure		
	B	C	D
115	NL	50'	20'
120	NL	30'	DR
130	60'	15'	DR
140	35'	DR	DR

For SI: 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s.
NL = Not limited by Table R703.3.1, DR = Design required.

R703.3.2 Fasteners. Exterior wall coverings shall be securely fastened with aluminum, galvanized, stainless steel or rust-preventative coated nails or staples in accordance with Table R703.3(1) or with other approved corrosion-resistant fasteners in accordance with the wall covering manufacturer's installation instructions. Nails and staples shall comply with ASTM F1667. Nails shall be T-head, modified round head, or round head with smooth or deformed shanks. Staples shall have a minimum crown width of $\frac{7}{16}$ inch (11.1 mm) outside diameter and be manufactured of minimum 16-gage wire. Where fiberboard, gypsum, or foam plastic sheathing backing is used, nails or staples shall be driven into the studs. Where wood or wood structural panel sheathing is used, fasteners shall be driven into studs unless otherwise permitted to be driven into sheathing in accordance with either the siding manufacturer's installation instructions or Table R703.3.2.

❖ See the commentary to Section R703.3.

R703.3.3 Minimum fastener length and penetration. Fasteners shall have the greater of the minimum length specified in Table R703.3(1) or as required to provide a minimum penetration into framing as follows:

1. Fasteners for horizontal aluminum siding, steel siding, particleboard panel siding, wood structural panel siding

in accordance with ANSI/APA-PRP 210, fiber-cement panel siding and fiber-cement lap siding installed over foam plastic sheathing shall penetrate not less than $1\frac{1}{2}$ inches (38 mm) into framing or shall be in accordance with the manufacturer's installation instructions.

2. Fasteners for hardboard panel and lap siding shall penetrate not less than $1\frac{1}{2}$ inches (38 mm) into framing.
3. Fasteners for vinyl siding and insulated vinyl siding installed over wood or wood structural panel sheathing shall penetrate not less than $1\frac{1}{4}$ inches (32 mm) into sheathing and framing combined. Vinyl siding and insulated vinyl siding shall be permitted to be installed with fasteners penetrating into or through wood or wood structural sheathing of minimum thickness as specified by the manufacturer's instructions or test report, with or without penetration into the framing. Where the fastener penetrates fully through the sheathing, the end of the fastener shall extend not less than $\frac{1}{4}$ inch (6.4 mm) beyond the opposite face of the sheathing. Fasteners for vinyl siding and insulated vinyl siding installed over foam plastic sheathing shall be in accordance with Section R703.11.2. Fasteners for vinyl siding and insulated vinyl siding installed over fiberboard or gypsum sheathing shall penetrate not less than $1\frac{1}{4}$ inches (32 mm) into framing.
4. Fasteners for vertical or horizontal wood siding shall penetrate not less than $1\frac{1}{2}$ inches (38 mm) into studs, studs and wood sheathing combined, or blocking.
5. Fasteners for siding material installed over foam plastic sheathing shall have sufficient length to accommodate foam plastic sheathing thickness and to penetrate framing or sheathing and framing combined, as specified in Items 1 through 4.

❖ See the commentary to Section R703.3.

R703.4 Flashing. Approved corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. Fluid-applied membranes used as flashing in exterior walls shall comply with AAMA 714. The flashing shall extend to the surface of the exterior wall finish. Approved corrosion-resistant flashings shall be installed at the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the sur-

**TABLE R703.3.2
OPTIONAL SIDING ATTACHMENT SCHEDULE FOR FASTENERS WHERE NO STUD PENETRATION NECESSARY**

APPLICATION	NUMBER AND TYPE OF FASTENER	SPACING OF FASTENERS ^b
Exterior wall covering (weighing 3 psf or less) attachment to wood structural panel sheathing, either direct or over foam sheathing a maximum of 2 inches thick. ^a Note: Does not apply to vertical siding.	Ring shank roofing nail (0.120" min. dia.)	12" o.c.
	Ring shank nail (0.148" min. dia.)	15" o.c.
	No. 6 screw (0.138" min. dia.)	12" o.c.
	No. 8 screw (0.164" min. dia.)	16" o.c.

For SI: 1 inch = 25.4 mm.

- a. Fastener length shall be sufficient to penetrate back side of the wood structural panel sheathing by at least $\frac{1}{4}$ inch. The wood structural panel sheathing shall be not less than $\frac{7}{16}$ inch in thickness.
- b. Spacing of fasteners is per 12 inches of siding width. For other siding widths, multiply "Spacing of Fasteners" above by a factor of 12/s, where "s" is the siding width in inches. Fastener spacing shall never be greater than the manufacturer's minimum recommendations.

WALL COVERING

face of the exterior wall finish or to the water-resistive barrier complying with Section 703.2 for subsequent drainage. Mechanically attached flexible flashings shall comply with AAMA 712. Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:

- 1.1. The fenestration manufacturer's installation and flashing instructions, or for applications not addressed in the fenestration manufacturer's instructions, in accordance with the flashing manufacturer's instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. Openings using pan flashing shall incorporate flashing or protection at the head and sides.
- 1.2. In accordance with the flashing design or method of a registered design professional.
- 1.3. In accordance with other approved methods.
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.

5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

❖ The code requires all points subject to the entry of moisture to be appropriately flashed. Roof and wall intersections and parapets create significant challenges, as do exterior wall openings exposed to the weather. Where wind-driven rain is expected, the concerns are even greater. Self-adhered flashing is required to comply with AAMA 711. Window and door manufacturers are required by Section R609.1 of the code to provide installation instructions for each window and door. Most window and door manufacturers require installation per their instructions and many window and door manufacturers are incorporating a pan flashing in their window and door installation instructions. Window and door manufacturers create installation and flashing instructions for a wide variety of wall conditions, but are unable to create installation instructions for every conceivable wall condition. Items 1.2 and 1.3 of the flashing methods allow necessary flexibility while retaining the performance requirements of Section R703.4. Although the code identifies a number of locations where flashing is specifically required, the entire exterior envelope must be weather tight to protect the interior from weather. Therefore, any location on the exterior envelope that provides a route for the admission of water or moisture into the building must be properly protected. Commentary Figure R703.4 illustrates examples of flashing.

R703.5 Wood, hardboard and wood structural panel siding. Wood, hardboard, and wood structural panel siding shall be installed in accordance with this section and Table R703.3(1). Hardboard siding shall comply with CPA/ANSI A135.6. Hardboard siding used as architectural trim shall comply with CPA/ANSI A 135.7.

- ❖ This section addresses the use of wood siding products as exterior wall coverings. Vertical, panel and horizontal siding are regulated.

R703.5.1 Vertical wood siding. Wood siding applied vertically shall be nailed to horizontal nailing strips or blocking set not more than 24 inches (610 mm) on center.

- ❖ Vertical wood siding must be attached to supports spaced not more than 24 inches on center.

R703.5.2 Panel siding. $\frac{3}{8}$ -inch (9.5 mm) wood structural panel siding shall not be applied directly to studs spaced more than 16 inches (406 mm) on center where long dimension is parallel to studs. Wood structural panel siding $\frac{7}{16}$ inch (11.1 mm) or thinner shall not be applied directly to studs spaced more than 24 inches (610 mm) on center. The stud spacing shall not exceed the panel span rating provided by the manufacturer unless the panels are installed with the face grain perpendicular to the studs or over sheathing approved for that stud spacing.

Joints in wood, hardboard or wood structural panel siding shall be made as follows unless otherwise approved. Vertical joints in panel siding shall occur over framing members, unless wood or wood structural panel sheathing is used, and shall be shiplapped or covered with a batten. Horizontal joints in panel siding shall be lapped not less than 1 inch (25 mm) or shall be shiplapped or flashed with Z-flashing and occur over solid blocking, wood or wood structural panel sheathing.

- ❖ The prescriptive requirements for stud spacing for wood structural panel siding from Note i of the 2012 IRC Table R704.3 have been moved into this section.

Plywood is acceptable as an exterior wall covering if the plywood is approved for use in an exterior location and the joints are made waterproof. Typical joint treatments include lapping joints horizontally, having the joints occur over framing and protecting those joints with a continuous wood batten using approved caulking, flashing or vertical or horizontal shiplaps [see Commentary Figures R703.5.2(1) and R703.5.2(2) for illustrations of joint treatment].

R703.5.3 Horizontal wood siding. Horizontal lap siding shall be installed in accordance with the manufacturer's recommendations. Where there are no recommendations the siding shall be lapped not less than 1 inch (25 mm), or $\frac{1}{2}$ inch (12.7 mm) if rabbeted, and shall have the ends caulked, covered with a batten or sealed and installed over a strip of flashing.

- ❖ To maintain the necessary weather protection, horizontal siding is required to be installed using the manufacturer's recommendations. Where a manufacturer does not provide installation recommendations, horizontal siding must have a minimum lap of at least 1 inch (25 mm), unless the siding is rabbeted, in which case the joint need be only $\frac{1}{2}$ inch (12.7 mm). Various methods can be used to protect the ends of horizontal siding, including the use of flashing, caulking or battens.

R703.6 Wood shakes and shingles. Wood shakes and shingles shall conform to CSSB *Grading Rules for Wood Shakes and Shingles*.

- ❖ Grading rules established by the Cedar Shake and Shingle Bureau are applicable to wood shakes and shingles used as exterior wall covering materials. The provisions of this section deal with the specific application and attachment of wood shakes and shingles to the exterior of a building.

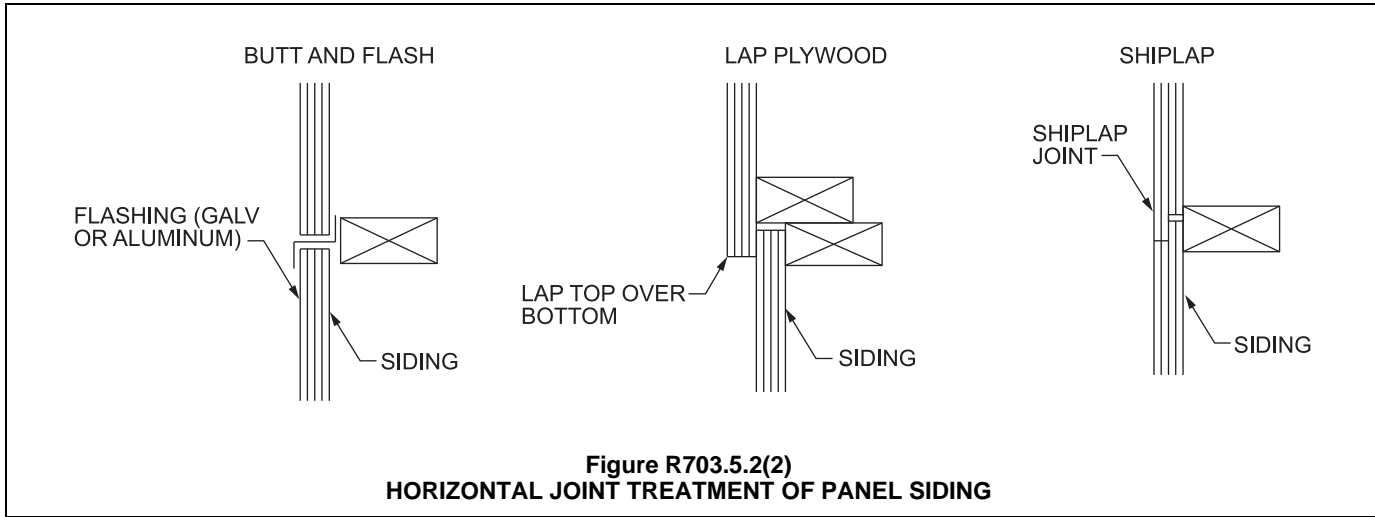

Figure R703.5.2(2)
HORIZONTAL JOINT TREATMENT OF PANEL SIDING

R703.6.1 Application. Wood shakes or shingles shall be applied either single course or double course over nominal 1/2-inch (12.7 mm) wood-based sheathing or to furring strips over 1/2-inch (12.7 mm) nominal nonwood sheathing. A water-resistive barrier shall be provided over all sheathing, with horizontal overlaps in the membrane of not less than 2 inches (51 mm) and vertical overlaps of not less than 6 inches (152 mm). Where horizontal furring strips are used, they shall be 1 inch by 3 inches or 1 inch by 4 inches (25 mm by 76 mm or 25 mm by 102 mm) and shall be fastened to the studs with minimum 7d or 8d box nails and shall be spaced a distance on center equal to the actual weather exposure of the shakes or shingles, not to exceed the maximum exposure specified in Table R703.6.1. When installing shakes or shingles over a nonpermeable water-resistive barrier, furring strips shall be placed first vertically over the barrier and in addition, horizontal furring strips shall be fastened to the vertical furring strips prior to attaching the shakes or shingles to the horizontal furring strips. The spacing between adjacent shingles to allow for expansion shall be 1/8 inch (3.2 mm) to 1/4 inch (6.4 mm) apart, and between adjacent shakes shall be 3/8 inch (9.5 mm) to 1/2 inch (12.7 mm) apart. The offset spacing between joints in adjacent courses shall be not less than 1 1/2 inches (38 mm).

❖ Where wood shakes and shingles are applied as an exterior wall covering, the sheathing must be covered with a water-resistive barrier prior to shingle or shake installation. The application of wood shakes and shingles may be over either solid sheathing or horizontal furring strips applied directly to the studs. Both vertical and horizontal furring strips must be used where applied over a nonpermeable water-resistive barrier. The minimum sheathing thickness and furring strip size and fastening are prescribed by the code. The spacing of the horizontal furring strips must not exceed the maximum weather exposure specified in Table R703.6.1. Wood shakes and shingles must not be applied with the vertical edges tight together. Tightly applied shakes and shingles do not leave room for expansion causing fish-mouthing, cupping and curling. The code prescribes minimum and maximum

spacing for shingles and shakes. To allow for expansion, a small space should be established between each shake or shingle. The spacing is limited to 1/4 inch (6.4 mm) between adjacent shingles and 1/2 inch (12.7 mm) between adjacent shakes. To avoid channels between the shakes or shingles where water penetration might occur, joints must be offset at least 1 1/2 inches (38 mm) in adjacent courses.

TABLE R703.6.1
MAXIMUM WEATHER EXPOSURE FOR WOOD SHAKES AND SHINGLES ON EXTERIOR WALLS^{a, b, c}
(Dimensions are in inches)

LENGTH	EXPOSURE FOR SINGLE COURSE	EXPOSURE FOR DOUBLE COURSE
Shingles ^a		
16	7	12 ^b
18	8	14 ^c
24	10 1/2	16 ^d
Shakes ^a		
18	8	14
24	10 1/2	18

For SI: 1 inch = 25.4 mm.

a. Dimensions given are for No. 1 grade.

b. A maximum 9-inch exposure is permitted for No. 2 grade.

c. A maximum 10-inch exposure is permitted for No. 2 grade.

d. A maximum 14-inch exposure is permitted for No. 2 grade.

R703.6.2 Weather exposure. The maximum weather exposure for shakes and shingles shall not exceed that specified in Table 703.6.1.

❖ Table R703.6.1 specifies the maximum weather exposure permitted for wood shakes and shingles installed on exterior walls. The exposure length for a single course of shingles and shakes is reduced from that specified in the 2012 code. The reduction was made because the longer exposure lengths previously allowed in the code are no longer considered practical. Exposure lengths have been decreased in accordance with manufacturer's installation requirements.

Depending on the length of the shingle and the number of courses, the table specifies the maximum length of exposure for weathering purposes. Shingles are available in three different lengths, while shakes are regulated for two lengths. Both single-course and double-course applications are addressed.

Where a single course of wood shingles is used, the maximum exposure varies from 7 inches to 10¹/₂ inches, depending on the length of the shingles. Maximum wood shake exposures are either 8 inches or 10¹/₂ inches for a single-course application. In double-course applications, the maximum exposures are increased for both shingles and shakes.

R703.6.3 Attachment. Wood shakes or shingles shall be installed according to this chapter and the manufacturer's instructions. Each shake or shingle shall be held in place by two stainless steel Type 304, Type 316 or hot-dipped zinc-coated galvanized corrosion-resistant box nails in accordance with Table R703.6.3(1) or R703.6.3(2). The hot-dipped zinc-coated galvanizing shall conform to minimum standard ASTM A153D, 1.0 ounce per square foot. Alternatively, 16-gage stainless steel Type 304 or Type 316 staples with crown widths ⁷/₁₆ inch (11 mm) minimum, ³/₄ inch (19 mm) maximum, shall be used and the crown of the staple shall be placed parallel with the butt of the shake or the shingle. In single-course application, the fasteners shall be concealed by the course above and shall be driven approximately 1 inch (25 mm) above the butt line of the succeeding course and ³/₄ inch (19 mm) from the edge. In double-course applications, the exposed shake or shingle shall be face-nailed with two fasteners, driven approximately 2 inches (51 mm) above the butt line and ³/₄ inch (19 mm) from each edge. Fasteners installed within 15 miles (24 km) of salt water coastal areas shall be stainless steel Type 316. Fasteners for fire-retardant-treated shakes or shingles in accordance with Section R902 or pressure-impregnated-preservative-treated shakes or shingles in accordance with AWWPA U1 shall be stainless steel Type 316. The fasteners shall penetrate the sheathing or fur-

ring strips by not less than ¹/₂ inch (13 mm) and shall not be overdriven. Fasteners for untreated (natural) and treated products shall comply with ASTM F1667.

❖ The general provisions of this chapter apply to the installation of wood shakes or shingles, as do the installation instructions of the manufacturer. In addition, this section sets forth specific requirements regulating the attachment methods for wood shakes or shingles. This section describes in detail the proper attachment of either staples or nails where used as fasteners for wood shakes and shingles applied to exterior walls. Both single-course and double-course application methods are described. Fasteners must be box nails in accordance with Tables R703.6.3(1) and R703.6.3(2). Fasteners must comply with ASTM F1667. Stainless steel staples are permitted in lieu of box nails. Fasteners for applying wood shakes or shingles must be stainless steel or hot-dipped galvanized. Only stainless steel fasteners are allowed for the following conditions:

1. Where wood shakes or shingles are located within 15 miles of salt water coastal areas.
2. Where wood shakes or shingles are fire-retardant treated.
3. Where wood shakes or shingles are preservative treated.

Only two nails or staples are to be used for each shake or shingle, and they must be placed in accordance with this section and the manufacturer's installation instructions. The depth of fastener penetration must be a minimum of ¹/₂ inch into the sheathing or furring strips. Care in spacing and driving the fasteners is necessary to provide maximum service from the wood shakes or shingles [see Commentary Figure R905.7.5 (2)].

TABLE R703.6.3(1)
SINGLE COURSE SIDEWALL FASTENERS

SINGLE COURSE SIDEWALL FASTENERS			
Product type	Nail type and minimum length (inches)	Minimum head diameter (inches)	Minimum shank thickness (inches)
R & R and sanded shingles	Type		
16" and 18" shingles	3d box 1 ¹ / ₄	0.19	0.08
24" shingles	4d box 1 ¹ / ₂	0.19	0.08
Grooved shingles	Type		
16" and 18" shingles	3d box 1 ¹ / ₄	0.19	0.08
24" shingles	4d box 1 ¹ / ₂	0.19	0.08
Split and sawn shakes	Type		
18" straight-split shakes	5d box 1 ³ / ₄	0.19	0.08
18" and 24" handsplit shakes	6d box 2	0.19	0.0915
24" tapersplit shakes	5d box 1 ³ / ₄	0.19	0.08
18" and 24" tapersawn shakes	6d box 2	0.19	0.0915

For SI: 1 inch = 25.4 mm.

TABLE R703.6.3(2)
DOUBLE COURSE SIDEWALL FASTENERS

DOUBLE COURSE SIDEWALL FASTENERS			
Product type	Nail type and minimum length	Minimum head diameter (inches)	Minimum shank thickness (inches)
R & R and sanded shingles			
16," 8" and 24" shingles	5d box 1 ³ / ₄ or same size casing nails	0.19	0.08
Grooved shingles			
16," 18" and 24" shingles	5d box 1 ³ / ₄	0.19	0.08
Split and sawn shakes			
18" straight-split shakes	7d box 2 ¹ / ₄ or 8d 2 ¹ / ₂	0.19	0.099
18" and 24" handsplit shakes	7d box 2 ¹ / ₄ or 8d 2 ¹ / ₂	0.19	0.099
24" tapersplit shakes	7d box 2 ¹ / ₄ or 8d 2 ¹ / ₂	0.19	0.099
18" and 24" tapersawn shakes	7d box 2 ¹ / ₄ or 8d 2 ¹ / ₂	0.19	0.099

For SI: 1 inch = 25.4 mm.

R703.6.4 Bottom courses. The bottom courses shall be doubled.

- ❖ In all cases, the bottom course of shakes and shingles in an exterior wall application is to be doubled.

R703.7 Exterior plaster. Installation of these materials shall be in compliance with ASTM C926, ASTM C1063 and the provisions of this code.

- ❖ Portland cement plaster is the only material approved by the code for exterior plaster. Gypsum plaster deteriorates under conditions of weather and moisture, which are prevalent on the exterior surfaces of buildings. Commentary Figures R703.7(1) and R703.7(2) illustrate exterior plastering systems. ASTM C926 is the standard specification for the installation of Portland-cement-based plaster. ASTM C926 provides the minimum requirements for the application of Portland cement-based plaster for exterior stucco) along with the tables necessary for proportioning various plaster mixes and thicknesses. ASTM C1063 is the standard specification for exterior lathing and furring for Portland-cement-based plastering, as specified in ASTM C926. Installation of exterior plaster must also comply with the provisions of this code.

R703.7.1 Lath. Lath and lath attachments shall be of corrosion-resistant materials. Expanded metal or woven wire lath shall be attached with 1¹/₂-inch-long (38 mm), 11 gage nails having a ⁷/₁₆-inch (11.1 mm) head, or ⁷/₈-inch-long (22.2 mm), 16 gage staples, spaced not more than 6 inches (152 mm), or as otherwise approved.

- ❖ Lath and its attachments must be of corrosion-resistant materials. Unless another fastening method is approved, lath must be attached to framing members with the nails or staples specified in this section and spaced at a maximum of 6 inches (152 mm) on center along the framing member.

R703.7.2 Plaster. Plastering with portland cement plaster shall be not less than three coats where applied over metal lath or wire lath and shall be not less than two coats where applied over masonry, concrete, pressure-preservative-treated wood or decay-resistant wood as specified in Section R317.1 or gypsum backing. If the plaster surface is completely covered by veneer or other facing material or is completely concealed, plaster application need be only two coats, provided the total thickness is as set forth in Table R702.1(1).

On wood-frame construction with an on-grade floor slab system, exterior plaster shall be applied to cover, but not extend below, lath, paper and screed.

The proportion of aggregate to cementitious materials shall be as set forth in Table R702.1(3).

- ❖ The code requires that exterior Portland cement plaster be applied in not less than three coats when applied over metal or wire-fabric lath, for the same reasons as discussed for interior plaster. Where the Portland cement plaster is applied over other approved plaster bases, the code requires only two-coat work. The code permits plaster work that is completely concealed to be of only two coats provided the total thickness is that required by Table R702.1(1), because the finish coat of plaster is to provide a surface for exterior finishes and to provide an aesthetic appearance. Thus, where the plaster surface is to be completely concealed, it is not necessary to apply a finish coat.

The code requires that the exterior plaster be installed to completely cover, but not extend below, the lath and paper-on-wood exterior wall construction supported by an on-grade concrete slab. This requirement, combined with the presence of a weep screed, prevents the entrapment of free moisture and the subsequent channeling of the moisture to the interior of the building.

For SI: 1 inch = 25.4 mm.

Figure R703.7(1)
EXTERIOR PLASTERING SYSTEM

Figure R703.7(2)
EXTERIOR PLASTER—WOOD FRAME ON CONCRETE FLOOR SLAB

R703.7.2.1 Weep screeds. A minimum 0.019-inch (0.5 mm) (No. 26 galvanized sheet gage), corrosion-resistant weep screed or plastic weep screed, with a minimum vertical attachment flange of 3½ inches (89 mm) shall be provided at or below the foundation plate line on exterior stud walls in accordance with ASTM C926. The weep screed shall be placed not less than 4 inches (102 mm) above the earth or 2 inches (51 mm) above paved areas and shall be of a type that will allow trapped water to drain to the exterior of the building. The weather-resistant barrier shall lap the attachment flange. The exterior lath shall cover and terminate on the attachment flange of the weep screed.

❖ Water and moisture can penetrate an exterior plaster wall for a variety of reasons and in a number of ways. Some moisture will penetrate the plaster in an exterior wall; therefore, the design of the wall should include a weep screed, which will provide a way to release the moisture [see Commentary Figure R703.7.2.1]. Once water or moisture penetrates the plaster, it will migrate down the exterior face of the weather-resistant barrier until it reaches the sill plate or mud sill. At this point, the water will seek a way out of the wall. If the exterior plaster system is not detailed and constructed with provisions to allow the moisture to escape to the exterior, it will find its own way out. This exit will almost certainly be through the interior of the wall and cause leaking, and therefore damage, to the interior of the building. For this reason, the code requires a continuous weep screed at the bottom of exterior walls to permit the moisture to escape to the exterior of the building.

R703.7.3 Water-resistant barriers. Water-resistant barriers shall be installed as required in Section R703.2 and, where applied over wood-based sheathing, shall include a water-

resistive vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper. The individual layers shall be installed independently such that each layer provides a separate continuous plane and any flashing (installed in accordance with Section R703.4) intended to drain to the water-resistant barrier is directed between the layers.

Exception: Where the water-resistant barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the stucco by an intervening, substantially nonwater-absorbing layer or designed drainage space.

❖ The code requires that a water-resistant barrier be installed behind exterior plaster for the reasons provided in Section R703.2. The code also requires that when the barrier is applied over wood-based sheathing such as plywood, the barrier is to be two layers of Grade D building paper.

This requirement is based on the observed problems that occur when one layer is applied over wood sheathing. The wood sheathing eventually exhibits dry rot due to the penetration of moisture. Cracking is then created in the plaster due to movement of the sheathing caused by alternate expansion and contraction. Field experience has shown that where two layers of building paper are used, the penetration of moisture is considerably decreased, as is the cracking of the plaster due to movement of the sheathing caused by the wet and dry cycles.

The code also requires each layer of the water-resistant barrier to be independently installed in a manner that provides a continuous drainage plane. The primary function of the inboard layer is to keep water away from the sheathing and also from penetrating into the stud cavity. This layer should be integrated with window and door flashings, the weep screed at the bottom of the wall as well as any through-wall flashing or expansion joints. The primary function of the outboard layer that comes in contact with the stucco is to separate the stucco from the inboard layer of the water-resistant barrier. This layer is at times referred to as a “sacrificial layer,” an “intervening layer” or a “bond break layer.”

This provision includes a reference to “Grade D paper” without defining the term or providing a reference to a standard. The reference to Grade D paper actually refers to Federal Specification UU-B-790a, *Federal Specifications for Building Paper, Vegetable Fiber—Kraft, Waterproofed, Water Repellent, and Fire Resistant*. This reference can be traced back to the *Uniform Building Code*® (UBC®) and UBC Standard 14-1, which was based on Federal Specification UU-B-790a. In Section 3.6.4 of that specification, the physical properties for Grade D paper are established. The reference to Kraft waterproof building paper is used because it has the appropriate water vapor permeability to prevent entrapment of moisture between the paper and the sheathing.

The exception permits the application of alternative standard practices by recognizing stucco systems in which one of the two layers of water-resistive barrier is replaced by a layer that although not a “Grade D paper” provides separation from the wet stucco application and provides a barrier to moisture from the stucco to the water-resistive barrier.

R703.7.4 Application. Each coat shall be kept in a moist condition for at least 48 hours prior to application of the next coat.

Exception: Applications installed in accordance with ASTM C926.

❖ Plaster should be kept moist prior to the application of the next coat. This is usually accomplished by fogging the surface with water at the start and again at the end of the workday. If it is excessively hot, dry and windy, more frequent moistening and covering with polyethylene plastic may be required to keep the plaster in a moist condition.

R703.7.5 Curing. The finish coat for two-coat cement plaster shall not be applied sooner than seven days after application of the first coat. For three-coat cement plaster, the second coat shall not be applied sooner than 48 hours after application of the first coat. The finish coat for three-coat cement plaster shall not be applied sooner than seven days after application of the second coat.

❖ Plaster must be allowed to cure sufficiently between coats. This promotes more intimate contact between the coats and allows a more complete curing of the coats already applied beneath. The finish plaster coat should only be applied after allowing the previous coat to cure seven days.

R703.8 Anchored stone and masonry veneer, general. Anchored stone and masonry veneer shall be installed in accordance with this chapter, Table R703.3(1) and Figure R703.8. These veneers installed over a backing of wood or cold-formed steel shall be limited to the first story above grade plane and shall not exceed 5 inches (127 mm) in thick-

For SI: 1 inch = 25.4 mm.

FIGURE R703.8
TYPICAL MASONRY VENEER WALL DETAILS

(continued)

WALL COVERING

ness. See Section R602.10 for wall bracing requirements for masonry veneer for wood-framed construction and Section R603.9.5 for wall bracing requirements for masonry veneer for cold-formed steel construction.

Exceptions:

1. For buildings in Seismic Design Categories A, B and C, exterior stone or masonry veneer, as specified in Table R703.8(1), with a backing of wood or steel framing shall be permitted to the height specified in Table R703.8(1) above a noncombustible foundation.
2. For detached one- or two-family dwellings in Seismic Design Categories D₀, D₁ and D₂, exterior stone or masonry veneer, as specified in Table R703.8(2),

with a backing of wood framing shall be permitted to the height specified in Table R703.8(2) above a noncombustible foundation.

- ❖ For the purposes of this section, stone and masonry veneers are nonstructural facing materials of natural or manufactured stone or clay or concrete brick installed as an anchored veneer providing ornamentation, protection or insulation. To be considered a veneer, the material cannot act structurally with the backing insofar as the structural strength of the assembly is concerned. Stone and masonry veneers can be used as either interior or exterior wall finishes. In addition to the provisions of this section, Table R703.3(1) and Figure R703.8 provide details for the installation of stone or masonry veneer. Because

For SI: 1 inch = 25.4 mm.

- a. See Sections R703.8.5, R703.8.6 and R703.4.
- b. See Sections R703.2 and R703.8.4.
- c. See Section R703.8.4.2 and Table 703.8.4.
- d. See Section R703.8.3.
- e. Figure R703.8 illustrates typical construction details for a masonry veneer wall. For the actual mandatory requirements of this code, see the indicated sections of text. Other details of masonry veneer wall construction shall be permitted provided the requirements of the indicated sections of text are met.

FIGURE R703.8—continued
TYPICAL MASONRY VENEER WALL DETAILS^a

of their weight, stone and masonry veneer can impose lateral loads upon the structure from seismic events that are more than the prescriptive loading permitted by Section R301.2.2.2.1 for wood or cold-formed steel construction. For this reason, stone or masonry veneer installed with a backing of wood or cold-formed steel is limited to the first story above grade and a maximum thickness of 5 inches (127 mm) unless it meets Exception 1 or 2.

Exception 1 allows stone or masonry veneer to be constructed to either two or three stories above grade on structures located in Seismic Design Category A, B, or C when installed with wood or cold-formed steel backing and with increased wall bracing [see Table R703.8(1) and Sections R602.10 and R603.9.5].

Exception 1 applies to townhouses or detached one- or two-family dwellings with a backing of wood or cold-formed steel frame that include a stone or masonry veneer.

Exception 2 applies only to detached one- and two-family dwellings with a backing of wood framing that include a stone or masonry veneer. Exception 2 allows stone or masonry veneer with wood backing, up to three stories above grade on structures located in Seismic Design Category D₀ or D₁, and two stories above grade for structures located in Seismic Design Category D₂ under certain conditions that include increasing the amount of wall bracing and providing hold-down connectors [see Table R703.8(2) and Sections R602.10 and R603.9.5].

TABLE R703.8(1)
STONE OR MASONRY VENEER LIMITATIONS AND REQUIREMENTS,
WOOD OR STEEL FRAMING, SEISMIC DESIGN CATEGORIES A, B AND C

SEISMIC DESIGN CATEGORY	NUMBER OF WOOD- OR STEEL-FRAMED STORIES	MAXIMUM HEIGHT OF VENEER ABOVE NONCOMBUSTIBLE FOUNDATION ^a (feet)	MAXIMUM NOMINAL THICKNESS OF VENEER (inches)	MAXIMUM WEIGHT OF VENEER (psf) ^b	WOOD- OR STEEL-FRAMED STORY
A or B	Steel: 1 or 2 Wood: 1, 2 or 3	30	5	50	all
C	1	30	5	50	1 only
	2	30	5	50	top
					bottom
	Wood only: 3	30	5	50	top
					middle
bottom					

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa.

a. An additional 8 feet is permitted for gable end walls. See also story height limitations of Section R301.3.

b. Maximum weight is installed weight and includes weight of mortar, grout, lath and other materials used for installation. Where veneer is placed on both faces of a wall, the combined weight shall not exceed that specified in this table.

TABLE R703.8(2)
STONE OR MASONRY VENEER LIMITATIONS AND REQUIREMENTS,
ONE- AND TWO-FAMILY DETACHED DWELLINGS, SEISMIC DESIGN CATEGORIES D₀, D₁ AND D₂

SEISMIC DESIGN CATEGORY	NUMBER OF WOOD-FRAMED STORIES ^a	MAXIMUM HEIGHT OF VENEER ABOVE NONCOMBUSTIBLE FOUNDATION OR FOUNDATION WALL (feet)	MAXIMUM NOMINAL THICKNESS OF VENEER (inches)	MAXIMUM WEIGHT OF VENEER (psf) ^b
D ₀	1	20 ^c	4	40
	2	20 ^c	4	40
	3	30 ^d	4	40
D ₁	1	20 ^c	4	40
	2	20 ^c	4	40
	3	20 ^c	4	40
D ₂	1	20 ^c	3	30
	2	20 ^c	3	30

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.

a. Cripple walls are not permitted in Seismic Design Categories D₀, D₁ and D₂.

b. Maximum weight is installed weight and includes weight of mortar, grout and lath, and other materials used for installation.

c. The veneer shall not exceed 20 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls, or 30 feet in height with an additional 8 feet for gable end walls where the lower 10 feet have a backing of concrete or masonry wall. See story height limitations of Section R301.3.

d. The veneer shall not exceed 30 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls. See story height limitations of Section R301.3.

WALL COVERING

R703.8.1 Interior veneer support. Veneers used as interior wall finishes shall be permitted to be supported on wood or cold-formed steel floors that are designed to support the loads imposed.

- ❖ Where designed to support the weight of the veneer, a wood-framed or cold-formed steel floor system may be used to support stone or masonry veneer used in an interior application.

R703.8.2 Exterior veneer support. Except in Seismic Design Categories D_0 , D_1 and D_2 , exterior masonry veneers having an installed weight of 40 pounds per square foot (195 kg/m²) or less shall be permitted to be supported on wood or cold-formed steel construction. Where masonry veneer supported by wood or cold-formed steel construction adjoins masonry veneer supported by the foundation, there shall be a movement joint between the veneer supported by the wood or cold-formed steel construction and the veneer supported by the foundation. The wood or cold-formed steel construction supporting the masonry veneer shall be designed to limit the deflection to $1/600$ of the span for the supporting members. The design of the wood or cold-formed steel construction shall consider the weight of the veneer and any other loads.

- ❖ Two criteria must be met to support exterior masonry veneer directly on wood or cold-formed steel construction rather than on a concrete or masonry foundation wall. First, the construction must be located in Seismic Design Category A, B or C. Second, the total installed weight of the veneer must not exceed 40 pounds per square foot (psf) (195 kg/m²). A movement joint must be provided between the exterior veneer supported by wood or steel and the adjacent exterior veneer supported by the foundation. The wood or cold-formed steel members supporting the masonry veneer are to be designed to have a maximum deflection of $1/600$ of the span of the supporting members.

R703.8.2.1 Support by steel angle. A minimum 6-inch by 4-inch by $5/16$ -inch (152 mm by 102 mm by 8 mm) steel angle, with the long leg placed vertically, shall be anchored to double 2-inch by 4-inch (51 mm by 102 mm) wood studs or double 350S162 cold-formed steel studs at a maximum on-center spacing of 16 inches (406 mm). Anchorage of the steel angle at every double stud spacing shall be not less than two $7/16$ -inch-diameter (11 mm) by 4-inch (102 mm) lag screws for wood construction or two $7/16$ -inch (11.1 mm) bolts with washers for cold-formed steel construction. The steel angle shall have a minimum clearance to underlying construction of $1/16$ inch (1.6 mm). Not less than two-thirds the width of the masonry veneer thickness shall bear on the steel angle. Flashing and weep holes shall be located in the masonry veneer in accordance with Figure R703.8.2.1. The maximum height of masonry veneer above the steel angle support shall be 12 feet 8 inches (3861 mm). The airspace separating the masonry veneer from the wood backing shall be in accordance with Sections R703.8.4 and R703.8.4.2. The method of support for the masonry veneer on wood construction shall be constructed in accordance with Figure R703.8.2.1

The maximum slope of the roof construction without stops shall be 7:12. Roof construction with slopes greater than 7:12

but not more than 12:12 shall have stops of a minimum 3-inch by 3-inch by $1/4$ -inch (76 mm by 76 mm by 6.4 mm) steel plate welded to the angle at 24 inches (610 mm) on center along the angle or as *approved by the building official*.

- ❖ As illustrated in Figure R703.8.2.1, a steel angle may be used to support exterior masonry veneer in wood-frame construction. The minimum size of the angle is specified, as are the details of anchorage and the minimum bearing length. Two limits are placed on this method of veneer support: the maximum veneer height bearing on the steel angle must be 12 feet, 8 inches (3861 mm), and the roof slope is limited to 7:12. A roof slope greater than 7:12 is permitted if stops are welded to the steel angle to prevent the veneer from sliding down the angle.

FIGURE R703.8.2.1
EXTERIOR MASONRY VENEER SUPPORT BY STEEL ANGLES

R703.8.2.2 Support by roof construction. A steel angle shall be placed directly on top of the roof construction. The roof supporting construction for the steel angle shall consist of not fewer than three 2-inch by 6-inch (51 mm by 152 mm) wood members for wood construction or three 550S162 cold-formed steel members for cold-formed steel light frame construction. A wood member abutting the vertical wall stud construction shall be anchored with not fewer than three $5/8$ -inch (15.9 mm) diameter by 5-inch (127 mm) lag screws to every wood stud spacing. Each additional wood roof member shall be anchored by the use of two 10d nails at every wood stud spacing. A cold-formed steel member abutting the vertical wall stud shall be anchored with not fewer than nine No. 8 screws to every cold-formed steel stud. Each additional cold-formed steel roof member shall be anchored to the adjoining roof member using two No. 8 screws at every stud spacing.

Not less than two-thirds the width of the masonry veneer thickness shall bear on the steel angle. Flashing and weep holes shall be located in the masonry veneer wythe in accordance with Figure R703.8.2.2. The maximum height of the masonry veneer above the steel angle support shall be 12 feet 8 inches (38.61 mm). The airspace separating the masonry veneer from the wood backing shall be in accordance with Sections R703.8.4 and R703.8.4.2. The support for the masonry veneer shall be constructed in accordance with Figure R703.8.2.2.

The maximum slope of the roof construction without stops shall be 7:12. Roof construction with slopes greater than 7:12 but not more than 12:12 shall have stops of a minimum 3-inch by 3-inch by $\frac{1}{4}$ -inch (76 mm by 76 mm by 6.4 mm) steel plate welded to the angle at 24 inches (610 mm) on center along the angle or as *approved by the building official*.

- ❖ In addition to the option of having a steel angle support exterior masonry veneer, the code also permits the wood roof construction itself to support the exterior veneer. As detailed in Figure R703.8.2.2, the masonry veneer must be supported by a steel angle that in turn distributes the veneer load to at least three 2-inch by 6-inch (51 mm by 152 mm) wood members. This section also addresses the attachment details and bearing conditions. As described for masonry veneer supported by steel angles, the maximum veneer height and maximum roof slope are also regulated. The roof slope is limited to 7:12; however, a roof slope greater than 7:12 is permitted if stops are welded to the steel angle to prevent the veneer from sliding down the angle.

FIGURE R703.8.2.2
EXTERIOR MASONRY VENEER SUPPORT BY ROOF MEMBERS

R703.8.3 Lintels. Masonry veneer shall not support any vertical load other than the dead load of the veneer above. Veneer above openings shall be supported on lintels of non-combustible materials. The lintels shall have a length of bearing not less than 4 inches (102 mm). Steel lintels shall be shop coated with a rust-inhibitive paint, except for lintels made of corrosion-resistant steel or steel treated with coatings to provide corrosion resistance. Construction of openings shall comply with either Section R703.8.3.1 or 703.8.3.2.

- ❖ Masonry veneer, like all veneers, is a nonload-bearing wall covering. It is not intended to support any loads, except for the dead load of the masonry veneer above. A noncombustible lintel is required above an opening through the masonry veneer. The lintel must be protected from rust. Lintels must be sized and installed in accordance with Section R703.8.3.1 or R703.8.3.2.

R703.8.3.1 Allowable span. The allowable span shall not exceed the values set forth in Table R703.8.3.1.

- ❖ A lintel meeting the requirements of this section must meet the requirements of Table R703.8.3.1. This table lists the maximum-size opening a certain lintel size is allowed to span based on the number of stories above the lintel. Note c stipulates that other steel members can be used as long as they meet the structural design requirements using standard engineering practice.

R703.8.3.2 Maximum span. The allowable span shall not exceed 18 feet 3 inches (5562 mm) and shall be constructed to comply with Figure R703.8.3.2 and the following:

1. Provide a minimum length of 18 inches (457 mm) of masonry veneer on each side of opening as shown in Figure R703.8.3.2.
2. Provide a minimum 5-inch by $3\frac{1}{2}$ -inch by $\frac{5}{16}$ -inch (127 mm by 89 mm by 7.9 mm) steel angle above the opening and shore for a minimum of 7 days after installation.
3. Provide double-wire joint reinforcement extending 12 inches (305 mm) beyond each side of the opening. Lap splices of joint reinforcement not less than 12 inches (305 mm). Comply with one of the following:
 - 3.1. Double-wire joint reinforcement shall be $\frac{3}{16}$ -inch (4.8 mm) diameter and shall be placed in the first two bed joints above the opening.
 - 3.2. Double-wire joint reinforcement shall be 9 gauge (0.144 inch or 3.66 mm diameter) and shall be placed in the first three bed joints above the opening.
4. Provide the height of masonry veneer above opening, in accordance with Table R703.8.3.2.

- ❖ A lintel meeting the requirements of this section can span an opening no longer than 18 feet 3 inches (5563 mm). Such openings are generally installed to accommodate a two-car garage door. A minimum-size steel angle must be installed with the long leg in the vertical position below the masonry veneer and a minimum size and amount of joint reinforcement must be

TABLE R703.8.3.1
ALLOWABLE SPANS FOR LINTELS SUPPORTING MASONRY VENEER^{a, b, c, d}

SIZE OF STEEL ANGLE ^{a, c, d} (inches)	NO STORY ABOVE	ONE STORY ABOVE	TWO STORIES ABOVE	NO. OF 1/2-INCH OR EQUIVALENT REINFORCING BARS IN REINFORCED LINTEL ^{b, d}
3 × 3 × 1/4	6'-0"	4'-6"	3'-0"	1
4 × 3 × 1/4	8'-0"	6'-0"	4'-6"	1
5 × 3 1/2 × 5/16	10'-0"	8'-0"	6'-0"	2
6 × 3 1/2 × 5/16	14'-0"	9'-6"	7'-0"	2
2-6 × 3 1/2 × 5/16	20'-0"	12'-0"	9'-6"	4

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Long leg of the angle shall be placed in a vertical position.

b. Depth of reinforced lintels shall be not less than 8 inches and all cells of hollow masonry lintels shall be grouted solid. Reinforcing bars shall extend not less than 8 inches into the support.

c. Steel members indicated are adequate typical examples; other steel members meeting structural design requirements shall be permitted to be used.

d. Either steel angle or reinforced lintel shall span opening.

installed in the courses above the veneer. In addition, the masonry veneer opening must comply with the requirements in Figure R703.8.3.2. The limits for the maximum and minimum height of masonry veneer as shown in Figure R703.8.3.2 must be in accordance with Table R703.8.3.2.

TABLE R703.8.3.2
HEIGHT OF MASONRY VENEER ABOVE OPENING

MINIMUM HEIGHT OF MASONRY VENEER ABOVE OPENING (INCH)	MAXIMUM HEIGHT OF MASONRY VENEER ABOVE OPENING (FEET)
13	< 5
24	5 to < 12
60	12 to height above support allowed by Section R703.8

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R703.8.3.2
MASONRY VENEER OPENING

R703.8.4 Anchorage. Masonry veneer shall be anchored to the supporting wall studs with corrosion-resistant metal ties embedded in mortar or grout and extending into the veneer a minimum of 1 1/2 inches (38 mm), with not less than 5/8-inch (15.9 mm) mortar or grout cover to outside face. Masonry veneer shall conform to Table R703.8.4.

❖ To maintain the attachment of the masonry veneer to the wall studs, proper anchorage must be provided. In all cases, corrosion-resistant metal ties must be used and be embedded into the back of the veneer a minimum distance. A minimum extent of mortar or grout is required to cover the tie from the outside face of the wall. As specified in Table R703.8.4, two types of ties are addressed for attachment to wood construction: corrugated sheet metal ties and metal strand wire ties. The distance between the veneer and the sheathing is limited and varies with the type of tie used. For corrugated sheet metal ties, this dimension is given as nominal since the back of the masonry veneer may not be true to a line due to the variation in masonry unit width allowed within most masonry unit standards and the alignment of the wall elements within the backing wall. Only adjustable metal strand wire ties may be used where the backing is of cold-formed steel studs. The distance between the steel backing and the masonry veneer is also limited.

Table R703.8.4 also specifies the fastening requirements of metal ties to the studs. Nails are not permitted for fastening of the ties in Seismic Design Categories D₀, D₁ or D₂. This is based on full-scale building shaking-table testing conducted at the University of California, San Diego. The report by Richard E. Klinger, published in the *TMS Journal*, found that “fasteners on one side of the specimen failed by extraction of nails under dynamic tensile loads, at levels of shaking less than the Design Basis Earthquake (DBE).”

R703.8.4.1 Size and spacing. Veneer ties, if strand wire, shall be not less in thickness than No. 9 U.S. gage [(0.148 inch) (4 mm)] wire and shall have a hook embedded in the

TABLE R703.8.4
TIE ATTACHMENT AND AIRSPACE REQUIREMENTS

BACKING AND TIE	MINIMUM TIE	MINIMUM TIE FASTENER ^a	AIRSPACE	
Wood stud backing with corrugated sheet metal	22 U.S. gage (0.0299 in.) × $\frac{7}{8}$ in. wide	8d common nail ^b (2½ in. × 0.131 in.)	Nominal 1 in. between sheathing and veneer	
Wood stud backing with metal strand wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	8d common nail ^b (2½ in. × 0.131 in.)	Minimum nominal 1 in. between sheathing and veneer	Maximum 4½ in. between backing and veneer
Cold-formed steel stud backing with adjustable metal strand wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	No. 10 screw extending through the steel framing a minimum of three exposed threads	Minimum nominal 1 in. between sheathing and veneer	Maximum 4½ in. between backing and veneer

For SI: 1 inch = 25.4 mm.

- a. In Seismic Design Category D₀, D₁ or D₂, the minimum tie fastener shall be an 8d ring-shank nail (2½ in. × 0.131 in.) or a No. 10 screw extending through the steel framing a minimum of three exposed threads.
- b. All fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

mortar joint, or if sheet metal, shall be not less than No. 22 U.S. gage by [(0.0299 inch) (0.76 mm)] $\frac{7}{8}$ inch (22 mm) corrugated. Each tie shall support not more than 2.67 square feet (0.25 m²) of wall area and shall be spaced not more than 32 inches (813 mm) on center horizontally and 24 inches (635 mm) on center vertically.

Exception: In Seismic Design Category D₀, D₁ or D₂ or townhouses in Seismic Design Category C or in wind areas of more than 30 pounds per square foot pressure (1.44 kPa), each tie shall support not more than 2 square feet (0.2 m²) of wall area.

- ❖ This section sets forth the minimum size of metal veneer ties for use with masonry veneer applications. The maximum amount of wall area that can be supported by a veneer tie is 2.67 square feet (0.248 m²). The spacing between the ties is also limited to a maximum horizontal distance of 32 inches (813 mm) and vertical distance of 24 inches (610 mm). An increased number of ties are required for buildings constructed in a high seismic design category or where a high wind load exists.

R703.8.4.1.1 Veneer ties around wall openings. Additional metal ties shall be provided around wall openings greater than 16 inches (406 mm) in either dimension. Metal ties around the perimeter of openings shall be spaced not more than 3 feet (914 mm) on center and placed within 12 inches (305 mm) of the wall opening.

- ❖ When an opening with at least one dimension larger than 16 inches (406 mm) is located through a masonry veneer, an increase in the number of metal ties around the opening is required. Openings of this size are often for windows and doors. This section contains requirements for the maximum spacing between ties and the maximum distance from the opening to the ties adjacent to it. Openings less than 16 inches (406 mm) in either dimension are exempt from these provisions.

R703.8.4.2 Grout fill. As an alternative to the airspace required by Table R703.8.4, grout shall be permitted to fill the airspace. Where the airspace is filled with grout, a water-resistive barrier is required over studs or sheathing. Where the airspace is filled, replacing the sheathing and water-resistive barrier with a wire mesh and *approved* water-resistive

barrier or an *approved* water-resistive barrier-backed reinforcement attached directly to the studs is permitted.

- ❖ The airspace required by Section R703.8.4 is permitted to be filled with grout when a water-resistive barrier is applied over studs and sheathing and the airspace is completely filled with the grout. The sheathing and water-resistive barrier are permitted to be replaced with a wire mesh and approved water-resistive barrier or an approved water-resistive barrier-backed reinforcement that is attached directly to the studs.

R703.8.5 Flashing. Flashing shall be located beneath the first course of masonry above finished ground level above the foundation wall or slab and at other points of support, including structural floors, shelf angles and lintels where masonry veneers are designed in accordance with Section R703.8. See Section R703.4 for additional requirements.

- ❖ Flashing is necessary to direct moisture in the air space behind the masonry veneer toward the exterior. Flashing is required to be located at the first course of masonry above the finished ground level, as well as at other points of support such as at shelf angles and lintels. Flashing beneath the first course of masonry above the finished ground level is also necessary to prevent water entry into the wall below. Flashing must be made from an approved corrosion-resistant material and comply with Section R703.4.

R703.8.6 Weepholes. Weepholes shall be provided in the outside wythe of masonry walls at a maximum spacing of 33 inches (838 mm) on center. Weepholes shall be not less than $\frac{3}{16}$ inch (5 mm) in diameter. Weepholes shall be located immediately above the flashing.

- ❖ Weepholes must be provided directly above the flashing mandated by Section R703.8.5 to allow for the escape of any moisture that may have penetrated the masonry veneer. Because moisture will adversely affect the integrity of the wall if not removed from the wall assembly, weep holes must be installed within the maximum spacing specified in this section. The minimum diameter of the weep holes is also stipulated.

R703.9 Exterior insulation and finish system (EIFS)/EIFS with drainage. Exterior insulation and finish systems (EIFS)

WALL COVERING

shall comply with this chapter and Section R703.9.1. EIFS with drainage shall comply with this chapter and Section R703.9.2.

❖ This section provides the requirements for exterior insulation and finish systems (EIFS) and exterior insulation and finish systems with drainage (EIFS with drainage) (see Section R202 for the definition for both).

- EIFS must comply with ASTM E2568. EIFS with drainage must comply with ASTM E2568 and ASTM E2273 in accordance with Section R703.9.2.
- EIFS and EIFS with drainage must be installed in accordance with manufacturers' instructions.
- EIFS with drainage require a water-resistive barrier in accordance with Section R703.9.2.
- EIFS and EIFS with drainage must not be located within 6 inches (152 mm) of the finished ground level. Additionally, decorative trim must not be face nailed through the EIFS or EIFS with drainage.

R703.9.1 Exterior insulation and finish systems (EIFS).

EIFS shall comply with the following:

1. ASTM E2568.
2. EIFS shall be limited to applications over substrates of concrete or masonry wall assemblies.
3. Flashing of EIFS shall be provided in accordance with the requirements of Section R703.4.
4. EIFS shall be installed in accordance with the manufacturer's instructions.
5. EIFS shall terminate not less than 6 inches (152 mm) above the finished ground level.
6. Decorative trim shall not be face-nailed through the EIFS.

❖ See the commentary to Section R703.9.

R703.9.2 Exterior insulation and finish system (EIFS) with drainage. EIFS with drainage shall comply with the following:

1. ASTM E2568.
2. EIFS with drainage shall be required over all wall assemblies with the exception of substrates of concrete or masonry wall assemblies.
3. EIFS with drainage shall have an average minimum drainage efficiency of 90 percent when tested in accordance with ASTM E2273.
4. The water-resistive barrier shall comply with Section R703.2 or ASTM E2570.
5. The water-resistive barrier shall be applied between the EIFS and the wall sheathing.
6. Flashing of EIFS with drainage shall be provided in accordance with the requirements of Section R703.4.
7. EIFS with drainage shall be installed in accordance with the manufacturer's instructions.

8. EIFS with drainage shall terminate not less than 6 inches (152 mm) above the finished ground level.

9. Decorative trim shall not be face-nailed through the EIFS with drainage.

❖ See the commentary to Section R703.9.

R703.10 Fiber cement siding.

❖ Fiber cement siding is manufactured from fiber-reinforced cement and is permitted as a weather-resistant siding in either panel or horizontal lap form.

R703.10.1 Panel siding. Fiber-cement panels shall comply with the requirements of ASTM C1186, Type A, minimum Grade II or ISO 8336, Category A, minimum Class 2. Panels shall be installed with the long dimension either parallel or perpendicular to framing. Vertical and horizontal joints shall occur over framing members and shall be protected with caulking, or with battens or flashing, or be vertical or horizontal shiplap, or otherwise designed to comply with Section R703.1. Panel siding shall be installed with fasteners in accordance with Table R703.3(1) or the approved manufacturer's instructions.

❖ Panel siding of fiber cement must meet the requirements of ASTM C1186, Type A, minimum Grade II or ISO 8336, Category A, minimum Class 2. Panels can be installed vertically or horizontally. All joints are required to be located over framing members. Joints must be sealed with caulking and covered with continuous battens or otherwise installed to comply with Section R703.1 to result in a weather-resistant exterior wall envelope. Panel fasteners must meet the requirements of Table R703.3 (1) or manufacturers' installation instructions.

R703.10.2 Lap siding. Fiber-cement lap siding having a maximum width of 12 inches (305 mm) shall comply with the requirements of ASTM C1186, Type A, minimum Grade II or ISO 8336, Category A, minimum Class 2. Lap siding shall be lapped a minimum of 1¹/₄ inches (32 mm) and lap siding not having tongue-and-groove end joints shall have the ends protected with caulking, covered with an H-section joint cover, located over a strip of flashing, or shall be designed to comply with Section R703.1. Lap siding courses shall be installed with the fastener heads exposed or concealed, in accordance with Table R703.3(1) or approved manufacturer's instructions.

❖ To maintain the necessary weather protection, horizontal siding must have a minimum lap of at least 1¹/₄ inches (32 mm). Lap siding without tongue-and-groove end joints must be treated with one of the following methods: sealed with caulk; covered with an H-section joint cover; or otherwise installed to comply with Section R703.1 to result in a weather-resistant exterior wall envelope. Fastener heads may be exposed or concealed in accordance with approved manufacturers' installation instructions.

R703.11 Vinyl siding. Vinyl siding shall be certified and labeled as conforming to the requirements of ASTM D3679 by an *approved* quality control agency.

- ❖ Polyvinyl chloride (PVC) siding is specifically addressed here as an exterior wall covering. PVC siding must conform to the provisions of ASTM D3679. The vinyl siding must bear a label, which means that the manufacturer must have regular inspections by a third-party quality control agency.

R703.11.1 Installation. Vinyl siding, soffit and accessories shall be installed in accordance with the manufacturer's instructions.

- ❖ Vinyl siding must be applied to conform to the water-resistive barrier requirements of Sections R703.1 and R703.2 and the attachment requirements of Section R703.3 (see commentary, Sections R703.1, R703.2 and R703.3).

The installation must also comply with the manufacturer's instructions. ASTM D3679 requires installation of the siding in accordance with Practice D4756 (ASTM D4756) and the manufacturer's instructions. These instructions are necessary for compliance with the performance requirements of this chapter.

In the 2012 code, information on vinyl siding fastener specifications, penetration, and spacing was found only in Table R703.4 and its notes. These requirements are moved into new Sections R703.11.1.1, R703.11.1.2 and R703.11.1.3. This places the requirements into the text of the code provision where they are easily located and more clearly stated.

Vinyl siding can be used in conjunction with a variety of sheathing types, some of which contribute to resisting fastener withdrawal. It is necessary to ensure that, regardless of the sheathing type, the total penetration into a material capable of holding fasteners is equivalent to what was used during testing of the siding. For typical siding installations, this is $\frac{3}{4}$ -inch penetration into framing plus approximately $\frac{1}{2}$ inch through wood sheathing, for a total of $1\frac{1}{4}$ inches of penetration into "nailable" material. This minimum penetration is required unless a different penetration is specified in the manufacturer's instructions. A definition of "nailable substrate" is added to define what is considered to be "nailable."

Where the siding is used over a nonnailable material, the total penetration must still be achieved, in this case by using a fastener long enough to accommodate the thickness of nonnailable material and penetrate the full $1\frac{1}{4}$ inches into framing or a combination of framing and other nailable material. By stating the requirement in terms of the total required penetration, it is clear what penetration is needed for all installations.

In addition, new Section R703.11.1.3 provides the maximum fastener spacing for both horizontal and vertical siding. The code previously had no provision for fastener spacing for vertical siding; the new requirement mirrors provisions in the *International Building Code*® (IBC)®.

Polyvinyl chloride (PVC) may be used to cover the soffit. The material must be installed as panels and fastened to a supporting component or in accordance with the manufacturer's installation instructions.

R703.11.1.1 Fasteners. Unless specified otherwise by the manufacturer's instructions, fasteners for vinyl siding shall be 0.120-inch (3 mm) shank diameter nail with a 0.313-inch (8 mm) head or 16-gage staple with a $\frac{3}{8}$ -inch (9.5 mm) to $\frac{1}{2}$ -inch (12.7 mm) crown.

- ❖ See the commentary to Section R703.11.1.

R703.11.1.2 Penetration depth. Unless specified otherwise by the manufacturer's instructions, fasteners shall penetrate into building framing. The total penetration into sheathing, furring framing or other nailable substrate shall be a minimum $1\frac{1}{4}$ inches (32 mm). Where specified by the manufacturer's instructions and supported by a test report, fasteners are permitted to penetrate into or fully through nailable sheathing or other nailable substrate of minimum thickness specified by the instructions or test report without penetrating into framing. Where the fastener penetrates fully through the sheathing, the end of the fastener shall extend a minimum of $\frac{1}{4}$ inch (6.4 mm) beyond the opposite face of the sheathing or nailable substrate.

- ❖ See the commentary to Section R703.11.1.

R703.11.1.3 Spacing. Unless specified otherwise by the manufacturer's instructions, the maximum spacing between fasteners for horizontal siding shall be 16 inches (406 mm), and for vertical siding 12 inches (305 mm) both horizontally and vertically. Where specified by the manufacturer's instructions and supported by a test report, greater fastener spacing is permitted.

- ❖ See the commentary to Section R703.11.1.

R703.11.1.4 Vinyl soffit panels. Soffit panels shall be individually fastened to a supporting component such as a nailing strip, fascia or subfascia component or as specified by the manufacturer's instructions.

- ❖ See the commentary to Section R703.11.1.

R703.11.2 Foam plastic sheathing. Vinyl siding and insulated vinyl siding used with foam plastic sheathing shall be installed in accordance with Section R703.11.2.1, R703.11.2.2 or R703.11.2.3.

Exception: Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing or other *approved* backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with Section R703.11.1.

- ❖ This section establishes a proper basis for vinyl siding and insulated vinyl siding applications with foam sheathing by applying appropriate adjustment factors to vinyl siding wind pressure ratings to address this specific assembly condition. Because the vinyl and foam sheathing assembly serve as the primary weather barrier or envelope for the building (when no additional structural sheathing is applied), the vinyl siding pressure rating values have been factored to pro-

vide a net safety factor of 2.0 instead of 1.5 as required by ASTM D3679 for applications of vinyl siding over “solid walls.” The adjustment factors specified in Section R703.11.2.2 also account for difference in pressure equalization effects addressed in ASTM D3679, Annex A for the specific wall assembly conditions where vinyl siding is used with a foam sheathing backing material.

The requirements of Section R703.11.2 are intended to improve the wind-resistant performance of combinations of foam sheathing and vinyl siding commonly used to meet or exceed energy code requirements and newer green building guidelines or standards. The prescriptive requirements and adjustment factors are based on certified testing of various combinations of foam sheathing and vinyl siding products conducted at the NAHB Research Center, Inc., and testing serving as the basis for the wind pressure rating method for vinyl siding as explained in ASTM D3679, Annex A.

An exception exempts foam plastic sheathing from having to contribute to resisting wind if the backing behind it can resist the wind load by itself. If it cannot, then the foam plastic sheathing and vinyl siding together must comply with one of the following three provisions:

1. If the structure is located where the ultimate design wind speed does not exceed 115 mph and is in an Exposure Category B or less, the installation must meet Section R703.11.2.1.
2. If the structure is located where the ultimate design wind speed exceeds 115 mph or is in an Exposure Category C or D or otherwise cannot fully comply with all the requirements of Section R703.11.2.1, the installation must meet Section R703.11.2.2.
3. If the vinyl siding manufacturer’s product specifications indicate that an approved design wind pressure rating when installed over foam plastic sheathing is provided, the vinyl siding and foam plastic sheathing are permitted to be installed in accordance with the manufacturer’s instructions as stipulated by Section R703.11.2.3.

R703.11.2.1 Basic wind speed not exceeding 115 miles per hour and Exposure Category B. Where the ultimate design wind speed does not exceed 115 miles per hour (51 m/s), the exposure category is B and gypsum board, gypsum panel product or equivalent is installed on the side of the wall opposite the foam plastic sheathing, the minimum siding fastener penetration into wood framing shall be $1\frac{1}{4}$ inches (32 mm) using minimum 0.120-inch-diameter (3 mm) nail (shank) with a minimum 0.313-inch-diameter head, 16 inches (406 mm) on center. The foam plastic sheathing shall be minimum $\frac{1}{2}$ -inch-thick (12.7 mm) (nominal) extruded polystyrene in accordance with ASTM C578, $\frac{1}{2}$ -inch-thick (12.7 mm) (nominal) polyisocyanurate in accordance with ASTM

C1289 or 1-inch-thick (25 mm) (nominal) expanded polystyrene in accordance with ASTM C578.

❖ See the commentary to Section R703.11.2.

R703.11.2.2 Basic wind speed exceeding 115 miles per hour or Exposure Categories C and D. Where the ultimate design wind speed exceeds 115 miles per hour (51 m/s), the exposure category is C or D, or all conditions of Section R703.11.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3). The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer’s product specifications shall be adjusted for the following wall assembly conditions:

1. For wall assemblies with foam plastic sheathing on the exterior side and gypsum wall board, gypsum panel product or equivalent on the interior side of the wall, the vinyl siding’s design wind pressure rating shall be multiplied by 0.39.
2. For wall assemblies with foam plastic sheathing on the exterior side and without gypsum wall board, gypsum panel product or equivalent on the interior side of wall, the vinyl siding’s design wind pressure rating shall be multiplied by 0.27.

❖ See the commentary to Section R703.11.2.

R703.11.2.3 Manufacturer specification. Where the vinyl siding manufacturer’s product specifications provide an *approved* design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer’s instructions.

❖ See the commentary to Section R703.11.2.

R703.12 Adhered masonry veneer installation. Adhered masonry veneer shall comply with the requirements of Section R703.7.3 and the requirements in Sections 12.1 and 12.3 of TMS 402/ACI 530/ASCE 5. Adhered masonry veneer shall be installed in accordance with Section R703.7.1, Article 3.3C of TMS 602/ACI 530.1/ASCE 6 or the manufacturer’s instructions.

❖ In the 2012 code, information on adhered masonry veneer installation was found only in Table R703.4 and its notes. These requirements were moved into this section and new Section R703.12.3, This places the requirements into the text of the code provision where they are easily located and more clearly stated. Adhered masonry veneer must be installed according to this section or the instructions of the manufacturer. A water-resistive barrier must be installed to comply with Sections R703.2 and R703.7.3 and the requirements of Sections 12.1 and 12.3 of TMS 402/ACI 530/ASCE 5. Where no instructions from the manufacturer are provided, adhered masonry veneer must be supported and fastened in accordance with the lath requirements in Section R703.7.1 or Article 3.3C of TMS 602/ACI 530.1/ASCE 6.

R703.12.1 Clearances. On exterior stud walls, adhered masonry veneer shall be installed:

1. Minimum of 4 inches (102 mm) above the earth;
2. Minimum of 2 inches (51 mm) above paved areas; or
3. Minimum of $\frac{1}{2}$ inch (12.7 mm) above exterior walking surfaces that are supported by the same foundation that supports the exterior wall.

❖ The clearance requirements for adhered masonry veneer installed on exterior stud walls are consistent with stucco applications, but goes one step further by specifying a minimum $\frac{1}{2}$ -inch (12.7 mm) clearance to exterior walking surfaces supported by the same foundation that supports the wall to which the exterior veneer is adhered. The requirement that both the wall and the walking surface be supported by the same foundation, along with the flashing performance requirements of Section R703.4 for exterior wall intersections with porches, decks or stairs, limits this $\frac{1}{2}$ -inch (12.7 mm) clearance to building elements stable to each other and required to be flashed to manage water. This $\frac{1}{2}$ -inch (12.7 mm) clearance requirement allows for architectural and aesthetic improvements in the installation of adhered masonry veneer.

R703.12.2 Flashing at foundation. A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26-gage galvanized or plastic with a minimum vertical attachment flange of $3\frac{1}{2}$ inches (89 mm) shall be installed to extend a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section R703.4.

❖ The requirements for flashing at the foundation for adhered masonry veneer are similar to the weep screed requirements for stucco and complement the flashing performance requirements of Section R703.4, while at the same time allowing for effective alternatives to the stucco-specific weep screed.

R703.12.3 Water-resistive barrier. A water-resistive barrier shall be installed as required by Section R703.2 and shall comply with the requirements of Section R703.7.3. The water-resistive barrier shall lap over the exterior of the attachment flange of the screed or flashing provided in accordance with Section R703.12.2.

❖ See the commentary to Section R703.12.

R703.13 Insulated vinyl siding. Insulated vinyl siding shall be certified and labeled as conforming to the requirements of ASTM D7793 by an approved quality control agency.

❖ Sections R703.13 and R703.13.1 set requirements based on the manufacturer's instructions and the current ASTM standard for insulated vinyl siding: ASTM D7793. Insulated vinyl siding is certified to an ASTM standard by an approved third-party quality control agency. Performance requirements are specified by the ASTM standard, verifying that insulated vinyl siding meets minimum requirements as a cladding insulation. Insulated vinyl siding is vinyl siding with rigid foam insulation laminated or permanently attached to the panel.

This change provides a method for building officials to verify that insulated vinyl siding is code compliant. In energy codes and energy efficiency programs, insulated siding is recognized as a form of "continuous insulation," or insulation installed on the exterior of the building that helps reduce energy loss through framing or other building material.

The insulated siding provides a supplemental rain screen that reduces the amount of water reaching the underlying water-resistive barrier. With a properly applied water-resistive barrier, insulated siding minimizes moisture penetration from the exterior into a wall assembly and provides a way for moisture to readily drain and dry. The presence of a layer of thermal insulation filling the space between insulated siding and wall sheathing also aids in moisture management

R703.13.1 Insulated vinyl siding and accessories. Insulated vinyl siding and accessories shall be installed in accordance with manufacturer's instructions.

❖ See the commentary to Section R703.13.

R703.14 Polypropylene siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of ASTM D7254 by an approved quality control agency.

❖ Section R703.14 introduces a new exterior wall covering material into the code. Polypropylene siding is not vinyl siding and a definition has been added to Section R202 that explains the difference. The definition conforms to the definition in ASTM D7254. Section R703.14 sets minimum performance requirements for polypropylene siding and requires a third-party quality control agency to verify compliance with an internationally accepted ASTM standard. Additionally, appropriate installation and use of polypropylene siding are detailed. Use of polypropylene siding is limited to walls with a fire separation distance of 5 feet or more and that are also 10 feet or more from a building on another lot.

The Vinyl Siding Institute (VSI) Product Certification Program added certification of polypropylene siding in 2010. Additionally, several manufacturers have code-compliant evaluation reports for their products. The VSI Product Certification Program allows manufacturers to certify, with independent third-party verification by an approved quality control agency, that certain polypropylene siding meets or exceeds the ASTM D7254, *Standard Specification for Polypropylene (PP) Siding*. The program is not exclusive to VSI members and any manufacturer can participate. It has been in place since 1998, when vinyl siding certification began.

Polypropylene siding certified through the program is verified by a third-party, approved quality control agency to meet or exceed the ASTM D7254 Standard Specification for Polypropylene (PP) Siding. Certified polypropylene siding is tested to:

- Weather the elements over time without cracking, chipping, flaking, pitting, or peeling.
- Meet impact-resistance requirements.
- Withstand wind pressures commensurate with wind speeds of 110 mph or more.

- Demonstrate flame spread performance equivalent to or better than wood materials commonly used in building construction.

Although polypropylene siding panels are specific to each manufacturer, there is general consensus among manufacturers on several installation requirements, including:

- Use of a water-resistive barrier.
- Substrate installed with polypropylene siding panels, typically OSB or plywood, must have a minimum fastener withdrawal resistance because fastener spacing varies from 5 inches to 12 inches. The fasteners must have a substrate to penetrate as they will not penetrate studs in most cases because of the typical 16-inch on center spacing.
- No attachment directly over studs.
- Fastener size and length are specified; staples are not allowed.
- Manufacturer-specified fastener spacing.

Specifications for installation, including underlayment and fasteners, are necessary for polypropylene siding, so building officials and specifiers recognize the differences between installation of vinyl siding and polypropylene siding.

For more information on polypropylene siding, go to www.vinylsiding.org/polypropylene-siding/.

R703.14.1 Polypropylene siding and accessories. Polypropylene siding and accessories shall be installed in accordance with manufacturer's installation instructions.

- ❖ See the commentary to Section R703.14.

R703.14.1.1 Installation. Polypropylene siding shall be installed over and attached to wood structural panel sheathing with minimum thickness of $\frac{7}{16}$ inch (11.1 mm), or other substrate, composed of wood or wood-based material and fasteners having equivalent withdrawal resistance.

- ❖ See the commentary to Section R703.14.

R703.14.1.2 Fastener requirements. Unless otherwise specified in the approved manufacturer's instructions, nails shall be corrosion resistant, with a minimum 0.120-inch (3 mm) shank and minimum 0.313-inch (8 mm) head diameter. Nails shall be a minimum of $1\frac{1}{4}$ inches (32 mm) long or as necessary to penetrate sheathing or substrate not less than $\frac{3}{4}$ inch (19.1 mm). Where the nail fully penetrates the sheathing or nailable substrate, the end of the fastener shall extend not less than $\frac{1}{4}$ inch (6.4 mm) beyond the opposite face of the sheathing or substrate. Staples are not permitted.

- ❖ See the commentary to Section R703.14.

R703.14.2 Fire separation. Polypropylene siding shall not be installed on walls with a fire separation distance of less than 5 feet (1524 mm) and walls closer than 10 feet (3048 mm) to a building on another lot.

Exception: Walls perpendicular to the line used to determine the fire separation distance.

- ❖ See the commentary to Section R703.14.

R703.15 Cladding attachment over foam sheathing to wood framing. Cladding shall be specified and installed in accordance with Section R703, the cladding manufacturer's approved instructions, including any limitations for use over foam plastic sheathing, or an approved design. In addition, the cladding or furring attachments through foam sheathing to framing shall meet or exceed the minimum fastening requirements of Section R703.15.1, Section R703.15.2, or an approved design for support of cladding weight.

Exceptions:

1. Where the cladding manufacturer has provided approved installation instructions for application over foam sheathing, those requirements shall apply.
 2. For exterior insulation and finish systems, refer to Section R703.9.
 3. For anchored masonry or stone veneer installed over foam sheathing, refer to Section R703.7.
- ❖ Where exterior siding (cladding) is attached over foam sheathing ranging in thickness up to 4 inches, the fastening method must be adequate to support the cladding weight or dead load. Section R703.15 provides attachment provisions for cladding over foam plastic sheathing to wood framing members. Section R703.16 provides attachment provisions for cladding over foam plastic sheathing to cold-formed steel framing. Section R703.17 contains provisions for cladding attachment over foam sheathing to concrete or masonry walls.

Tables R703.15.1 and R703.16.1 provide the attachment requirements for cladding installed over foam sheathing without furring strips. Tables R703.15.2 and R703.16.2 provide the attachment requirements where furring strips are used over the foam plastic sheathing for cladding attachment.

Tables R703.15.1, R703.15.2, R703.16.1 and R703.16.2 were developed based on data from a project sponsored by the New York State Energy Research and Development Agency (NYSERDA).

The project report, "10-11 Fastening Systems for Continuous Insulation Final Report," is available for download at: <http://www.nyserda.ny.gov/Publications/Research-and-Development-Technical-Reports/Other-Technical-Reports.aspx>. The report explains the technical basis for the requirements, which have been modified for these provisions, to increase the reduction factor to control deflection from 1.5 to 3 (fastener strength halved) to provide better long-term deflection control. For comparison, the reduction factor used in the NDS provisions for fastener-shear-resistance calculation is 2.2.

The purpose of the NYSERDA project was to develop prescriptive fastening requirements that provide adequate performance of cladding materials installed over foam sheathing. The project included testing of cladding attachments through various thicknesses of foam sheathing using various fastener types on steel frame wall assemblies. Supplemental testing also was sponsored by the Foam Sheathing Coalition (lab report available at <http://fsc.americanchemis->

try.com/Building-Code/Installation-of-Cladding) to address attachments to wood framing. The resulting data is included in the data set analyzed and presented in the NYSERDA project report. The proposed cladding attachment requirements and foam sheathing thickness limits are based on rational analysis verified by the extensive test data to limit cladding connection movement to no more than 0.015-inch slip under cladding weight or dead load. This deflection controlled approach resulted in safety factors commonly in the range of 5 to 8 relative to average shear capacity. Similar tests by other independent parties, such as Wiss, Janney, Elstner (unpublished data) and also Building Science Corporation for the U.S. Department of Energy's (DOE's) Building America Program have shown similar results and have contributed to the verification of these attachment methods.

Section R703.17 requires an engineered design of cladding attachment through foam sheathing to masonry or concrete wall construction because a prescriptive solution for attachment of cladding to masonry or concrete walls through foam sheathing has not been developed. Research is not yet available to develop prescriptive "off-the-shelf" solutions with standardized types of concrete or masonry fasteners. In fact, many fasteners best suited for this application are proprietary and engineered design is required. The exceptions recognize cases where appropriate attachment solutions may already exist.

R703.15.1 Direct attachment. Where cladding is installed directly over foam sheathing without the use of furring, cladding minimum fastening requirements to support the cladding weight shall be as specified in Table R703.15.1.

❖ See the commentary to Section R703.15.

R703.15.2 Furred cladding attachment. Where wood furring is used to attach cladding over foam sheathing, furring minimum fastening requirements to support the cladding weight shall be as specified in Table R703.15.2. Where placed horizontally, wood furring shall be preservative-treated wood in accordance with Section R317.1 or naturally durable wood and fasteners shall be corrosion resistant in accordance Section R317.3.

❖ See the commentary to Section R703.15.

R703.16 Cladding attachment over foam sheathing to cold-formed steel framing. Cladding shall be specified and installed in accordance with Section R703, the cladding manufacturer's approved instructions, including any limitations for use over foam plastic sheathing, or an approved design. In addition, the cladding or furring attachments through foam sheathing to framing shall meet or exceed the minimum fastening requirements of Section R703.16.1, Section R703.16.2 or an approved design for support of cladding weight.

Exceptions:

1. Where the cladding manufacturer has provided approved installation instructions for application over foam sheathing, those requirements shall apply.

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

DR = Design required.

o.c. = On center.

- Wood framing and furring shall be Spruce-pine-fir or any wood species with a specific gravity of 0.42 or greater in accordance with AWC NDS.
- Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths.
- Where the required cladding fastener penetration into wood material exceeds 3/4 inch and is not more than 1 1/2 inches, a minimum 2× wood furring or an approved design shall be used.
- Foam sheathing shall have a minimum compressive strength of 15 psi in accordance with ASTM C578 or ASTM C1289.
- Furring shall be spaced not more than 24 inches on center, in a vertical or horizontal orientation. In a vertical orientation, furring shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, the indicated 8-inch and 12-inch fastener spacing in furring shall be achieved by use of two fasteners into studs at 16 inches and 24 inches on center, respectively.

- For exterior insulation and finish systems, refer to Section R703.9.
- For anchored masonry or stone veneer installed over foam sheathing, refer to Section R703.7.

❖ See the commentary to Section R703.15.

R703.16.1 Direct attachment. Where cladding is installed directly over foam sheathing without the use of furring, cladding minimum fastening requirements to support the cladding weight shall be as specified in Table R703.16.1.

❖ See the commentary to Section R703.15.

R703.16.2 Furred cladding attachment. Where steel or wood furring is used to attach cladding over foam sheathing, furring minimum fastening requirements to support the cladding weight shall be as specified in Table R703.16.2. Where placed horizontally, wood furring shall be preservative-treated wood in accordance with Section R317.1 or naturally durable wood and fasteners shall be corrosion resistant in accordance with Section R317.3. Steel furring shall have a minimum G60 galvanized coating.

❖ See the commentary to Section R703.15.

R703.17 Cladding attachment over foam sheathing to masonry or concrete wall construction. Cladding shall be

specified and installed in accordance with Section 703.3 and the cladding manufacturer's instructions or an approved design. Foam sheathing shall be attached to masonry or concrete construction in accordance with the insulation manufacturer's installation instructions or an approved design. Furring and furring attachments through foam sheathing into concrete or masonry substrate shall be designed to resist design loads determined in accordance with Section R301, including support of cladding weight as applicable. Fasteners used to attach cladding or furring through foam sheathing to masonry or concrete substrates shall be approved for application into masonry or concrete material and shall be installed in accordance with the fastener manufacturer's instructions.

Exceptions:

- Where the cladding manufacturer has provided approved installation instructions for application over foam sheathing and connection to a masonry or concrete substrate, those requirements shall apply.
- For exterior insulation and finish systems, refer to Section R703.9.
- For anchored masonry or stone veneer installed over foam sheathing, refer to Section R703.7

❖ See the commentary to Section R703.15.

**TABLE R703.16.1
CLADDING MINIMUM FASTENING REQUIREMENTS FOR DIRECT ATTACHMENT
OVER FOAM PLASTIC SHEATHING TO SUPPORT CLADDING WEIGHT^a**

CLADDING FASTENER THROUGH FOAM SHEATHING INTO:	CLADDING FASTENER TYPE AND MINIMUM SIZE ^b	CLADDING FASTENER VERTICAL SPACING (inches)	MAXIMUM THICKNESS OF FOAM SHEATHING ^d (inches)

				24	4	2	DR	4	0.5	DR

For SI: 1 inch = 25.4 mm, 1 mil = 0.0254 mm, 1 pound per square foot = 0.0479 kPa, 1 pound per square inch = 6.895 kPa.

DR = Design required.

o.c. = On center.

a. Wood furring shall be Spruce-pine-fir or any softwood species with a specific gravity of 0.42 or greater. Steel furring shall be minimum 33 ksi steel. Steel studs shall be minimum 33 ksi steel for 33mil and 43 mil thickness, and 50 ksi steel for 54 mil steel or thicker.

b. Screws shall comply with the requirements of ASTM C1513.

c. Where the required cladding fastener penetration into wood material exceeds $\frac{3}{4}$ inch and is not more than $1\frac{1}{2}$ inches, a minimum 2-inch nominal wood furring or an approved design shall be used.

d. Foam sheathing shall have a minimum compressive strength of 15 psi in accordance with ASTM C578 or ASTM C1289.

e. Furring shall be spaced not more than 24 inches (610 mm) on center, in a vertical or horizontal orientation. In a vertical orientation, furring shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, the indicated 8-inch and 12-inch fastener spacing in furring shall be achieved by use of two fasteners into studs at 16 inches and 24 inches on center, respectively.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

- ASTM C557–03 (2009)e01, *Specification for Adhesives for Fastening Gypsum Wallboard to Wood Framing*. West Conshohocken, PA: ASTM International, 2009.

Chapter 8: Roof-ceiling Construction

General Comments

Section R801 establishes the scope of the chapter as well as performance requirements for roof and ceiling construction. There are two types of roof-ceiling framing systems: wood framing and cold-formed steel framing. Section R802 addresses wood roof and ceiling framing, while Section R804 deals with cold-formed steel roof and ceiling framing. Section R803 specifies requirements for roof sheathing to be used with either of these framing systems. Other topics covered in this chapter are the application of ceiling finishes in Section R805, the proper ventilation of concealed spaces in roofs (e.g., enclosed attics and enclosed rafter spaces) and unvented attics and rafter spaces in Section R806, and the “access into attic” criteria in Section R807.

Purpose

Chapter 8 regulates the design and construction of roof-ceiling systems. Proper roof-member design provides

for the support of the required design live and snow loads as well as providing for the transfer of these loads to supporting walls. Attics must be identified as “no storage” or “limited storage” zones so that ceiling joists can be appropriately sized. Allowable span tables are provided to simplify the selection of rafter and ceiling joist size for wood roof framing and cold-formed steel framing.

Roof systems must resist wind uplift, and tiedowns must be installed when necessary. Also, a roof system composed of sheathing fastened to either wood or cold-formed steel framing serves as a diaphragm, which is a key lateral load path element in resisting the forces of wind and earthquakes.

Chapter 8 also provides requirements for the application of ceiling finishes, the proper ventilation of concealed spaces in roofs (e.g., enclosed attics and enclosed rafter spaces), unvented attics and rafter spaces and attic access.

SECTION R801 GENERAL

R801.1 Application. The provisions of this chapter shall control the design and construction of the roof-ceiling system for buildings.

- ❖ The provisions of Chapter 8 address conventionally framed roof-ceiling construction.

R801.2 Requirements. Roof and ceiling construction shall be capable of accommodating all loads imposed in accordance with Section R301 and of transmitting the resulting loads to the supporting structural elements.

- ❖ This section states the performance expectations for roof and ceiling construction.

R801.3 Roof drainage. In areas where expansive or collapsible soils are known to exist, all *dwelling*s shall have a controlled method of water disposal from roofs that will collect and discharge roof drainage to the ground surface not less than 5 feet (1524 mm) from foundation walls or to an *approved* drainage system.

- ❖ Saturated expansive or collapsible soils can lead to foundation failures because their additional loads are imposed on the foundation wall. To minimize the potential for the soil adjacent to the foundation wall to become saturated by roof drainage, the code requires that the roofs drain 5 feet (1524 mm) from the foundation. This requirement applies to foundation walls only

and does not apply to slab-on-grade foundations.

Although this section is specific to discharging the roof drainage away from foundation walls, discharging the roof drainage away from other types of foundations, such as slab-on-grade on expansive or collapsible soil, may need consideration. Industry standards and/or the engineered design for other types of foundations may also require roof drainage.

SECTION R802 WOOD ROOF FRAMING

R802.1 General. Wood and wood-based products used for load-supporting purposes shall conform to the applicable provisions of this section.

- ❖ Sections R802.1.1 through R802.1.7 contain the prescriptive requirements for wood and wood-based products used in wood roof framing.

R802.1.1 Sawn lumber. Sawn lumber shall be identified by a grade mark of an accredited lumber grading or inspection agency and have design values certified by an accreditation body that complies with DOC PS 20. In lieu of a grade mark, a certificate of inspection issued by a lumber grading or inspection agency meeting the requirements of this section shall be accepted.

- ❖ See the commentaries to Section R502.1.1 and Figure R502.1.

R802.1.1.1 End-jointed lumber. *Approved* end-jointed lumber identified by a grade mark conforming to Section R802.1.1 shall be permitted to be used interchangeably with solid-sawn members of the same species and grade. End-jointed lumber used in an assembly required elsewhere in this code to have a fire-resistance rating shall have the designation “Heat-Resistant Adhesive” or “HRA” included in its grade mark.

❖ See the commentary to Section R502.1.1.2.

R802.1.2 Structural glued laminated timbers. Glued laminated timbers shall be manufactured and identified as required in ANSI/AITC A190.1 and ASTM D3737.

❖ This section states that glulam timbers must be manufactured following ANSI/AITC A190.1 and ASTM D3737. Knowing the standard these products must meet makes it easier to determine that the product found in the field will meet the design requirements.

R802.1.3 Structural log members. Structural log members shall comply with the provisions of ICC 400.

❖ The material requirements for structural logs, such as stress grading, grade mark or Certificate of Inspection, must be in accordance with ICC 400, *Standard on the Design and Construction of Log Structures*.

R802.1.4 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

❖ See the commentary to Section R502.1.5.

R802.1.5 Fire-retardant-treated wood. Fire-retardant-treated wood (FRTW) is any wood product that, when impregnated with chemicals by a pressure process or other means during manufacture, shall have, when tested in accordance with ASTM E84 or UL 723, a listed flame spread index of 25 or less and shows no evidence of significant progressive combustion where the test is continued for an additional 20-minute period. In addition, the flame front shall not progress more than 10.5 feet (3200 mm) beyond the center line of the burners at any time during the test.

❖ Fire-retardant-treated wood (FRTW) is plywood and lumber that has been pressure impregnated with chemicals to improve its flame spread characteristics beyond those of untreated wood. The effectiveness of the pressure-impregnated fire-retardant treatment is determined by subjecting the material to tests conducted in accordance with ASTM E84 or UL 723, with the modification that the test is extended to 30 minutes rather than 15 minutes. Using this procedure, a flame spread index is established during the standard 10-minute test period. The test is continued for an additional 20 minutes. During this added time period, there must not be any significant flame spread. At no time must the flame spread more than 10¹/₂ feet (3200 mm) past the centerline of the burners.

The result of impregnating wood with fire-retardant chemicals is a chemical reaction at certain temperature ranges. This reaction reduces the release of certain intermediate products that contribute to the flaming of wood, and the reaction also results in the

formation of a greater percentage of charcoal and water. Some chemicals are effective in reducing the oxidation rate for charcoal residue. Fire-retardant chemicals also reduce the heat release rate of FRTW when it is burning over a wide range of temperatures. This section gives provisions for the treatment and use of FRTW.

R802.1.5.1 Pressure process. For wood products impregnated with chemicals by a pressure process, the process shall be performed in closed vessels under pressures not less than 50 pounds per square inch gauge (psig) (344.7 kPa).

❖ This section elaborates on the requirements of treatment using a pressure process.

R802.1.5.2 Other means during manufacture. For wood products produced by other means during manufacture the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product.

❖ This section elaborates on the requirements of treatment using other means during manufacture.

R802.1.5.3 Testing. For wood products produced by other means during manufacture, other than a pressure process, all sides of the wood product shall be tested in accordance with and produce the results required in Section R802.1.5. Testing of only the front and back faces of wood structural panels shall be permitted.

❖ This section provides for added testing of wood products with treatments that are not impregnated by a pressure process. Requiring equivalent performance from all sides of the wood product eliminates any concern over the orientation when it is installed.

R802.1.5.4 Labeling. Fire-retardant-treated lumber and wood structural panels shall be *labeled*. The *label* shall contain:

1. The identification *mark* of an *approved agency* in accordance with Section 1703.5 of the *International Building Code*.
2. Identification of the treating manufacturer.
3. The name of the fire-retardant treatment.
4. The species of wood treated.
5. Flame spread index and smoke-developed index.
6. Method of drying after treatment.
7. Conformance to applicable standards in accordance with Sections R802.1.5.5 through R802.1.5.10.
8. For FRTW exposed to weather, or a damp or wet location, the words “No increase in the listed classification when subjected to the Standard Rain Test” (ASTM D2898).

❖ For continued quality, each piece of fire-retardant-treated wood must be identified by an approved agency having a reinspection service. The identification must show the performance rating of the material, including the 30-minute ASTM E84 or UL 723 test results determined in Section R802.1.5 and the design adjustment values determined in Section R802.1.5.5.

The third-party agency that provides the FRTW label is also required to state on the label that the FRTW complies with the requirements of Section R802.1.5 and that design adjustment values have been determined for the FRTW in compliance with the provisions of Section R802.1.5.5.

The FRTW label must be distinct from the grading label to avoid confusion between the two. The grading label provides information about the properties of wood before it is fire-retardant treated; the FRTW label shows properties of the wood after FRTW treatment. It is imperative that the FRTW label be presented in a manner that complements the grading label and does not create confusion over which label takes precedence.

R802.1.5.5 Strength adjustments. Design values for untreated lumber and wood structural panels as specified in Section R802.1 shall be adjusted for fire-retardant-treated wood. Adjustments to design values shall be based upon an *approved* method of investigation that takes into consideration the effects of the anticipated temperature and humidity to which the fire-retardant-treated wood will be subjected, the type of treatment and redrying procedures.

- ❖ Experience has shown that certain factors can affect the physical properties of FRTW. Among these factors are the pressure treatment and redrying processes used and the extremes of temperature and humidity that the FRTW will be subjected to once installed. The design values for all FRTW must be adjusted for the effects of the treatment and environmental conditions, such as high temperature and humidity in attic installations. This section requires the determination of these design adjustment values, based on an investigation procedure that includes subjecting the FRTW to similar temperatures and humidities and that has been approved by the code official. The FRTW tested must be identical to that which is produced. Items to be considered by the code official reviewing the test procedure include species and grade of the untreated wood and conditioning of the wood, such as drying before the fire-retardant treatment process. A fire-retardant wood treater may choose to have its treatment process evaluated by model code evaluation services.

The FRTW is required by Section R802.1.5.4 to be labeled with the design adjustment values. These can take the form of factors that are multiplied by the original design values of the untreated wood to determine its allowable stresses or new allowable stresses that have already been factored down in consideration of the FRTW treatment.

R802.1.5.6 Wood structural panels. The effect of treatment and the method of redrying after treatment, and exposure to high temperatures and high humidities on the flexure properties of fire-retardant-treated softwood plywood shall be determined in accordance with ASTM D5516. The test data developed by ASTM D5516 shall be used to develop adjustment factors, maximum loads and spans, or both for untreated plywood design values in accordance with ASTM D6305. Each manufacturer shall publish the allowable maximum

loads and spans for service as floor and roof sheathing for their treatment.

- ❖ This section references the test standard developed to evaluate the flexural properties of fire-retardant-treated plywood that is exposed to high temperatures. Note that while the section title refers to wood structural panels, the standard is specifically for softwood plywood. Therefore, judgment is required in determining the effects of elevated temperature and humidity on other types of wood structural panels.

R802.1.5.7 Lumber. For each species of wood treated, the effect of the treatment and the method of redrying after treatment and exposure to high temperatures and high humidities on the allowable design properties of fire-retardant-treated lumber shall be determined in accordance with ASTM D5664. The test data developed by ASTM D5664 shall be used to develop modification factors for use at or near room temperature and at elevated temperatures and humidity in accordance with ASTM D6841. Each manufacturer shall publish the modification factors for service at temperatures of not less than 80°F (27°C) and for roof framing. The roof framing modification factors shall take into consideration the climatological location.

- ❖ This section references the test standards developed to determine the necessary adjustments to design values for lumber that has been fire-retardant treated and includes the effects of elevated temperatures and humidity.

R802.1.5.8 Exposure to weather. Where fire-retardant-treated wood is exposed to weather or damp or wet locations, it shall be identified as “Exterior” to indicate there is not an increase in the listed flame spread index as defined in Section R802.1.5 when subjected to ASTM D2898.

- ❖ Some fire-retardant treatments are soluble when exposed to the weather or used under high-humidity conditions. The humidity threshold established for interior applications in Section R802.1.5.9 is 92 percent. Therefore, FRTW used in an interior location that will exceed this threshold must comply with this section. When an FRTW product is to be exposed to any of the conditions noted in this section, it must be further tested in accordance with ASTM D2898. Testing requires the material to meet the performance criteria listed in Section R802.1.5. The material is then subjected to the ASTM weathering test and retested after drying. There must not be any significant differences in the performance recorded before and after the weathering test.

R802.1.5.9 Interior applications. Interior fire-retardant-treated wood shall have a moisture content of not over 28 percent when tested in accordance with ASTM D3201 procedures at 92-percent relative humidity. Interior fire-retardant-treated wood shall be tested in accordance with Section R802.1.5.6 or R802.1.5.7. Interior fire-retardant-treated wood designated as Type A shall be tested in accordance with the provisions of this section.

- ❖ The environment in which the FRTW is used can affect its performance. To make sure that performance will

ROOF-CEILING CONSTRUCTION

be adequate in a humid interior condition, testing in accordance with ASTM D3201 as well as testing specified in Section R802.1.5.6 or R802.1.5.7 is required for all interior wood. Requiring all interior wood to be tested for the effects of high temperature and humidity reduces the chance of a premature failure resulting from improper use of FRTW.

R802.1.5.10 Moisture content. Fire-retardant-treated wood shall be dried to a moisture content of 19 percent or less for lumber and 15 percent or less for wood structural panels before use. For wood kiln dried after treatment (KDAT) the kiln temperatures shall not exceed those used in kiln drying the lumber and plywood submitted for the tests described in Section R802.1.5.6 for plywood and R802.1.5.7 for lumber.

❖ These moisture content thresholds are necessary to prevent leaching of the fire retardant from the wood. Section R802.1.5.5 requires that the strength adjustments consider the redrying procedure, and this section clarifies that the drying temperatures for wood kiln dried after treatment must be consistent with those on which the adjustment factors were based.

R802.1.6 Cross-laminated timber. Cross-laminated timber shall be manufactured and identified as required by ANSI/APA PRG 320.

❖ Cross-laminated timber (CLT) was first developed in Europe nearly 20 years ago, where it has been used extensively. It is generally analogous to large section members currently associated with heavy timber. Although the primary use is for nonresidential construction, it's currently being used in some residential applications. As a new product in North America, ANSI/APA PRG 320 provides a consensus manufacturing standard for CLT.

R802.1.7 Engineered wood rim board. Engineered wood rim boards shall conform to ANSI/APA PRR 410 or shall be evaluated in accordance with ASTM D7672. Structural capacities shall be in accordance with ANSI/APA PRR 410 or established in accordance with ASTM D7672. Rim boards conforming to ANSI/APA PRR 410 shall be marked in accordance with that standard.

❖ Engineered rim board is a key structural element in wood floor construction where both structural load path through the perimeter member and dimensional change compatibility are design considerations. Both ANSI/APA PRR 410 and ASTM D7672 address the fundamental requirements for testing and evaluation of engineered rim board. PRR 410 also includes performance categories for engineered wood products used in engineered rim board applications. Under PRR 410, products are assigned a grade based on performance category (e.g., categories based on structural capacity) and will bear a mark in accordance with the grade. In contrast, ASTM D7672 is applicable for determination of product-specific rim board performance (i.e., structural capacities) for engineered wood products that may be recognized in manufacturers' literature or product evaluation reports.

R802.2 Design and construction. The framing details required in Section R802 apply to roofs having a minimum slope of three units vertical in 12 units horizontal (25-percent slope) or greater. Roof-ceilings shall be designed and constructed in accordance with the provisions of this chapter and Figures R606.11(1), R606.11(2) and R606.11(3) or in accordance with AWC NDS. Components of roof-ceilings shall be fastened in accordance with Table R602.3(1).

❖ The prescriptive framing requirements of Section R802 apply only to roofs having a minimum slope of 3 units vertical in 12 units horizontal (25-percent slope). Wood roof-ceiling construction must comply with Section R802 or AWC NDS, *National Design Specification for Wood Construction*. The references to Chapter 6 figures are meant for buildings using masonry wall construction.

R802.3 Framing details. Rafters shall be framed not more than 1½-inches (38 mm) offset from each other to ridge board or directly opposite from each other with a gusset plate as a tie. Ridge board shall be not less than 1-inch (25 mm) nominal thickness and not less in depth than the cut end of the rafter. At valleys and hips there shall be a valley or hip rafter not less than 2-inch (51 mm) nominal thickness and not less in depth than the cut end of the rafter. Hip and valley rafters shall be supported at the ridge by a brace to a bearing partition or be designed to carry and distribute the specific load at that point. Where the roof pitch is less than three units vertical in 12 units horizontal (25-percent slope), structural members that support rafters and ceiling joists, such as ridge beams, hips and valleys, shall be designed as beams.

❖ Traditional practice is to provide a ridgeboard between opposite rafters as a nailing base and to provide a full bearing for the rafter. Rafters must be placed directly opposite each other, with an offset tolerance of 1½ inches, and the ridgeboard must have a depth equal to the end of the rafter as illustrated in Commentary Figure R802.3(1). Commentary Figure R802.3(2) shows an option for framing opposing rafters using a gusset plate.

R802.3.1 Ceiling joist and rafter connections. Ceiling joists and rafters shall be nailed to each other in accordance with Table R802.5.1(9), and the rafter shall be nailed to the top wall plate in accordance with Table R602.3(1). Ceiling joists shall be continuous or securely joined in accordance with Table R802.5.1(9) where they meet over interior partitions and are nailed to adjacent rafters to provide a continuous tie across the building where such joists are parallel to the rafters.

Where ceiling joists are not connected to the rafters at the top wall plate, joists connected higher in the *attic* shall be installed as rafter ties, or rafter ties shall be installed to provide a continuous tie. Where ceiling joists are not parallel to rafters, rafter ties shall be installed. Rafter ties shall be not less than 2 inches by 4 inches (51 mm by 102 mm) (nominal), installed in accordance with the connection requirements in Table R802.5.1(9), or connections of equivalent capacities shall be provided. Where ceiling joists or rafter ties are not provided, the ridge formed by these rafters shall be supported by a wall or girder designed in accordance with accepted engineering practice.

Collar ties or ridge straps to resist wind uplift shall be connected in the upper third of the *attic* space in accordance with Table R602.3(1).

Collar ties shall be not less than 1 inch by 4 inches (25 mm by 102 mm) (nominal), spaced not more than 4 feet (1219 mm) on center.

❖ The requirements of this section describe connections to resist horizontal thrust from gravity loads and ridge uplift from wind loads. Ceiling joists or rafter ties are the framing members used to resist the horizontal thrust from gravity loads. A ceiling joist or rafter tie is required at every rafter. Collar ties or ridge straps are used to resist the ridge uplift caused by the wind load. Collar ties or ridge straps must be spaced not further than every 4 feet (1219 mm) on center.

Ceiling joists located at the top plate and parallel to the rafters must be connected as shown in Commentary Figure R802.3.1(1). The connection must be in

accordance with Table R802.5.1(9).

Ceiling joists located at the top plate and parallel to the rafters must be continuous or lap joined as shown in Commentary Figures R802.3.1(3) and R802.3.2(1). The lap splice connection must be in accordance with Table R802.5.1(9), Note e.

Where ceiling joists or rafter ties are located above the top plate or the ceiling joists are not parallel to the rafters, as shown in Commentary Figure R802.3.1(2), the connections must be in accordance with Table R802.5.1(9).

Cathedral ceilings (where ceiling joists or rafter ties are not installed) must be designed so the wall or ridge beam carries the full load of the roof. This would require the walls to be supported by a continuous foundation and/or beams and girders. The ridge beam must

also be capable of supporting the full load exerted by the tributary area of the rafters. The ridge beam must be stiff enough to minimize the deflection from the rafter loads so that rafter thrust does not displace the walls.

Collar ties or ridge straps must be located in the upper one-third of the attic space, be a minimum of 1 inch by 4 inches (25 mm by 102 mm), be spaced not more than 4 feet (1219 mm) on center and connected in accordance with Table R602.3(1). The minimum prescriptive connections in Table R602.3(1) for collar ties and ridge straps apply to roofs having a minimum slope of 3:12, a maximum wind speed of 100 mph and a maximum roof span of 36 feet. The minimum prescriptive connections were determined using the 2001 *Wood Frame Construction Manual* [see Commentary Figures R802.3.1(2) and R802.3.1(3)].

R802.3.2 Ceiling joists lapped. Ends of ceiling joists shall be lapped not less than 3 inches (76 mm) or butted over bearing partitions or beams and toenailed to the bearing member. Where ceiling joists are used to provide resistance to rafter

thrust, lapped joists shall be nailed together in accordance with Table R802.5.1(9) and butted joists shall be tied together in a manner to resist such thrust. Joists that do not resist thrust shall be permitted to be nailed in accordance with Table R602.3(1).

❖ Where ceiling joists function as a structural element, providing resistance to rafter thrust, proper connection through a lapped joint or butted joint connection to form a continuous tie is required [see Commentary Figures R802.3.2(1) and R802.3.2(2)].

The lap splice nailing of Table R602.3(1) applies only if the ceiling joist is not attached to parallel rafters. For a ceiling joist attached parallel to the rafter, the connection must be in accordance with Note e of Table R802.5.1(9) (see commentary, Section R802.3.1).

R802.3.3 Blocking. Blocking shall be a minimum of utility grade lumber.

❖ Because blocking is a less demanding task than load carrying, the code permits the use of utility-grade lumber.

R802.4 Allowable ceiling joist spans. Spans for ceiling joists shall be in accordance with Tables R802.4(1) and R802.4(2). For other grades and species and for other loading conditions, refer to the AWC STJR.

❖ Tables R802.4(1) and R802.4(2) list allowable ceiling joist spans for common lumber sizes, species and grades based on spacing and design loads. The span tables have been updated from the 2012 *International Residential Code*® (IRC®) to account for changes in design values for Douglas fir-larch, Hem-fir and Southern pine (see the commentary to Section R802.5). The tables provide ceiling joist spans for live loads of 10 and 20 pounds per square foot (psf) (479 Pa and 958 Pa) and dead loads of 5 and 10 psf (239 and 479 Pa). The weight of the ceiling joist is included in the 5 or 10 psf (239 or 479 Pa) dead load.

The dead load of the combined roof and ceiling assemblies must not exceed 15 psf (718.2 Pa) for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁ and D₂. Section R301.2.2.2.1 provides an exception for exceeding the 15 psf restriction (see commentary, Section R301.2.2.2.1).

R802.5 Allowable rafter spans. Spans for rafters shall be in accordance with Tables R802.5.1(1) through R802.5.1(8). For other grades and species and for other loading conditions, refer to the AWC STJR. The span of each rafter shall be measured along the horizontal projection of the rafter.

❖ Tables R802.5.1(1) through R802.5.1(8) list allowable rafter spans for common lumber sizes, species and grades based on spacing and design loads. The span tables have been updated from the 2012 IRC to account for changes in design values for Douglas fir-larch, Hem-fir and Southern pine. The allowable spans for some grades of Southern pine have been reduced from that in the 2012 IRC. The allowable spans for some grades of Douglas fir-larch and Hem-fir have been increased from that in the 2012 IRC.

The reduced design values for visually-graded Southern pine lumber were approved by the American Lumber Standards Committee (ALSC) in 2013. Values are a result of 2 years of testing current lumber available on the market to identify what changes had occurred in the strength of the Southern pine lumber inventory.

Although the increased design values for Douglas fir-larch and Hem-fir were approved in the 1990s, the values were never incorporated into the *International Building Code*® (IBC®) and IRC allowable span tables. Recent testing of current stock has validated the 1990s values.

The 2015 IRC span tables are now in agreement with the wood standards' span tables with the revisions for Southern pine, Douglas fir-larch and Hemlock fir. The new design values apply only to new construction. The integrity of existing structures designed and built using design values meeting the applicable building codes in effect at the time of permitting does not change.

Tables R802.5.1(3) through R802.5.1(8) are based on ground snow loads of 30 psf (1.44 kPa), 50 psf (2.39 kPa) and 70 psf (3.35 kPa). The snow loads are based on ASCE 7-95 criteria as follows:

a. for balanced condition:

$$p_s = C_s \times p_f$$

$$\text{where } p_f = 0.7 C_e \times C_t \times C_s \times p_g$$

$$C_s = 1.0$$

$$C_e = 1.0$$

$$C_t = 1.1$$

$$\text{Thus } p_s = 0.77 \times p_g$$

b. for unbalanced condition:

$$p_s = 1.3 (C_s p_f) / C_e$$

$$\text{where } p_f = 0.7 C_e \times C_t \times p_g$$

$$C_s = 1.0$$

$$C_e = 1.0$$

$$C_t = 1.1$$

$$\text{Thus } p_s = 1.00 \times p_g$$

The unbalanced condition controls. By inspection, the unbalanced condition is equal to the ground snow load.

Tables R802.5.1(1) through R802.5.1(8) provide rafter spans for dead loads of 10 and 20 psf (479 Pa and 958 Pa). The weight of the rafter is included in the 10 or 20 psf (479 Pa or 958 Pa) dead load.

The dead load of the combined roof and ceiling assemblies must not exceed 15 psf (718 Pa) for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁ and D₂. Section R301.2.2.2.1 provides an exception for exceeding the 15 psf (718 Pa) restriction (see commentary, Section R301.2.2.2.1).

Example 1 in the commentary for Table R802.5.1(1) explains the allowable spans for clear-span roof rafters using the code tables. As illustrated in Figure R802.5.1, the horizontal projection of the rafter must be used for the span length rather than using the true length of the rafter measured along the slope of the roof.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Span exceeds 26 feet in length.

R802.5.1 Purlins. Installation of purlins to reduce the span of rafters is permitted as shown in Figure R802.5.1. Purlins shall be sized not less than the required size of the rafters that they support. Purlins shall be continuous and shall be supported by 2-inch by 4-inch (51 mm by 102 mm) braces installed to bearing walls at a slope not less than 45 degrees (0.79 rad) from the horizontal. The braces shall be spaced not more than 4 feet (1219 mm) on center and the unbraced length of braces shall not exceed 8 feet (2438 mm).

❖ This section contains specific instructions for the installation of purlins that will provide intermediate support for the rafters and thus reduce the rafter span. The purlins must be at least the same size as the rafters that they support. The rafters must bear on the purlin to provide proper support for the rafters. See Commentary Figure R802.5.1(1) for an example of typical installation of purlins. Example 2 in the commentary for Table R802.5.1(1) shows the effect on rafter design and roof purlin requirements when braces to interior bearing walls support the roof purlins.

TABLE R802.5.1(1). See page 8-15.

❖ Adjustment factors, listed in Note a of rafter span Tables R802.5(1-8), are limited to cases where the ceiling

joists or rafter ties are in the lower third of the attic space. When the ceiling joist or rafter ties are located higher in the attic space, lateral deflection of the rafter below the rafter ties can become excessive and require additional engineering analysis. The following examples assume that the ceiling joists are located at the top plate.

Example 1:

You wish to design a rafter system using Douglas fir-larch #2 lumber for a 20 psf (958 Pa) live load, with rafters spaced 24 inches (610 mm) on center and having a horizontal projection of the rafter span of 14 feet, 6 inches (4420 mm). The rafters do not support a ceiling, and the roof slope is 3 units vertical in 12 units horizontal. Assume the roof dead load is 10 psf (479 Pa).

Solution:

The object is to locate a tabulated span value of 14 feet, 6 inches (4420 mm) or more. Going to Table R802.5.1(1) under the portion headed "DEAD LOAD = 10 psf," note that 2-inch by 8-inch (51 mm by 208 mm) rafters at 24 inches (610 mm) on center will span 15 feet, 1 inch (4521 mm).

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 degree = 0.018 rad.

Note: Where ceiling joists run perpendicular to the rafter, rafter ties shall be installed in accordance with Section R802.3.1.

H_C = Height of ceiling joists or rafter ties measured vertically above the top of rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

FIGURE R802.5.1
BRACED RAFTER CONSTRUCTION

Figure R802.5.1(1)
EXAMPLE OF PURLIN INSTALLATION

Example 2:

To find a substitute for the 2-inch by 8-inch (51 mm by 208 mm) rafters of Example 1, determine the required rafter size for a condition that uses a purlin and 2-inch by 4-inch (51 mm by 102 mm) braces (located at mid span of the rafters) at 4 feet (1219 mm) on center as depicted in Figure R802.5.1. Assume the same loads, rafter spacing, and 14-foot, 6-inch (4420 mm) horizontal rafter projection. Between the exterior wall and ridge, use Hem-fir #3 lumber.

Solution:

The rafter span, identified in Figure R802.5.1, is reduced to 7 feet, 3 inches (2210 mm) by adding the purlin at mid span. In Table R802.5.1(1), 2-inch by 6-inch (51 mm by 152 mm) rafters at 24 inches (610 mm) on center will span 8 feet, 10 inches (2692 mm).

TABLE R802.5.1(9). See page 8-31.

- ❖ This table contains requirements for the connection between roof rafters and ceiling joists to be used in areas with ground snow loads of 20 psf (1.44 kPa) up to 70 psf (3.35 kPa). The connection is essential to resist the thrust in the roof rafter where the ridge board does not provide vertical support of the roof rafter. Section R802.3 requires a designed ridge beam if the roof slope is less than 3:12. The 20 psf (1.44 kPa) ground snow load connection must also be used where the minimum roof live load is 20 psf (1.44 kPa) or less. See Note g of this table. Adjustment factors for the heel joint connection in Note h are limited to cases where the ceiling joists or rafter ties are in the lower third of the attic space. When the ceiling joists or rafter ties are located higher in the attic space, lateral deflection of the rafter below the rafter ties can become excessive and require additional engineering analysis (see commentary, Section R802.3.1).

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

b. Span exceeds 26 feet in length.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

b. Span exceeds 26 feet in length.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

b. Span exceeds 26 feet in length.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

b. Span exceeds 26 feet in length.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

b. Span exceeds 26 feet in length.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

Check sources for availability of lumber in lengths greater than 20 feet.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. The tabulated rafter spans assume that ceiling joists are located at the bottom of the attic space or that some other method of resisting the outward push of the rafters on the bearing walls, such as rafter ties, is provided at that location. Where ceiling joists or rafter ties are located higher in the attic space, the rafter spans shall be multiplied by the following factors:

H_C/H_R	Rafter Span Adjustment Factor
1/3	0.67
1/4	0.76
1/5	0.83
1/6	0.90
1/7.5 or less	1.00

where:

H_C = Height of ceiling joists or rafter ties measured vertically above the top of the rafter support walls.

H_R = Height of roof ridge measured vertically above the top of the rafter support walls.

TABLE R802.5.1(9)

	24	3	4	6	7	3	4	6	7	3	6	8	10	4	7	10	13
12:12	12	3	3	3	3	3	3	3	3	3	3	3	4	3	3	4	5
	16	3	3	4	4	3	3	3	4	3	3	4	5	3	4	5	7
	24	3	4	4	5	3	3	4	6	3	4	6	8	3	6	8	10

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- a. 40d box nails shall be permitted to be substituted for 16d common nails.
- b. Nailing requirements shall be permitted to be reduced 25 percent if nails are clinched.
- c. Heel joint connections are not required where the ridge is supported by a load-bearing wall, header or ridge beam.
- d. Where intermediate support of the rafter is provided by vertical struts or purlins to a load-bearing wall, the tabulated heel joint connection requirements shall be permitted to be reduced proportionally to the reduction in span.
- e. Equivalent nailing patterns are required for ceiling joist to ceiling joist lap splices.
- f. Where rafter ties are substituted for ceiling joists, the heel joint connection requirement shall be taken as the tabulated heel joint connection requirement for two-thirds of the actual rafter slope.
- g. Applies to roof live load of 20 psf or less.
- h. Tabulated heel joint connection requirements assume that ceiling joists or rafter ties are located at the bottom of the attic space. Where ceiling joists or rafter ties are located higher in the attic, heel joint connection requirements shall be increased by the following factors:

H_C/H_R	Heel Joint Connection Adjustment Factor
1/3	1.5
1/4	1.33
1/5	1.25
1/6	1.2
1/10 or less	1.11

ROOF-CEILING CONSTRUCTION

R802.6 Bearing. The ends of each rafter or ceiling joist shall have not less than 1½ inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on masonry or concrete. The bearing on masonry or concrete shall be direct, or a sill plate of 2-inch (51 mm) minimum nominal thickness shall be provided under the rafter or ceiling joist. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 mm²).

❖ The requirements for roof rafters and ceiling joists bearing on wood, metal and masonry are similar to the requirements for floor joists. See the commentary to Section R502.6 relative to the bearing requirements for wood, metal and masonry.

R802.6.1 Finished ceiling material. If the finished ceiling material is installed on the ceiling prior to the attachment of the ceiling to the walls, such as in construction at a factory, a compression strip of the same thickness as the finished ceiling material shall be installed directly above the top plate of bearing walls if the compressive strength of the finished ceiling material is less than the loads it will be required to withstand. The compression strip shall cover the entire length of such top plate and shall be not less than one-half the width of the top plate. It shall be of material capable of transmitting the loads transferred through it.

❖ In prefabricated (panelized) construction where the finished ceiling material is attached to the roof assembly before it is attached to the walls, care must be taken to provide a compression strip to line up with the top plate of the supporting walls in order to have an adequate bearing surface.

R802.7 Cutting, drilling and notching. Structural roof members shall not be cut, bored or notched in excess of the limitations specified in this section.

❖ The limitations on cutting and notching roof rafters and ceiling joists are similar to those for cutting and notching floor joists (see commentary, Section R502.8).

R802.7.1 Sawn lumber. Cuts, notches and holes in solid lumber joists, rafters, blocking and beams shall comply with the provisions of Section R502.8.1 except that cantilevered portions of rafters shall be permitted in accordance with Section R802.7.1.1.

❖ Figure R502.8 illustrates cutting and notching limitations. The tension side of a member 4 inches (102 mm) or more in thickness can be notched only at the ends (also see commentary, Section R502.8).

R802.7.1.1 Cantilevered portions of rafters. Notches on cantilevered portions of rafters are permitted provided the dimension of the remaining portion of the rafter is not less than 3½ inches (89 mm) and the length of the cantilever does not exceed 24 inches (610 mm) in accordance with Figure R802.7.1.1.

❖ Where a cantilevered rafter is notched at the top plate, the rafter must have a minimum depth at the notch of 3½ inches (89 mm), as shown in Figure R802.7.1.1.

R802.7.1.2 Ceiling joist taper cut. Taper cuts at the ends of the ceiling joist shall not exceed one-fourth the depth of the member in accordance with Figure R802.7.1.2.

❖ The depth of the taper at the ends of ceiling joists is measured at the inside face of the support, as shown in Figure R802.7.1.2.

For SI: 1 inch = 25.4 mm.

**FIGURE R802.7.1.1
RAFTER NOTCH**

R802.7.2 Engineered wood products. Cuts, notches and holes bored in trusses, structural composite lumber, structural glue-laminated members, cross-laminated timber members or I-joists are prohibited except where permitted by the manufacturer's recommendations or where the effects of such alterations are specifically considered in the design of the member by a registered design professional.

❖ The cutting and notching limitations for sawn lumber do not apply to engineered wood products. Structural composite lumber is a generic term that encompasses a variety of engineered composite wood products, including laminated veneer lumber (LVL). Also included in the term are laminated strand lumber (LSL), parallel strand lumber (PSL) and oriented strand lumber (OSL). The prohibitions in this section apply to all of these products.

Engineered wood products must not be cut, notched or bored unless those alterations are considered in the design of the member. That consideration is to be made either by the manufacturer and reflected in use recommendations (which is common in I-joists, permitting some limited alterations to webs) or by a registered design professional.

R802.8 Lateral support. Roof framing members and ceiling joists having a depth-to-thickness ratio exceeding 5 to 1 based on nominal dimensions shall be provided with lateral support at points of bearing to prevent rotation. For roof rafters with ceiling joists attached in accordance with Table R602.3(1), the depth-to-thickness ratio for the total assembly shall be determined using the combined thickness of the rafter plus the attached ceiling joist.

Exception: Roof trusses shall be braced in accordance with Section R802.10.3.

❖ Rafters and ceiling joists must be laterally supported to prevent twisting at the supports. See the commentary to Section R802.10.3 for bracing for roof trusses.

R802.8.1 Bridging. Rafters and ceiling joists having a depth-to-thickness ratio exceeding 6 to 1 based on nominal dimensions shall be supported laterally by solid blocking, diagonal bridging (wood or metal) or a continuous 1-inch by 3-inch (25 mm by 76 mm) wood strip nailed across the rafters or ceiling joists at intervals not exceeding 8 feet (2438 mm).

❖ Bridging must be installed for rafters and ceiling joists. This is similar to the requirements for floor joists in Section R502.7.1.

R802.9 Framing of openings. Openings in roof and ceiling framing shall be framed with header and trimmer joists. Where the header joist span does not exceed 4 feet (1219 mm), the header joist shall be permitted to be a single member the same size as the ceiling joist or rafter. Single trimmer joists shall be permitted to be used to carry a single header joist that is located within 3 feet (914 mm) of the trimmer joist bearing. Where the header joist span exceeds 4 feet (1219 mm), the trimmer joists and the header joist shall be doubled and of sufficient cross section to support the ceiling joists or rafter framing into the header. *Approved* hangers shall be used for the header joist to trimmer joist connections where the header joist span exceeds 6 feet (1829 mm). Tail joists over 12 feet (3658 mm) long shall be supported at the header by framing anchors or on ledger strips not less than 2 inches by 2 inches (51 mm by 51 mm).

❖ Requirements for framing at roof openings are similar to those of Section R502.10 for floor openings.

FIGURE R802.7.1.2
CEILING JOIST TAPER CUT

R802.10 Wood trusses.

R802.10.1 Truss design drawings. Truss design drawings, prepared in conformance to Section R802.10.1, shall be provided to the *building official* and *approved* prior to installation. Truss design drawings shall be provided with the shipment of trusses delivered to the job site. Truss design drawings shall include, at a minimum, the following information:

1. Slope or depth, span and spacing.
2. Location of all joints.
3. Required bearing widths.
4. Design loads as applicable.
 - 4.1. Top chord live load (as determined from Section R301.6).
 - 4.2. Top chord dead load.
 - 4.3. Bottom chord live load.
 - 4.4. Bottom chord dead load.
 - 4.5. Concentrated loads and their points of application.
 - 4.6. Controlling wind and earthquake loads.
5. Adjustments to lumber and joint connector design values for conditions of use.
6. Each reaction force and direction.
7. Joint connector type and description such as size, thickness or gage and the dimensioned location of each joint connector except where symmetrically located relative to the joint interface.
8. Lumber size, species and *grade for each member*.
9. Connection requirements for:
 - 9.1. Truss to girder-truss.
 - 9.2. Truss ply to ply.
 - 9.3. Field splices.
10. Calculated deflection ratio and/or maximum description for live and total load.
11. Maximum axial compression forces in the truss members to enable the building designer to design the size, connections and anchorage of the permanent continuous lateral bracing. Forces shall be shown on the truss design drawing or on supplemental documents.
12. Required permanent truss member bracing location.

❖ See the definition in Chapter 2 of “Truss design drawing.” Also see the commentary to Section R802.10.2.

R802.10.2 Design. Wood trusses shall be designed in accordance with accepted engineering practice. The design and manufacture of metal-plate-connected wood trusses shall comply with ANSI/TPI 1. The truss design drawings shall be prepared by a registered professional where required by the statutes of the *jurisdiction* in which the project is to be constructed in accordance with Section R106.1.

❖ The code contains no prescriptive provisions for the design and installation of wood trusses. A design is

required in accordance with accepted engineering practice. For snow load, the truss design must be checked for both the balanced and unbalanced condition. Although the unbalanced condition controls for rafter design, that is not necessarily the case for truss design. The balanced condition could control. See the commentary to Section R802.5 for the snow load criteria. In recognition of the extensive use of trusses in residential construction, the code references ANSI/TPI 1, *National Design Standard for Metal-plate-connected Wood Truss Construction*. This standard provides regulations for the design and installation of metal-plate-connected wood trusses, including the procedures for full-scale tests and testing methods for evaluating metal-plate connectors. In addition to adequate design, the trusses must be handled and erected properly so the performance capabilities of the trusses are not compromised. A truss member should never be cut without approval from the design engineer.

Usually trusses are delivered in bundles, which reduces the potential for damage. Sufficient slings and spreader bars should be used to reduce stresses caused by sway and bending.

Shop drawings showing the lumber schedule, design loads and panel point details (size, location and attachment of plates) should be filed with the building permit application and should be available at the time of inspection.

R802.10.2.1 Applicability limits. The provisions of this section shall control the design of truss roof framing when snow controls for buildings, not greater than 60 feet (18 288 mm) in length perpendicular to the joist, rafter or truss span, not greater than 36 feet (10 973 mm) in width parallel to the joist, rafter or truss span, not more than three stories above grade plane in height, and roof slopes not smaller than 3:12 (25 percent slope) or greater than 12:12 (100-percent slope). Truss roof framing constructed in accordance with the provisions of this section shall be limited to sites subjected to a maximum design wind speed of 140 miles per hour (63 m/s), Exposure B or C, and a maximum ground snow load of 70 psf (3352 Pa). For consistent loading of all truss types, roof snow load is to be computed as: $0.7 p_g$.

❖ This section defines the applicability limits of the snow load for wood trusses to be consistent with the snow load applicable to wood or steel rafters.

The roof snow load is based on a maximum ground snow load of 70 pounds per square foot (3.35 kPa). The roof snow load is taken as $0.7 p_g$, where p_g is equal to the ground snow load.

Applied roof snow loads were calculated by multiplying the ground snow load by an 0.7 conversion factor in accordance with ASCE 7 (ASCE, 1998). No further reductions were made for special cases.

The sloped roof snow load, from ASCE 7 is: $p_s = C_s \times p_f$, where p_f is the flat roof snow load. $p_f = 0.7 \times C_e \times C_t \times I \times p_g$.

Unbalanced snow loads, sliding snow loads, and snow drifts on lower roofs were not considered due to the lack of evidence for damage from unbalanced

loads on homes and the lack of data to typify the statistical uncertainties associated with this load pattern on residential structures. Rain-on-snow surcharge load was also not considered in the calculations. Roof slopes in this document exceed the $\frac{1}{2}$ inch (12.7 mm) per foot requirement by ASCE 7 for the added load to be considered. Therefore, roof snow load was computed as: $1.0 \times 0.7 \times 1.0 \times 1.0 \times p_g = 0.7 p_g$.

R802.10.3 Bracing. Trusses shall be braced to prevent rotation and provide lateral stability in accordance with the requirements specified in the *construction documents* for the building and on the individual truss design drawings. In the absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practice such as the SBCA *Building Component Safety Information (BCSI) Guide to Good Practice for Handling, Installing & Bracing of Metal Plate Connected Wood Trusses*.

- ❖ To prevent their collapse during construction, and until permanent bracing is installed, trusses should be adequately braced temporarily. When braced for use, trusses should be positioned as close to vertical as possible; tilted trusses will not perform as required.

The construction documents and the individual truss design drawings should specify the bracing.

R802.10.4 Alterations to trusses. Truss members shall not be cut, notched, drilled, spliced or otherwise altered in any way without the approval of a registered *design professional*. Alterations resulting in the addition of load such as HVAC equipment water heater that exceeds the design load for the truss shall not be permitted without verification that the truss is capable of supporting such additional loading.

- ❖ The addition of loads in excess of the design load is allowed only if the truss is shown to have the additional capacity. See the commentary to Section R502.8.2.

R802.11 Roof tie-down.

- ❖ Because roof uplift caused by wind can be a significant factor in roof-system damage, the code requires roof-to-wall connections capable of resisting this force.

R802.11.1 Uplift resistance. Roof assemblies shall have uplift resistance in accordance with Sections R802.11.1.1 and R802.11.1.2.

Where the uplift force does not exceed 200 pounds (90.8 kg), rafters and trusses spaced not more than 24 inches (610 mm) on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

Where the basic wind speed does not exceed 115 mph, the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet (9754 mm) or less, rafters and trusses spaced not more than 24 inches (610 mm) on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

- ❖ In Table R602.3(1), the nailing of the rafter or roof truss to the top plate provides a 200-pound maximum

uplift capacity where the rafter or truss is spaced not more than 24 inches (610 mm) on center. The basis of the capacity of this nailing is calculated from AWC NDS. The 200-pound uplift capacity is adequate for an ultimate design speed of 115 miles per hour, Exposure B, with a 32-foot (9754 mm) roof span and a 5:12 or greater pitch.

For trusses, there are three options provided for determining the roof uplift: the truss design drawings, Table R802.11 or an engineered design. In many jurisdictions (particularly rural ones), an engineered truss design is not required and the local truss fabricator will run the software from the plate company. These jurisdictions may also have limited or no plan review. Thus, there is less opportunity to ensure that the proper wind speed, building dimensions, mean roof height, etc., are used, and a possibility that overly conservative roof uplift loads will be generated on the truss design drawing. Hence, the ability to determine an uplift load from Table R802.11, even when there are truss drawings, is provided; however, use of Table R802.11 is limited to roof rafters and single-ply trusses within the applicability limits of Section R802.10.1.2. Girder trusses and roof beams require engineered connections and/or use of the truss design drawing values.

For rafters, there are two options provided for determining the roof uplift: Table R802.11 or an engineered design.

Table R802.11 is based on Table 2.2A of the AWC WFCM, which is based on the latest ASCE 7 wind-load provisions. The new table expands upon the AWC WFCM table by incorporating values for high-slope roofs. These factors were derived using the ASCE 7 wind provisions and the calculation method used to develop Table 2.2A of the AWC WFCM. A factor for hip roofs is also added, as hip roofs have seen similar improved performance in high-wind events.

Determination of the uplift connection forces is as follows: Ultimate design wind speed is as set forth in Table R301.2(1) and the wind exposure category is determined in accordance with Section R301.2.1.4. Using this wind speed and exposure, the designer selects the uplift forces from Table R802.11 based on the rafter or truss spacing, roof span and pitch. The uplift connection of the rafter or truss to the wall must have the capacity to resist the uplift force specified in Table R802.11.

R802.11.1.1 Truss uplift resistance. Trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as specified on the truss design drawings for the ultimate design wind speed as determined by Figure R301.2(4)A and listed in Table R301.2(1) or as shown on the construction documents. Uplift forces shall be permitted to be determined as specified by Table R802.11, if applicable, or as determined by accepted engineering practice.

- ❖ See the commentary to Section R802.11.1.

TABLE R802.11
RAFTER OR TRUSS UPLIFT CONNECTION FORCES FROM WIND (ASD) (POUNDS PER CONNECTION)^{a, b, c, d, e, f, g, h}

	48	512	468	604	556	698	646	900	840	1120	1048

- For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s, 1 pound = 0.454 kg, 1 pound per square foot = 47.9 N/m², 1 plf = 14.6 N/m.
- The uplift connection forces are based on a maximum 33-foot mean roof height and Wind Exposure Category B or C. For Exposure D, the uplift connection force shall be selected from the Exposure C portion of the table using the next highest tabulated ultimate design wind speed. The adjustment coefficients in Table R301.2(3) shall not be used to multiply the tabulated forces for Exposures C and D or for other mean roof heights.
 - The uplift connection forces include an allowance for roof and ceiling assembly dead load of 15 psf.
 - The tabulated uplift connection forces are limited to a maximum roof overhang of 24 inches.
 - The tabulated uplift connection forces shall be permitted to be multiplied by 0.75 for connections not located within 8 feet of building corners.
 - For buildings with hip roofs with 5:12 and greater pitch, the tabulated uplift connection forces shall be permitted to be multiplied by 0.70. This reduction shall not be combined with any other reduction in tabulated forces.
 - For wall-to-wall and wall-to-foundation connections, the uplift connection force shall be permitted to be reduced by 60 plf for each full wall above.
 - Linear interpolation between tabulated roof spans and wind speeds shall be permitted.
 - The tabulated forces for a 12-inch on-center spacing shall be permitted to be used to determine the uplift load in pounds per linear foot.

R802.11.1.2 Rafter uplift resistance. Individual rafters shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by Table R802.11 or as determined by accepted engineering practice. Connections for beams used in a roof system shall be designed in accordance with accepted engineering practice.

- ❖ See the commentary to Section R802.11.1.

**SECTION R803
ROOF SHEATHING**

R803.1 Lumber sheathing. Allowable spans for lumber used as roof sheathing shall conform to Table R803.1. Spaced lumber sheathing for wood shingle and shake roofing shall conform to the requirements of Sections R905.7 and R905.8. Spaced lumber sheathing is not allowed in Seismic Design Category D₂.

- ❖ Table R803.1 specifies the minimum thickness of lumber roof sheathing based on rafter spacing. Spaced lumber sheathing used in conjunction with wood shingle or shake roofs is permitted when installed in accordance with Section R905. Because spaced lumber sheathing does not provide a roof diaphragm capable of transferring high in-plane loads to the supporting shear walls or braced wall lines, it is prohibited in structures classified as Seismic Design Category D₂.

**TABLE R803.1
MINIMUM THICKNESS OF LUMBER ROOF SHEATHING**

RAFTER OR BEAM SPACING (inches)	MINIMUM NET THICKNESS (inches)
24	⁵ / ₈
48 ^a	1½ T & G
60 ^b	
72 ^c	

For SI: 1 inch = 25.4 mm.

- a. Minimum 270 F_b, 340,000 E.
- b. Minimum 420 F_b, 660,000 E.
- c. Minimum 600F_b, 1,150,000 E.

- ❖ See the commentary to Section R803.1.

R803.2 Wood structural panel sheathing.

R803.2.1 Identification and grade. Wood structural panels shall conform to DOC PS 1, DOC PS 2, CSA O437 or CSA O325, and shall be identified for grade, bond classification and performance category by a grade mark or certificate of inspection issued by an *approved* agency. Wood structural panels shall comply with the grades specified in Table R503.2.1.1(1).

- ❖ Span rating and installation requirements for wood structural panels used as roof sheathing are similar to those of Section R503.2 for floor sheathing.

R803.2.1.1 Exposure durability. Wood structural panels, when designed to be permanently exposed in outdoor applications, shall be of an exterior exposure durability. Wood structural panel roof sheathing exposed to the underside shall

be permitted to be of interior type bonded with exterior glue, identified as Exposure 1.

- ❖ Exterior-type wood structural panels are required when the wood structural panels are exposed to the environment. Exterior wood structural panels use a moisture-resistant glue that may penetrate the outer veneer lamination. Additionally, exterior wood structural panels typically use a higher grade of veneer for the inner plies, which are compatible with the exterior glue-line performance. Wood structural panel roof sheathing exposed only on the underside, such as eave overhangs, is permitted to be of the interior type with exterior glue because of the decrease in exposure hazard relative to moisture.

R803.2.1.2 Fire-retardant-treated plywood. The allowable unit stresses for fire-retardant-treated plywood, including fastener values, shall be developed from an *approved* method of investigation that considers the effects of anticipated temperature and humidity to which the fire-retardant-treated plywood will be subjected, the type of treatment and redrying process. The fire-retardant-treated plywood shall be graded by an *approved agency*.

- ❖ See the commentary to Section R802.1.5.

R803.2.2 Allowable spans. The maximum allowable spans for wood structural panel roof sheathing shall not exceed the values set forth in Table R503.2.1.1(1), or APA E30.

- ❖ Table 503.2.1.1(1) and APA E30 list allowable spans and loads for wood structural panel roof sheathing (also see commentary, Section R503.2.2).

R803.2.3 Installation. Wood structural panel used as roof sheathing shall be installed with joints staggered or not staggered in accordance with Table R602.3(1), APA E30 for wood roof framing or with Table R804.3 for cold-formed steel roof framing.

- ❖ This section refers to the fastening schedule in Chapter 6 for attachment to wood roof framing. Note f to Table R602.3(1) establishes zones requiring increased nailing based on criteria such as ultimate design wind speed. APA E30, *APA Design and Construction Guide*, is referenced as an alternative to the Chapter 6 fastening schedule.

This section also gives a cross reference to the Roof Framing Fastening Schedule, Table R804.3, for attachments to cold-formed steel roof framing.

**SECTION R804
COLD-FORMED STEEL ROOF FRAMING**

R804.1 General. Elements shall be straight and free of any defects that would significantly affect their structural performance. Cold-formed steel roof framing members shall be in accordance with the requirements of this section.

- ❖ The provisions of this section govern cold-formed steel roof and ceiling framing.

R804.1.1 Applicability limits. The provisions of this section shall control the construction of cold-formed steel roof framing for buildings not greater than 60 feet (18 288 mm) perpendicular to the joist, rafter or truss span, not greater than 40 feet (12 192 mm) in width parallel to the joist span or truss, less than or equal to three stories above *grade* plane and with roof slopes not less than 3:12 (25-percent slope) or greater than 12:12 (100-percent slope). Cold-formed steel roof framing constructed in accordance with the provisions of this section shall be limited to sites where the ultimate design wind speed is less than 139 miles per hour (62 m/s), Exposure Category B or C, and the ground snow load is less than or equal to 70 pounds per square foot (3350 Pa).

❖ Other than providing roof slope limits, this section is identical to Section R505.1.1 and the limitations illustrated in Commentary Figure R505.1.1.

R804.1.2 In-line framing. Cold-formed steel roof framing constructed in accordance with Section R804 shall be located in line with load-bearing studs in accordance with Figure R804.1.2 and the tolerances specified as follows:

1. The maximum tolerance shall be $\frac{3}{4}$ inch (19.1 mm) between the centerline of the horizontal framing member and the centerline of the vertical framing member.
2. Where the centerline of the horizontal framing member and bearing stiffener are located to one side of the centerline of the vertical framing member, the maximum

tolerance shall be $\frac{1}{8}$ inch (3.2 mm) between the web of the horizontal framing member and the edge of the vertical framing member.

❖ The code does not anticipate loads on the top plate of a wall that would cause bending of the top plate. Therefore, roof-framing members must be located directly in line with load-bearing studs of the supporting steel-framed walls as indicated in Figure R804.1.2. The permitted offset provides some tolerance for rafter location while not adversely affecting the top plate (see commentary, Section R505.1.2).

R804.2 Structural framing. Load-bearing, cold-formed steel roof framing members shall be in accordance with this section.

❖ Sections R804.2.1 through R804.2.6 specify the requirements for cold-formed steel sections used for ceiling joists and roof rafters.

R804.2.1 Material. Load-bearing, cold-formed steel framing members shall be cold formed to shape from structural quality sheet steel complying with the requirements of ASTM A1003, Structural Grades 33 Type H and 50 Type H.

❖ Load-bearing steel framing members must be cold formed to shape from structural quality sheet steel complying with the applicable material standards. The steel grades specified have the ductility and strength to meet the intent of these provisions.

For SI: 1 inch = 25.4 mm.

**FIGURE R804.1.2
IN-LINE FRAMING**

ROOF-CEILING CONSTRUCTION

R804.2.2 Corrosion protection. Load-bearing, cold-formed steel framing shall have a metallic coating complying with ASTM A1003 and one of the following:

1. A minimum of G 60 in accordance with ASTM A653.
 2. A minimum of AZ 50 in accordance with ASTM A792.
- ❖ The specified metallic coatings correspond to requirements in the referenced material standards. The minimum coating designations assume normal exposure conditions that are best defined as having the framing members enclosed within a building envelope or wall assembly within a controlled environment. When more severe exposure conditions are probable, such as industrial or marine atmospheres, consideration should be given to specifying a heavier coating.

R804.2.3 Dimension, thickness and material grade. Load-bearing, cold-formed steel roof framing members shall comply with Figure R804.2.3(1) and with the dimensional and thickness requirements specified in Table R804.2.3. Additionally, C-shaped sections shall have a minimum flange width of 1.625 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for C-shaped sections shall be $\frac{1}{2}$ inch (12.7 mm). Tracks shall comply with Figure R804.2.3(2) and shall have a minimum flange width of $1\frac{1}{4}$ inches (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified.

❖ C-shaped sections must comply with Figure R804.2.3(1) and the dimensional and minimum thickness requirements of Table R804.2.3. Note a to Table R804.2.3 explains the meaning of the alphanumeric member designation used for all steel framing members in the code. This system replaces the varied designation approaches that were used by each individual manufacturer. In addition, the designation is used to identify not only a specific steel framing member, but also the section properties of that same member through the use of the product technical information document. The flange width of C-shaped sections must be from $1\frac{1}{2}$ inches to 2 inches with a minimum lip of $\frac{1}{2}$ inch.

Steel track sections are to serve in nonload-bearing applications only and are shown in Figure R804.2.3(2). They must have a minimum flange width of $1\frac{1}{4}$ inches (32 mm).

Steel thickness is expressed in mils, measuring the base metal thickness prior to painting or the application of metallic (corrosion-resistant) coatings. The base metal thickness is typically stamped or embossed on the member by the manufacturer. Table R804.2.3 also references the equivalent thickness in inches.

Minimum Grade 33 ksi steel must be used where the thickness is 33 or 43 mil. Where the thickness is 54 or 68 mil, the minimum grade must be Grade 50 ksi steel.

TABLE R804.2.3. See page 8-41.

❖ See the commentary to Section R804.2.3.

FIGURE R804.2.3(1). See page 8-41.

❖ See the commentary to Section R804.2.3.

FIGURE R804.2.3(2). See page 8-41.

See the commentary to Section R804.2.3.

R804.2.4 Identification. Load-bearing, cold-formed steel framing members shall have a legible *label*, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer's identification.
2. Minimum base steel thickness in inches (mm).
3. Minimum coating designation.
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

❖ Load-bearing steel framing members must have a legible label, stencil, stamp or embossment. This identification allows for verification that installed materials are consistent with the design and meet the intent of the code.

R804.2.5 Fastening requirements. Screws for steel-to-steel connections shall be installed with a minimum edge distance and center-to-center spacing of $\frac{1}{2}$ inch (12.7 mm), shall be self-drilling tapping and shall conform to ASTM C1513. Structural sheathing shall be attached to cold-formed steel roof rafters with minimum No. 8 self-drilling tapping screws that conform to ASTM C1513. Screws for attaching structural sheathing to cold-formed steel roof framing shall have a minimum head diameter of 0.292 inch (7.4 mm) with countersunk heads and shall be installed with a minimum edge distance of $\frac{3}{8}$ inch (9.5 mm). Gypsum board ceilings shall be attached to cold-formed steel joists with minimum No. 6 screws conforming to ASTM C954 or ASTM C1513 with a bugle-head style and shall be installed in accordance with Section R805. For all connections, screws shall extend through the steel a minimum of three exposed threads. Fasteners shall have rust-inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

❖ Fasteners meeting the referenced standards and installed in accordance with this section will provide a load capacity consistent with these prescriptive provisions. This section specifies self-drilling tapping screws conforming to ASTM C1513, *Specification for Steel Tapping Screws for Cold-formed Steel Framing Connection*, for all steel-to-steel connections as well as for fastening floor sheathing to steel joists. All fasteners must have rust-inhibitive coating or be manufactured from material not susceptible to corrosion. Gypsum board must be attached to steel joists with No. 6 screws (minimum) conforming to ASTM C954, *Standard Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness*, or ASTM C1513 (see Section R702 for installation). For all connections, screws must extend through the steel a minimum of three exposed threads.

R804.2.6 Web holes, web hole reinforcing and web hole patching. Web holes, web hole reinforcing and web hole patching shall be in accordance with this section.

❖ Sections R804.2.6.1 through R804.2.6.3 specify the criteria for web holes, web hole reinforcing and web hole patching in roof framing members.

R804.2.6.1 Web holes. Web holes in roof framing members shall comply with all of the following conditions:

1. Holes shall conform to Figure R804.2.6.1.
2. Holes shall be permitted only along the centerline of the web of the framing member.
3. Center-to-center spacing of holes shall not be less than 24 inches (610 mm).
4. The web hole width shall be not greater than one-half the member depth, or 2½ inches (64 mm).
5. Holes shall have a web hole length not exceeding 4½ inches (114 mm).

6. The minimum distance between the edge of the bearing surface and the edge of the web hole shall be not less than 10 inches (254 mm).

Framing members with web holes not conforming to Items 1 through 6 shall be reinforced in accordance with Section R804.2.6.2, patched in accordance with Section R804.2.6.3 or designed in accordance with accepted engineering practices.

❖ To allow for routing utilities through steel-framed roof framing members, holes (also referred to as penetrations, utility holes and punchouts) are permitted in the webs of roof framing members. To avoid adversely affecting the strength of roof framing members, the web holes are limited to the locations along the centerline of the web of the framing member as illustrated in Figure R804.2.6.1.

To avoid overstressing the joist web through high shear, these web holes must occur more than 10 inches (254 mm) from the edge of a load-bearing sur-

TABLE R804.2.3
LOAD-BEARING COLD-FORMED STEEL ROOF FRAMING MEMBER SIZES AND THICKNESSES

MEMBER DESIGNATION ^a	WEB DEPTH (inches)	MINIMUM BASE STEEL THICKNESS mil (inches)
350S162-t	3.5	33 (0.0329), 43 (0.0428), 54 (0.0538)
550S162-t	5.5	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
800S162-t	8	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
1000S162-t	10	43 (0.0428), 54 (0.0538), 68 (0.0677)
1200S162-t	12	43 (0.0428), 54 (0.0538), 68 (0.0677)

For SI: 1 inch = 25.4 mm

a. The member designation is defined by the first number representing the member depth in hundredths of an inch, the letter “s” representing a stud or joist member, the second number representing the flange width in hundredths of an inch and the letter “t” shall be a number representing the minimum base metal thickness in mils.

FIGURE R804.2.3(1)
C-SHAPED SECTION

FIGURE R804.2.3(2)
TRACK SECTION

face. Patching of web holes must extend at least 1 inch (25 mm) beyond all edges of the hole, and it must be fastened to the web with No. 8 screws having a minimum edge distance of 1/2 inch (12.7 mm). Framing members with web holes exceeding these limits must be reinforced, patched or designed in accordance with accepted engineering practice (see commentary, Sections R804.2.6.2 and R804.2.6.3).

FIGURE R804.2.6.1. See below.

❖ See the commentary to Section R804.2.6.1.

R804.2.6.2 Web hole reinforcing. Reinforcement of web holes in ceiling joists not conforming to the requirements of Section R804.2.6.1 shall be permitted if the hole is located fully within the center 40 percent of the span and the depth and length of the hole do not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shaped section with a hole that does not exceed the web hole size limitations of Section R804.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not greater than 1 inch (25 mm) center to center along the edges of the patch with minimum edge distance of 1/2 inch (12.7 mm).

❖ Web holes that are not within the criteria of Section R804.2.6.1 are permitted if they are reinforced and comply with the criteria of this section.

The reinforcing provisions of this section were developed based on engineering judgement and accepted engineering practice and confirmed by testing.

R804.2.6.3 Hole patching. Patching of web holes in roof framing members not conforming to the requirements in Section R804.2.6.1 shall be permitted in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practices where web holes exceed either of the following size limits:

- 1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web.

- 1.2. The length of the hole measured along the web, exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.

2. Web holes not exceeding the dimensional requirements in Section R804.2.6.3, Item 1, shall be patched with a solid steel plate, stud section or track section in accordance with Figure R804.2.6.3. The steel patch shall, as a minimum, be the same thickness as the receiving member and shall extend not less than 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced not greater than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of 1/2 inch (12.7 mm).

❖ Framing members with web holes exceeding the limits outlined in Item 1 of this section must be replaced or designed in accordance with accepted engineering practice. Framing members with web holes within the limits of Item 1, but exceeding the limits of Section R804.2.6.1, must be patched in accordance with Item 2 of this section (see commentary, Section R804.2.6.1).

FIGURE R804.2.6.3. See page 8-43.

❖ See the commentary to Section R804.2.6.3.

R804.3 Roof construction. Cold-formed steel roof systems constructed in accordance with the provisions of this section shall consist of both ceiling joists and rafters in accordance with Figure R804.3 and fastened in accordance with Table R804.3.

❖ Figure R804.3 illustrates steel roof system components. The roof framing fastening schedule in Table R804.3 specifies the minimum connection requirements for components of the roof framing system.

For SI: 1 inch = 25.4 mm.

FIGURE R804.2.6.1
ROOF FRAMING MEMBER WEB HOLES

For SI: 1 inch = 25.4 mm.

FIGURE R804.2.6.3
ROOF FRAMING MEMBER WEB HOLE PATCH

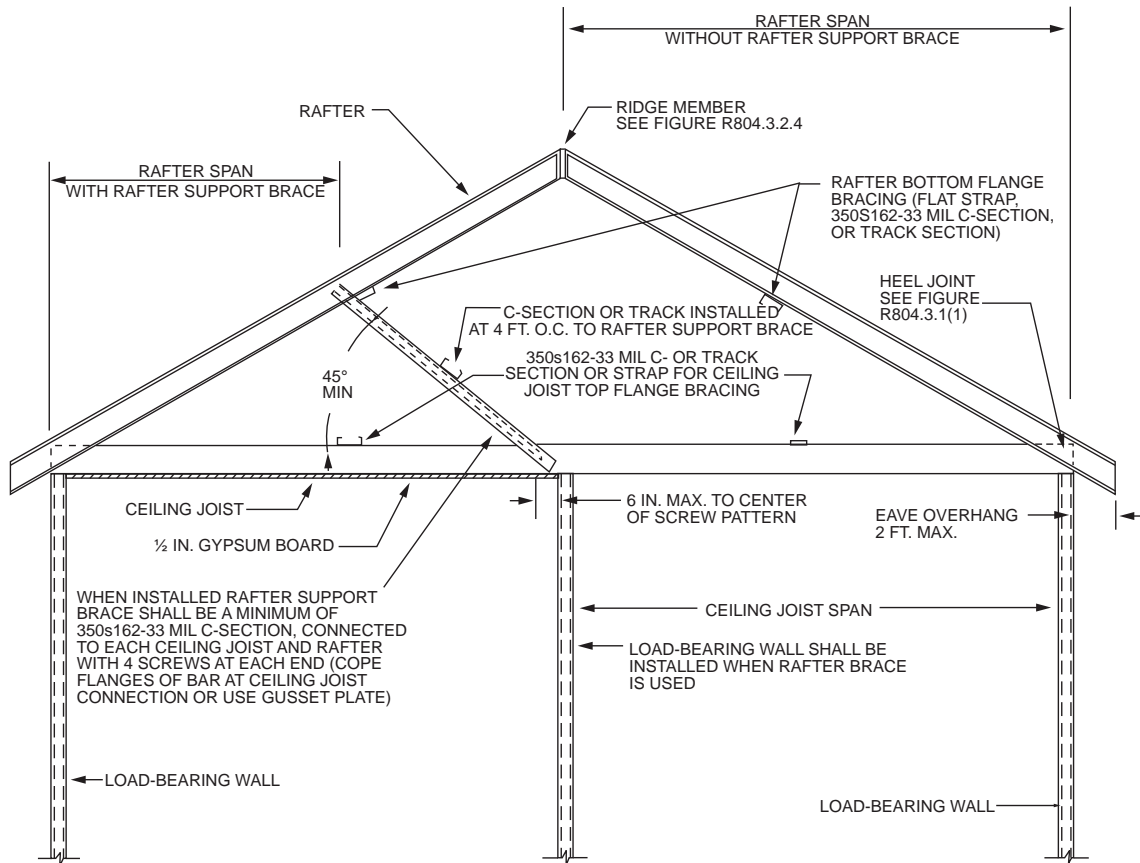

R804.3.1 Ceiling joists. Cold-formed steel ceiling joists shall be in accordance with this section.

❖ Sections R804.3.1.1 through R804.3.1.4 provide the requirements for ceiling joist size, bearing stiffeners, bottom flange bracing, top flange bracing, and splicing.

R804.3.1.1 Minimum ceiling joist size. Ceiling joist size and thickness shall be determined in accordance with the limits set forth in Tables R804.3.1.1(1) and R804.3.1.1(2). When determining the size of ceiling joists, the lateral support of the top flange shall be classified as unbraced, braced at midspan or braced at third points in accordance with Section R804.3.1.4. Where sheathing material is attached to the top flange of ceiling joists or where the bracing is spaced closer than third point of the joists, the “third point” values from Tables R804.3.1.1(1) and R804.3.1.1(2) shall be used.

Ceiling joists shall have a bearing support length of not less than 1½ inches (38 mm) and shall be connected to roof rafters (heel joint) with No. 10 screws in accordance with Figure R804.3.1.1 and Table 804.3.1.1(3).

Where continuous joists are framed across interior bearing supports, the interior bearing supports shall be located within 24 inches (610 mm) of midspan of the ceiling joist, and the

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mil = 0.0254 mm.

FIGURE R804.3
COLD-FORMED STEEL ROOF CONSTRUCTION

ROOF-CEILING CONSTRUCTION

individual spans shall not exceed the applicable spans in Tables R804.3.1.1(1) and R804.3.1.1(2).

Where the *attic* is to be used as an occupied space, the ceiling joists shall be designed in accordance with Section R505.

❖ Allowable spans for ceiling joists are given in Table R804.3.1.1(1) for live loads of 10 psf (479 Pa) and Table R804.3.1.1(2) for live loads of 20 psf (958 Pa). An attic with occupied space requires the use of higher design live loads, and the ceiling joists must be designed in accordance with Section R505.3.2. Ceiling joists must be connected to rafters in accordance with Figure R804.3.1.1 and Table R804.3.1.1(3). The use of the allowable span tables is illustrated below.

Example:

Steel ceiling joists at 16 inches (406 mm) on center support a ceiling with limited attic storage and are braced at mid span. Their span is 17 feet, 6 inches (5334 mm) in a 35-foot-wide (10 668 mm) building with a roof slope of 8:12 and 30 psf (1436 Pa) snow load. Determine the required joist size, minimum grade of steel and the required connection to rafters.

Solution:

The live load is 20 psf (958 Pa) for limited attic storage. In Table R804.3.1.1(2), under the column

headed "Mid-span Bracing," look under 16-inch joist spacing. Note that 800S162-68 has an allowable span of 18 feet, 5 inches (5613 mm), which is greater than the required span. Since the thickness is 68 mil, the steel must be minimum Grade 50 ksi.

The joist-rafter connection in Table R804.3.1.1(3) requires four No. 10 screws fastened in accordance with Figure R804.3.1.1.

Where continuous joists are framed across interior bearing supports, such supports must be located within 24 inches (610 mm) of mid span of the ceiling joist, and the individual spans must not exceed the applicable spans in Table R804.3.1.1(1) or R804.3.1.1(2).

The tables provide ceiling joist spans for a ceiling dead load of 5 psf (239 Pa).

The dead load of the combined roof and ceiling assemblies must not exceed 15 psf for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁ and D₂. Section R301.2.2.2.1 provides an exception for exceeding the 15 psf (718 Pa) restriction (see commentary, Section R301.2.2.2.1).

TABLE R804.3
ROOF FRAMING FASTENING SCHEDULE^{a, b}

DESCRIPTION OF BUILDING ELEMENTS			NUMBER AND SIZE OF FASTENERS ^a				SPACING OF FASTENERS		
Roof sheathing (oriented strand board or plywood) to rafter			No. 8 screws				6" o.c. on edges and 12" o.c. at interior supports. 6" o.c. at gable end truss		
Gable end truss to end wall top track			No. 10 screws				12" o.c.		
Rafter to ceiling joist			Minimum No. 10 screws, in accordance with Table R804.3.1.1(3)				Evenly spaced, not less than 1/2" from all edges.		
Ceiling joist or roof truss to top track of bearing wall ^b	Ceiling Joist Spacing (in.)	Roof Span (ft)	Ultimate Design Wind Speed (mph) and Exposure Category				Each ceiling joist or roof truss		
			126 B 110 C	<139 B 115 C	126 C	<139 C			
			16	24	2	2		2	3
				28	2	2		3	3
				32	2	2		3	4
	36	2		2	3	4			
	24	40	2	2	3	4			
		24	2	2	3	4			
		28	2	2	4	5			
		32	2	3	4	5			
		36	2	3	4	6			
		40	2	3	5	6			

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa, 1 mil = 0.0254 mm.

a. Screws are a minimum No. 10 unless noted otherwise.

b. Indicated number of screws shall be applied through the flanges of the truss or ceiling joist or through each leg of a 54 mil clip angle. See Section R804.3.8 for additional requirements to resist uplift forces.

R804.3.1.2 Ceiling joist bottom flange bracing. The bottom flanges of ceiling joists shall be laterally braced by the application of gypsum board or continuous steel straps installed perpendicular to the joist run in accordance with one of the following:

1. Gypsum board shall be fastened with No. 6 screws in accordance with Section R702.
2. Steel straps with a minimum size of 1½ inches by 33 mils (38 mm by 0.84 mm) shall be installed at a maximum spacing of 4 feet (1219 mm). Straps shall be fastened to the bottom flange at each joist with one No. 8 screw and shall be fastened to blocking with two No. 8 screws. Blocking shall be installed between joists at a maximum spacing of 12 feet (3658 mm) measured along a line of continuous strapping (perpendicular to the joist run). Blocking shall also be located at the termination of all straps.

❖ Steel ceiling joists must have the bottom flanges laterally braced either with gypsum board or continuous steel strapping. Strap bracing requires the installation

of solid blocking in line with the straps at the termination of all straps and at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the joist run.

R804.3.1.3 Ceiling joist top flange bracing. The top flanges of ceiling joists shall be laterally braced as required by Tables R804.3.1.1(1) and R804.3.1.1(2), in accordance with one of the following:

1. Minimum 33-mil (0.84 mm) C-shaped member in accordance with Figure R804.3.1.3(1).
2. Minimum 33-mil (0.84 mm) track section in accordance with Figure R804.3.1.3(1).
3. Minimum 33-mil (0.84 mm) hat section in accordance with Figure R804.3.1.3(1).
4. Minimum 54-mil (1.37 mm) 1½-inch (38 mm) cold-rolled channel section in accordance with Figure R804.3.1.3(1).
5. Minimum 1½-inch by 33-mil (38 mm by 0.84 mm) continuous steel strap in accordance with Figure R804.3.1.3(2).

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mil = 0.0254 mm, 1 pound per square foot = 0.0479 kPa.

a. Deflection criterion: L/240 for total loads.

b. Ceiling dead load = 5 psf.

c. Minimum Grade 33 ksi steel shall be used for 33 mil and 43 mil thicknesses. Minimum Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

ROOF-CEILING CONSTRUCTION

Lateral bracing shall be installed perpendicular to the ceiling joists and shall be fastened to the top flange of each joist with one No. 8 screw. Blocking shall be installed between joists in line with bracing at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the joists. Ends of lateral bracing shall be attached to blocking or anchored to a stable building component with two No. 8 screws.

- ❖ The application of lateral support to the top flanges of the ceiling joists, at mid span or at third-point of the span will permit longer spans in accordance with Tables R804.3.1.1(1) and R804.3.1.1(2). This section permits the top flange bracing to be C-section, track section, hat section, cold-rolled channel section or steel strap [see Figures R804.3.1.3(1) and R804.3.1.3(2) for details]. In addition to the top flange, bracing blocking must be installed in line with the bracing at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the joist run. Splice for the steel

strap bracing must occur at blocking [see Figure R804.3.1.3(2)].

R804.3.1.4 Ceiling joist splicing. Splices in ceiling joists shall be permitted, if ceiling joist splices are supported at interior bearing points and are constructed in accordance with Figure R804.3.1.4. The number of screws on each side of the splice shall be the same as required for the heel joint connection in Table R804.3.1.1(3).

- ❖ Steel ceiling joists are permitted to be spliced only at supports at interior bearing points (see Figure R804.3.1.4).

R804.3.2 Roof rafters. Cold-formed steel roof rafters shall be in accordance with this section.

- ❖ Sections R804.3.2.1 through R804.3.2.5 provide the requirements for roof rafter size, support brace, splice, connection to ceiling joist and ridge and bottom flange bracing.

For SI: 1 inch = 25.4 mm.

FIGURE R804.3.1.4
SPLICED CEILING JOISTS

R804.3.2.1 Minimum roof rafter sizes. Roof rafter size and thickness shall be determined in accordance with the limits set forth in Table R804.3.2.1(1) based on the horizontal projection of the roof rafter span. For determination of roof rafter sizes, reduction of roof spans shall be permitted where a roof rafter support brace is installed in accordance with Section R804.3.2.2. The reduced roof rafter span shall be taken as the larger of the distances from the roof rafter support brace to the ridge or to the heel measured horizontally.

For the purpose of determining roof rafter sizes in Table R804.3.2.1(1), ultimate design wind speeds shall be converted to equivalent ground snow loads in accordance with Table R804.3.2.1(2). Roof rafter sizes shall be based on the higher of the ground snow load or the equivalent snow load converted from the ultimate design wind speed.

❖ Table R804.3.2.1(1) lists allowable rafter spans based on ground snow loads. To account for wind loading on rafters, Table R804.3.2.1(2) must be used to convert ultimate design wind speed to an equivalent ground snow load. Then, the allowable rafter span is determined from Table R804.3.2.1(1) based on the larger of either the ground snow load or the equivalent snow load converted from the wind speed. The rafter span is permitted to be reduced when a support brace is installed (see Section R804.3.2.2). The reduced rafter span is the larger of the distance from the ridge to the support brace or from the support brace to the heel.

Table R804.3.2.1(1) provides rafter spans for a roof dead load of 12 psf (575 Pa).

The dead load of the combined roof and ceiling assemblies must not exceed 15 psf (718 Pa) for townhouses in Seismic Design Category C and all structures in Seismic Design Categories D₀, D₁ and D₂. Section R301.2.2.2.1 provides an exception for exceeding the 15 psf (718 Pa) restriction (see commentary, Section R301.2.2.2.1).

❖ Use of the allowable span table is illustrated below.

Example 1:

You wish to design a rafter system for a 20-psf (958 Pa) ground snow load, and ultimate design wind speed of 100 mph, Exposure B. The rafter spacing is 24 inches (610 mm) on center with a horizontal projection of the rafter span of 16 feet, 4 inches. The roof slope is 12 units vertical in 12 units horizontal (100-percent slope).

Solution 1:

Convert the wind speed to an equivalent ground snow load from Table R804.3.2.1(2). For an ultimate design wind speed of 100 mph (44 m/s), Exposure B and a roof slope of 12:12, the equivalent ground snow load is 50 psf (2.4 kPa). The 50 psf (2.4 kPa) snow load is greater than the 20 psf (0.96 kPa); therefore you must use the 50-psf ground snow load.

ROOF-CEILING CONSTRUCTION

The object is to locate a tabulated span value of 16 feet, 4 inches or more. Going to Table R804.3.2.1(1), under the portion headed “Ground snow load 50” and “Rafter spacing 24” note that rafter size 800S162-68 will span 16 feet, 8 inches (4978 mm), which is greater than the required span. Since the thickness is 68 mil, the steel must be minimum Grade 50 ksi.

Example 2:

To find a substitute for the 800S162-68 rafters of Example 1, determine the required rafter size for a condition that uses a rafter brace located at mid span of each rafter as depicted in Figure R804.3. Assume the same loads, rafter spacing, and 16-

foot, 4-inch (4978 mm) horizontal rafter span between the exterior wall and ridge.

Solution 2:

The rafter span, identified in Figure R804.3, is reduced to 8 feet, 2 inches (2489 mm) by adding the rafter brace at mid span.

The object is to locate a tabulated span value of 8 feet, 2 inches (51 mm) or more. Going to Table R804.3.2.1(1) under the portion headed “Ground snow load 50” and “Rafter spacing 24,” note that rafter size 550S162-43 will span 9 feet, 5 inches, which is greater than the required span. Since the thickness is 43 mil, the steel must be minimum Grade 33 ksi.

TABLE R804.3.2.1(1)

1200S162-68	36'-4"	31'-9"	31'-9"	27'-0"	26'-5"	21'-6"	22'-6"	18'-6"

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

- a. Table provides maximum horizontal rafter spans in feet and inches for slopes between 3:12 and 12:12.
- b. Deflection criteria: L/240 for live loads and L/180 for total loads.
- c. Roof dead load = 12 psf.
- d. Grade 33 ksi steel is permitted to be used for 33 mil and 43 mil thicknesses. Grade 50 ksi steel shall be used for 54 and 68 mil thicknesses.

TABLE R804.3.2.1(2)
ULTIMATE DESIGN WIND SPEED TO EQUIVALENT SNOW LOAD CONVERSION

BASIC WIND SPEED AND EXPOSURE		EQUIVALENT GROUND SNOW LOAD (psf)									
		Roof slope									
Exp. B	Exp. C	3:12	4:12	5:12	6:12	7:12	8:12	9:12	10:12	11:12	12:12
85 mph	—	20	20	20	20	20	20	30	30	30	30
100 mph	85 mph	20	20	20	20	30	30	30	30	50	50
110 mph	100 mph	20	20	20	20	30	50	50	50	50	50
—	110 mph	30	30	30	50	50	50	70	70	70	—

For SI: 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa.

R804.3.2.1.1 Eave overhang. Eave overhangs shall not exceed 24 inches (610 mm) measured horizontally.

❖ Figure R804.3 shows the permitted eave overhang. In addition to limiting the gravity load, this provision places a cap on the amount of wind uplift on the eave overhang that must be considered when determining the roof tie-down.

R804.3.2.1.2 Rake overhangs. Rake overhangs shall not exceed 12 inches (305 mm) measured horizontally. Outlookers at gable endwalls shall be installed in accordance with Figure R804.3.2.1.2.

❖ Rake overhang at cable endwalls is limited to 12 inches (305 mm) and must be constructed as outlook rafters as shown in Option 1 or Option 2 in Figure R804.3.2.1.2.

R804.3.2.2 Roof rafter support brace. When used to reduce roof rafter spans in determining roof rafter sizes, a roof rafter support brace shall meet all of the following conditions:

1. Minimum 350S162-33 C-shaped brace member with maximum length of 8 feet (2438 mm).
2. Minimum brace member slope of 45 degrees (0.785 rad) to the horizontal.
3. Minimum connection of brace to a roof rafter and ceiling joist with four No.10 screws at each end.
4. Maximum 6 inches (152 mm) between brace/ceiling joist connection and load-bearing wall below.
5. Each roof rafter support brace greater than 4 feet (1219 mm) in length, shall be braced with a supplemental brace having a minimum size of 350S162-33 or

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**FIGURE R804.3.2.1.2
GABLE ENDWALL OVERHANG DETAILS**

ROOF-CEILING CONSTRUCTION

350T162-33 such that the maximum unsupported length of the roof rafter support brace is 4 feet (1219 mm). The supplemental brace shall be continuous and shall be connected to each roof rafter support brace using two No. 8 screws.

- ❖ This section provides the requirements and installation details of a rafter support brace. The rafter support brace is to be installed at each rafter and must be no greater than 8 feet (2438 mm) in length. Each rafter support brace that is greater than 4 feet (1219 mm) in length must have a continuous horizontal brace (purlin) perpendicular to the rafter support brace span such that the maximum unsupported length of the rafter support brace is 4 feet (1219 mm) (see Figure R804.3).

R804.3.2.3 Roof rafter splice. Roof rafters shall not be spliced.

- ❖ Splicing of roof rafters is not permitted.

R804.3.2.4 Roof rafter to ceiling joist and ridge member connection. Roof rafters shall be connected to a parallel ceiling joist to form a continuous tie between exterior walls in accordance with Figure R804.3.1.1 and Table R804.3.1.1(3). Ceiling joists shall be connected to the top track of the load-bearing wall in accordance with Table R804.3, either with the required number of No. 10 screws applied through the flange of the ceiling joist or by using a 54-mil (1.37 mm) clip angle with the required number of No.10 screws in each leg. Roof rafters shall be connected to a ridge member with a minimum 2-inch by 2-inch (51 mm by 51 mm) clip angle fastened with No. 10 screws to the ridge member in accordance with Figure R804.3.2.4 and Table R804.3.2.4. The clip angle shall have a steel thickness equivalent to or greater than the roof rafter thickness and shall extend the depth of the roof rafter member to the extent possible. The ridge member shall be fabricated from a C-shaped member and a track section that shall have a minimum size and steel thickness equivalent to or greater than that of adjacent roof rafters and shall be installed in accordance with Figure R804.3.2.4. The ridge member shall extend the full depth of the sloped roof rafter cut.

- ❖ The requirements of this section describe connections to resist horizontal thrust from gravity loads and ridge

uplift from wind loads. Ceiling joists or rafter ties are the framing members used to resist the horizontal thrust from gravity loads. The ridge member connections are used to resist the ridge uplift caused by the wind load.

Ceiling joists must be located at the top track of the exterior walls and parallel to the rafters.

A ceiling joist or rafter tie is required to be connected to the top track and to each rafter (see Figure R804.3.1.1). Each rafter must be connected to a ridge member. The ridge member depth must equal or exceed the depth of the sloped rafter cut (see Figure R804.3.2.4).

R804.3.2.5 Roof rafter bottom flange bracing. The bottom flanges of roof rafters shall be continuously braced, at a maximum spacing of 8 feet (2440 mm) as measured parallel to the roof rafters, with one of the following members:

1. Minimum 33-mil (0.84 mm) C-shaped member.
2. Minimum 33-mil (0.84 mm) track section.
3. Minimum 1 $\frac{1}{2}$ -inch by 33-mil (38 mm by 0.84 mm) steel strap.

The bracing element shall be fastened to the bottom flange of each roof rafter with one No. 8 screw and shall be fastened to blocking with two No. 8 screws. Blocking shall be installed between roof rafters in-line with the continuous bracing at a maximum spacing of 12 feet (3658 mm) measured perpendicular to the roof rafters. The ends of continuous bracing shall be fastened to blocking or anchored to a stable building component with two No. 8 screws.

- ❖ Installation of bracing to the rafter bottom flange is necessary to provide resistance to twisting and/or lateral displacement of the rafters. The rafter bottom flange bracing must be spaced no greater than 8 feet (2440 mm) as measured parallel to the rafter. The rafter bottom flange bracing is permitted to be either a C-section, track section or steel strap. In addition to the bottom flange bracing, blocking must be installed in line with the bracing, at the termination of all bracing and at a maximum spacing of 12 feet (3658 mm), measured perpendicular to the joist run.

TABLE R804.3.2.4
SCREWS REQUIRED AT EACH LEG OF CLIP ANGLE FOR ROOF RAFTER TO RIDGE MEMBER CONNECTION^a

BUILDING WIDTH (feet)	NUMBER OF SCREWS			
	Ground snow load (psf)			
	0 to 20	21 to 30	31 to 50	51 to 70
24	2	2	3	4
28	2	3	4	5
32	2	3	4	5
36	3	3	5	6
40	3	4	5	7

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.0479 kPa.

a. Screws shall be No. 10 minimum.

R804.3.3 Cutting and notching. Flanges and lips of load-bearing, cold-formed steel roof framing members shall not be cut or notched.

- ❖ Flanges and lips of load-bearing steel roof framing members must not be cut or notched because this would affect their structural integrity.

R804.3.4 Headers. Roof-ceiling framing above wall openings shall be supported on headers. The allowable spans for headers in load-bearing walls shall not exceed the values set forth in Section R603.6 and Tables R603.6(1) through R603.6(6).

- ❖ Headers must be located immediately below the ceiling or roof framing (for example, at the top of the track), above wall openings, in all exterior walls and in interior load-bearing walls in accordance with Section R603.6. Tables R603.6(1) through R603.6.1(6) gives the allowable spans for headers in bearing walls. See the commentary to Section R603.6.

R804.3.5 Framing of openings in roofs and ceilings. Openings in roofs and ceilings shall be framed with header and trimmer joists. Header joist spans shall not exceed 4 feet (1219 mm) in length. Header and trimmer joists shall be fabricated from joist and track members having a minimum size and thickness equivalent to the adjacent ceiling joists or roof rafters and shall be installed in accordance with Figures R804.3.5(1) and R804.3.5(2). Each header joist shall be connected to trimmer joists with not less than four 2-inch by 2-inch (51 by 51 mm) clip angles. Each clip angle shall be fastened to both the header and trimmer joists with four No. 8 screws, evenly spaced, through each leg of the clip angle. The steel thickness of the clip angles shall be not less than that of the ceiling joist or roof rafter. Each track section for a built-up header or trimmer joist shall extend the full length of the joist (continuous).

- ❖ Roof openings must be framed as illustrated in Figures R804.3.5(1) and R804.3.5(2). Each header joist must

be connected to the trimmer joists with a minimum of four 2-inch by 2-inch (51 mm by 51 mm) clip angles, which must be fastened to both the header and trimmer joists with four No. 8 screws, evenly spaced, through each leg. The clip angle's thickness must not be less than that of the ceiling joist or roof rafter.

R804.3.6 Roof trusses. Cold-formed steel trusses shall be designed and installed in accordance with AISI S100, Section D4. In the absence of specific bracing requirements, trusses shall be braced in accordance with accepted industry practices, such as the SBCA *Cold-Formed Steel Building Component Safety Information (CFSBCSI) Guide to Good Practice for Handling, Installing & Bracing of Cold-Formed Steel Trusses*. Trusses shall be connected to the top track of the load-bearing wall in accordance with Table R804.3, either with two No. 10 screws applied through the flange of the truss or by using a 54-mil (1.37 mm) clip angle with two No. 10 screws in each leg.

- ❖ The code contains no prescriptive provisions for the design and installation of cold-formed steel trusses. A design is required that complies with accepted engineering practice. Recognizing the extensive use of trusses in residential construction, the code references AISI S100, Section D4. Section D4 of AISI S100 specifies the criteria for the design of cold-formed steel light-frame construction and requires trusses to be designed in accordance with AISI S214. The standard provides regulations for the design and installation of cold-formed steel trusses, including quality assurance and the procedures for full-scale tests. In addition to adequate design, it is important that the handling and erection of the trusses be performed properly so that the performance capability of the trusses is not compromised. A truss member must never be cut, notched or altered without approval from the design professional.

For SI: 1 inch = 25.4 mm.

FIGURE R804.3.5(2)
HEADER TO TRIMMER CONNECTION

R804.3.7 Ceiling and roof diaphragms. Ceiling and roof diaphragms shall be in accordance with this section.

- ❖ This section provides the prescriptive requirements for ceiling and roof diaphragms. Sections R804.3.7.1 and R804.3.7.2 provide the details for ceiling diaphragms of gypsum board or wood structural panel and roof diaphragms of wood structural panel.

R804.3.7.1 Ceiling diaphragms. At gable endwalls a ceiling diaphragm shall be provided by attaching a minimum 1/2-inch (12.7 mm) gypsum board or a minimum 3/8-inch (9.5 mm) wood structural panel sheathing, that complies with Section R803, to the bottom of ceiling joists or roof trusses and connected to wall framing in accordance with Figures R804.3.7.1(1) and R804.3.7.1(2), unless studs are designed as full height without bracing at the ceiling. Flat blocking shall consist of C-shaped or track section with a minimum thickness of 33 mils (0.84 mm). For a gypsum board sheathed ceiling, the diaphragm length shall be in accordance with Table R804.3.7.1. For a wood structural panel sheathed ceiling, the diaphragm length shall be not less than 12 feet (3658 mm) for building widths less than 36 feet (10 973 mm), or not less than 14 feet (4267 mm) for building widths greater than or equal to 36 feet (10 973 mm).

The ceiling diaphragm shall be secured with screws spaced at a maximum 6 inches (152 mm) o.c. at panel edges and a

maximum 12 inches (305 mm) o.c. in the field. The required lengths in Table R804.3.7.1 for gypsum board sheathed ceiling diaphragms shall be permitted to be multiplied by 0.35 if all panel edges are blocked. Multiplying the required lengths in Table R804.3.7.1 for gypsum board sheathed ceiling diaphragms by 0.9 shall be permitted if all panel edges are secured with screws spaced at 4 inches (102 mm) o.c.

- ❖ A ceiling diaphragm is required unless the gable end-wall studs are designed to extend full height to the roof without bracing at the ceiling line. The ceiling diaphragm is constructed of either gypsum board or wood panel sheathing. See Figures R804.3.7.1(1) and R804.3.7.1(2) for connection to the gable endwall and sidewall.

The required length of gypsum board ceiling diaphragm is specified in Table R804.3.7.1.

The required length of gypsum board ceiling diaphragm is permitted to be reduced, to 35 percent of that specified in the tables, if all panel edges are blocked.

The required length of gypsum board ceiling diaphragm is permitted to be reduced to 90 percent of that specified in the tables, if panel edge screws are spaced at 4 inches (102 mm).

**TABLE R804.3.7.1
REQUIRED LENGTHS FOR CEILING DIAPHRAGMS AT GABLE ENDWALLS
GYPSUM BOARD SHEATHED, CEILING HEIGHT = 8 FEET^{a, b, c, d, e, f, g}**

EXPOSURE CATEGORY		ULTIMATE DESIGN WIND SPEED (mph)			
B		126	< 139	—	—
C		110	—	126	< 139
Roof pitch	Building endwall width (feet)	Minimum diaphragm length (feet)			
3:12 to 6:12	24 - 28	20	22	28	32
	> 28 - 32	22	28	32	38
	> 32 - 36	26	32	38	44
	> 36 - 40	30	36	44	50
6:12 to 9:12	> 24 - 28	22	26	32	36
	> 28 - 32	26	32	38	44
	> 32 - 36	32	38	44	52
	> 36 - 40	36	44	52	60
9:12 to 12:12	> 24 - 28	26	30	36	42
	> 28 - 32	30	36	42	50
	> 32 - 36	36	42	50	60
	> 36 - 40	42	50	60	70

For SI: 1 inch = 25.4 mm, 1 pound per square foot = 0.0479 kPa, 1 mile per hour = 0.447 m/s, 1 foot = 304.8 mm, 1 mil = 0.0254 mm.

- Ceiling diaphragm is composed of 1/2-inch gypsum board (min. thickness) secured with screws spaced at 6 inches o.c. at panel edges and 12 inches o.c. in field. Use No. 8 screws (min.) where framing members have a designation thickness of 54 mils or less and No. 10 screws (min.) where framing members have a designation thickness greater than 54 mils.
- Maximum aspect ratio (length/width) of diaphragms is 2:1.
- Building width is in the direction of horizontal framing members supported by the wall studs.
- Required diaphragm lengths are to be provided at each end of the structure.
- Multiplying required diaphragm lengths by 0.35 is permitted if all panel edges are blocked.
- Multiplying required diaphragm lengths by 0.9 is permitted if all panel edges are secured with screws spaced at 4 inches o.c.
- To determine the minimum diaphragm length for buildings with ceiling heights of 9 feet or 10 feet values in the table above shall be multiplied by 1.15.

ROOF-CEILING CONSTRUCTION

For SI: 1 inch = 25.4 mm.

**FIGURE R804.3.7.1(1)
CEILING DIAPHRAGM TO GABLE ENDWALL DETAIL**

For SI: 1 inch = 25.4 mm.

**FIGURE R804.3.7.1(2)
CEILING DIAPHRAGM TO SIDEWALL DETAIL**

R804.3.7.2 Roof diaphragm. A roof *diaphragm* shall be provided by attaching a minimum of $\frac{3}{8}$ -inch (9.5 mm) wood structural panel which complies with Section R803 to roof rafters or truss top chords in accordance with Table R804.3. Buildings with 3:1 or larger plan *aspect ratio* and with roof rafter slope (pitch) of 9:12 or larger shall have the roof rafters and ceiling joists blocked in accordance with Figure R804.3.7(2).

❖ A roof diaphragm consisting of minimum $\frac{3}{8}$ -inch-thick (9.5 mm) wood structural panel sheathing is required in accordance with this section. Roof blocking is required where the building plan aspect ratio is equal to or greater than 3:1 and the roof pitch is equal to or greater than 9:12 [see Figure R804.3.7(2) for roof blocking details].

R804.3.8 Roof tie-down. Roof assemblies shall be connected to walls below in accordance with Table R804.3. A continuous

load path shall be provided to transfer uplift loads to the foundation.

❖ Steel-framed roof assemblies require rafter-to-bearing wall ties with a capacity determined in the manner described in Section R802.11.

**SECTION R805
CEILING FINISHES**

R805.1 Ceiling installation. Ceilings shall be installed in accordance with the requirements for interior wall finishes as provided in Section R702.

❖ This section provides a reference to the ceiling installation requirements found in Section R702.

For SI: 1 mil = 0.0254 mm, 1 inch = 25.4 mm.

**FIGURE R804.3.7(2)
ROOF BLOCKING DETAIL**

SECTION R806 ROOF VENTILATION

R806.1 Ventilation required. Enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof rafters shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain or snow. Ventilation openings shall have a least dimension of $\frac{1}{16}$ inch (1.6 mm) minimum and $\frac{1}{4}$ inch (6.4 mm) maximum. Ventilation openings having a least dimension larger than $\frac{1}{4}$ inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth or similar material with openings having a least dimension of $\frac{1}{16}$ inch (1.6 mm) minimum and $\frac{1}{4}$ inch (6.4 mm) maximum. Openings in roof framing members shall conform to the requirements of Section R802.7. Required ventilation openings shall open directly to the outside air.

❖ Large amounts of water vapor migrate by air movement or diffusion through the building envelope materials because of a vapor pressure difference. The sources of water vapor include cooking, laundering, bathing and human breathing and perspiration. These can account for an average daily production of 25 pounds (11.3 kg) of water vapor in a typical family-of-four dwelling. The average can be much higher where appliances such as humidifiers, washers and dryers are used.

As the vapor moves into the attic, it may reach its dew point, condensing on wood roof components. This wetting and drying action will cause rotting and decay. To avoid this, the attic must be ventilated to prevent the accumulation of water on building components. The installation of a vapor retarder acts to prevent the passage of moisture to the attic, and an effective vapor retarder allows a decrease in ventilation. Vapor retarders are ineffective when openings in the barrier allow moisture to be carried by air into the attic. This is also the reason exhaust fans must terminate outdoors and not in the attic. Care should be exercised to assure that attic vent openings remain unobstructed.

To minimize condensation problems within attic and enclosed rafter spaces, free-flow ventilation of such spaces is required. Ventilation openings must be screened to prevent the entry of animals. Ventilation openings requiring cutting or notching of the roof framing member must comply with Section R802.7.

R806.2 Minimum vent area. The minimum net free ventilating area shall be $\frac{1}{150}$ of the area of the vented space.

Exception: The minimum net free ventilation area shall be $\frac{1}{300}$ of the vented space provided one or more of the following conditions are met:

1. In Climate Zones 6, 7 and 8, a Class I or II vapor retarder is installed on the warm-in-winter side of the ceiling.
2. Not less than 40 percent and not more than 50 percent of the required ventilating area is provided by ventilators located in the upper portion of the attic or rafter space. Upper ventilators shall be located not

more than 3 feet (914 mm) below the ridge or highest point of the space, measured vertically, with the balance of the required ventilation provided by eave or cornice vents. Where the location of wall or roof framing members conflicts with the installation of upper ventilators, installation more than 3 feet (914 mm) below the ridge or highest point of the space shall be permitted.

❖ The attic vent size required by the code should not be overlooked. The net-free area can be as much as 50 percent less than the gross opening area. For example, one manufacturer's 24-inch square (610 mm) gable vent [gross area equals 576 square inches (0.37 m²)] is listed in its catalog as having a net free area of 308 square inches (0.20 m²), which is about 53 percent of the gross area. The manufacturer's literature should be consulted to obtain free-area information.

The exception permits a reduction in the required venting area if one of the two conditions is met. Condition 1 recognizes that in cold climates, a vapor retarder is required and permits a reduction based on the vapor retarder being installed on the warm-in-winter side of the ceiling. Condition 2 allows a reduction, provided cross ventilation is supplied as specified.

R806.3 Vent and insulation clearance. Where eave or cornice vents are installed, insulation shall not block the free flow of air. Not less than a 1-inch (25 mm) space shall be provided between the insulation and the roof sheathing and at the location of the vent.

❖ Vent openings must be maintained clear, and they must not block the free flow of air; therefore, the code requires that insulation be held back from the vent opening a minimum of 1 inch (25 mm). The 1-inch (25 mm) clearance must be maintained not only at the vent but throughout the attic and rafter spaces.

R806.4 Installation and weather protection. Ventilators shall be installed in accordance with manufacturer's instructions. Installation of ventilators in roof systems shall be in accordance with the requirements of Section R903. Installation of ventilators in wall systems shall be in accordance with the requirements of Section R703.1.

❖ The section requires that ventilators be installed in accordance with the manufacturer's instructions. This is essential so that ventilators provide the proper cross ventilation and perform as intended. Additionally, this section requires roof or wall ventilator installations to comply with the proper code-required weather protection, including flashing.

R806.5 Unvented attic and unvented enclosed rafter assemblies. Unvented *attics* and unvented enclosed roof framing assemblies created by ceilings that are applied directly to the underside of the roof framing members and structural roof sheathing applied directly to the top of the roof framing members/rafters, shall be permitted where all the following conditions are met:

1. The unvented *attic* space is completely within the *building thermal envelope*.

2. No interior Class I vapor retarders are installed on the ceiling side (*attic* floor) of the unvented *attic* assembly or on the ceiling side of the unvented enclosed roof framing assembly.
 3. Where wood shingles or shakes are used, a minimum $\frac{1}{4}$ -inch (6.4 mm) vented airspace separates the shingles or shakes and the roofing underlayment above the structural sheathing.
 4. In Climate Zones 5, 6, 7 and 8, any *air-impermeable insulation* shall be a Class II vapor retarder, or shall have a Class II vapor retarder coating or covering in direct contact with the underside of the insulation.
 5. Insulation shall be located in accordance with the following:
 - 5.1. Item 5.1.1, 5.1.2, 5.1.3 or 5.1.4 shall be met, depending on the air permeability of the insulation directly under the structural roof sheathing.
 - 5.1.1. Where only *air-impermeable insulation* is provided, it shall be applied in direct contact with the underside of the structural roof sheathing.
 - 5.1.2. Where *air-permeable insulation* is provided inside the building thermal envelope, it shall be installed in accordance with Section 5.1. In addition to the *air-permeable insulation* installed directly below the structural sheathing, rigid board or sheet insulation shall be installed directly above the structural roof sheathing in accordance with the *R*-values in Table R806.5 for condensation control.
 - 5.1.3. Where both *air-impermeable* and *air-permeable insulation* are provided, the *air-impermeable insulation* shall be applied in direct contact with the underside of the structural roof sheathing in accordance with Item 5.1.1 and shall be in accordance with the *R*-values in Table R806.5 for condensation control. The *air-permeable insulation* shall be installed directly under the *air-impermeable insulation*.
 - 5.1.4. Alternatively, sufficient rigid board or sheet insulation shall be installed directly above the structural roof sheathing to maintain the monthly average temperature of the underside of the structural roof sheathing above 45°F (7°C). For calculation purposes, an interior air temperature of 68°F (20°C) is assumed and the exterior air temperature is assumed to be the monthly average outside air temperature of the three coldest months.
 - 5.2. Where preformed insulation board is used as the air-impermeable insulation layer, it shall be sealed at the perimeter of each individual sheet interior surface to form a continuous layer.
- ❖ Unvented attics are attics where the insulation and air barrier boundary are directly above the attic space, instead of on top of the ceiling. Unvented attics elimi-

nate the extreme temperatures of the attic, thereby placing the HVAC, ducts, pipes, and anything in the attic space into a more favorable environment. Unvented attics increase energy efficiency and decrease wear and tear on equipment in the attic. This section describes such attics, where conditions are similar to the conditions of the residential space below. The primary benefit of having the insulation and air barrier above the attic is that ducts and/or HVAC equipment in the attic are not delivering cooled air through a hot summer attic and heated air through a cold winter attic. Another benefit is to eliminate the attic vents that sometimes allow moisture to condense inside the attic, admit rain during extreme weather and possibly admit sparks in fires.

Because this space is inside the building's thermal envelope, the traditional attic ventilation required by Sections R806.1 and R806.2 is not required. Unvented attics require water/moisture control. Water moves in (or out) of buildings three main ways. The greatest amount of moisture is moved as bulk water (rain or any kind of water flow). Less moisture is moved by moving moist air, such as with infiltration. The least amount of moisture is moved by moisture migration through materials. As with any attic, the roof itself is the main barrier for keeping water from entering the attic.

Unvented cathedral ceilings (enclosed roof framing assemblies) are permitted under this section. Unvented attics and unvented cathedral ceilings are similar. The governing physics are identical so these requirements work for both.

The provisions of this section can be applied to any attic area that is in compliance with this section. The attic is a traditional attic space, with the exception that it need not be ventilated and it will not get as hot or as cold as an attic that is open to the exterior.

It is very important that all of the five listed conditions be reviewed and considered for each building that uses the provisions of this section.

Item 1 requires that the attic space be completely contained within the building thermal envelope.

Item 2, which applies to all climate zones, prohibits the installation of a Class I vapor retarder where it is typically installed at the ceiling level (*attic* floor) of a traditional ventilated attic. This ensures that no barrier is installed that would separate the conditioned attic area from the remaining portion of the home. This requirement gives the attic space a limited potential to dry into the space beneath the attic so that small amounts of excess moisture can be removed from the attic.

Item 3 applies to all climate zones and contains special requirements that apply to wood shingles and shakes roof coverings. Wood shakes and shingles require a vented space under them to allow the wood to dry after it gets wet from rain.

Item 4 applies only to Climate Zones 5 or higher. The air-impermeable insulation must qualify as a Class II vapor retarder or have a Class II vapor

retarder coating or covering in direct contact with the insulation on the underside (interior) face of the insulation.

Item 5 requires sufficient insulation to keep moisture from condensing on the “condensing surface” inside the attic in “average conditions.” The insulation works to prevent condensation by keeping the condensing surface above the temperature where condensation will occur. Small amounts of condensation may occasionally occur at more extreme conditions; however, this is not a concern. The condensing surface is the interior side of the roof deck for air-permeable insulation and the interior of the insulation for air-impermeable insulation. The condensing surfaces differ because attic air can circulate through air-permeable insulation to contact the roof deck but can get only to the interior of air-impermeable insulation. The requirement for “air-impermeable” insulation will ensure that air and the moisture it can contain will not pass through the insulation to reach a point where it could condense because of the temperature. Item 5 specifies that air-impermeable insulation be in direct contact with the interior side of the roof deck. Air-impermeable insulation prevents the movement of moist air that comes in as infiltration through the roof into the interior of the attic. Air-impermeable insulation is defined as having an air permeance of 0.02 L/s-m² (at 75 Pa pressure) or less. Expanding spray foams and insulated sheathing (hard-foam sheathing board) are common types of air-impermeable insulation. When using insulated sheathing, attention to the details of completing the air sealing is required as the sheathing is installed in the roof. Fiberglass and cellulose are common types of air-permeable insulation.

Note that the insulation required by Item 5 may be more or less than the insulation required for energy efficiency in Chapter 11. If the amount of insulation required by Item 5 varies from the amount specified in Chapter 11, the provisions of Section R1102 would apply, and the higher insulation value would be required. The insulation provided to comply with Item 5 may be considered as contributing to the insulation required in Chapter 11.

It is important to realize that this section cannot be viewed as modifying or eliminating requirements found elsewhere in the code. Examples of sections that still affect these attic areas include Sections R302.10, R302.13, R316, R807, N1102.1 and others. Because the insulation typically used with this provision is some type of foam plastic, the requirements of Section R316 must be applied. The provisions of Section R806.4 do not in any way modify or eliminate the requirements for a thermal barrier (Section R316.4) or protection from ignition (Section R316.5.3). See the commentary to Sections R302.10 and R316 for a complete discussion regarding these requirements and the options available. Ducts in this unvented attic construction would be considered as being inside the building thermal envelope and would not require insulation (see Section N1103.3.1).

The provisions of this section consider the attic assembly as a “conditioned” space; there is no requirement for the space to be provided with conditioned air supply. The attic space is considered indirectly conditioned because of omission of the air barrier, insulation at the ceiling and leakage around the attic access opening. An attic assembly complying with Section R806.5 will generally fall within the temperature ranges specified in the definition of “Conditioned space.”

The key concept of this section is to move the thermal envelope (insulation) above the attic, resulting in the attic being in a conditioned (or sometimes semi-conditioned) space. Direct air supply to the attic is not required if the attic floor is not insulated; the attic temperature would be similar to interior conditioned spaces. Ducts and/or HVAC equipment in the attic also help moderate the attic conditions.

**TABLE R806.5
INSULATION FOR CONDENSATION CONTROL**

CLIMATE ZONE	MINIMUM RIGID BOARD ON AIR-IMPERMEABLE INSULATION R-VALUE ^{a, b}
2B and 3B tile roof only	0 (none required)
1, 2A, 2B, 3A, 3B, 3C	R-5
4C	R-10
4A, 4B	R-15
5	R-20
6	R-25
7	R-30
8	R-35

- a. Contributes to but does not supersede the requirements in Section N1102.
- b. Alternatively, sufficient continuous insulation shall be installed directly above the structural roof sheathing to maintain the monthly average temperature of the underside of the structural roof sheathing above 45°F (7°C). For calculation purposes, an interior air temperature of 68°F (20°C) is assumed and the exterior air temperature is assumed to be the monthly average outside air temperature of the three coldest months.

❖ Section R806.5 provides three options for installing insulation at the roof line for unvented attics and unvented rafter spaces: air-impermeable insulation (typically foam plastic) installed directly below the roof sheathing; a combination of air-impermeable and air-permeable insulation installed below the roof sheathing; and air-impermeable insulation (rigid board or sheet insulation) installed above the structural roof sheathing. In the last case, the minimum R-value for the rigid board or sheet insulation is determined from Table R806.5 based on climate zone to prevent condensation on the underside of the structural roof sheathing. Note b provides a calculation procedure to determine necessary rigid board or air-impermeable insulation R-values for roof assemblies that do not meet the requirements of Table R806.5.

SECTION R807 ATTIC ACCESS

R807.1 Attic access. Buildings with combustible ceiling or roof construction shall have an *attic* access opening to *attic* areas that have a vertical height of 30 inches (762 mm) or greater over an area of not less than 30 square feet (2.8 m²). The vertical height shall be measured from the top of the ceiling framing members to the underside of the roof framing members.

The rough-framed opening shall be not less than 22 inches by 30 inches (559 mm by 762 mm) and shall be located in a hallway or other readily accessible location. Where located in a wall, the opening shall be not less than 22 inches wide by 30 inches high (559 mm wide by 762 mm high). Where the access is located in a ceiling, minimum unobstructed headroom in the *attic* space shall be 30 inches (762 mm) at some point above the access measured vertically from the bottom of ceiling framing members. See Section M1305.1.3 for access requirements where mechanical *equipment* is located in *attics*.

❖ The requirement for an attic access is predicated on the likelihood that during the life of the structure, access to an attic space for repair of piping, electrical and mechanical systems will be required.

Chapter 9: Roof Assemblies

General Comments

Although a small portion of this chapter regulates the fire classification of roof covering materials, the major emphasis is on the materials and installation methods that will result in a weather-tight exterior envelope. The code limits the requirements for fire-retardant roof coverings to two scenarios: where the local or state ordinances in effect mandate a classified roof covering; and where the edge of the roof is in close proximity to a property line. Otherwise, the provisions of the chapter focus on the weather-protection features of a roof assembly.

The chapter contains a number of specific code requirements for various types of roof covering materials. These requirements may place limitations on roof slope, identify the proper attachment methods, mandate the use of underlayment and address flashing at appropriate points. In addition, the code often references a specification or installation standard for a particular type of roof covering. In all cases, it is important that the manufacturer's installation instructions be followed.

This chapter contains provisions for the design and construction of roof assemblies, primarily focusing on the materials and installation of roof coverings. The general requirements for roof assemblies found in the code deal with the role of the roof as a portion of the exterior envelope that provides weather protection for the building. Fire classifications, roof drainage, roof insulation, rooftop-mounted photovoltaic systems and reroofing operations are also addressed.

Section R901 states the scope of the chapter, including both the materials and the quality of roof construction. Section R902 deals with fire-classification requirements for roof covering materials where the roof extends very close to an adjoining property line. Section R903 establishes the general requirements for weather protection, including provisions for flashing and roof drainage.

Section R904 establishes general requirements for roofing materials. Section R905 discusses the many different types of roof covering materials regulated by the code, including asphalt shingles, clay and concrete tile,

metal roof shingles, mineral-surfaced roll roofing, wood shakes and shingles, slate and slate-type shingles, built-up roofs, metal roof panels, modified bitumen roofing, thermoset and thermoplastic single-ply roofing, sprayed polyurethane foam roofing, liquid-applied coatings and photovoltaic modules/shingles. Section R906 allows the installation of above-deck thermal installation where appropriately listed. Section R907 addresses the installation requirements for rooftop-mounted photovoltaic panels and modules. Section R908 establishes the methods and materials acceptable for recovering or replacing an existing roof. Section R909 specifies the structural and installation requirements for rooftop-mounted photovoltaic panel systems.

Purpose

Chapter 9 regulates the design and construction of roof assemblies. A roof assembly includes the roof deck, vapor retarder, substrate or thermal barrier, insulation, vapor retarder and roof covering. This chapter provides the requirement for wind resistance of roof coverings.

Roof assemblies fulfill a variety of functions; however, this chapter deals primarily with roof coverings for weather protection. The requirements address the design and construction of roof assemblies, with a focus on the materials and quality of installation. Although a number of requirements are specified directly from the code, the majority of the regulations applicable to roof coverings come from the material standards. In addition, the manufacturer's installation instructions should always be followed for the specific roof covering material under consideration. Flashing and roof drainage criteria are also important aspects of weather-protection features. Many common roof coverings are addressed by detailed provisions regulating the roof deck, roof slope, underlayment, application and attachment. Where a new roof is required for an existing building, the code sets specific guidelines for either recovering or replacing the existing roof covering.

SECTION R901 GENERAL

R901.1 Scope. The provisions of this chapter shall govern the design, materials, construction and quality of roof assemblies.

❖ The focus of this chapter is on roof coverings. A variety of roof-covering materials are included, such as

asphalt shingles, clay and concrete tile, metal roof shingles, wood shingles and shakes and metal roof panels. Roof classification, drainage, insulation and flashing are also regulated, as is the reroofing of an existing roof.

**SECTION R902
FIRE CLASSIFICATION**

R902.1 Roofing covering materials. Roofs shall be covered with materials as set forth in Sections R904 and R905. Class A, B or C roofing shall be installed in jurisdictions designated by law as requiring their use or where the edge of the roof is less than 3 feet (914 mm) from a lot line. Class A, B and C roofing required by this section to be listed shall be tested in accordance with UL 790 or ASTM E108.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
 2. Class A roof assemblies include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on noncombustible decks.
 3. Class A roof assemblies include minimum 16 ounces per square foot copper sheets installed over combustible decks.
 4. Class A roof assemblies include slate installed over underlayment over combustible decks.
- ❖ The code identifies two conditions under which roof assembly classifications A, B, or C are required. First, where local, state or other governing ordinance requires the use of Class A, B or C roofing, it must be installed as designated by the law. Second, on roofs that project within 3 feet (914 mm) of the lot line, a Class A, B or C roof must be installed. Testing for such roofing must be in accordance with either ASTM E108 or UL 790.

Roof coverings classified as Class A, B or C have been shown through testing to provide protection of the roof against severe, moderate and light fire exposures, respectively. These exposures are external and are generally created by fires in adjoining structures, wild fires and fires from the subject building that extend up the exterior and onto the top surface of the roof. Wild fires and some structure fires create flying and flaming brands that can ignite nonclassified roof coverings.

By their nature, roof coverings composed of brick, masonry, exposed concrete roof deck, slate, clay tile, concrete tile, ferrous or copper shingles or sheets and metal sheets or shingles are considered excellent materials for resisting fire spread. The exceptions permit these materials to be considered Class A and exempt from testing to UL 790 or ASTM E108. The materials in Exception 2 must be installed on noncombustible decks to be considered Class A and exempt from testing.

Where installed on a combustible deck, during brush fire conditions in the field, roof coverings can be exposed to burning brands that may break slate or clay or concrete roof tile, since they are brittle materi-

als, and expose the roof deck to the fire. Further, high winds caused by a brush fire can lift the butt ends of slate or concrete or clay roof tiles, allowing the entry of embers under the roof covering and igniting the combustible deck.

These materials in Exception 2 must be tested if installed on a combustible deck.

Exception 3 permits 16 ounce/square foot copper sheets to be considered Class A and exempt from testing where installed over combustible decks. Exception 4 will allow slate to be considered Class A where the slate is installed over underlayment on a combustible deck.

R902.2 Fire-retardant-treated shingles and shakes. Fire-retardant-treated wood shakes and shingles shall be treated by impregnation with chemicals by the full-cell vacuum-pressure process, in accordance with AWPA C1. Each bundle shall be marked to identify the manufactured unit and the manufacturer, and shall be *labeled* to identify the classification of the material in accordance with the testing required in Section R902.1, the treating company and the quality control agency.

- ❖ This section recognizes the process of impregnating wood shakes and shingles with chemicals in order to make them fire retardant. AWPA C1, regulating the preservative treatment of timber products by pressure processes, is the referenced standard. During the impregnation process the cells of wood shakes and shingles are exposed to a vacuum that draws all of the air and moisture from the material. Fire-retardant chemicals are then impregnated into the shakes and shingles by pressurization. After proper curing, the shakes and shingles are then classified. The fire classification must be marked on each bundle of materials, along with other manufacturing information. Identification will also include the name of the company performing the pressure-treatment process, as well as the quality control agency reviewing for compliance with the test standard.

R902.3 Building-integrated photovoltaic product. Building-integrated photovoltaic products installed as the roof covering shall be tested, listed and labeled for fire classification in accordance with Section R902.1.

- ❖ Photovoltaic products used as roof covering must be tested to comply with Section R902.1.

R902.4 Rooftop-mounted photovoltaic panels and modules. Rooftop-mounted photovoltaic panels and modules installed on or above the roof covering shall be tested, listed and identified with a fire classification in accordance with UL 1703. Class A, B or C photovoltaic panels and modules shall be installed in jurisdictions designated by law as requiring their use or where the edge of the roof is less than 3 feet (914 mm) from a lot line.

- ❖ Rooftop-mounted photovoltaic panels and modules must have a fire classification of Class A, B or C in accordance with UL 1703.

SECTION R903 WEATHER PROTECTION

R903.1 General. Roof decks shall be covered with *approved* roof coverings secured to the building or structure in accordance with the provisions of this chapter. Roof assemblies shall be designed and installed in accordance with this code and the *approved* manufacturer's instructions such that the roof assembly shall serve to protect the building or structure.

❖ In all cases, a roof must be designed to provide protection from the elements. For the roof to adequately perform this function, it must be designed in accordance with this chapter. This section requires flashing where the roof intersects vertical elements such as walls, chimneys, dormers, plumbing stacks, plumbing vents and other penetrations of the weather-protective barrier. Roof drainage to remove water from the roof to an approved location is also regulated.

Materials and installation methods for roof decks and supporting elements are regulated by Chapter 8 of the code. A complying roof deck must then be covered in an approved manner to provide the necessary weather protection mandated by the code. This chapter includes the necessary provisions for such a weatherproof barrier. In addition, and just as important, the approved manufacturer's installation instructions must be adhered to.

R903.2 Flashing. Flashings shall be installed in a manner that prevents moisture from entering the wall and roof through joints in copings, through moisture permeable materials and at intersections with parapet walls and other penetrations through the roof plane.

❖ As with flashing required for other locations at the building's exterior, it is critical that locations where moisture may penetrate the exterior membrane at the roof be adequately protected. General locations identified include joints at the coping, intersections with parapet walls and other penetrations through the roof plane.

R903.2.1 Locations. Flashings shall be installed at wall and roof intersections, wherever there is a change in roof slope or direction and around roof openings. A flashing shall be installed to divert the water away from where the eave of a sloped roof intersects a vertical sidewall. Where flashing is of metal, the metal shall be corrosion resistant with a thickness of not less than 0.019 inch (0.5 mm) (No. 26 galvanized sheet).

❖ This section identifies specific roof locations for the installation of flashings. In those cases where metal is used as the flashing material, it must be corrosion resistant and a minimum No. 26 galvanized sheet.

R903.2.2 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration more than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

Exception: Unit skylights installed in accordance with Section R308.6 and flashed in accordance with the manu-

facturer's instructions shall be permitted to be installed without a cricket or saddle.

❖ Where a chimney is more than 30 inches (762 mm) wide, as measured perpendicular to the slope, a cricket or saddle must be installed on the ridge side of the chimney to divert water away from the chimney penetration of the roof. A chimney of such width creates the potential for standing water that, despite appropriate flashing, can be detrimental to the roof's performance.

The exception permits engineered skylights that are designed to prevent water infiltration without the use of a cricket.

R903.3 Coping. Parapet walls shall be properly coped with noncombustible, weatherproof materials of a width not less than the thickness of the parapet wall.

❖ The top of an exterior wall, typically a masonry parapet wall, must have a coping. It is typically sloped to prevent standing water, and it must be of noncombustible, weatherproof materials. To maintain protection at the top of the wall, the coping must extend the full thickness of the parapet wall.

R903.4 Roof drainage. Unless roofs are sloped to drain over roof edges, roof drains shall be installed at each low point of the roof.

❖ In most residential construction, drainage water from the roof simply flows down the roof's slope and over the roof edge, often to a gutter and downspout system that carries the water away from the building. In situations where the roof design does not allow for water flow over the roof edges, roof drains must be installed in the roof surface. The drains will be at the low points of the roof, sized and located to remove all roof water. In a case where the low points occur at parapets of the exterior walls, scuppers through the parapets must be provided, constructed with the flow points level with the roof surface at the low points and located based on the roof slope and contributing roof area.

R903.4.1 Secondary (emergency overflow) drains or scuppers. Where roof drains are required, secondary emergency overflow roof drains or scuppers shall be provided where the roof perimeter construction extends above the roof in such a manner that water will be entrapped if the primary drains allow buildup for any reason. Overflow drains having the same size as the roof drains shall be installed with the inlet flow line located 2 inches (51 mm) above the low point of the roof, or overflow scuppers having three times the size of the roof drains and having a minimum opening height of 4 inches (102 mm) shall be installed in the adjacent parapet walls with the inlet flow located 2 inches (51 mm) above the low point of the roof served. The installation and sizing of overflow drains, leaders and conductors shall comply with Sections 1106 and 1108 of the *International Plumbing Code*, as applicable.

Overflow drains shall discharge to an *approved* location and shall not be connected to roof drain lines.

❖ It is quite possible that roof drains may become clogged or blocked by debris, resulting in insufficient

drainage. This could cause structural failure of portions of the roof system resulting from the increased weight on the roof caused by the impounded water. This section addresses such concerns by requiring overflow drains or overflow scuppers for those roofs that do not drain over the roof edges.

Although the required roof drains must be located at the low points of the roof, the overflow drain inlets need to be located 2 inches (51 mm) vertically above the low points. The same criterion applies where overflow scuppers are provided. In addition, overflow scuppers must be sized with a minimum opening height of 4 inches (102 mm) and have an opening area at least three times that of the roof drains. The *International Plumbing Code*[®] (IPC[®]) sets forth the specific details for the installation and sizing of overflow drains, leaders and conductors.

The overflow drains must not be connected to the roof drains. In the event a blockage occurs in the drainage line beyond the point of connection, both the roof drain and the overflow drain would be affected. The overflow drain should discharge to an approved location, typically a highly visible location that would indicate the overflow system is in use. This will provide an alert that there is some sort of blockage in the primary roof drain system.

SECTION R904 MATERIALS

R904.1 Scope. The requirements set forth in this section shall apply to the application of roof covering materials specified herein. Roof assemblies shall be applied in accordance with this chapter and the manufacturer's installation instructions. Installation of roof assemblies shall comply with the applicable provisions of Section R905.

- ❖ Roof assemblies and roof covering materials must conform to the provisions of this chapter, the applicable referenced standards listed in Chapter 44 and the manufacturer's installation instructions. This section provides general conditions for the application of roof covering materials referenced elsewhere in Chapter 9. A cross reference to Section R905 is provided for requirements dealing with the installation of specific roof coverings.

R904.2 Compatibility of materials. Roof assemblies shall be of materials that are compatible with each other and with the building or structure to which the materials are applied.

- ❖ The materials used in a roof assembly must be compatible in order to avoid a decrease or failure in the performance of the roof. Not only must the roofing materials be compatible with each other, they must also be suitable for the building as a whole.

R904.3 Material specifications and physical characteristics. Roof covering materials shall conform to the applicable standards listed in this chapter.

- ❖ Materials used as roof coverings are regulated by an applicable standard. Roof covering materials are identified in this chapter, and also listed in Chapter 44.

R904.4 Product identification. Roof covering materials shall be delivered in packages bearing the manufacturer's identifying marks and *approved* testing agency *labels* required. Bulk shipments of materials shall be accompanied by the same information issued in the form of a certificate or on a bill of lading by the manufacturer.

- ❖ Identification of roof covering materials provides much of the information necessary for acceptance of the materials by the building official. Because it is often difficult, if not impossible, to identify complying roof covering materials by visual observation, other proper identification of the materials is mandatory. Packaging of roof covering materials must include the manufacturer's identification marks. If the code or applicable standard requires review by an approved testing agency, the identifying marks of the testing agency must also be shown. The code also addresses the identification requirements for bulk shipments of materials.

SECTION R905 REQUIREMENTS FOR ROOF COVERINGS

R905.1 Roof covering application. Roof coverings shall be applied in accordance with the applicable provisions of this section and the manufacturer's installation instructions. Unless otherwise specified in this section, roof coverings shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

- ❖ In addition to the minimum requirements specified for roof coverings in the code, manuals published by various associations provide detailed discussions of the proper methods of installing roof coverings. These methods have been established based on many years of experience with the materials and their performance. Although the provisions in these documents are not specific code requirements, this section mandates the use of the manufacturer's installation instructions. It is important that roof coverings remain intact and in place when subjected to wind. Without an intact roof covering, the building would be subjected to either water damage, which could reduce its structural stability, or to higher wind pressures than the building is designed for. Unless Section R905 specifies otherwise, roof coverings must be installed to resist the wind pressures determined from Table R301.2(2) [see commentaries, Tables R301.2(2) and R301.2(3)].

R905.1.1 Underlayment. Underlayment for asphalt shingles, clay and concrete tile, metal roof shingles, mineral-surfaced roll roofing, slate and slate-type shingles, wood shingles, wood shakes and metal roof panels shall conform to the applicable standards listed in this chapter. Underlayment materials required to comply with ASTM D226, D1970, D4869 and D6757 shall bear a label indicating compliance to the standard designation and, if applicable, type classification indicated in Table R905.1.1(1). Underlayment shall be applied in accordance with Table R905.1.1(2). Underlayment shall be attached in accordance with Table R905.1.1(3).

Exceptions:

1. As an alternative, self-adhering polymer-modified bitumen underlayment complying with ASTM D1970 installed in accordance with both the underlayment manufacturer's and roof covering manufacturer's instructions for the deck material, roof ventilation configuration and climate exposure for the roof covering to be installed, shall be permitted.
2. As an alternative, a minimum 4-inch-wide (102 mm) strip of self-adhering polymer-modified bitumen membrane complying with ASTM D1970, installed in accordance with the manufacturer's instructions for the deck material, shall be applied over all joints in the roof decking. An approved underlayment for the applicable roof covering for maximum ultimate design wind speeds, V_{ult} , less than 140 miles per hour shall be applied over the entire roof over the 4-inch-wide (102 mm) membrane strips.

❖ Section R905.1.1 reorganizes the underlayment provisions contained in the *International Residential Code*® (IRC®). In the 2012 IRC, underlayment provisions were specified individually for each type of roof covering. Many of the roof covering provisions contained identical requirements for underlayment type, application, and attachment. The underlayment requirements for roof covering have been relocated to Section R905.1.1. There are three new tables that address underlayment type [Table R905.1.1(1)], application [Table R905.1.1(2)], and attachment [Table R905.1.1(3)] for each roof covering in the code that requires underlayment. Consolidating the underlayment requirements into a single section makes provisions easier to locate and highlights key differences between requirements for underlayment for different types of roof coverings. The exceptions permit the use of self-adhering underlayment. The exceptions clarify the permitted installations of the self-adhering membrane that would provide an equivalent or better level of water intrusion prevention to the underlayment requirements for high wind. The criteria specified are consistent with the Insurance Institute for Business and Home Safety FORTIFIED® program requirements

for creating a "sealed roof deck." Additionally, the provisions of this proposal are the most widely accepted methods recognized by insurance companies for providing discounts and credits in high-wind regions.

Table R905.1.1(1) specifies the underlayment material types required for the various roof coverings listed. Where the ultimate design wind speed is equal to or greater than 140 mph, Table R905.1.1(1) requires a more robust underlayment. For example, tests and studies have shown that ASTM D226, Type I (No. 15) underlayment performs very poorly in areas subject to wind speeds of 120 mph or greater. Observations of roof underlayment performance following Hurricane Ike in Texas and in two sets of tests conducted at the University of Florida and Florida International University demonstrated that ASTM D226, Type I underlayment performed poorly when subjected to wind over about 110 mph. In laboratory tests, specimens covered with ASTM D226, Type I and Type II underlayment performed dramatically differently. ASTM D226, Type I felt (No.15) material completely blew off some portions of the specimen as winds exceeded 110 mph and pulled over the plastic caps on other parts of the specimen. In contrast, the ASTM D226, Type II (No. 30) material remained in place and showed very few signs of distress. Plastic caps deformed more than the metal caps in several installations.

Table R905.1.1(2) specifies the underlayment application for both low-slope and high-slope roofs. Low-slope roofs present a potential problem because water drains slowly, and this creates the opportunity for water backup. Wind-driven rain can also pose a problem. Therefore, a special underlayment application method is used so that the roof remains weather tight. All portions of the roof will be protected by a minimum of two layers of underlayment if the installer follows the instructions found in Table R905.1.1(2). Commentary Figure R905.1.1 illustrates the required application of underlayment for a low-slope application. Only one layer of underlayment, applied in shingle fashion in accordance with this section, is mandated for high-slope roofs.

Table R905.1.1(3) specifies the required underlayment attachment. Where located in low-wind regions (maximum ultimate design wind speed less than 140 mph), the underlayment must be fastened sufficiently to hold in place and in accordance with the manufacturer's installation instruction. Where located in high-wind regions (ultimate design wind speed of 140 mph or greater) the underlayment must be attached with corrosion-resistant fasteners in a grid pattern. Metal or plastic cap nails or cap staples must be used to attach the underlayment to the roof sheathing.

TABLE R905.1.1(1)
UNDERLAYMENT TYPES

ROOF COVERING	SECTION	MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} < 140$ MPH	MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} \geq 140$ MPH
Asphalt shingles	R905.2	ASTM D226 Type I ASTM D4869 Type I, II, III or IV ASTM D6757	ASTM D226 Type II ASTM D4869 Type IV ASTM D6757
Clay and concrete tile	R905.3	ASTM D226 Type II ASTM D2626 Type I ASTM D6380 Class M mineral-surfaced roll roofing	ASTM D226 Type II ASTM D2626 Type I ASTM D6380 Class M mineral-surfaced roll roofing
Metal roof shingles	R905.4	ASTM D226 Type I or II ASTM D4869 Type I, II, III or IV	ASTM D226 Type II ASTM D4869 Type IV

UNDERLAYMENT ATTACHMENT**

ROOF COVERING	SECTION	MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} < 140$ MPH	MAXIMUM ULTIMATE DESIGN WIND SPEED, $V_{ult} \geq 140$ MPH
Asphalt shingles	R905.2	Fastened sufficiently to hold in place	<p>The underlayment shall be attached with corrosion-resistant fasteners in a grid pattern of 12 inches between side laps with a 6-inch spacing at the side laps.</p> <p>Underlayment shall be attached using metal or plastic cap nails or cap staples with a nominal cap diameter of not less than 1 inch. Metal caps shall have a thickness of not less than 32-gage sheet metal. Power-driven metal caps shall have a minimum thickness of 0.010 inch. Minimum thickness of the outside edge of plastic caps shall be 0.035 inch. The cap nail shank shall be not less than 0.083 inch for ring shank cap nails and 0.091 inch for smooth shank cap nails. Staples shall be not less than 21 gage. Cap nail shank and cap staple legs shall have a length sufficient to penetrate through the roof sheathing or not less than $\frac{3}{4}$ inch into the roof sheathing.</p>
Clay and concrete tile	R905.3		
Metal roof shingles	R905.4	Manufacturer's installation instructions.	<p>The underlayment shall be attached with corrosion-resistant fasteners in a grid pattern of 12 inches between side laps with a 6-inch spacing at the side laps.</p> <p>Underlayment shall be attached using metal or plastic cap nails or cap staples with a nominal cap diameter of not less than 1 inch. Metal caps shall have a thickness of at least 32-gage sheet metal. Power-driven metal caps shall have a minimum thickness of 0.010 inch. Minimum thickness of the outside edge of plastic caps shall be 0.035 inch. The cap nail shank shall be not less than 0.083 inch for ring shank cap nails and 0.091 inch for smooth shank cap nails. Staples shall be not less than 21 gage. Cap nail shank and cap staple legs shall have a length sufficient to penetrate through the roof sheathing or not less than $\frac{3}{4}$ inch into the roof sheathing.</p>
Mineral-surfaced roll roofing	R905.5		
Slate and slate-type shingles	R905.6		
Wood shingles	R905.7		
Wood shakes	R905.8		
Metal panels	R905.10		

For SI: 1 inch = 25.4 mm.

R905.1.2 Ice barriers. In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(1), an ice barrier shall be installed for asphalt shingles, metal roof shingles, mineral-surfaced roll roofing, slate and slate-type shingles, wood shingles and wood shakes. The ice barrier shall consist of not fewer than two layers of underlayment cemented together, or a self-adhering polymer-modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point not less than 24 inches (610 mm) inside the exterior wall line of the building. On roofs with slope equal to or greater than 8 units vertical in 12 units horizontal, the ice barrier shall also be applied not less than 36 inches (914 mm) measured along the roof slope from the eave edge of the building.

Exception: Detached accessory structures not containing conditioned floor area.

- ❖ Where ice dams may be formed along the eave because snow continually freezes and thaws or frozen slush backs up in gutters, the underlayment application must be modified to prevent ice dams from forcing water under the roof covering, which could damage ceilings, walls and insulation [see Commentary Figure R905.1.2(1)]. Two layers of underlayment should be cemented together with asphalt cement from the lowest edge of the roof up the roof to a point that is at least 24 inches (610 mm) inside the interior wall line of the building, as shown in Commentary Figure R905.1.2(2). The environment within the envelope of the building provides adequate warmth to prevent ice dams from forming above the heated space; therefore, the two layers of cemented underlayment are permitted to terminate 24 inches (610 mm) inside the interior wall line of the building. The local jurisdiction is responsible for determining whether the ice barrier is required based on weather records, and it must so indicate in Table R301.2(1). Section R905.1.2 applies only to roof coverings of asphalt shingles, metal roof shingles, mineral-surfaced roll roofing, slate shingles, wood shingles and wood shakes.

An exception to this section exempts unheated accessory buildings from such restrictions because they are unheated structures where the need for protection against ice dams is unnecessary.

R905.2 Asphalt shingles. The installation of asphalt shingles shall comply with the provisions of this section.

- ❖ This section regulates asphalt shingles composed of organic felt or glass felt and coated with mineral granules. Provisions address requirements for sheathing, roof slope, underlayment, fasteners and attachment.

R905.2.1 Sheathing requirements. Asphalt shingles shall be fastened to solidly sheathed decks.

- ❖ The code requires a solid roof surface for the installation of asphalt shingles. Section R803 regulates solid sheathing.

For SI: 1 inch = 25.4 mm.

**Figure R905.1.2(2)
PROTECTIVE ICE BARRIER**

ROOF ASSEMBLIES

R905.2.2 Slope. Asphalt shingles shall be used only on roof slopes of two units vertical in 12 units horizontal (2:12) or greater. For roof slopes from two units vertical in 12 units horizontal (2:12) up to four units vertical in 12 units horizontal (4:12), double underlayment application is required in accordance with Section R905.1.1.

❖ The performance of all roof coverings is based in part on the slope of the roof surface. As the slope of the roof decreases, water drainage is slowed, and the potential for water intrusion increases because of the greater potential of water backup under the roofing.

Asphalt shingles, because of their configuration and installation methods, are restricted to use on roofs having a minimum slope of 2:12. Where the slope is no steeper than 4:12, the underlayment must be doubled to provide a greater barrier to leakage. Section R905.2.7 specifies the method of such double underlayment. Commentary Figure R905.2.2(1) shows an example of asphalt roof shingles installed on a high-slope roof (4:12 minimum), while Commentary Figure R905.2.2(2) depicts a low-slope roof installation (between 2:12 and 4:12).

R905.2.3 Underlayment. Underlayment shall comply with Section R905.1.1.

❖ See the commentary to Section R905.1.1.

R905.2.4 Asphalt shingles. Asphalt shingles shall comply with ASTM D3462.

❖ Asphalt shingles must comply with ASTM D3462. ASTM D3462 is the standard specification for asphalt shingles made from glass felt and surfaced with mineral granules.

R905.2.4.1 Wind resistance of asphalt shingles. Asphalt shingles shall be tested in accordance with ASTM D7158. Asphalt shingles shall meet the classification requirements of Table R905.2.4.1 for the appropriate ultimate design wind speed. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D7158 and the required classification in Table R905.2.4.1.

Exception: Asphalt shingles not included in the scope of ASTM D7158 shall be tested and labeled to indicate compliance with ASTM D3161 and the required classification in Table R905.2.4.1.

❖ This section provides requirements for the testing, classification and labeling of asphalt shingles to demonstrate resistance to wind forces. The asphalt shingles must meet the classification requirement for the appropriate ultimate design wind speed and comply with the appropriate product standard. The required standard is ASTM D7158 with an exception for products outside the scope of ASTM D7158. ASTM D7158 provides a method of testing that is appropriate for sealed asphalt shingles. The exception references ASTM D3161 and is necessary for unsealed shingles. Table R905.2.4.1 provides the proper application of the two standards. The table will assist in the selection of asphalt shingles based upon the appropriate ultimate design wind speed and the applicable standard.

TABLE R905.2.4.1. See below.

❖ See the commentary to Section 905.2.4.1.

R905.2.5 Fasteners. Fasteners for asphalt shingles shall be galvanized steel, stainless steel, aluminum or copper roofing nails, minimum 12-gage [0.105 inch (3 mm)] shank with a minimum 3/8-inch-diameter (9.5 mm) head, complying with ASTM F1667, of a length to penetrate through the roofing materials and not less than 3/4 inch (19.1 mm) into the roof sheathing. Where the roof sheathing is less than 3/4 inch (19.1 mm) thick, the fasteners shall penetrate through the sheathing.

❖ Roofing nails must be of a corrosion-resistant material, specified in this section as either galvanized steel, stainless steel, aluminum or copper. A roofing nail must have a minimum 12-gage shank with a head at least 3/8 inch (9.5 mm) in diameter. To provide the necessary holding power, roofing nails must penetrate the roof sheathing a minimum of 3/4 inch (19.1 mm). For roof sheathing having a thickness less than 3/4 inch (19.1 mm), the nails must penetrate completely through the sheathing. The material specification standard for roofing nails is ASTM F1667.

R905.2.6 Attachment. Asphalt shingles shall have the minimum number of fasteners required by the manufacturer, but not less than four fasteners per strip shingle or two fasteners per individual shingle. Where the roof slope exceeds 21 units vertical in 12 units horizontal (21:12, 175-percent slope), shingles shall be installed as required by the manufacturer.

❖ Section R905.2.4.1 requires the wind resistance of asphalt shingles to be determined by ASTM D7158 or ASTM D3161. The ASTM D7158 test method covers the procedure for calculating the wind resistance of asphalt shingles when applied in accordance with the manufacturer's instruction and sealed under defined conditions. The ASTM D3161 test method covers the procedure for testing asphalt shingles that are resistant to wind blow-up or blow-off when applied on low slopes in accordance with the manufacturer's instructions. This test method may be used to test self-sealing or interlocked shingles.

**TABLE R905.2.4.1
CLASSIFICATION OF ASPHALT ROOF SHINGLES**

MAXIMUM ULTIMATE DESIGN WIND SPEED, V_{ult} FROM FIGURE R301.2(4)A (mph)	MAXIMUM BASIC WIND SPEED, V_{ASD} FROM TABLE R301.2.1.3 (mph)	ASTM D7158* SHINGLE CLASSIFICATION	ASTM D3161 SHINGLE CLASSIFICATION
110	85	D, G or H	A, D or F
116	90	D, G or H	A, D or F
129	100	G or H	A, D or F
142	110	G or H	F
155	120	G or H	F
168	130	H	F
181	140	H	F
194	150	H	F

For SI: 1 foot = 304.8 mm; 1 mph = 0.447 m/s.

a. The standard calculations contained in ASTM D7158 assume Exposure Category B or C and building height of 60 feet or less. Additional calculations are required for conditions outside of these assumptions.

Neither of these tests is a test of the fasteners. However, fastening in accordance with the manufacturer's instruction is required for shingles that pass these tests.

The minimum number of fasteners for asphalt shingles must be the number required by the manufacturer's instructions. Except for steep roof slopes, the minimum quantity of fasteners per shingle is four for strip shingles and two for individual shingles.

For steep roof slopes (slopes greater than 21:12), the manufacturer's installation instructions and minimum quantity of fasteners per shingles must be followed.

R905.2.7 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

❖ See the commentary to Section R905.1.2.

R905.2.8 Flashing. Flashing for asphalt shingles shall comply with this section.

❖ This section sets forth the special conditions for flashing installed as a part of an asphalt shingle roof system. Specific flashing locations addressed include base and cap flashing, valleys, crickets and saddles and sidewall flashing.

R905.2.8.1 Base and cap flashing. Base and cap flashing shall be installed in accordance with manufacturer's instructions. Base flashing shall be of either corrosion-resistant metal of minimum nominal 0.019-inch (0.5 mm) thickness or mineral-surfaced roll roofing weighing not less than 77 pounds per 100 square feet (4 kg/m²). Cap flashing shall be corrosion-resistant metal of minimum nominal 0.019-inch (0.5 mm) thickness.

❖ If metal is used as cap or base flashing, it must be corrosion resistant and have a minimum nominal thickness of 0.019 inch (0.483 mm). Mineral-surfaced roll roofing may also be used as base flashing, if it has a minimum weight of 77 pounds per 100 square feet (4 kg/m²).

R905.2.8.2 Valleys. Valley linings shall be installed in accordance with the manufacturer's instructions before applying shingles. Valley linings of the following types shall be permitted:

1. For open valleys (valley lining exposed) lined with metal, the valley lining shall be not less than 24 inches (610 mm) wide and of any of the corrosion-resistant metals in Table R905.2.8.2.
2. For open valleys, valley lining of two plies of mineral-surfaced roll roofing, complying with ASTM D3909 or ASTM D6380 Class M, shall be permitted. The bottom layer shall be 18 inches (457 mm) and the top layer not less than 36 inches (914 mm) wide.
3. For closed valleys (valley covered with shingles), valley lining of one ply of smooth roll roofing complying with ASTM D6380 and not less than 36 inches wide (914 mm) or valley lining as described in Item 1 or 2 shall be permitted. Self-adhering polymer modified

bitumen underlayment complying with ASTM D1970 shall be permitted in lieu of the lining material.

❖ Open valley linings may be of either metal or mineral-surfaced roll roofing as set forth in this section. Closed valleys are also permitted with a number of lining alternatives available. Commentary Figures R905.2.8.2(1) and R905.2.8.2(2) illustrate typical valley flashings for open and closed (woven) valleys, respectively.

TABLE R905.2.8.2. See page below.

❖ If exposed corrosion-resistant metal materials are used as valley linings, they are regulated by this table. The table identifies a variety of acceptable metal linings, including copper, aluminum, stainless steel, galvanized steel, zinc alloy, lead and painted terne. The materials are regulated by their thickness, gage or weight.

R905.2.8.3 Sidewall flashing. Base flashing against a vertical sidewall shall be continuous or step flashing and shall be not less than 4 inches (102 mm) in height and 4 inches (102 mm) in width and shall direct water away from the vertical sidewall onto the roof or into the gutter. Where siding is provided on the vertical sidewall, the vertical leg of the flashing shall be continuous under the siding. Where anchored masonry veneer is provided on the vertical sidewall, the base flashing shall be provided in accordance with this section and counterflashing

shall be provided in accordance with Section R703.7.2.2. Where exterior plaster or adhered masonry veneer is provided on the vertical sidewall, the base flashing shall be provided in accordance with this section and Section R703.6.3.

❖ Continuous or step flashing must be used to flash along the intersection of a roof and a vertical sidewall. Commentary Figure R905.2.8.3 shows an example of flashing at a sidewall.

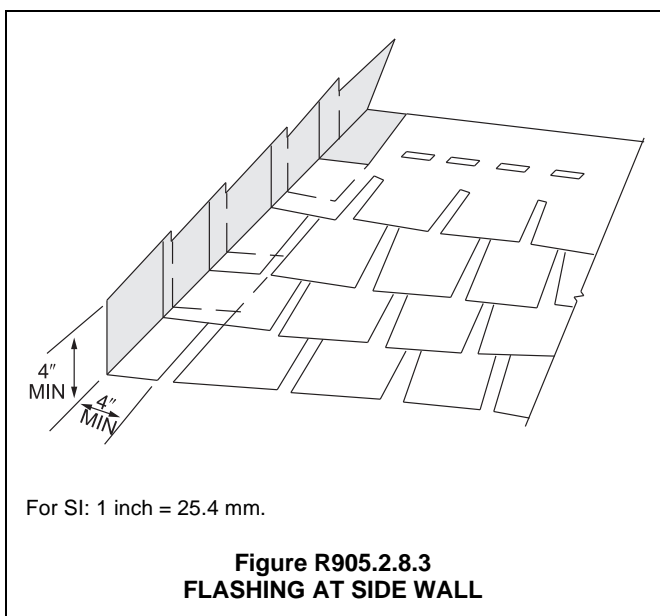

R905.2.8.4 Other flashing. Flashing against a vertical front wall, as well as soil stack, vent pipe and chimney flashing, shall be applied in accordance with the asphalt shingle manufacturer’s printed instructions.

❖ The installation of flashing at vertical roof penetrations such as chimneys, soil stacks and vent pipes must conform to the instructions provided by the asphalt shingle manufacturer. Commentary Figure R905.2.8.4 shows an example of chimney flashing.

**TABLE R905.2.8.2
VALLEY LINING MATERIAL**

MATERIAL	MINIMUM THICKNESS (inches)	GAGE	WEIGHT (pounds)
Cold-rolled copper	0.0216 nominal	—	ASTM B370, 16 oz. per square foot
Lead-coated copper	0.0216 nominal	—	ASTM B101, 16 oz. per square foot
High-yield copper	0.0162 nominal	—	ASTM B370, 12 oz. per square foot
Lead-coated high-yield copper	0.0162 nominal	—	ASTM B101, 12 oz. per square foot
Aluminum	0.024	—	—
Stainless steel	—	28	—
Galvanized steel	0.0179	26 (zinc coated G90)	—
Zinc alloy	0.027	—	—
Lead	—	—	2½
Painted terne	—	—	20

For SI: 1 inch = 25.4 mm, 1 pound = 0.454 kg.

R905.2.8.5 Drip edge. A drip edge shall be provided at eaves and rake edges of shingle roofs. Adjacent segments of drip edge shall be overlapped not less than 2 inches (51 mm). Drip edges shall extend not less than 1/4 inch (6.4 mm) below the roof sheathing and extend up back onto the roof deck not less than 2 inches (51 mm). Drip edges shall be mechanically fastened to the roof deck at not more than 12 inches (305 mm) o.c. with fasteners as specified in Section R905.2.5. Underlayment shall be installed over the drip edge along eaves and under the drip edge along rake edges.

❖ Drip edge is a metal flashing or other overhanging component applied at the roof edge that is intended to control the direction of dripping water and help protect the underlying building components. Drip edge has an outward projecting lower edge to direct the water away from the building. It is also used to break the continuity of contact between the roof perimeter and the wall components to help prevent capillary action.

Metal drip edge is a formed metal flashing that extends back from and bends down over the roof edge. Along the roof eave, the drip edge is applied under the underlayment. Along the roof rake, the drip edge is applied over the underlayment.

R905.3 Clay and concrete tile. The installation of clay and concrete tile shall comply with the provisions of this section.

❖ This section addresses both concrete tile and clay tile. Commentary Figure R905.3 depicts several examples of clay and concrete roof tile.

Figure R905.3
ROLL AND FLAT TILE EXAMPLES

R905.3.1 Deck requirements. Concrete and clay tile shall be installed only over solid sheathing or spaced structural sheathing boards.

❖ Both solid sheathing and spaced structural sheathing boards are permitted as a base for the installation of clay or concrete roof tile.

R905.3.2 Deck slope. Clay and concrete roof tile shall be installed on roof slopes of two and one-half units vertical in 12 units horizontal (2 1/2:12) or greater. For roof slopes from two and one-half units vertical in 12 units horizontal (2 1/2:12) to four units vertical in 12 units horizontal (4:12), double underlayment application is required in accordance with Section R905.3.3.

❖ To keep the roof covering weather tight and promote proper drainage, clay and concrete tile cannot be installed on a roof having a slope of less than 2 1/2:12. The application of two layers of underlayment is mandated on roofs of 4:12 and less. The provisions of Section R905.3.3 address the full requirements for underlayment on concrete or clay tile roofs.

R905.3.3 Underlayment. Underlayment shall comply with Section R905.1.1.

❖ See the commentary to Section R905.1.1.

R905.3.4 Clay tile. Clay roof tile shall comply with ASTM C1167.

❖ ASTM C1167 regulates clay roof tiles manufactured from clay, shale or similar natural earthy substances. The standard addresses a variety of performance requirements, including durability, strength and permeability.

R905.3.5 Concrete tile. Concrete roof tile shall comply with ASTM C1492.

❖ ASTM C1492 regulates concrete roof tiles manufactured from Portland cement, water and mineral aggregates with or without the inclusion of other materials. Lightweight or normal-weight aggregates or both are used in the manufacture of concrete tiles. The tiles are shaped during manufacturing by molding, pressing or extrusion. The tiles are usually planar or undulating rectangular shapes available in a variety of cross-sectional areas, profiles, shapes, sizes, surface textures and colors. The standard addresses a variety of performance tests including dimensional tolerances, freeze/thaw, transverse strength, permeability and water absorption.

R905.3.6 Fasteners. Nails shall be corrosion resistant and not less than 11 gage, 5/16-inch (11 mm) head, and of sufficient length to penetrate the deck not less than 3/4 inch (19 mm) or through the thickness of the deck, whichever is less. Attaching wire for clay or concrete tile shall not be smaller than 0.083 inch (2 mm). Perimeter fastening areas include three tile courses but not less than 36 inches (914 mm) from either side of hips or ridges and edges of eaves and gable rakes.

❖ Roofing nails for fastening clay or concrete tiles must be corrosion resistant. A roofing nail must have a minimum 11-gage shank with a head at least 5/16 inch (10.6 mm) in diameter. To provide the necessary holding power, roofing nails must penetrate the roof sheathing a minimum of 3/4 inch (19.1 mm). For roof sheathing having a thickness less than 3/4 inch (19.1 mm), the nails must penetrate completely through the sheathing. The portions of the roof considered as

perimeter fastening areas include a minimum of three tile courses, but in no case are they less than 36 inches (914 mm) from the edges of eaves and gable rakes or from either side of hips and ridges.

R905.3.7 Application. Tile shall be applied in accordance with this chapter and the manufacturer’s installation instructions, based on the following:

1. Climatic conditions.
2. Roof slope.
3. Underlayment system.
4. Type of tile being installed.

Clay and concrete roof tiles shall be fastened in accordance with this section and the manufacturer’s installation instructions. Perimeter tiles shall be fastened with not less than one fastener per tile. Tiles with installed weight less than 9 pounds per square foot (0.4 kg/m²) require not less than one fastener per tile regardless of roof slope. Clay and concrete roof tile attachment shall be in accordance with the manufacturer’s installation instructions where applied in areas where the ultimate design wind speed exceeds 130 miles per hour (58 m/s) and on buildings where the roof is located more than 40 feet (12 192 mm) above grade. In areas subject to snow, not less than two fasteners per tile are required. In other areas, clay and concrete roof tiles shall be attached in accordance with Table R905.3.7.

❖ This section identifies four key issues that must be taken into consideration when using the code and the manufacturer’s installation instructions in the proper application of clay and concrete roof tile. At least one fastener is required for each roof tile for those tiles at the perimeter of the roof, as well as any tiles weighing less than 9 pounds per square foot (0.4 kg/m²). In

areas where the roof is exposed to a roof snow load, at least two fasteners are required for each tile. Because of the special concerns in high-wind areas, or where the roof height is well above grade, the manufacturer’s installation instructions must be referred to in the determination of the minimum number of fasteners.

If none of the above-mentioned conditions occur, Table R905.3.7 must be used to determine proper fastening. The type of sheathing (spaced or solid), the presence of battens and the slope of the roof all impact the minimum number of fasteners required. Commentary Figures R905.3.7(1) through (4) illustrate some of the common shapes of tile and installation techniques.

**TABLE R905.3.7
CLAY AND CONCRETE TILE ATTACHMENT**

SHEATHING	ROOF SLOPE	NUMBER OF FASTENERS
Solid without battens	All	One per tile
Spaced or solid with battens and slope < 5:12	Fasteners not required	—
Spaced sheathing without battens	5:12 ≤ slope < 12:12	One per tile/every other row
	12:12 ≤ slope < 24:12	One per tile

❖ This table sets forth the number of fasteners required to attach clay or concrete tile to various types of sheathing. The table is not applicable where the ultimate design wind speed exceeds 130 mph (58 m/s), where the building’s roof is located more than 40 feet (12 192 mm) above grade or in locales subject to snow. Under all other conditions, the table indicates the number of fasteners required based on the type of sheathing and, in some cases, the slope of the roof.

**Figure R905.3.7(1)
APPLICATION OF ROLL TILE**

TILE ROOF EAVE SECTION

Figure R905.3.7(4)
TILE ROOF RIDGE SECTION

R905.3.8 Flashing. At the juncture of roof vertical surfaces, flashing and counterflashing shall be provided in accordance with this chapter and the manufacturer’s installation instructions and, where of metal, shall be not less than 0.019 inch (0.5 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend not less than 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) in height at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). For roof slopes of three units vertical in 12 units horizontal (25-percent slope) and greater, valley flashing shall have a 36-inch-wide (914 mm) underlayment of one layer of Type I underlayment running the full length of the valley, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less, metal valley flashing underlayment shall be solid-cemented to the roofing underlayment for slopes less than seven units vertical in 12 units horizontal (58-percent slope) or be of self-adhering polymer modified bitumen sheet.

- ❖ Flashing for clay and concrete roof tile is important because the shape of the tile may terminate 2 or 3 inches (51 or 76 mm) above the roof sheathing. Flashing details, therefore, must be constructed in accordance

with the code and the manufacturer’s installation instructions for the tile shape being used. Some common methods of providing flashing at different locations are illustrated in Commentary Figures R905.3.8(1) through (4).

R905.4 Metal roof shingles. The installation of metal roof shingles shall comply with the provisions of this section.

- ❖ Metal roof shingles differ from the metal roof panels regulated by Section R905.10. By definition, a metal roof shingle must have an installed weather exposure of less than 3 square feet (0.28 m²) per shingle or sheet. While decking and slope limitations differ to some degree, the provisions for underlayment and flashing are very similar to those for other types of shingle applications.

R905.4.1 Deck requirements. Metal roof shingles shall be applied to a solid or closely fitted deck, except where the roof covering is specifically designed to be applied to spaced sheathing.

- ❖ Unless manufacturers of metal shingles indicate that their particular shingle may be placed over a roof deck having spaced sheathing, metal roof shingles must be installed on a solid or closely fitted deck.

Figure R905.3.8(3)
TILE ROOF CHIMNEY FLASHING DETAIL

Figure R905.3.8(4)
TILE ROOF FLASHING FOR A VENT PIPE

R905.4.2 Deck slope. Metal roof shingles shall not be installed on roof slopes below three units vertical in 12 units horizontal (25-percent slope).

- ❖ Based on the characteristics of shape, size and method of attachment, metal roof shingles must not be applied to roofs having a slope of less than 3:12. A lesser slope increases the potential for leakage to an unacceptable level.

R905.4.3 Underlayment. Underlayment shall comply with Section R905.1.1.

- ❖ See the commentary to Section R905.1.1.

R905.4.3.1 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

- ❖ See the commentary to Section R905.1.2.

R905.4.4 Material standards. Metal roof shingle roof coverings shall comply with Table R905.10.3(1). The materials used for metal roof shingle roof coverings shall be naturally corrosion resistant or be made corrosion resistant in accordance with the standards and minimum thicknesses listed in Table R905.10.3(2).

- ❖ Table R905.10.3(1) lists the metal roof covering types and their material standards. Many of the materials listed are inherently corrosion resistant, such as aluminum, copper and lead. For these materials, listing a material standard for the base material is sufficient. However, for steel roofing products, coatings are added to the base material to provide the necessary corrosion resistance.

Table R905.10.3(2) lists the minimum coating thickness required to provide minimum corrosion resistance for the base steel. Note a to Table R905.10.3(2) specifies that the paint systems are intended to be applied to steel having one of the corrosion-resistant coatings listed.

R905.4.5 Application. Metal roof shingles shall be secured to the roof in accordance with this chapter and the *approved* manufacturer's installation instructions.

- ❖ The proper application of metal roof shingles is typically based on the installation instructions of the shingle manufacturer. Where the code sets forth specific requirements for the attachment of metal shingles, those requirements must be met.

R905.4.6 Flashing. Roof valley flashing shall be of corrosion-resistant metal of the same material as the roof covering or shall comply with the standards in Table R905.10.3(1). The valley flashing shall extend not less than 8 inches (203 mm) from the centerline each way and shall have a splash diverter rib not less than $\frac{3}{4}$ inch (19 mm) in height at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). The metal valley flashing shall have a 36-inch-wide (914 mm) underlayment directly under it consisting of one layer of underlayment running the full length of the valley, in addition to underlayment required for metal roof shingles. In areas where the average daily temperature in January is 25°F (-4°C) or less, the metal valley flashing underlayment shall be solid cemented to the roofing underlayment for roof slopes under seven units vertical in 12 units horizontal (58-percent slope) or self-adhering polymer modified bitumen sheet.

- ❖ This section specifies two approaches to roof valley flashing for metal-shingle roofs. The first is the use of material consistent with that of the shingles for the flashing. As an option, the flashing must be accomplished in compliance with the applicable material standard listed in Table R905.10.3. This table identifies the various types of metal roof covering and the corresponding application standard. This section specifies installation details for the valley flashing as well as the requirement for underlayment running the

full length of the valley. In cold-weather areas, the special underlayment techniques to eliminate ice dams apply to valley flashing underlayment.

R905.5 Mineral-surfaced roll roofing. The installation of mineral-surfaced roll roofing shall comply with this section.

- ❖ This section addresses the decking requirements and slope, underlayment, materials standards and application methods for mineral-surfaced roll roofing.

R905.5.1 Deck requirements. Mineral-surfaced roll roofing shall be fastened to solidly sheathed roofs.

- ❖ The deck must be solidly sheathed for mineral-surfaced roll roofing to be installed.

R905.5.2 Deck slope. Mineral-surfaced roll roofing shall not be applied on roof slopes below one unit vertical in 12 units horizontal (8-percent slope).

- ❖ Although mineral-surfaced roll roofing provides a virtually weather-tight roof surface, it is still necessary that water flow be positive toward the drainage points. Therefore, a minimum slope of 1:12 is mandated for roof decks that are covered with mineral-surfaced roll roofing.

R905.5.3 Underlayment. Underlayment shall comply with Section R905.1.1.

- ❖ See the commentary to Section R905.1.1.

R905.5.3.1 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

- ❖ See the commentary to Section R905.1.2.

R905.5.4 Material standards. Mineral-surfaced roll roofing shall conform to ASTM D3909 or ASTM D6380, Class M.

- ❖ The code recognizes two materials standards for the regulation of mineral-surfaced roll roofing: ASTM D3909 for asphalt roll roofing of glass felt surfaced with mineral granules and ASTM D6380, Class M for asphalt roll roofing of organic felt surfaced with mineral granules.

R905.5.5 Application. Mineral-surfaced roll roofing shall be installed in accordance with this chapter and the manufacturer's instructions.

- ❖ The general provisions of this chapter apply to the installation of mineral-surfaced roll roofing, as do the installation instructions of the manufacturer of the specific roofing system.

R905.6 Slate shingles. The installation of slate shingles shall comply with the provisions of this section.

- ❖ This section establishes the materials standards and installation criteria for shingles of slate materials. It includes specific provisions related to deck slope, underlayment, shingle application and flashing.

R905.6.1 Deck requirements. Slate shingles shall be fastened to solidly sheathed roofs.

- ❖ Only solidly-sheathed roofs can be used as the deck for the installation of slate and slate-type shingles.

R905.6.2 Deck slope. Slate shingles shall be used only on slopes of four units vertical in 12 units horizontal (33-percent slope) or greater.

- ❖ Shingles of slate materials pose special problems because of the inconsistency of the shingles' shape and size. To keep the roof covering weather tight and promote proper drainage, slate and slate-type shingles cannot be installed on a roof having a slope of less than 4:12. Lower-sloped roofs present a potential problem because water drains slowly and, thus, creates the opportunity for water backup. Wind-driven rain can also pose a problem.

R905.6.3 Underlayment. Underlayment shall comply with Section R905.1.1.

- ❖ See the commentary to Section R905.1.1.

R905.6.3.1 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

- ❖ See the commentary to Section R905.1.2.

R905.6.4 Material standards. Slate shingles shall comply with ASTM C406.

- ❖ The standard applicable to roofing slate is ASTM C406.

R905.6.5 Application. Minimum headlap for slate shingles shall be in accordance with Table R905.6.5. Slate shingles shall be secured to the roof with two fasteners per slate. Slate shingles shall be installed in accordance with this chapter and the manufacturer's instructions.

- ❖ The general provisions of this chapter apply to the installation of slate and slate-type shingles, as do the manufacturer's installation instructions for the specific roofing materials. In addition, this section sets forth two requirements specific to slate roofing. First, two fasteners must be used to secure each slate shingle in place. Second, Table R905.6.5 mandates the minimum headlap at each shingle course. Taking into account the effects of both water traveling down the roof's surface and wind-driven rain, the minimum headlap is reduced as the slope of the roof increases.

**TABLE R905.6.5
SLATE SHINGLE HEADLAP**

SLOPE	HEADLAP (inches)
4:12 ≤ slope < 8:12	4
8:12 ≤ slope < 20:12	3
Slope ≤ 20:12	2

For SI: 1 inch = 25.4 mm.

- ❖ If slate shingles are installed, they must have a minimum lap at each course as required by this table. Because of the potential for water infiltration, as the slope of the roof decreases, the minimum headlap increases. The extended lap aids in resisting the effects of slow-traveling water and wind-driven rain.

R905.6.6 Flashing. Flashing and counterflashing shall be made with sheet metal. Valley flashing shall be not less than 15 inches (381 mm) wide. Valley and flashing metal shall be a minimum uncoated thickness of 0.0179-inch (0.5 mm) zinc coated G90. Chimneys, stucco or brick walls shall have not less than two plies of felt for a cap flashing consisting of a 4-inch-wide (102 mm) strip of felt set in plastic cement and extending 1 inch (25 mm) above the first felt and a top coating of plastic cement. The felt shall extend over the base flashing 2 inches (51 mm).

❖ Special requirements are necessary for the sheet metal flashing and counterflashing of roofs covered with slate shingles. The provisions address flashing for roof valleys and for the roof intersections with chimneys and stucco or brick walls.

R905.7 Wood shingles. The installation of wood shingles shall comply with the provisions of this section.

❖ Wood shingles differ from wood shakes in that wood shingles are sawed materials and have a uniform butt thickness across the individual shingle length. Wood shakes are split from logs, shaped by the manufacturer, and have varying butt thicknesses. This section establishes the material standards and installation criteria for wood shingles. Also included are specific provisions related to deck requirements and slope, underlayment, shingle application and valley flashing.

R905.7.1 Deck requirements. Wood shingles shall be installed on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall be not less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners.

❖ Either solid or spaced sheathing is permitted as a deck for the installation of wood shingles. If spaced sheathing is used, the minimum 1-inch by 4-inch (25.4 mm by 102 mm) sheathing boards are required. The placement of the spaced sheathing is important, with the center-to-center spacing of the sheathing boards equivalent to the weather exposure of the wood shingles. This method allows a consistent fastening pattern for applying the wood-shingle roof covering materials. Table R905.7.5(1) contains the maximum permitted weather exposure for wood shingles.

R905.7.1.1 Solid sheathing required. In areas where the average daily temperature in January is 25°F (-4°C) or less, solid sheathing is required on that portion of the roof requiring the application of an ice barrier.

❖ In cold-weather climates where an ice shield is required in accordance with Section R905.7.3, solid sheathing must be installed for decking. The solid sheathing need be located only where the ice shield is applied, typically a point from the eave's edge to at least 24 inches (610 mm) inside the exterior wall line of the building.

R905.7.2 Deck slope. Wood shingles shall be installed on slopes of three units vertical in 12 units horizontal (25-percent slope) or greater.

❖ Wood shingle roofs pose special problems for weather protection because of the texture of the materials. To keep the roof covering weather tight and to promote proper drainage, wood shingles cannot be installed on a roof having a slope of less than 3:12. Lower-sloped roofs present a potential problem because water drains slowly, creating an opportunity for water back-up. Wind-driven rain can also pose a problem.

R905.7.3 Underlayment. Underlayment shall comply with Section R905.1.1.

❖ See the commentary to Section R905.1.1.

R905.7.3.1 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

❖ See the commentary to Section R905.1.2.

R905.7.4 Material standards. Wood shingles shall be of naturally durable wood and comply with the requirements of Table R905.7.4.

❖ Wood shingles are manufactured in 24-, 18- and 16-inch (610, 457 and 406 mm) lengths and are graded into three categories: 1, 2 and 3. The Cedar Shake and Shingle Bureau establishes grading rules for wood shingles. Table R905.7.4 describes each grade. Commentary Figure R905.7.4 shows an example label.

**TABLE R905.7.4
WOOD SHINGLE MATERIAL REQUIREMENTS**

MATERIAL	MINIMUM GRADES	APPLICABLE GRADING RULES
Wood shingles of naturally durable wood	1, 2 or 3	Cedar Shake and Shingle Bureau

❖ This table identifies the basic material requirements for wood roof shingles. It states that the shingles must be of naturally durable wood; graded as No. 1, 2 or 3; and subject to the applicable grading rules of the Cedar Shake and Shingle Bureau. Each grade is mentioned in Table R905.7.4. Commentary Figure R905.7.4 is an example of the required identification label of an approved grading or inspection bureau or agency.

**Figure R905.7.4
WOOD SHINGLE GRADE DESCRIPTION
AND EXAMPLE LABEL**

R905.7.5 Application. Wood shingles shall be installed in accordance with this chapter and the manufacturer’s instructions. Wood shingles shall be laid with a side lap not less than 1½ inches (38 mm) between joints in courses, and two joints shall not be in direct alignment in any three adjacent courses. Spacing between shingles shall be not less than ¼ inch to ⅜ inch (6.4 mm to 9.5 mm). Weather exposure for wood shingles shall not exceed those set in Table R905.7.5(1). Fasteners for untreated (naturally durable) wood shingles shall be box nails in accordance with Table R905.7.5(2). Nails shall be stainless steel Type 304 or 316 or hot-dipped galvanized with a coating weight of ASTM A153 Class D (1.0 oz/ft²). Alternatively, two 16-gage stainless steel Type 304 or 316 staples with crown widths ⅞ inch (11.1 mm) minimum, ¾ inch (19.1 mm) maximum, shall be used. Fasteners installed within 15 miles (24 km) of salt water coastal areas shall be stainless steel Type 316. Fasteners for fire-retardant-treated shingles in accordance with Section R902 or pressure-impregnated-preservative-treated shingles of naturally durable wood in accordance with AWP A U1 shall be stainless steel Type 316. All fasteners shall have a minimum penetration into the sheathing of ¾ inch (19.1 mm). For sheathing less than ¾ inch (19.1 mm) thickness, each fastener shall penetrate through the sheathing. Wood shingles shall be attached to the roof with two fasteners per shingle, positioned in accordance with the manufacturer’s installation instructions. Fastener packaging shall bear a label indicating the appropriate grade material or coating weight.

❖ The general provisions of this chapter apply to the installation of wood shingles, as do the installation instructions of the manufacturer of the specific roofing materials. In addition, this section sets forth specific requirements regulating the installation method for wood shingles. Many of these requirements are shown in Commentary Figure R905.7.5(1).

Fasteners must be box nails in accordance with Table R905.7.5 (2). Stainless steel staples are permitted in lieu of box nails. Fasteners for applying wood shingles must be stainless steel or hot-dipped galvanized. Only stainless steel fasteners are allowed for the following conditions:

1. Where wood shingles are located within 15 miles of salt water coastal areas.
2. Where wood shingles are fire-retardant treated.
3. Where wood shingles are preservative treated.

Only two nails or staples are to be used for each shingle, and they must be placed in accordance with the manufacturer’s installation instructions. The depth of fastener penetration must be a minimum of ¾ inch into the sheathing or completely through sheathing less than ¾ inch thick. Care in spacing and driving the fasteners is necessary to provide maximum service from the roof covering [see Commentary Figure R905.7.5(2)].

**TABLE R905.7.5(1)
WOOD SHINGLE WEATHER EXPOSURE AND ROOF SLOPE**

ROOFING MATERIAL	LENGTH (inches)	GRADE	EXPOSURE (inches)	
			3:12 pitch to < 4:12	4:12 pitch or steeper
Shingles of naturally durable wood	16	No. 1	3¾	5
		No. 2	3½	4
		No. 3	3	3½
	18	No. 1	4¼	5½
		No. 2	4	4½
		No. 3	3½	4
	24	No. 1	5¾	7½
		No. 2	5½	6½
		No. 3	5	5½

For SI: 1 inch = 25.4 mm.

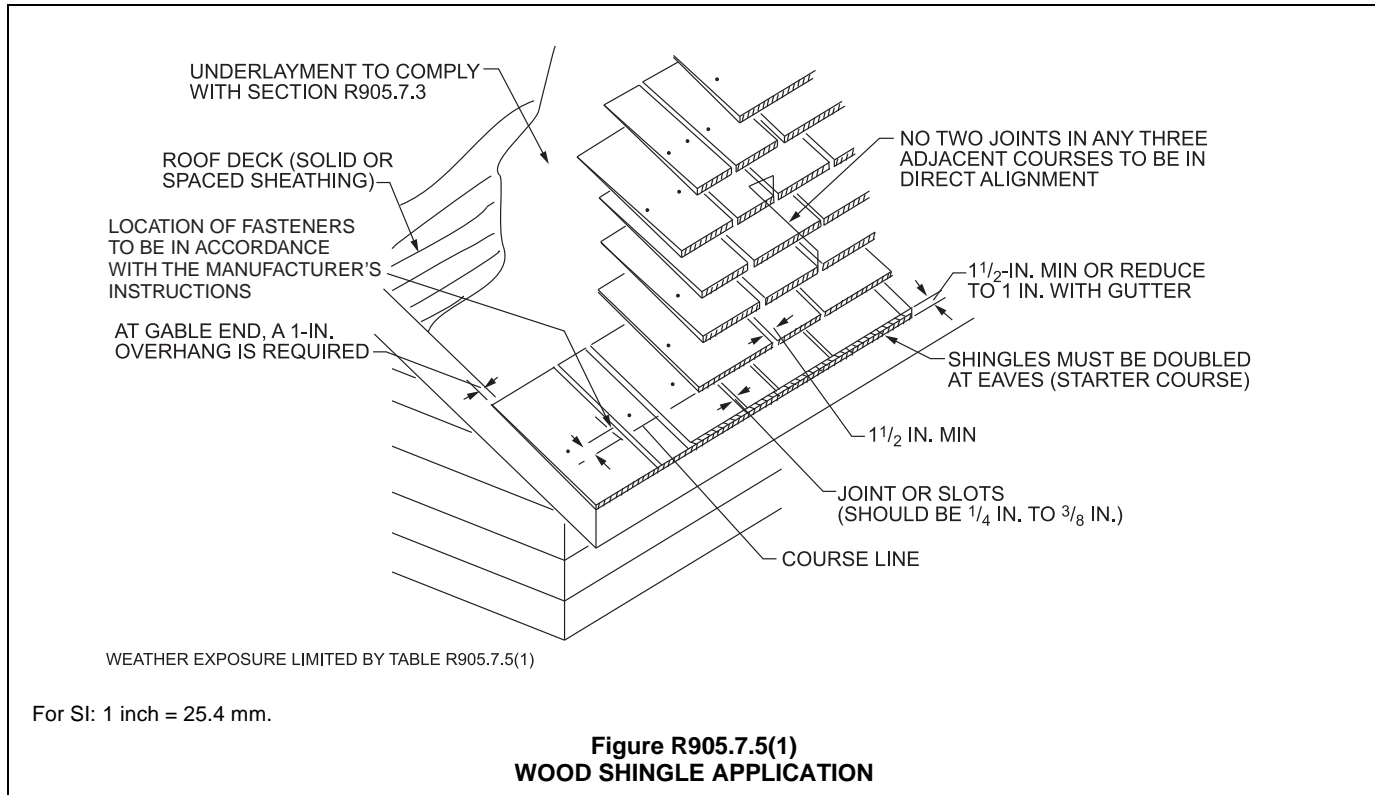

❖ Table R905.7.5(1) specifies wood shingle exposure. Depending on the grade of the material, the total shingle length and the slope of the roof deck, the table specifies the maximum length of exposure for weathering purposes. The grade of the shingle is listed on the label required for wood shingles. Each of the three different grades is available in three different lengths. For lower-sloped roofs (3:12 to 4:12) where wind uplift is more significant, the maximum weather exposure is always less than for the steeper sloped roofs (4:12 and greater).

**TABLE R905.7.5(2)
NAIL REQUIREMENTS FOR WOOD SHAKES AND WOOD SHINGLES**

SHAKES	NAIL TYPE AND MINIMUM LENGTH	MINIMUM HEAD SIZE	MINIMUM SHANK DIAMETER
18" straight-split	5d box 1¾"	0.19"	.080"
18" and 24" handsplit and resawn	6d box 2"	0.19"	.0915"
24" taper-split	5d box 1¾"	0.19"	.080"
18" and 24" tapersawn	6d box 2"	0.19"	.0915"
Shingles	Nail Type and Minimum Length		
16" and 18"	3d box 1¼"	0.19"	.080"
24"	4d box 1½"	0.19"	.080"

R905.7.6 Valley flashing. Roof flashing shall be not less than No. 26 gage [0.019 inches (0.5 mm)] corrosion-resistant sheet metal and shall extend 10 inches (254 mm) from the centerline each way for roofs having slopes less than 12 units vertical in 12 units horizontal (100-percent slope), and 7 inches (178 mm) from the centerline each way for slopes of 12 units vertical in 12 units horizontal and greater. Sections of flashing shall have an end lap of not less than 4 inches (102 mm).

❖ Valleys formed by the intersection of two sloping roofs are vulnerable to leakage because of the high concen-

tration of water; therefore, valley flashing must be maintained to prevent blockage. This section requires the use of minimum No. 26 gage (0.019 inch/0.48 mm) corrosion-resistant sheet metal for this purpose. Commentary Figure R905.7.6 illustrates the code provisions for valley flashing.

R905.7.7 Label required. Each bundle of shingles shall be identified by a *label* of an *approved* grading or inspection bureau or agency.

- ❖ To verify compliance with the material standards set forth in Section R905.7.4, every bundle of wood shingles must be labeled. The label, a sample of which is shown in Commentary Figure R905.7.4, must indicate

the name of the approved grading or inspection bureau or agency.

R905.8 Wood shakes. The installation of wood shakes shall comply with the provisions of this section.

- ❖ Wood shakes differ from wood shingles in that wood shakes are split from logs, shaped by the manufacturer and have varying butt thicknesses. Wood shingles are sawed materials and have a uniform butt thickness across the individual shingle length. This section establishes the materials standards and installation criteria for wood shakes. Also included are specific provisions related to deck requirements and slope, underlayment, interlayment, shingle application and valley flashing.

R905.8.1 Deck requirements. Wood shakes shall be used only on solid or spaced sheathing. Where spaced sheathing is used, sheathing boards shall be not less than 1-inch by 4-inch (25 mm by 102 mm) nominal dimensions and shall be spaced on centers equal to the weather exposure to coincide with the placement of fasteners. Where 1-inch by 4-inch (25 mm by 102 mm) spaced sheathing is installed at 10 inches (254 mm) on center, additional 1-inch by 4-inch (25 mm by 102 mm) boards shall be installed between the sheathing boards.

- ❖ Either solid or spaced sheathing is permitted as a deck for the installation of wood shakes. If spaced sheathing is used, the minimum 1-inch by 4-inch (25 mm by 102 mm) sheathing boards are required. The placement of the spaced sheathing is important, with the center-to-center spacing of the sheathing boards equivalent to the weather exposure of the wood shakes. This method allows for a consistent fastening pattern for applying wood shake roof covering materials. Table R905.8.6 contains the maximum permitted weather exposure for wood shakes. If the greatest allowable exposure of 10 inches (254 mm) is used in accordance with Table R905.8.6, an additional 1-inch by 4-inch (25 mm by 102 mm) board must be installed between the sheathing boards.

R905.8.1.1 Solid sheathing required. In areas where the average daily temperature in January is 25°F (-4°C) or less, solid sheathing is required on that portion of the roof requiring an ice barrier.

- ❖ In cold-weather climates where an ice barrier is required in accordance with Section R905.8.3.1, solid sheathing must be installed for decking. The solid

sheathing need be located only where the ice shield is applied, typically a point from the eave's edge to at least 24 inches (610 mm) inside the exterior wall line of the building.

R905.8.2 Deck slope. Wood shakes shall only be used on slopes of three units vertical in 12 units horizontal (25-percent slope) or greater.

- ❖ Wood shake roofs pose special problems for weather protection because of the texture of the materials. To keep the roof covering weather tight and to promote proper drainage, wood shakes cannot be installed on a roof having a slope of less than 3:12. Lower-sloped roofs present a potential problem because water drains slowly, creating an opportunity for water backup. Wind-driven rain can also pose a problem. The use of an interlayment as installed in accordance with Section R905.8.7 also plays an important part in maintaining the weathertightness of the roof.

R905.8.3 Underlayment. Underlayment shall comply with Section R905.1.1.

- ❖ See the commentary to Section R905.1.1.

R905.8.3.1 Ice barrier. Where required, ice barriers shall comply with Section R905.1.2.

- ❖ See the commentary to Section R905.1.2.

R905.8.4 Interlayment. Interlayment shall comply with ASTM D226, Type I.

- ❖ Wood shakes must be installed with an interlayment of minimum No. 30 felt shingled between each course in the manner described by Section R905.8.7. The inter-

layment must be in compliance with ASTM D226, Type I, for asphalt-saturated organic felt.

R905.8.5 Material standards. Wood shakes shall comply with the requirements of Table R905.8.5.

- ❖ Wood shakes are divided into five material classifications in the code, identified in Table R905.8.5. There are two grades of wood shakes: No. 1 and No. 2. The shakes are cut into 18-inch (457 mm) and 24-inch (610 mm) lengths.

**TABLE R905.8.5
WOOD SHAKE MATERIAL REQUIREMENTS**

MATERIAL	MINIMUM GRADES	APPLICABLE GRADING RULES
Wood shakes of naturally durable wood	1	Cedar Shake and Shingle Bureau
Tapersawn shakes of naturally durable wood	1 or 2	Cedar Shake and Shingle Bureau
Preservative-treated shakes and shingles of naturally durable wood	1	Cedar Shake and Shingle Bureau
Fire-retardant-treated shakes and shingles of naturally durable wood	1	Cedar Shake and Shingle Bureau
Preservative-treated tapersawn shakes of Southern pine treated in accordance with AWPAs Standard U1 (Commodity Specification A, Use Category 3B and Section 5.6)	1 or 2	Forest Products Laboratory of the Texas Forest Services

- ❖ Wood shakes are regulated based on the type of shake material, the treatment applied to the shake and the cut of the shake. Most of the grading rules applicable to wood shakes come from the Cedar Shake and Shingle Bureau. If preservative-treated tapersawn Southern Yellow Pine wood shakes are to be installed, they are governed under the grading rules of the Forest Products Laboratory of the Texas Forest Services. The minimum grade required by the table must be shown on the approved label required on each bundle of wood shakes.

R905.8.6 Application. Wood shakes shall be installed in accordance with this chapter and the manufacturer’s installation instructions. Wood shakes shall be laid with a side lap not less than 1½ inches (38 mm) between joints in adjacent courses. Spacing between shakes in the same course shall be 3⁄8 inch to 5⁄8 inch (9.5 mm to 15.9 mm) including tapersawn shakes. Weather exposures for wood shakes shall not exceed those set in Table R905.8.6. Fasteners for untreated (naturally durable) wood shakes shall be box nails in accordance with Table R905.7.5(2). Nails shall be stainless steel Type 304, or Type 316 or hot-dipped with a coating weight of ASTM A153 Class D (1.0 oz/ft²). Alternatively, two 16-gage Type 304 or Type 316 stainless steel staples, with crown widths 7⁄16 inch (11.1 mm) minimum, 3⁄4 inch (19.1 mm) maximum, shall be used. Fasteners installed within 15 miles (24 km) of salt water coastal areas shall be stainless steel Type 316. Wood shakes shall be attached to the roof with two fasteners per shake positioned in accordance with the manufacturer’s installation instructions. Fasteners for fire-retardant-treated (as defined in Section R902) shakes or pressure-impregnated-preservative-treated shakes of naturally durable wood in accordance with AWPAs U1 shall be stainless steel Type 316.

All fasteners shall have a minimum penetration into the sheathing of 3⁄4 inch (19.1 mm). Where the sheathing is less than 3⁄4 inch (19.1 mm) thick, each fastener shall penetrate through the sheathing. Fastener packaging shall bear a label indicating the appropriate grade material or coating weight.

- ❖ The general provisions of this chapter apply to the installation of wood shakes, as do the manufacturer’s installation instructions for the specific roofing materials. In addition, this section sets forth specific requirements regulating the installation method for wood shakes. The minimum spacing of 3⁄8 inch between shakes is necessary to prevent the accumulation of leaves and/or needles from evergreen trees in the spaces. A smaller space would cause accumulation and premature aging of the shakes. Commentary Figure R905.8.6 shows many of these requirements.

Fasteners must be box nails in accordance with Table R905.7.5(2). Stainless steel staples are permitted in lieu of box nails. Fasteners for applying wood shakes must be stainless steel or hot-dipped galvanized. Only stainless steel fasteners are allowed for the following conditions:

1. Where wood shakes are located within 15 miles of salt water coastal areas.
2. Where wood shakes are fire-retardant treated.
3. Where wood shakes are preservative treated.

Only two nails or staples are to be used for each shake, and they must be placed in accordance with the manufacturer’s installation instructions. The depth of fastener penetration must be a minimum of 3⁄4 inch into the sheathing or completely through sheathing less than 3⁄4 inch thick. Care in spacing and driving the fasteners is necessary to provide maximum service from the roof covering [see Commentary Figure R905.7.5(2)].

TABLE R905.8.6. See page 9-25.

- ❖ Table R905.8.6 specifies wood shake exposure. Depending on the grade of the material and the total shingle length, the table specifies the maximum length of exposure for weathering purposes. The grade of the shingle will be listed in the label required for wood shingles.

R905.8.7 Shake placement. The starter course at the eaves shall be doubled and the bottom layer shall be either 15-inch (381 mm), 18-inch (457 mm) or 24-inch (610 mm) wood shakes or wood shingles. Fifteen-inch (381 mm) or 18-inch (457 mm) wood shakes shall be permitted to be used for the final course at the ridge. Shakes shall be interlaid with 18-inch-wide (457 mm) strips of not less than No. 30 felt shingled between each course in such a manner that no felt is exposed to the weather by positioning the lower edge of each felt strip above the butt end of the shake it covers a distance equal to twice the weather exposure.

- ❖ To provide as weather tight a roof as possible where using wood shakes as the roof covering material, a special installation method is described in this section. At the eaves, the starter course must be two layers of

shakes. Going up the roof toward the ridge, the shakes must be supplemented with 18-inch (457 mm) interlayer strips of minimum No. 30 felt. The manner of interlayment must prevent any felt being exposed to the weather. This is illustrated in Commentary Figure R905.8.7.

R905.8.8 Valley flashing. Roof valley flashing shall be not less than No. 26 gage [0.019 inch (0.5 mm)] corrosion-resistant sheet metal and shall extend not less than 11 inches (279 mm) from the centerline each way. Sections of flashing shall have an end lap of not less than 4 inches (102 mm).

- ❖ Valleys formed by the intersection of two sloping roofs are vulnerable to leakage because of the high concen-

tration of water; therefore, valley flashing must be maintained to prevent blockage. This section requires the use of minimum No. 26 gage (0.019 inch/0.48 mm) corrosion-resistant sheet metal for this purpose.

R905.8.9 Label required. Each bundle of shakes shall be identified by a *label* of an *approved* grading or inspection bureau or agency.

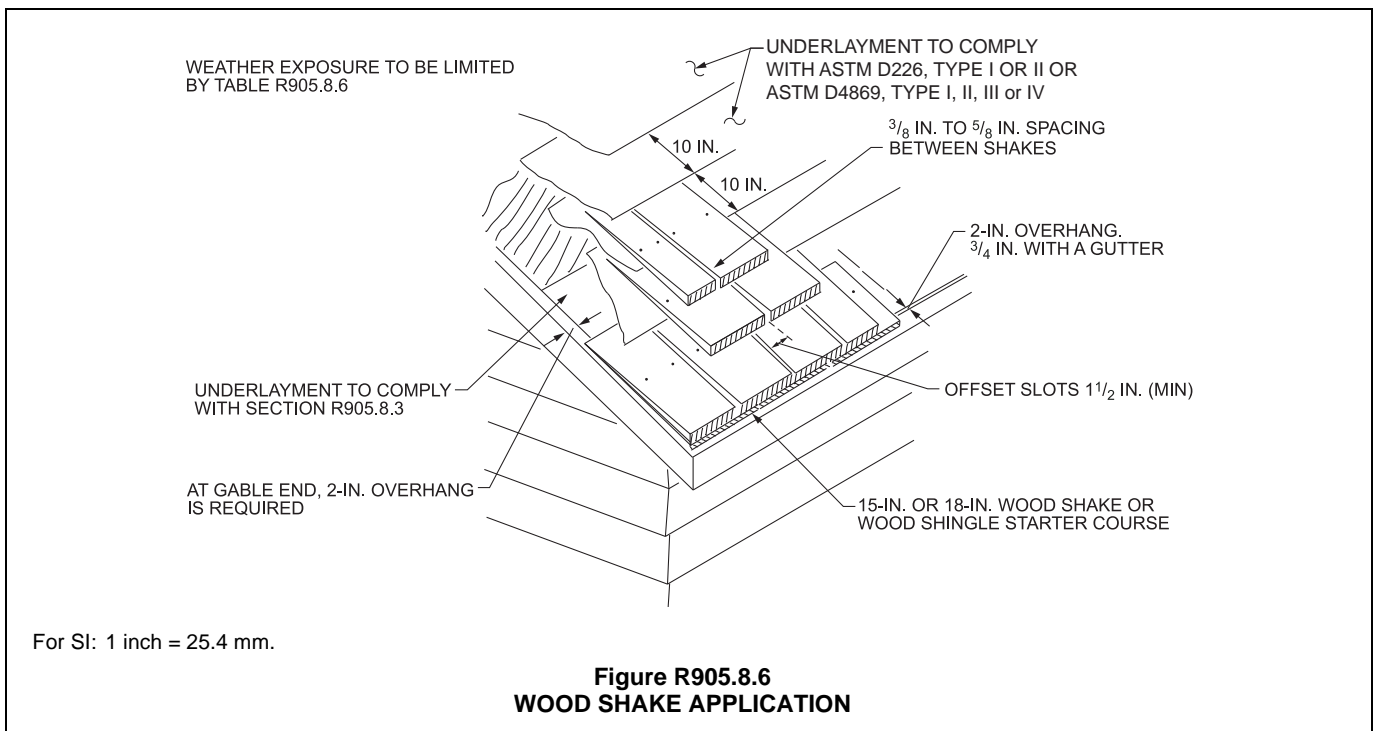

- ❖ To verify compliance with the material standards set forth in Section R905.7.4, every bundle of wood shakes must be labeled. The label, a sample of which is shown in Commentary Figure R905.8.9, must show the name of the approved grading or inspection bureau or agency.

TABLE R905.8.6
WOOD SHAKE WEATHER EXPOSURE AND ROOF SLOPE

ROOFING MATERIAL	LENGTH (inches)	GRADE	EXPOSURE (inches)
			4:12 pitch or steeper
Shakes of naturally durable wood	18	No. 1	7½
	24	No. 1	10 ^a
Preservative-treated tapersawn shakes of Southern Yellow Pine	18	No. 1	7½
	24	No. 1	10
	18	No. 2	5½
	24	No. 2	7½
Taper-sawn shakes of naturally durable wood	18	No. 1	7½
	24	No. 1	10
	18	No. 2	5½
	24	No. 2	7½

For SI: 1 inch = 25.4 mm.

a. For 24-inch by ¾-inch handsplit shakes, the maximum exposure is 7½ inches.

For SI: 1 inch = 25.4 mm.

Figure R905.8.6
WOOD SHAKE APPLICATION

ROOF ASSEMBLIES

R905.9 Built-up roofs. The installation of built-up roofs shall comply with the provisions of this section.

- ❖ A built-up roof is a roof covering system built at the job site. The provisions of this section deal with the fundamental requirements for such roofs. With all of the different products available, the possible combinations of built-up roof systems are almost endless.

Asphalt and coal tar are the bitumens used for a built-up roof. They become fluid when heated and bond the felt layers together. To fuse the roof felts properly, the bitumens must be applied at the proper temperature. Too low a temperature will cause inadequate fusion, and overheating may change the properties of the bitumens or cause a fire hazard.

R905.9.1 Slope. Built-up roofs shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-

percent slope) for drainage, except for coal-tar built-up roofs, which shall have a design slope of a minimum one-eighth unit vertical in 12 units horizontal (1-percent slope).

- ❖ Built-up roofs are often chosen for very low-slope applications because they can be installed on roof decks having a minimum slope of 1/4 inch per foot (1/4:12), just enough to allow positive drainage. Only where coal-tar built-up roofs are installed must the roof deck slope to a greater degree. A minimum roof slope of 1:12 is required for coal-tar built-up roofs.

R905.9.2 Material standards. Built-up roof covering materials shall comply with the standards in Table R905.9.2 or UL 55A.

- ❖ Table R905.9.2 sets forth the appropriate material standards for the various types of built-up roofs. Eighth-

WOOD SHAKE DESCRIPTION AND EXAMPLE LABELS

teen different types of roofing systems are identified, and the corresponding specification standard for each is noted.

Also, as an alternative to the material standards in Table R905.9.2, the code permits compliance with UL 55A. UL 55A has been in use since 1919 and is still used to evaluate the following materials used in the construction of built-up roof coverings: hot-mopping asphalt; asphalt-saturated and organic felt; coal-tar pitch; coal-tar saturated organic felt; and asphalt-coated glass-fire mat (felt). Several listed roofing systems, evaluated to UL 790 or ASTM E108, are based on compliance with UL 55A.

TABLE R905.9.2. See below.

- ❖ The types of materials used in built-up roofing must comply with the following standards:
 - ASTM D6083, which covers a liquid-applied water-dispersed 100-percent acrylic elastomeric latex coating used as a protective coating for roofs.
 - ASTM D1863, which covers the quality and grading of crushed stone, crushed slag and water-worn gravel suitable for use as aggregate surfacing on built-up roofs.
 - ASTM D3747, which covers emulsified asphalt adhesive for use in adhering preformed roof insulation to steel roof decks with inclines up to 33 per-

cent. When applied as a continuous film over an acceptable deck surface, the emulsion functions as both an adhesive and a vapor retarder.

- ASTM D3019, D2822 and D4586, which cover asphalt cements used in roofing:
 - ASTM D3019 covers lap cement consisting of asphalt dissolved in a volatile petroleum solvent with or without mineral or other stabilizers, or both, for use with roll roofing.
 - ASTM D2822 covers asphalt roof cement used for trowel application to roofings and flashings.
 - ASTM D4586 covers asbestos-free asphalt roof cement suitable for trowel application to roofings and flashings.
- ASTM D4601, which covers asphalt-impregnated and coated glass fiber base sheet, with or without perforations, for use as the first ply of the built-up roofing. When not perforated, this sheet may be used as a vapor retarder under or between roof insulation with a solid top coating of asphaltic material.
- ASTM D1227, D2823, D2824 and D4479, which cover asphalt coatings used in roofing:
 - ASTM D1227 covers emulsified asphalt suitable for use as a protective coating for built-up roofs and other exposed surfaces with inclines of not less than 4 percent.

**TABLE R905.9.2
BUILT-UP ROOFING MATERIAL STANDARDS**

MATERIAL STANDARD	STANDARD
Acrylic coatings used in roofing	ASTM D6083
Aggregate surfacing	ASTM D1863
Asphalt adhesive used in roofing	ASTM D3747
Asphalt cements used in roofing	ASTM D2822; D3019; D4586
Asphalt-coated glass fiber base sheet	ASTM D4601
Asphalt coatings used in roofing	ASTM D1227; D2823; D2824; D4479
Asphalt glass felt	ASTM D2178
Asphalt primer used in roofing	ASTM D41
Asphalt-saturated and asphalt-coated organic felt base sheet	ASTM D2626
Asphalt-saturated organic felt (perforated)	ASTM D226
Asphalt used in roofing	ASTM D312
Coal-tar cements used in roofing	ASTM D4022; D5643
Coal-tar primer used in roofing, dampproofing and waterproofing	ASTM D43
Coal-tar saturated organic felt	ASTM D227
Coal-tar used in roofing	ASTM D450, Type I or II
Glass mat, coal tar	ASTM D4990
Glass mat, venting type	ASTM D4897
Mineral-surfaced inorganic cap sheet	ASTM D3909
Thermoplastic fabrics used in roofing	ASTM D5665; D5726

ROOF ASSEMBLIES

- ASTM D2823 covers asphalt roof coatings of brushing or spraying consistency.
- ASTM D2824 covers aluminum-pigmented asphalt roof coating, including nonfibered, asbestos-fibered and fibered without asbestos.
- ASTM D4479 covers asbestos-free asphalt roof coating of brushing or spraying consistency.
- ASTM D2178, which covers glass felt impregnated to varying degrees with asphalt, which may be used with asphalts conforming to the requirements of ASTM D312 in the construction of built-up roofs, and with asphalts conforming to the requirements of ASTM D449 in the membrane system of waterproofing.
- ASTM D41, which covers asphaltic primer suitable for use with asphalt in roofing, dampproofing and waterproofing below or above ground level, for application to concrete, masonry, metal and asphalt surfaces.
- ASTM D2626, which covers base sheet with fine mineral surfacing on the top side, with or without perforations, for use as the first ply of a built-up roof. When not perforated, this sheet may be used as a vapor retarder under roof insulation.
- ASTM D226, which covers asphalt-saturated organic felts, with perforations, that may be used with asphalts conforming to the requirements of ASTM D312 in the construction of built-up roofs, and with asphalts conforming to the requirements of ASTM D449 in the membrane system of waterproofing.
- ASTM D312, which covers four types of asphalt intended for use in built-up roof construction. The specification is for general classification purposes only and does not imply restrictions on the slope at which an asphalt must be used. There are four classifications:
 - Type I includes asphalts that are relatively susceptible to flow at roof temperatures with good adhesive and self-sealing properties.
 - Type II includes asphalts that are moderately susceptible to flow at roof temperatures.
 - Type III includes asphalts that are relatively not susceptible to flow at roof temperatures for use in built-up roof construction on slope inclines from 8.3 percent to 25 percent.
 - Type IV includes asphalts that are generally not susceptible to flow at roof temperatures for use in built-up roof construction on slope inclines from approximately 16.7 percent to 50 percent.
- ASTM D4022 and D5643, which cover coal-tar cements used in roofing:
 - ASTM D4022 covers coal-tar roof cement suitable for trowel application in coal-tar roofing and flashing systems.
 - ASTM D5643 covers asbestos-free coal-tar roof cement suitable for trowel application in coal-tar roofing and flashing systems.
- ASTM D227, which covers coal-tar saturated organic felt that may be used with coal-tar pitches conforming to the requirements of ASTM D450 in the construction of built-up roofs and in the membrane system of waterproofing.
- ASTM D43 covers coal-tar primer suitable for use with coal-tar pitch in roofing, dampproofing and waterproofing below or above ground level for application to concrete, masonry and coal tar surfaces.
- ASTM D450, Types I and II, which cover coal-tar pitch suitable for use in the construction of built-up roofing, dampproofing and membrane waterproofing systems:
 - Type I is suitable for use in built-up roofing systems with felts conforming to the requirements of ASTM D227 or as specified by the manufacturer.
 - Type II is suitable for use in dampproofing and in membrane waterproofing systems.
- ASTM D4990, which covers glass felt impregnated with coal tar intended to be used with coal-tar pitch conforming to the requirements of ASTM D450 in construction of built-up roofs and waterproofing systems.
- ASTM D4897, which covers asphalt-impregnated and coated glass fiber base sheet with mineral surfacing on the top side and coarse mineral granules on the bottom side for use as the first ply of a roofing membrane. These base sheets provide for the lateral release of pressure in roofing systems because they are not solidly attached, and the coarse granular surface provides an open, porous channel in the horizontal plane beneath the membrane. The base sheets can be with or without perforations or embossings.
- ASTM D3909, which covers asphalt-impregnated and coated glass felt roll roofing surfaced on the weather side with mineral granules, for use as a cap sheet in the construction of built-up roofs.
- ASTM D5665 and D5726, which cover thermoplastic fabrics used in roofing:
 - ASTM D5665 covers thermoplastic fabrics such as polyester, polyester/polyamide bicomponent or composites with fiberglass or polyester scrims that can be used during the construction of cold-applied roofing and waterproofing.
 - ASTM D5726 covers thermoplastic fabrics such as polyester, polyester/polyamide bicomponent or composites with fiberglass or polyester scrims that can be used during the construction of hot-applied roofing and waterproofing.

R905.9.3 Application. Built-up roofs shall be installed in accordance with this chapter and the manufacturer’s instructions.

- ❖ The general provisions of this chapter apply to the installation of built-up roofs, as do the installation instructions of the manufacturer of the specific roofing system. Commentary Figures R905.9.3(1) through (3) illustrate examples of the application of the base ply to nailable and nonnailable decks.

R905.10 Metal roof panels. The installation of metal roof panels shall comply with the provisions of this section.

- ❖ Metal roof panels differ from metal roof shingles regulated by Section R905.4. By definition, a metal roof panel must have an installed weather exposure of at least 3 square feet (0.28 m²) per shingle or sheet. This section addresses the deck requirements, deck slope and attachment requirements for metal roof panels.

R905.10.1 Deck requirements. Metal roof panel roof coverings shall be applied to solid or spaced sheathing, except where the roof covering is specifically designed to be applied to spaced supports.

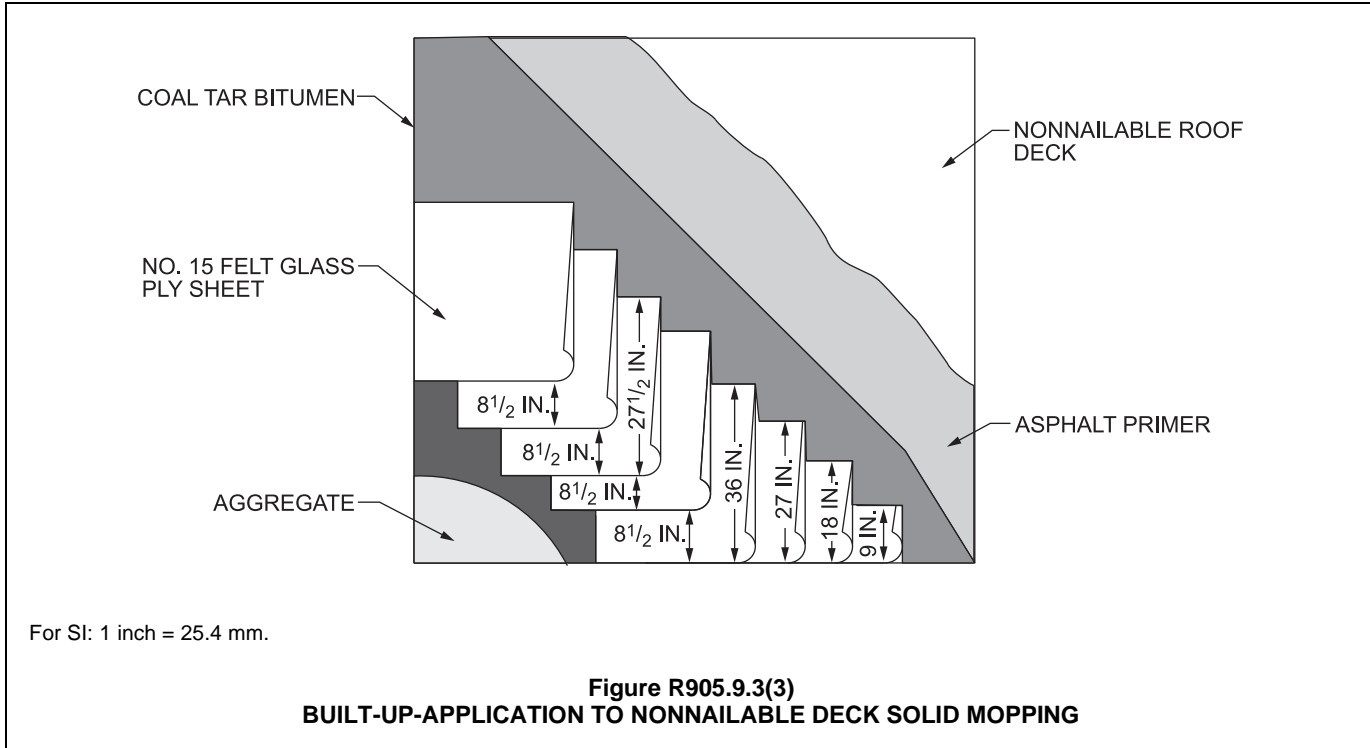

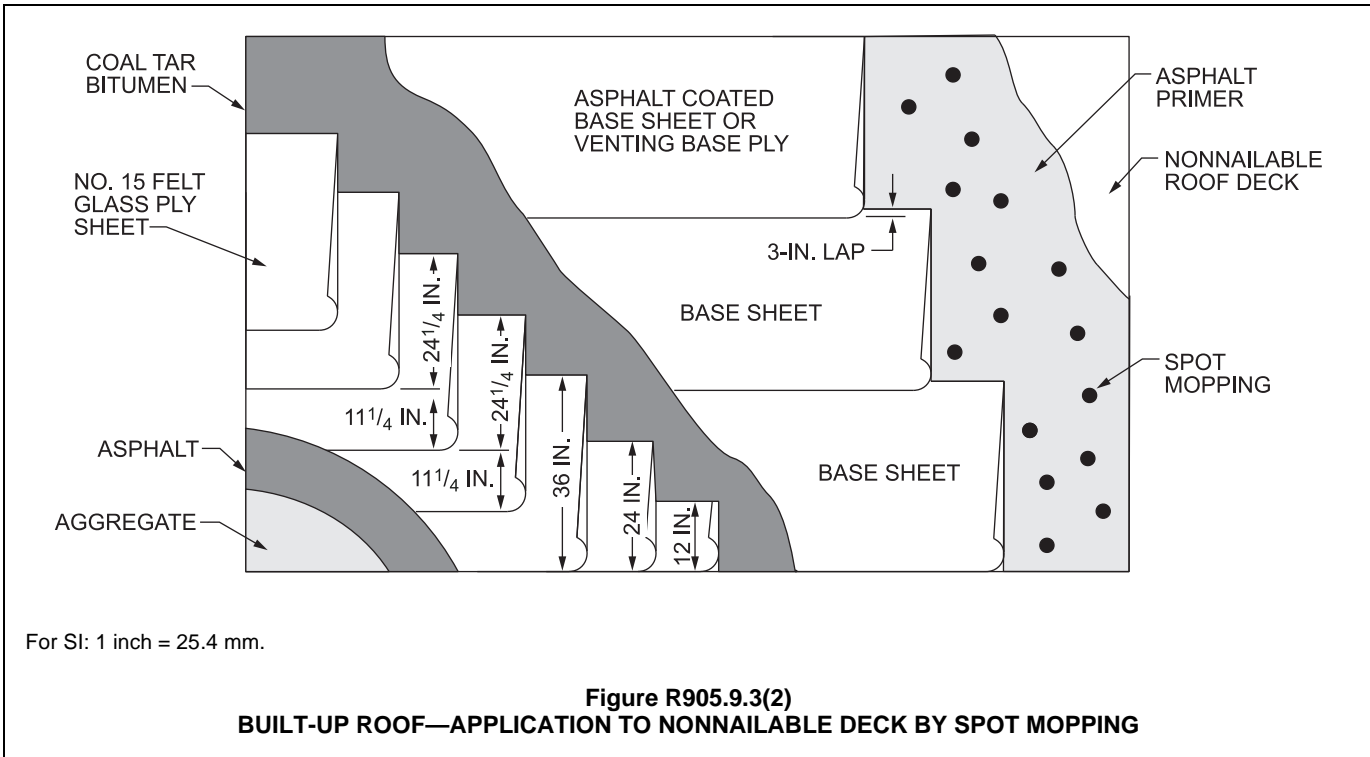

- ❖ Unless specifically limited, metal roof panels may be applied to either solidly sheathed decks or spaced sheathing. In cases where specific metal panels are designed to be installed only on spaced supports, the manufacturer’s instructions govern.

R905.10.2 Slope. Minimum slopes for metal roof panels shall comply with the following:

1. The minimum slope for lapped, nonsoldered-seam metal roofs without applied lap sealant shall be three units vertical in 12 units horizontal (25-percent slope).
 2. The minimum slope for lapped, nonsoldered-seam metal roofs with applied lap sealant shall be one-half unit vertical in 12 units horizontal (4-percent slope). Lap sealants shall be applied in accordance with the *approved* manufacturer’s installation instructions.
 3. The minimum slope for standing-seam roof systems shall be one-quarter unit vertical in 12 units horizontal (2-percent slope).
- ❖ The minimum slope permitted for a roof deck supporting metal roof panels varies based on the type of panels being installed. Three different types of metal roof panel systems are regulated: lapped, nonsoldered seam metal roofs without applied lap sealant; lapped, nonsoldered seam metal roofs with applied lap sealant; and standing seam metal roof systems. The slope limitations vary based on the ability of the metal panel roof system to shed water without water intrusion. This section allows lower minimum roof slopes for lapped nonsoldered seam metal roofs when lap sealants are used. To help ensure that lap sealants perform as part of the overall roofing system, the lap sealant must be installed in accordance with the approved manufacturer’s instructions.

ROOF ASSEMBLIES

R905.10.3 Material standards. Metal-sheet roof covering systems that incorporate supporting structural members shall be designed in accordance with the *International Building Code*. Metal-sheet roof coverings installed over structural decking shall comply with Table R905.10.3(1). The materials used for metal-sheet roof coverings shall be naturally corrosion resistant or provided with corrosion resistance in accordance with the standards and minimum thicknesses shown in Table R905.10.3(2).

❖ If the metal roof panel system uses the structural members of the roof construction for support, it is necessary to design the roof system in accordance with the *International Building Code*® (IBC®). Only where the metal roof coverings are installed and supported by structural decking may the provisions of the code be used. Under such conditions, Tables R905.10.3(1) and R905.10.3(2) must be consulted.

Table R905.10.3(1) lists the metal roof covering types and their material standards. Many of the materials listed are inherently corrosion resistant, such as aluminum, copper and lead. For these materials, listing a material standard for the base material is sufficient. However, for steel roofing products, coatings are added to the base material to provide the necessary corrosion resistance.

Table R905.10.3(2) lists the minimum coating thickness required to provide minimum corrosion resistance for the base steel. Note a to Table R905.10.3(2) specifies that the paint systems are intended to be applied to steel having one of the corrosion-resistant coatings listed.

TABLE R905.10.3(1). See below.

❖ See the commentaries to Sections R905.10.3 and R905.4.4. CDA 4115-1929, *Copper in Architecture—Design Handbook*, is no longer listed as a reference for

copper roof covering; however, the provisions of CDA 4115-1929 may be useful as a guideline.

**TABLE R905.10.3(2)
MINIMUM CORROSION RESISTANCE**

55% aluminum-zinc alloy coated steel	ASTM A792 AZ 50
5% aluminum alloy-coated steel	ASTM A875 GF60
Aluminum-coated steel	ASTM A463 T2 65
Galvanized steel	ASTM A653 G-90
Prepainted steel	ASTM A755 ^a

a. Paint systems in accordance with ASTM A755 shall be applied over steel products with corrosion-resistant coatings complying with ASTM A792, ASTM A875, ASTM A463, or ASTM A653.

❖ See the commentaries to Sections R905.10.3 and R905.4.4.

R905.10.4 Attachment. Metal roof panels shall be secured to the supports in accordance with this chapter and the manufacturer’s installation instructions. In the absence of manufacturer’s installation instructions, the following fasteners shall be used:

- Galvanized fasteners shall be used for steel roofs.
- Copper, brass, bronze, copper alloy and 300-series stainless steel fasteners shall be used for copper roofs.
- Stainless steel fasteners are acceptable for metal roofs.

❖ The general provisions of this chapter apply to the installation of metal panel roofing, as do the manufacturer’s installation instructions for the specific roofing system. The code requires various types of fasteners based on specific types of metal roofs unless the manufacturer’s installation instructions specify otherwise.

R905.10.5 Underlayment. Underlayment shall comply with Section R905.1.1.

❖ See the commentary to Section R905.1.1.

**TABLE R905.10.3(1)
METAL ROOF COVERING STANDARDS**

ROOF COVERING TYPE	STANDARD APPLICATION RATE/THICKNESS
Galvanized steel	ASTM A653 G90 Zinc coated
Stainless steel	ASTM A240, 300 Series alloys
Steel	ASTM A924
Lead-coated copper	ASTM B101
Cold-rolled copper	ASTM B370 minimum 16 oz/sq ft and 12 oz/sq ft high-yield copper for metal-sheet roof covering systems; 12 oz/sq ft for preformed metal shingle systems.
Hard lead	2 lb/sq ft
Soft lead	3 lb/sq ft
Aluminum	ASTM B209, 0.024 minimum thickness for roll-formed panels and 0.019-inch minimum thickness for pressformed shingles.
Terne (tin) and terne-coated stainless	Terne coating of 40 lb per double base box, field painted where applicable in accordance with manufacturer’s installation instructions.
Zinc	0.027 inch minimum thickness: 99.995% electrolytic high-grade zinc with alloy additives of copper (0.08 - 0.20%), titanium (0.07% - 0.12%) and aluminum (0.015%).

For SI: 1 ounce per square foot = 0.305 kg/m², 1 pound per square foot = 4.214 kg/m², 1 inch = 25.4 mm, 1 pound = 0.454 kg.

R905.11 Modified bitumen roofing. The installation of modified bitumen roofing shall comply with the provisions of this section.

❖ This section establishes the materials standards and installation criteria for modified bitumen roofing systems.

R905.11.1 Slope. Modified bitumen membrane roofs shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

❖ Where a modified bitumen roofing system is to be installed, the roof design slope must be a minimum of 1:48, more often recognized as 1/4 inch per foot.

R905.11.2 Material standards. Modified bitumen roof coverings shall comply with the standards in Table R905.11.2.

❖ Table R905.11.2 must be referenced for the installer to determine the appropriate specification standard for various materials that may be used in the application of modified bitumen roofing. The table identifies referenced standards for the membrane, primer, cement, adhesive and coatings that may be a part of the roof installation.

**TABLE R905.11.2
MODIFIED BITUMEN ROOFING MATERIAL STANDARDS**

MATERIAL	STANDARD
Acrylic coating	ASTM D6083
Asphalt adhesive	ASTM D3747
Asphalt cement	ASTM D3019
Asphalt coating	ASTM D1227; D2824
Asphalt primer	ASTM D41
Modified bitumen roof membrane	ASTM D6162; D6163; D6164; D6222; D6223; D6298; CGSB 37-GP-56M

❖ The materials used in modified bitumen roof coverings must comply with the following standards: ASTM D6162, D6163, D6164, D6222, D6223, D6298 and CGSB 37-56M, which cover modified bitumen roof membranes.

- ASTM D6162 covers prefabricated modified bituminous sheet materials reinforced with a combination of polyester fabric and glass fiber, with or without granules, which use styrene-butadiene-styrene (SBS) thermoplastic elastomer as the primary modifier and are intended for use in the fabrication of multiple-ply roofing and waterproofing membranes.
- ASTM D6163 covers prefabricated modified bituminous sheet materials with glass fiber reinforcement, with or without granules, which use SBS thermoplastic elastomer as the primary modifier and are intended for use in the fabrication of multiple-ply roofing and waterproofing membranes.
- ASTM D6164 covers prefabricated modified bituminous sheet materials reinforced with poly-

ester fabric, with or without granules, which use SBS thermoplastic elastomer as the primary modifier and are intended for use in the fabrication of multiple-ply roofing and waterproofing membranes.

- ASTM D6222 covers atactic polypropylene (APP) modified bituminous sheet materials using polyester reinforcement.
- ASTM D6223 covers APP modified bituminous sheet materials using a combination of polyester and glass fiber reinforcement.
- ASTM D6298 covers fiberglass reinforced modified bituminous sheet materials that use SBS thermoplastic elastomer as the primary modifier and are surfaced with a factory-applied continuous metal foil.
- CGSB 37-56M covers prefabricated modified bituminous membrane reinforced for roofing applications.
- ASTM D41 covers asphaltic primer suitable for use with asphalt in roofing, dampproofing and waterproofing below or above ground level, for application to concrete, masonry, metal and asphalt surfaces.
- ASTM D3019 covers lap cement consisting of asphalt dissolved in a volatile petroleum solvent with or without mineral or other stabilizers, or both, for use with roll roofing.
- ASTM D3747 covers emulsified asphalt adhesive for use in adhering preformed roof insulation to steel roof decks with inclines up to 33 percent. When applied as a continuous film over an acceptable deck surface, the emulsion functions as both an adhesive and a vapor retarder.
- ASTM D1227 and D2824 cover asphalt roof coatings:
 - ASTM D1227 covers emulsified asphalt suitable for use as a protective coating for built-up roofs and other exposed surfaces with inclines of not less than 4 percent.
 - ASTM D2824 covers aluminum-pigmented asphalt roof coatings, including nonfibered, asbestos-fibered, and asbestos-free fibered materials.
- ASTM D6083 covers a liquid-applied water-dispersed 100-percent acrylic elastomeric latex coating used as a protective coating for roofs.

R905.11.3 Application. Modified bitumen roofs shall be installed in accordance with this chapter and the manufacturer’s instructions.

❖ The general provisions of this chapter apply to the installation of modified bitumen roofing, as do the installation instructions of the manufacturer of the specific roofing materials or system.

R905.12 Thermoset single-ply roofing. The installation of thermoset single-ply roofing shall comply with the provisions of this section.

- ❖ This section establishes the materials standards and installation criteria for thermoset single-ply roofing systems.

R905.12.1 Slope. Thermoset single-ply membrane roofs shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

- ❖ If a thermoset single-ply roof system is to be installed, the roof design slope must be a minimum of 1:48, more often recognized as 1/4 inch per foot.

R905.12.2 Material standards. Thermoset single-ply roof coverings shall comply with ASTM D4637, ASTM D5019 or CGSB 37-GP-52M.

- ❖ The code recognizes three materials standards for the regulation of thermoset single-ply membrane roofs. The standards include ASTM D4637 for ethylene-propylene-diene-terpolymer (EPDM) sheets, ASTM D5019 for reinforced nonvulcanized polymeric sheet made from chlorosulfonated polyethylene (CSPE) and polyisobutylene (PIB) and CGSB 37-GP-52M for sheet-applied elastomeric roofing and waterproofing membrane.

R905.12.3 Application. Thermoset single-ply roofs shall be installed in accordance with this chapter and the manufacturer's instructions.

- ❖ The general provisions of this chapter apply to the installation of thermoset single-ply roofing, as do the installation instructions of the manufacturer of the specific roofing system.

R905.13 Thermoplastic single-ply roofing. The installation of thermoplastic single-ply roofing shall comply with the provisions of this section.

- ❖ This section sets forth the materials standards and installation criteria for single-ply roof systems consisting of polyvinyl chloride material.

R905.13.1 Slope. Thermoplastic single-ply membrane roofs shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-percent slope).

- ❖ If a thermoplastic single-ply roof system is to be installed, the roof design slope must be a minimum of 1:48, more often recognized as 1/4 inch per foot (21 mm/m).

R905.13.2 Material standards. Thermoplastic single-ply roof coverings shall comply with ASTM D4434, ASTM D6754, ASTM D6878 or CGSB CAN/CGSB 37.54.

- ❖ Four materials standards, ASTM D4434, ASTM D6754, ASTM D6878 and CGSB CAN/CGSB 37.54, are recognized for the regulation of thermoplastic single-ply membrane roofs and are acceptable standards in determining the appropriateness of the roofing system.

R905.13.3 Application. Thermoplastic single-ply roofs shall be installed in accordance with this chapter and the manufacturer's instructions.

- ❖ The general provisions of this chapter apply to the installation of thermoplastic single-ply roofing, as do the installation instructions of the manufacturer of the roofing system.

R905.14 Sprayed polyurethane foam roofing. The installation of sprayed polyurethane foam roofing shall comply with the provisions of this section.

- ❖ This section establishes the materials standards and installation criteria for sprayed polyurethane foam roofing systems.

R905.14.1 Slope. Sprayed polyurethane foam roofs shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-percent slope) for drainage.

- ❖ Where a sprayed polyurethane foam roof system is to be installed, the roof design slope must be a minimum of 1:48, more often recognized as 1/4 inch per foot (21 mm/m).

R905.14.2 Material standards. Spray-applied polyurethane foam insulation shall comply with ASTM C1029, Type III or IV or ASTM D7425.

- ❖ ASTM C1029, Type III or IV and ASTM D7425 are the standards for the regulation of spray-applied rigid cellular polyurethane thermal insulation.

R905.14.3 Application. Foamed-in-place roof insulation shall be installed in accordance with this chapter and the manufacturer's instructions. A liquid-applied protective coating that complies with Table R905.14.3 shall be applied not less than 2 hours nor more than 72 hours following the application of the foam.

- ❖ The general provisions of this chapter address the installation of spray-applied rigid cellular polyurethane thermal membrane roofing, as do the installation instructions of the manufacturer of the roofing system. In addition, a liquid-applied protective coating must be provided to protect the exterior surface of the foam. The protective coating specified in Table R905.14.3 must be applied between 2 and 72 hours following the installation of the foam insulation.

**TABLE R905.14.3
PROTECTIVE COATING MATERIAL STANDARDS**

MATERIAL	STANDARD
Acrylic coating	ASTM D6083
Silicone coating	ASTM D6694
Moisture-cured polyurethane coating	ASTM D6947

- ❖ See the commentary to Section 905.14.3.

R905.14.4 Foam plastics. Foam plastic materials and installation shall comply with Section R316.

- ❖ The foam-plastics provisions of Section R316, particularly those of Section R316.5.2 specific to roof cover-

ing assemblies, are applicable to roof assemblies containing sprayed polyurethane foam. The use of wood structural-panel roof sheathing is permitted in lieu of a thermal barrier for separating the interior of the building from the sprayed polyurethane foam-plastic roofing material. Sections R316.5.2 and R803 contain specific requirements for wood structural-panel sheathing.

R905.15 Liquid-applied roofing. The installation of liquid-applied roofing shall comply with the provisions of this section.

- ❖ This section establishes the material standards and installation criteria for liquid-applied roofing.

R905.15.1 Slope. Liquid-applied roofing shall have a design slope of not less than one-fourth unit vertical in 12 units horizontal (2-percent slope).

- ❖ If a liquid-applied roofing is to be installed, the roof design slope must be a minimum of 1:48, more often recognized as $\frac{1}{4}$ inch per foot (21 mm/m).

R905.15.2 Material standards. Liquid-applied roofing shall comply with ASTM C836, C957, D1227, D3468, D6083, D6694 or D6947.

- ❖ The code recognizes several materials standards for the regulation of liquid-applied roofing. They include ASTM C836 for cold-liquid-applied elastomeric waterproofing membranes that require the installation of separate wearing surfaces, ASTM C957 for cold-liquid-applied elastomeric waterproofing membranes that provide integral wearing surfaces, ASTM D1227 for emulsified asphalt used as a protective coating for built-up roofing systems, ASTM D3468 for liquid-applied neoprene and chlorosulfanated polyethylene materials used in roofing and waterproofing, ASTM D6083 for liquid-applied acrylic roof coatings, ASTM D6694 for silicone-based elastomeric coating for spray polyethylene foam insulation and ASTM D6947 for liquid-applied moisture-cured polyurethane.

R905.15.3 Application. Liquid-applied roofing shall be installed in accordance with this chapter and the manufacturer's instructions.

- ❖ The general provisions of this chapter apply to the installation of liquid-applied roofing, as do the installation instructions of the manufacturer of the roofing system.

R905.16 Photovoltaic shingles. The installation of photovoltaic shingles shall comply with the provisions of this section, Section R324 and NFPA 70.

- ❖ The section provides guidance for installers and code officials regarding the installation of photovoltaic shingles. These shingles are integrated with the building and provide both a roof covering and source of electrical power. The installation must also comply with the applicable portions of Section R324 and the NFPA 70. These provisions supply requirements and limitations for roof decks, roof deck slope, underlayment, underlayment application, ice barriers and underlayment attachment in high-wind regions that are considered

appropriate for the installation of photovoltaic shingles. The specific requirements included here have been adapted from and are intended to be consistent with similar attributes for other shingle-type roof coverings. Section 905.16.1 is adapted from Section R905.4.1; Section R905.16.2 is adapted from Section R905.2.2; Sections R905.16.3, R905.16.4 and R905.16.4.2 are adapted from Section R905.1.1 and Section R905.16.4.1 is adapted from Section R905.1.2.

R905.16.1 Deck requirements. Photovoltaic shingles shall be applied to a solid or closely-fitted deck, except where the roof covering is specifically designed to be applied over spaced sheathing.

- ❖ See the commentary to Section R905.16.

R905.16.2 Deck slope. Photovoltaic shingles shall be used only on roof slopes of two units vertical in 12 units horizontal (2:12) or greater.

- ❖ See the commentary to Section R905.16.

R905.16.3 Underlayment. Unless otherwise noted, required underlayment shall conform to ASTM D4869 or ASTM D6757.

- ❖ See the commentary to Section R905.16.

R905.16.4 Underlayment application. Underlayment shall be applied shingle fashion, parallel to and starting from the eave, lapped 2 inches (51 mm) and fastened sufficiently to hold in place.

- ❖ See the commentary to Section R905.16.

R905.16.4.1 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, as designated in Table R301.2(1), an ice barrier that consists of not less than two layers of underlayment cemented together or of a self-adhering polymer modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point not less than 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

- ❖ See the commentary to Section R905.16.

R905.16.4.2 Underlayment and high winds. Underlayment applied in areas subject to high winds [above 140 mph (63 m/s), in accordance with Figure R301.2(4)A] shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the ultimate design wind speed equals or exceeds 150 mph (67 m/s) shall comply with ASTM D4869 Type IV, or ASTM D6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6-inch (152 mm) spacing at the side laps. Underlayment shall be applied as required for asphalt shingles in accordance with Table R905.1.1(2). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 inch (25 mm) with a thick-

ness of not less than 32-gage sheet metal. The cap-nail shank shall be not less than 12 gage (0.105 inches) with a length to penetrate through the roof sheathing or not less than $\frac{3}{4}$ inch (19 mm) into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D1970 shall be permitted.

❖ See the commentary to Section R905.16.

R905.16.5 Material standards. Photovoltaic shingles shall be listed and labeled in accordance with UL 1703.

❖ This section references UL 1703 as the standard used for determining code compliance of photovoltaic shingles.

R905.16.6 Attachment. Photovoltaic shingles shall be attached in accordance with the manufacturer's installation instructions.

❖ Referring to the manufacturer's instructions is appropriate since the required slope and fastening of the photovoltaic shingles are different for each manufacturer's product.

R905.16.7 Wind resistance. Photovoltaic shingles shall be tested in accordance with procedures and acceptance criteria in ASTM D3161. Photovoltaic shingles shall comply with the classification requirements of Table R905.2.4.1 for the appropriate maximum basic wind speed. Photovoltaic shingle packaging shall bear a label to indicate compliance with the procedures in ASTM D3161 and the required classification from Table R905.2.4.1.

❖ For wind resistance, the procedures and acceptance criteria used in ASTM D3161 for asphalt shingles are appropriate when adapted for photovoltaic shingles.

**SECTION R906
ROOF INSULATION**

R906.1 General. The use of above-deck thermal insulation shall be permitted provided such insulation is covered with an *approved* roof covering and complies with FM 4450 or UL 1256.

❖ During these days of energy consciousness, roof insulation has become increasingly prevalent. It has distinct benefits not only in energy conservation but also in building-occupant comfort. Insulation also provides a smooth, uniform substrate for application of the roofing materials. The code requires that above-deck thermal insulation be covered by an approved roof covering and be in compliance with FM 4450 or UL 1256. Although UL 1256 specifies the testing methods for determining the fire resistance of roof covering materials, FM 4450 deals with Class I insulated steel deck roofs only.

R906.2 Material standards. Above-deck thermal insulation board shall comply with the standards in Table R906.2.

❖ The referenced material standards provide additional guidance on the physical properties of roof insulation

when used as above-deck components of roof assemblies.

**TABLE R906.2
MATERIAL STANDARDS FOR ROOF INSULATION**

Cellular glass board	ASTM C552
Composite boards	ASTM C1289, Type III, IV, V or VI
Expanded polystyrene	ASTM C578
Extruded polystyrene board	ASTM C578
Perlite board	ASTM C728
Polyisocyanurate board	ASTM C1289, Type I or II
Wood fiberboard	ASTM C208
Fiber-reinforced gypsum board	ASTM C1278
Glass-faced gypsum board	ASTM C1177

❖ This table incorporates industry-recognized material standards into the code for materials commonly used in above-roof deck insulation practices.

**SECTION R907
ROOFTOP-MOUNTED PHOTOVOLTAIC SYSTEMS**

R907.1 Rooftop-mounted photovoltaic systems. Rooftop-mounted photovoltaic panels or modules shall be installed in accordance with this section, Section R324 and NFPA 70.

❖ Rooftop-mounted photovoltaic (PV) systems are designed to convert light energy into direct current (DC) electricity. They have no moving parts and do not contain fluids. The light-to-electricity conversion begins at the PV cell, which is commonly a semiconductor device that generates electricity when exposed to light. To be effective, PV cells are assembled into PV modules, which are then assembled into PV panels. These panels are assembled onto a frame or a flexible substrate that can be affixed to the roof of buildings to create a PV array. PV arrays and modules are wired together and generally operate in a series electrical circuit. An inverter is used to convert the DC power into alternating current (AC) that can be used to power the electrical loads in the dwelling.

Section R907 provides guidance for installers and code officials regarding the installation of rooftop-mounted PV panels or modules. Section R907 provides requirements and limitations for wind resistance, fire classification, installation and listing and labeling that are considered appropriate for the installation of rooftop-mounted PV panels or modules. The installation must also comply with the applicable portions of Section R324 and NFPA 70. PV panels and modules must be listed and labeled to show that they meet the requirements of UL 1703.

R907.2 Wind resistance. Rooftop-mounted photovoltaic panel or modules systems shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

❖ See the commentary to Section R907.1.

R907.3 Fire classification. Rooftop-mounted photovoltaic panels or modules shall have the same fire classification as the roof assembly required in Section R902.

❖ See the commentary to Section R907.1.

R907.4 Installation. Rooftop-mounted photovoltaic panels or modules shall be installed in accordance with the manufacturer's instructions.

❖ See the commentary to Section R907.1.

R907.5 Photovoltaic panels and modules. Rooftop-mounted photovoltaic panels and modules shall be listed and labeled in accordance with UL 1703 and shall be installed in accordance with the manufacturer's printed instructions.

❖ See the commentary to Section R907.1.

SECTION R908 REROOFING

R908.1 General. Materials and methods of application used for re-covering or replacing an existing roof covering shall comply with the requirements of Chapter 9.

Exceptions:

1. Reroofing shall not be required to meet the minimum design slope requirement of one-quarter unit vertical in 12 units horizontal (2-percent slope) in Section R905 for roofs that provide positive roof drainage.
 2. For roofs that provide positive drainage, re-covering or replacing an existing roof covering shall not require the secondary (emergency overflow) drains or scuppers of Section R903.4.1 to be added to an existing roof.
- ❖ This section addresses the concerns associated with unregulated reroofing operations. The provisions require that when an existing building is reroofed, the existing roof be structurally sound and in a proper condition to receive the new roofing. It is often necessary to remove the existing roof covering prior to installing the new roofing materials. This section identifies those situations where the reroofing cannot occur over an existing roof covering.
- If new roof covering materials are to be installed as a replacement for an existing roof covering, or if the new roof covering is applied directly over an existing roof, the roof covering materials and the application process must conform to the provisions for a new roof covering installation.

There may be occasions where only a small portion of the existing roof covering is in need of replacement or a limited amount of the roof is in need of repair. Appendix J of the code addresses those situations, in

particular Section AJ301. This section of Appendix J permits repair of nonstructural elements using the same materials that are already in place. In other words, repair of the existing roof covering may be made using the same materials and methods found on the existing roof. It is assumed that the repairs will not cause the building to be reduced in code compliance from the previous level.

R908.2 Structural and construction loads. The structural roof components shall be capable of supporting the roof covering system and the material and equipment loads that will be encountered during installation of the roof covering system.

❖ A fundamental requirement throughout the code is the recognition of the impact of any new repair or replacement work on the structural system. If a new roof covering system is installed, the structural members of the roof and any additional structural members that carry roof loads must be reviewed for their ability to support the loads that will be imposed during the installation process. This includes the weight of the new roof covering materials as well as any installation equipment that is placed on the roof.

R908.3 Roof replacement. Roof replacement shall include the removal of existing layers of roof coverings down to the roof deck.

Exception: Where the existing roof assembly includes an ice barrier membrane that is adhered to the roof deck, the existing ice barrier membrane shall be permitted to remain in place and covered with an additional layer of ice barrier membrane in accordance with Section R905.

❖ This section requires that all existing layers of the roof covering materials must be removed prior to the installation of new roof covering. The base for application of new roofing materials must provide a sound and consistent installation surface. The code will not permit the installation of new roof coverings over existing roof coverings where there is a potential for future problems with the roof's effectiveness. The exception permits an adhered ice barrier membrane to remain in place. In roof-removal situations where an existing ice barrier membrane is adhered to the existing roof deck, it is oftentimes difficult, if not impossible, to remove the existing layer of the adhered ice barrier membrane without damaging or replacing the roof deck. This exception is intended to account for this situation by allowing the existing adhered ice barrier membrane to remain in place and be covered with a new ice barrier membrane as required in Section R905.1.2 followed by the installation of the new primary roof covering material.

R908.3.1 Roof re-cover. The installation of a new roof covering over an existing roof covering shall be permitted where any of the following conditions occur:

1. Where the new roof covering is installed in accordance with the roof covering manufacturer's approved instructions.

2. Complete and separate roofing systems, such as standing-seam metal roof systems, that are designed to transmit the roof loads directly to the building's structural system and do not rely on existing roofs and roof coverings for support, shall not require the removal of existing roof coverings.
 3. Metal panel, metal shingle and concrete and clay tile roof coverings shall be permitted to be installed over existing wood shake roofs where applied in accordance with Section R908.4.
 4. The application of a new protective coating over an existing spray polyurethane foam roofing system shall be permitted without tear-off of existing roof coverings.
- ❖ This section permits a new roof covering to be installed over an existing roof cover where certain conditions exist. Condition 1 permits re-cover where allowed by the approved manufacturer's instructions. Condition 2 states that new roofing systems designed to transmit all roof loads directly to the structural supports of the building do not necessitate that the existing roofing system be removed. Condition 3 permits the installation of a new roof covering over wood shakes or shingle roofs only if the surface below the new roofing is properly protected in accordance with Section R908.4. Condition 4 permits recoating of an existing spray polyurethane foam roofing system without removal of the spray polyurethane foam roof covering. Recoating does not add significant weight to the roof assembly or compromise the long-term performance of the roofing assembly. Industry practices for the recoat of an existing spray polyurethane foam roofing system are detailed in ASTM D6705, *Standard Guide for the Repair and Recoat of Spray Polyurethane Foam Roofing Systems*.

R908.3.1.1 Roof re-cover not allowed. A *roof re-cover* shall not be permitted where any of the following conditions occur:

1. Where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing.
 2. Where the existing roof covering is slate, clay, cement or asbestos-cement tile.
 3. Where the existing roof has two or more applications of any type of roof covering.
- ❖ Section R908.3.1.1 prohibits installation of a new roof covering over an existing roof covering where certain conditions exist.

If the existing roof or roof covering is water soaked, the concealment of the existing roof in such a condition will lead to problems of deterioration and failure in the future. Any situation where the existing roof construction does not provide for an acceptable base is reason to remove all existing roof-covering materials prior to reroofing. In addition, roofing materials such as wood shakes, clay tiles and similar materials are not generally acceptable as a base for a new roof covering because of the variation in their surfaces.

A maximum of two roof coverings is permitted by the code, based primarily on the dead load weight that is accumulated on the roof for every layer of roofing materials. Where two or more applications of any roof covering are present, the existing materials must be removed prior to installation of the new roof covering.

R908.4 Roof re-covering. Where the application of a new roof covering over wood shingle or shake roofs creates a combustible concealed space, the entire existing surface shall be covered with gypsum board, mineral fiber, glass fiber or other *approved* materials securely fastened in place.

- ❖ A new roof covering can be applied over the top of an existing roof of wood shakes or shingles only if the existing roof surface is protected to address the concern of concealed combustible spaces. The application of a new roof over wood shakes or shingles creates an extensive amount of concealed area, all with a high degree of combustible materials. By using gypsum board, mineral fiber, glass fiber or other similar materials in the reroofing installation, the combustible shakes or shingles will be protected by materials suitable for fireblocking.

R908.5 Reinstallation of materials. Existing slate, clay or cement tile shall be permitted for reinstallation, except that damaged, cracked or broken slate or tile shall not be reinstalled. Any existing flashings, edgings, outlets, vents or similar devices that are a part of the assembly shall be replaced where rusted, damaged or deteriorated. Aggregate surfacing materials shall not be reinstalled.

- ❖ Because all roofing materials should make a building weathertight, their reuse is strictly limited. Unless damaged, existing tile of cement, slate or clay may be reused. The reuse of all other roofing materials is prohibited. Roof accessories, such as metal edgings, flashing, drain outlets and collars, may be reinstalled only if they are in a suitable condition.

R908.6 Flashings. Flashings shall be reconstructed in accordance with *approved* manufacturer's installation instructions. Metal flashing to which bituminous materials are to be adhered shall be primed prior to installation.

- ❖ During reroofing operations, all flashings that are to remain must be reconstructed in a manner consistent with the manufacturer's instructions. In those cases where bituminous materials are applied to any existing metal flashing, a primer must be applied to the flashing to increase adhesion to the surface.

SECTION R909 ROOFTOP-MOUNTED PHOTOVOLTAIC PANEL SYSTEMS

R909.1 General. The installation of photovoltaic panel systems that are mounted on or above the roof covering shall comply with this section, Section R324 and NFPA 70.

- ❖ Rooftop-mounted photovoltaic (PV) panel systems can be mounted on or above the roof covering. The PV panel system must comply with Section R909, the

applicable portions of Section R324 and NFPA 70 and the manufacturer's installation instructions. PV panel systems installed on or above the roof covering must be securely fastened to the roof/rafter system. Often, solar collector systems are installed with manufactured metal mounting brackets that can be attached to the roofing system or wood blocking, or with sleepers using lag bolts or other secure mounting systems. The manufacturer's mounting specifications must be followed so that the panels are properly mounted. This is especially important in areas with high wind loads. Also, the weight of the collector system must be checked to confirm that the roof structure is designed to meet the increased load. Roof penetrations must be sealed during and after installation of the PV panel systems. At a minimum, there will be roof penetrations for the electrical conduits connecting to the panels. PV panel systems mounted above the roof covering will require penetrations into the rafter system or blocking to attach the collectors to the roof, and care must be taken to seal the penetrations.

R909.2 Structural requirements. Rooftop-mounted photovoltaic panel systems shall be designed to structurally support the system and withstand applicable gravity loads in accordance with Chapter 3. The roof upon which these systems are installed shall be designed and constructed to support the loads imposed by such systems in accordance with Chapter 8.

❖ See the commentary to Section R909.1.

R909.3 Installation. Rooftop-mounted photovoltaic systems shall be installed in accordance with the manufacturer's instructions. Roof penetrations shall be flashed and sealed in accordance with this chapter.

❖ See the commentary to Section R909.1.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

ASTM C1167–11, *Specification for Clay Roof Tiles*. West Conshohocken, PA: ASTM International, 2011.

Chapter 10: Chimneys and Fireplaces

General Comments

Chapter 10 regulates two basic types of chimneys and fireplaces: factory-built and those constructed on site of masonry and other approved materials. Chimneys and fireplaces constructed of masonry rely on prescriptive requirements for the details of their construction; the factory-built type rely on the listing and labeling method of approval. This chapter also contains provisions for unvented gas log heaters. Seismic issues related to fireplaces and chimneys, including reinforcing requirements, are also addressed in Chapter 10.

Section R1001 regulates the construction of masonry fireplaces. Section R1002 establishes the standards for the use and installation of masonry heaters. Section R1003 regulates the construction of masonry chimneys.

Section R1004 establishes the standards for the use and installation of factory-built fireplaces including the

use of unvented gas log heaters. Section R1005 establishes the standards for the use and installation of factory-built chimneys. Section R1006 requires the installation of an exterior air supply for use with both factory-built and masonry fireplaces.

Purpose

Chapter 10 contains requirements for the safe construction of masonry chimneys and fireplaces and establishes the standards for the use and installation of factory-built chimneys, fireplaces and masonry heaters. Chimneys and fireplaces constructed of masonry rely on prescriptive requirements for the details of their construction; the factory-built type relies on the listing and labeling method of approval. This chapter also provides the requirements for seismic reinforcing and anchorage of masonry fireplaces and chimneys.

SECTION R1001 MASONRY FIREPLACES

R1001.1 General. Masonry fireplaces shall be constructed in accordance with this section and the applicable provisions of Chapters 3 and 4.

- ❖ This section covers details for masonry fireplaces. Table R1001.1 and Figure R1001.1 show details for masonry fireplaces and chimneys.

TABLE R1001.1. See page 10-2.

- ❖ This table provides a summary of the requirements for masonry fireplaces and chimneys directly correlated to Figure R1001.1. The first column lists various parts of the fireplace. The second column shows a letter designation corresponding to the item in the figure with the same letter. The third column contains the requirements for that particular fireplace or chimney.

R1001.2 Footings and foundations. Footings for masonry fireplaces and their chimneys shall be constructed of concrete or *solid masonry* not less than 12 inches (305 mm) thick and shall extend not less than 6 inches (152 mm) beyond the face of the fireplace or foundation wall on all sides. Footings shall be founded on natural, undisturbed earth or engineered fill below frost depth. In areas not subjected to freezing, footings shall be not less than 12 inches (305 mm) below finished *grade*.

- ❖ The dead-load bearing pressure for a building structure, particularly if it is a light wood-frame building, is usually quite low, even though the bearing pressure on the foundation for a masonry or concrete fireplace and chimney can be several times higher. It is good practice to proportion the foundation of a masonry fireplace and chimney to have approximately the same bearing

pressure as is present under the building structure itself, although the codes do not require such a design. Where the soil is compressible, differential settlements between the fireplace and chimney and its surrounding structure can cause cracking of the finish materials in the vicinity of the fireplace and chimney. Also, firestopping may be displaced so that a draft opening is created.

R1001.2.1 Ash dump cleanout. Cleanout openings located within foundation walls below fireboxes, when provided, shall be equipped with ferrous metal or masonry doors and frames constructed to remain tightly closed except when in use. Cleanouts shall be accessible and located so that ash removal will not create a hazard to combustible materials.

- ❖ Noncombustible, tightly sealed cleanout doors must reduce the danger of fire spread through the cleanout openings. Cleanout openings must be easily accessible to allow ash removal. The ashes and other materials left in the fireplace may remain hot for some time. Cleanout doors must be tight closing to prevent air from entering the firebox and causing the unburned materials to reignite. The cleanout door must be located so that ashes and other unburned materials that may still be hot can be removed without creating a hazard to combustible materials.

R1001.3 Seismic reinforcing. Masonry or concrete chimneys in Seismic Design Category D₀, D₁ or D₂ shall be reinforced. Reinforcing shall conform to the requirements set forth in Table R1001.1 and Section R606.

- ❖ Masonry and concrete have inherently brittle natures, and they are therefore weak when subjected to tensile forces. Using steel, an inherently ductile material, pro-

CHIMNEYS AND FIREPLACES

vides ductility in masonry and concrete construction. Chimneys, in general, and unreinforced masonry and concrete chimneys, in particular, do not perform well in earthquakes because of their tall and slender geometry. Observation of buildings after earthquakes has shown that chimneys suffered severe damage and sometimes completely collapsed. To improve the performance of masonry and concrete chimneys under severe earthquake loading, steel-reinforcing bars are required as shown in Table R1001.1. This reinforcement is required in Seismic Design Categories D₀, D₁ and D₂ only. Reinforcement is not required in Seismic Design Categories A, B and C, and buildings in seismic design categories higher than D must be designed

in accordance with the *International Building Code*[®] (IBC[®]) (see Section R301.2.2).

R1001.3.1 Vertical reinforcing. For chimneys up to 40 inches (1016 mm) wide, four No. 4 continuous vertical bars shall be placed between wythes of *solid masonry* or within the cells of hollow unit masonry and grouted in accordance with Section R606. Grout shall be prevented from bonding with the flue liner so that the flue liner is free to move with thermal expansion. For chimneys more than 40 inches (1016 mm) wide, two additional No. 4 vertical bars shall be provided for each additional flue incorporated into the chimney or for each additional 40 inches (1016 mm) in width or fraction thereof.

❖ To keep the chimney structure together and prevent severe damage or fracture, four No. 4 bars, continu-

**TABLE R1001.1
SUMMARY OF REQUIREMENTS FOR MASONRY FIREPLACES AND CHIMNEYS**

ITEM	LETTER ^a	REQUIREMENTS
Hearth slab thickness	A	4"
Hearth extension (each side of opening)	B	8" fireplace opening < 6 square foot. 12" fireplace opening ≥ 6 square foot.
Hearth extension (front of opening)	C	16" fireplace opening < 6 square foot. 20" fireplace opening ≥ 6 square foot.
Hearth slab reinforcing	D	Reinforced to carry its own weight and all imposed loads.
Thickness of wall of firebox	E	10" solid brick or 8" where a firebrick lining is used. Joints in firebrick 1/4" maximum.
Distance from top of opening to throat	F	8"
Smoke chamber wall thickness Unlined walls	G	6" 8"
Chimney Vertical reinforcing ^b	H	Four No. 4 full-length bars for chimney up to 40" wide. Add two No. 4 bars for each additional 40" or fraction of width or each additional flue.
Horizontal reinforcing	J	1/4" ties at 18" and two ties at each bend in vertical steel.
Bond beams	K	No specified requirements.
Fireplace lintel	L	Noncombustible material.
Chimney walls with flue lining	M	Solid masonry units or hollow masonry units grouted solid with not less than 4-inch nominal thickness.
Distances between adjacent flues	—	See Section R1003.13.
Effective flue area (based on area of fireplace opening)	P	See Section R1003.15.
Clearances Combustible material Mantel and trim Above roof	R	See Sections R1001.11 and R1003.18. See Section R1001.11, Exception 4. 3' at roofline and 2' at 10'.
Anchorage ^b Strap Number Embedment into chimney Fasten to Bolts	S	3/16" × 1" Two 12" hooked around outer bar with 6" extension. 4 joists Two 1/2" diameter.
Footing Thickness Width	T	12" min. 6" each side of fireplace wall.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

Note: This table provides a summary of major requirements for the construction of masonry chimneys and fireplaces. Letter references are to Figure R1001.1, which shows examples of typical construction. This table does not cover all requirements, nor does it cover all aspects of the indicated requirements. For the actual mandatory requirements of the code, see the indicated section of text.

a. The letters refer to Figure R1001.1.

b. Not required in Seismic Design Category A, B or C.

ous from bottom to top, are required. The bars are typically placed at the four corners, similar to the placement of vertical bars in concrete columns. The hollow cells in hollow unit masonry are used for placement of vertical bars, and if solid masonry is used, the reinforcing steel must be placed between the wythes.

For wider chimneys or chimneys with more than one flue, four No. 4 bars are not adequate, and reinforcing bars in increments of two are added for each additional flue or each additional 40 inches (1016 mm) of chimney width.

BRICK FIREBOX AND CHIMNEY—SECTIONAL SIDE VIEW ON WOOD FLOOR

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

FIGURE R1001.1
FIREPLACE AND CHIMNEY DETAILS

R1001.3.2 Horizontal reinforcing. Vertical reinforcement shall be placed within $1/4$ -inch (6.4 mm) ties, or other reinforcing of equivalent net cross-sectional area, placed in the bed joints in accordance with Section R606 at not less than every 18 inches (457 mm) of vertical height. Two such ties shall be installed at each bend in the vertical bars.

- ❖ Vertical reinforcement under high seismic loading tends to buckle, then burst out of the concrete or masonry. To prevent this action, the vertical reinforcing required under Section R1001.3.1 must be placed in $1/4$ -inch (6.4 mm) ties that are placed in the bed joints in accordance with Section R607. The ties are required at no more than 18-inch (457 mm) vertical intervals to form an effective cage for the vertical reinforcement. Where the vertical reinforcing bars have bends and abrupt changes in direction as a result of changes in sections of the chimney, two horizontal ties are required at each bend to handle the additional effects of stress concentration.

R1001.4 Seismic anchorage. Masonry or concrete chimneys in Seismic Design Category D₀, D₁ or D₂ shall be anchored at each floor, ceiling or roof line more than 6 feet (1829 mm) above *grade*, except where constructed completely within the exterior walls. Anchorage shall conform to the requirements of Section R1001.4.1.

- ❖ The sway of a chimney under earthquake lateral movement may cause it to impact the roof and floor framing and ultimately pull away from the framing. To control or prevent this action in Seismic Design Categories D₀, D₁ and D₂, masonry and concrete chimneys must be anchored at each floor, ceiling or roof line to provide lateral bracing. Such anchorage is not required in three situations: 1. In Seismic Design Categories A, B and C; 2. At floor, ceiling or roof lines 6 feet (1829 mm) or less above grade; and 3. Where the chimney is constructed completely within the exterior walls and is therefore braced by the building elements surrounding it.

In Seismic Design Categories E and F, the reinforcing and anchorage must be designed in accordance with the IBC.

R1001.4.1 Anchorage. Two $3/16$ -inch by 1-inch (5 mm by 25 mm) straps shall be embedded not less than 12 inches (305 mm) into the chimney. Straps shall be hooked around the outer bars and extend 6 inches (152 mm) beyond the bend. Each strap shall be fastened to not less than four floor ceiling or floor joists or rafters with two $1/2$ -inch (12.7 mm) bolts.

- ❖ The anchors required under Section R1001.4 consist of a minimum of two straps, each $3/16$ inch by 1 inch (4.8 mm by 25 mm). The straps must be firmly connected to the building framing and chimney to control or prevent the chimney from pulling away or buckling. To accomplish this firm connection, the straps must be bolted to at least four joists or rafters using $1/2$ -inch (12.7 mm) bolts. At the other end, they must be embedded at least 12 inches (305 mm) into the chimney and hooked around the outer vertical reinforcing

bars. Short hooks might pull out in earthquakes, and for this reason the minimum length of the hook around the vertical bar is 6 inches (152 mm).

R1001.4.1.1 Cold-formed steel framing. Where cold-formed steel framing is used, the location where the $1/2$ -inch (12.7 mm) bolts are used to attach the straps to the framing shall be reinforced with not less than a 3-inch × 3-inch × 0.229-inch (76 mm × 76 mm × 5.8 mm) steel plate on top of the strap that is screwed to the framing with not fewer than seven No. 6 screws for each bolt.

- ❖ The provisions in Section R1001.4.1 for anchoring masonry chimneys to residential buildings were developed with the concept of anchoring to wood framing. Cold-formed steel framing can function equivalently in this respect to wood framing, except that the bearing area between the bolt and the cold-formed steel framing is small and therefore needs to be reinforced to prevent the local failure of the steel. The 0.229-inch (essentially $1/4$ -inch) steel plate will provide this reinforcement and spread the load from the bolt to a wider area in the framing to prevent the localized failure of the framing. The minimum of seven No. 6 screws (a total shear capacity transfer of 1,050 pounds in 33-mil cold-formed steel) provide the transfer mechanism to spread the force in the bolt (a maximum of 933 pounds for a $1/2$ -inch A307 bolt in 2-inch nominal Douglas-fir lumber with a $1/4$ -inch-thick-steel side member).

R1001.5 Firebox walls. Masonry fireboxes shall be constructed of *solid masonry* units, hollow masonry units grouted solid, stone or concrete. Where a lining of firebrick not less than 2 inches (51 mm) thick or other *approved* lining is provided, the minimum thickness of back and sidewalls shall each be 8 inches (203 mm) of *solid masonry*, including the lining. The width of joints between firebricks shall not be greater than $1/4$ inch (6.4 mm). Where a lining is not provided, the total minimum thickness of back and side walls shall be 10 inches (254 mm) of *solid masonry*. Firebrick shall conform to ASTM C27 or C1261 and shall be laid with medium duty refractory mortar conforming to ASTM C199.

- ❖ This section specifies the minimum thicknesses of refractory brick or solid masonry necessary to contain the generated heat.

Solid masonry walls forming the firebox must have a minimum total thickness of 8 inches (204 mm), including the refractory lining.

The refractory lining is to consist of a low-duty, fire-clay refractory brick with a minimum thickness of 2 inches (51 mm), laid with medium-duty refractory mortar. Mortar joints are generally $1/16$ to $3/16$ inch (1.6 to 4.8 mm) thick, but not thicker than $1/4$ inch (6.4 mm), to reduce thermal movements and prevent joint deterioration.

Where a firebrick lining is not used in firebox construction, the wall thickness is not to be less than 10 inches (254 mm) of solid masonry. Firebrick must conform to ASTM C27 or ASTM C1261 and must be laid with medium-duty refractory mortar conforming to ASTM C199.

R1001.5.1 Steel fireplace units. Installation of steel fireplace units with *solid masonry* to form a masonry fireplace is permitted when installed either in accordance with the requirements of their listing or the requirements of this section. Steel fireplace units incorporating a steel firebox lining shall be constructed with steel not less than 1/4 inch (6.4 mm) thick, and an air-circulating chamber that is ducted to the interior of the building. The firebox lining shall be encased with *solid masonry* to provide a total thickness at the back and sides of not less than 8 inches (203 mm), of which not less than 4 inches (102 mm) shall be of *solid masonry* or concrete. Circulating air ducts used with steel fireplace units shall be constructed of metal or masonry.

❖ Steel fireplace units and an air chamber may be used as part of the required thickness of masonry fireplaces so that the combined thickness of the masonry and steel is 8 inches (203 mm). The steel may not be less than 1/4 inch (6.4 mm) thick, and the masonry must be at least 4 inches thick. Where ducts are used as part of a steel fireplace unit to circulate warm air, they must be constructed of metal or masonry.

R1001.6 Firebox dimensions. The firebox of a concrete or masonry fireplace shall have a minimum depth of 20 inches (508 mm). The throat shall not be less than 8 inches (203 mm) above the firebox opening. The throat opening shall not be less than 4 inches (102 mm) deep. The cross-sectional area of the passageway above the firebox, including the

throat, damper and smoke chamber, shall not be less than the cross-sectional area of the flue.

Exception: Rumford fireplaces shall be permitted provided that the depth of the fireplace is not less than 12 inches (305 mm) and not less than one-third of the width of the fireplace opening, that the throat is not less than 12 inches (305 mm) above the lintel and is not less than 1/20 the cross-sectional area of the fireplace opening.

❖ The proper functioning of the fireplace depends on the size of the face opening and the chimney dimensions, which in turn are related to the room size [see Commentary Figure R1001.6(1)]. This section specifies a minimum depth of 20 inches (508 mm) for the combustion chamber because that depth influences the draft requirement. The dimensions of the firebox (depth, opening size and shape) are usually based on two considerations: aesthetics and the need to prevent the room from overheating. Suggested dimensions for single-opening fireboxes are given in technical publications of the Brick Institute of America (BIA) and the National Concrete Masonry Association (NCMA).

This section also contains additional criteria for the throat's location and minimum cross-sectional area. Those criteria are based on many years of construction of successfully functioning fireplaces. The exception permits the use of Rumford fireplaces, which are tall, shallow fireplaces that can radiate a large amount of heat into a room.

The code reference to “depth of fireplace” is interpreted as the depth of the firebox [see Commentary Figure R1001.6(2)]. The throat must be made at least 12 inches (305 mm) above the lintel and must be at least 5 percent ($\frac{1}{20}$) of the cross-sectional area of the fireplace opening. Smoke chambers and flues for Rumford fireplaces should be sized and built like those of other masonry fireplaces. Even though those who build Rumford fireplaces do not totally agree about how they work, many books and guides address their construction.

R1001.7 Lintel and throat. Masonry over a fireplace opening shall be supported by a lintel of noncombustible material. The minimum required bearing length on each end of the fireplace opening shall be 4 inches (102 mm). The fireplace throat or damper shall be located not less than 8 inches (203 mm) above the lintel.

- ❖ A noncombustible lintel with a minimum bearing length of 4 inches (102 mm) on each end must be provided to support masonry above the fireplace opening. Provisions should be made to allow for expansion of the steel lintels when they are heated.

R1001.7.1 Damper. Masonry fireplaces shall be equipped with a ferrous metal damper located not less than 8 inches (203 mm) above the top of the fireplace opening. Dampers shall be installed in the fireplace or the chimney venting the fireplace, and shall be operable from the room containing the fireplace.

- ❖ A damper is used to close the chimney flue when the fireplace is not in use. This section provides guidance on its location and construction.

R1001.8 Smoke chamber. Smoke chamber walls shall be constructed of *solid masonry* units, hollow masonry units grouted solid, stone or concrete. The total minimum thickness of front, back and side walls shall be 8 inches (203 mm) of *solid masonry*. The inside surface shall be parged smooth with refractory mortar conforming to ASTM C199. Where a lining of firebrick not less than 2 inches (51 mm) thick, or a lining of vitrified clay not less than $\frac{5}{8}$ inch (16 mm) thick, is provided, the total minimum thickness of front, back and side walls shall be 6 inches (152 mm) of *solid masonry*, including the lining. Firebrick shall conform to ASTM C1261 and shall be laid with medium duty refractory mortar conforming to ASTM C199. Vitrified clay linings shall conform to ASTM C315.

- ❖ The smoke chamber is located directly above the firebox and must be constructed of solid masonry. A smoke shelf located behind the damper deflects downdrafts. As the downdraft hits the smoke shelf, it is turned upward by the damper assembly. Curved smoke shelves perform better; however, flat smoke shelves are acceptable.

Parging the inside surface smooth with refractory mortar meeting ASTM C199 will provide a liner with the ability to withstand temperatures up to 1800°F (983°C), as required for other lining materials.

R1001.8.1 Smoke chamber dimensions. The inside height of the smoke chamber from the fireplace throat to the beginning of the flue shall not be greater than the inside width of the fireplace opening. The inside surface of the smoke chamber shall not be inclined more than 45 degrees (0.79 rad) from vertical where prefabricated smoke chamber linings are used or where the smoke chamber walls are rolled or sloped rather than corbeled. Where the inside surface of the smoke cham-

ber is formed by corbeled masonry, the walls shall not be corbeled more than 30 degrees (0.52 rad) from vertical.

❖ This section provides specific dimensions for the smoke chamber of masonry fireplaces, which are necessary to provide proper flow of the smoke and products of combustion out of the fireplace and through the chimney. The height of the smoke chamber cannot exceed the inside width of the fireplace opening. The inside surface of the smoke chamber may be sloped 45 degrees (0.79 rad) from the vertical when constructed of a prefabricated smoke chamber lining or the smoke chamber walls are rolled or sloped. If the smoke chamber is sloped using corbeled masonry, the slope is limited to be no more than 30 degrees (0.52 rad) from the vertical. The slope is restricted more when using corbeled masonry because the surface is not smooth and will tend to create turbulence within the smoke chambers, thus affecting the flow of smoke to the flue.

R1001.9 Hearth and hearth extension. Masonry fireplace hearths and hearth extensions shall be constructed of concrete or masonry, supported by noncombustible materials, and reinforced to carry their own weight and all imposed loads. Combustible material shall not remain against the underside of hearths and hearth extensions after construction.

❖ The hearth includes both the floor of the firebox and the projection in front of it. The hearth extension protects wood, carpet and combustible materials from being ignited by sparks, hot embers or ashes that may fall from the fire box.

R1001.9.1 Hearth thickness. The minimum thickness of fireplace hearths shall be 4 inches (102 mm).

❖ The minimum thickness of fireplace hearths is 4 inches (102 mm).

R1001.9.2 Hearth extension thickness. The minimum thickness of hearth extensions shall be 2 inches (51 mm).

Exception: Where the bottom of the firebox opening is raised not less than 8 inches (203 mm) above the top of the hearth extension, a hearth extension of not less than $\frac{3}{8}$ -inch-thick (10 mm) brick, concrete, stone, tile or other approved noncombustible material is permitted.

❖ The hearth extension must be 2 inches (51 mm) thick unless the bottom of the fireplace opening is raised at least 8 inches (203 mm) above the top of the hearth extension. Where the bottom of the fireplace opening is raised at least 8 inches (203 mm) above the hearth extension, the hearth extension can be reduced to a thickness of $\frac{3}{8}$ -inch-thick (9.5 mm) brick, concrete, stone, tile or other approved noncombustible material.

R1001.10 Hearth extension dimensions. Hearth extensions shall extend not less than 16 inches (406 mm) in front of and not less than 8 inches (203 mm) beyond each side of the fireplace opening. Where the fireplace opening is 6 square feet (0.6 m²) or larger, the hearth extension shall extend not less

than 20 inches (508 mm) in front of and not less than 12 inches (305 mm) beyond each side of the fireplace opening.

❖ The hearth must extend in front of and to the side of the firebox opening a sufficient dimension to prevent burning embers from landing on combustible surfaces.

R1001.11 Fireplace clearance. Wood beams, joists, studs and other combustible material shall have a clearance of not less than 2 inches (51 mm) from the front faces and sides of masonry fireplaces and not less than 4 inches (102 mm) from the back faces of masonry fireplaces. The airspace shall not be filled, except to provide fireblocking in accordance with Section R1001.12.

Exceptions:

1. Masonry fireplaces *listed* and *labeled* for use in contact with combustibles in accordance with UL 127 and installed in accordance with the manufacturer's instructions are permitted to have combustible material in contact with their exterior surfaces.
 2. Where masonry fireplaces are part of masonry or concrete walls, combustible materials shall not be in contact with the masonry or concrete walls less than 12 inches (306 mm) from the inside surface of the nearest firebox lining.
 3. Exposed combustible trim and the edges of sheathing materials such as wood siding, flooring and gypsum board shall be permitted to abut the masonry fireplace sidewalls and hearth extension in accordance with Figure R1001.11, provided such combustible trim or sheathing is not less than 12 inches (305 mm) from the inside surface of the nearest firebox lining.
 4. Exposed combustible mantels or trim may be placed directly on the masonry fireplace front surrounding the fireplace opening providing such combustible materials are not placed within 6 inches (152 mm) of a fireplace opening. Combustible material within 12 inches (306 mm) of the fireplace opening shall not project more than $\frac{1}{8}$ inch (3 mm) for each 1-inch (25 mm) distance from such an opening.
- ❖ A 2-inch (51 mm) clearance is required from the front and side surfaces of the fireplace. A 4-inch (102 mm) clearance is required from the back of the fireplace. This airspace created around the fireplace cannot be filled, except for approved fireblocking (see Figure R1001.11).

There are four exceptions to this section that allow combustible materials to come in contact with the fireplace. The first allows factory-built fireplaces constructed in accordance with UL 127 to be in contact with combustibles. The installation must carefully follow the manufacturer's instructions.

The second exception applies to masonry fireplaces constructed in concrete or masonry walls. In this case combustible materials must keep at least 12 inches

(305 mm) from the inside surface of the firebox lining because of the conductive nature of the concrete or masonry walls.

Exception 3 permits combustible trim and edges of certain sheathing materials to abut the fireplace in accordance with Figure R1001.11. This exception permits the combustible trim to cover openings that would otherwise occur between the fireplace and other construction.

Exception 4 provides specific dimensions that protect combustible trim from radiant heat.

R1001.12 Fireplace fireblocking. Fireplace fireblocking shall comply with the provisions of Section R602.8.

❖ See the commentary to Section R602.8.

**SECTION R1002
MASONRY HEATERS**

R1002.1 Definition. A masonry heater is a heating *appliance* constructed of concrete or *solid masonry*, hereinafter referred to as masonry, that is designed to absorb and store heat from a solid-fuel fire built in the firebox by routing the exhaust gases through internal heat exchange channels in which the flow path downstream of the firebox includes flow in a horizontal or downward direction before entering the chimney and that delivers heat by radiation from the masonry surface of the heater.

❖ Masonry heaters are appliances designed to absorb and store heat from a relatively small fire and to radiate that heat into a building interior. They are thermally more efficient than traditional fireplaces because of their design. Interior passageways through the heater allow hot exhaust gases from the fire to transfer heat into the masonry, which then radiates into the building.

R1002.2 Installation. Masonry heaters shall be installed in accordance with this section and comply with one of the following:

1. Masonry heaters shall comply with the requirements of ASTM E1602.

2. Masonry heaters shall be *listed* and *labeled* in accordance with UL 1482 or CEN 15250 and installed in accordance with the manufacturer’s instructions.

❖ ASTM E1602, UL 1482 and CEN 15250 contain guidelines for the installation of masonry heaters.

R1002.3 Footings and foundation. The firebox floor of a masonry heater shall be a minimum thickness of 4 inches (102 mm) of noncombustible material and be supported on a noncombustible footing and foundation in accordance with Section R1003.2.

❖ This section prescribes the minimum foundation requirements that will adequately support a masonry heating appliance. Section R1003.2 goes into specific detail on footings and foundations for masonry chimneys.

R1002.4 Seismic reinforcing. In Seismic Design Categories D₀, D₁ and D₂, masonry heaters shall be anchored to the masonry foundation in accordance with Section R1003.3. Seismic reinforcing shall not be required within the body of a masonry heater whose height is equal to or less than 3.5 times its body width and where the masonry chimney serving the heater is not supported by the body of the heater. Where the masonry chimney shares a common wall with the facing of the masonry heater, the chimney portion of the structure shall be reinforced in accordance with Section R1003.

❖ Because of the large bulk and squat geometry of these heaters, seismic reinforcement is not typically required. Flexural tensile stresses, which typically cause damage to unreinforced masonry, rarely occur. Where chimneys extend above these heaters, however, seismic reinforcement is required by Section R1003.3. See the commentary to Sections R1003.3 and R1003.4 for seismic reinforcements and anchorage for chimneys.

R1002.5 Masonry heater clearance. Combustible materials shall not be placed within 36 inches (914 mm) of the outside surface of a masonry heater in accordance with NFPA 211 Section 8-7 (clearances for solid-fuel-burning *appliances*), and the required space between the heater and combustible

For SI: 1 inch = 25.4 mm.

**FIGURE R1001.11
CLEARANCE FROM COMBUSTIBLES**

material shall be fully vented to permit the free flow of air around all heater surfaces.

Exceptions:

1. Where the masonry heater wall is not less than 8 inches (203 mm) thick of *solid masonry* and the wall of the heat exchange channels is not less than 5 inches (127 mm) thick of *solid masonry*, combustible materials shall not be placed within 4 inches (102 mm) of the outside surface of a masonry heater. A clearance of not less than 8 inches (203 mm) shall be provided between the gas-tight capping slab of the heater and a combustible ceiling.
 2. Masonry heaters listed and labeled in accordance with UL 1482 or CEN 15250 shall be installed in accordance with the listing specifications and the manufacturer's written instructions.
- ❖ Heat conducted through masonry heater walls can ignite combustible structural materials in contact with these walls. For this reason, a minimum required clearance to combustibles from masonry heaters has been established. Because masonry heaters typically generate more heat for a longer period of time than traditional fireplaces, greater clearances to combustible materials are needed to reduce the risk of fire.

**SECTION R1003
MASONRY CHIMNEYS**

R1003.1 Definition. A masonry chimney is a chimney constructed of *solid masonry* units, hollow masonry units grouted solid, stone or concrete, hereinafter referred to as masonry. Masonry chimneys shall be constructed, anchored, supported and reinforced as required in this chapter.

- ❖ A masonry chimney is a field-constructed assembly that can consist of solid masonry units, hollow masonry units grouted solid, concrete or rubble stone. A masonry chimney is permitted to serve residential (low-heat), medium-heat and high-heat appliances. This section outlines the general code requirements regarding construction details for all masonry chimneys, including those serving masonry fireplaces regulated by Section R1001.

R1003.2 Footings and foundations. Footings for masonry chimneys shall be constructed of concrete or *solid masonry* not less than 12 inches (305 mm) thick and shall extend not less than 6 inches (152 mm) beyond the face of the foundation or support wall on all sides. Footings shall be founded on natural undisturbed earth or engineered fill below frost depth. In areas not subjected to freezing, footings shall be not less than 12 inches (305 mm) below finished *grade*.

- ❖ Masonry fireplaces and chimneys must be supported on adequate foundations because of their weight and the forces imposed on them by wind, earthquakes and other effects. This section prescribes minimum foundation requirements that are typically adequate to support a standard chimney (see Commentary Figure R1003.2).

R1003.3 Seismic reinforcing. Masonry or concrete chimneys shall be constructed, anchored, supported and reinforced as required in this chapter. In Seismic Design Category D₀, D₁ or D₂ masonry and concrete chimneys shall be reinforced and anchored as detailed in Sections R1003.3.1, R1003.3.2 and R1003.4. In Seismic Design Category A, B or C, reinforcement and seismic anchorage are not required.

- ❖ Unreinforced fireplaces and chimneys subjected to strong ground motion have been severely damaged in past earthquakes. The requirements in this section provide minimum reinforcement in an effort to keep these structures together during such events. More substantial reinforcement, however, may be required in areas of high seismicity or for atypical chimneys.

R1003.3.1 Vertical reinforcing. For chimneys up to 40 inches (1016 mm) wide, four No. 4 continuous vertical bars, anchored in the foundation, shall be placed in the concrete, or between wythes of *solid masonry*, or within the cells of hollow unit masonry, and grouted in accordance with Section R609.1.1. Grout shall be prevented from bonding with the flue liner so that the flue liner is free to move with thermal expansion. For chimneys more than 40 inches (1016 mm) wide, two additional No. 4 vertical bars shall be installed for each additional 40 inches (1016 mm) in width or fraction thereof.

- ❖ These requirements are traditional minimum prescriptive provisions to help maintain the structural integrity of fireplaces and chimneys during earthquakes. More reinforcement may be required in areas of high seismicity or for atypical chimneys.

R1003.3.2 Horizontal reinforcing. Vertical reinforcement shall be placed enclosed within ¹/₄-inch (6.4 mm) ties, or other reinforcing of equivalent net cross-sectional area, spaced not to exceed 18 inches (457 mm) on center in concrete, or placed in the bed joints of unit masonry, at not less than every 18 inches (457 mm) of vertical height. Two such ties shall be installed at each bend in the vertical bars.

- ❖ These requirements are traditional minimum prescriptive provisions to help maintain the structural integrity of fireplaces and chimneys during earthquakes. The vertical reinforcement required by Section R1003.3.1 must be enclosed within the horizontal reinforcement required by this section. More reinforcement may be required in areas of high seismicity or for atypical chimneys.

R1003.4 Seismic anchorage. Masonry and concrete chimneys and foundations in Seismic Design Category D₀, D₁ or D₂ shall be anchored at each floor, ceiling or roof line more than 6 feet (1829 mm) above *grade*, except where constructed completely within the exterior walls. Anchorage shall conform to the requirements in Section R1003.4.1.

- ❖ Fireplaces and chimneys must be connected to floor and roof diaphragms to prevent overturning during earthquakes. Chimneys must be anchored at the ceiling line of roof and ceiling assemblies and at floor levels below the roof. Such anchorage is of lesser importance where the floor assembly is 6 feet (1829 mm) or less above *grade*.

CHIMNEYS AND FIREPLACES

R1003.4.1 Anchorage. Two $\frac{3}{16}$ -inch by 1-inch (5 mm by 25 mm) straps shall be embedded not less than 12 inches (305 mm) into the chimney. Straps shall be hooked around the outer bars and extend 6 inches (152 mm) beyond the bend. Each strap shall be fastened to not less than four floor joists with two $\frac{1}{2}$ -inch (12.7 mm) bolts.

❖ The prescriptive requirements in this section are traditional for typical fireplaces and chimneys. More substantial anchorage may be required in areas of high seismicity, for large fireplaces or where the distance between floor and roof diaphragms is large.

R1003.4.1.1 Cold-formed steel framing. Where cold-formed steel framing is used, the location where the $\frac{1}{2}$ -inch (12.7 mm) bolts are used to attach the straps to the framing shall be reinforced with not less than a 3-inch \times 3-inch \times 0.229-inch (76 mm \times 76 mm \times 5.8 mm) steel plate on top of a strap that is screwed to the framing with not fewer than seven No. 6 screws for each bolt.

❖ The provisions in Section R1003.4.1 for anchoring masonry chimneys to residential buildings were developed with the concept of anchoring to wood framing.

Cold-formed steel framing can function equivalently in this respect to wood framing, except that the bearing area between the bolt and the cold-formed steel framing is small and therefore needs to be reinforced to prevent the local failure of the steel. The 0.229-inch (essentially $\frac{1}{4}$ -inch) steel plate will provide this reinforcement and spread the load from the bolt to a wider area in the framing to prevent the localized failure of the framing. The minimum of seven No. 6 screws (a total shear capacity transfer of 1,050 pounds in 33-mil cold-formed steel) provide the transfer mechanism to spread the force in the bolt (a maximum of 933 pounds for a $\frac{1}{2}$ -inch A307 bolt in 2-inch nominal Douglas-fir lumber with $\frac{1}{4}$ -inch-thick-steel side member).

R1003.5 Corbeling. Masonry chimneys shall not be corbelled more than one-half of the chimney's wall thickness from a wall or foundation, nor shall a chimney be corbelled from a wall or foundation that is less than 12 inches (305 mm) thick unless it projects equally on each side of the wall, except that on the second *story* of a two-story *dwelling*, corbeling of chimneys on the exterior of the enclosing walls may equal the wall thickness. The projection of a single course shall not exceed

one-half the unit height or one-third of the unit bed depth, whichever is less.

- ❖ Corbeling is the projection of masonry from the surface of the wall or fireplace in small increments for each course of masonry. The chimney should not be corbeled more than one-half of its wall thickness from the wall or foundation. A single course is not permitted to project more than one-half of the individual unit height or more than one-third of the individual unit depth. Exceeding these amounts could cause the unit to fail because it might not be able to carry the intended load [see Commentary Figure R1003.5(1)].

Additionally, masonry walls are not to be corbeled more than one-half of the chimney's wall thickness from the wall or foundation unless it projects equally on each side of the wall. If the corbeling is not equal on each side, the chimney might overturn or crack [see Commentary Figure R1003.5(2)].

R1003.6 Changes in dimension. The chimney wall or chimney flue lining shall not change in size or shape within 6 inches (152 mm) above or below where the chimney passes through floor components, ceiling components or roof components.

- ❖ Changes in the size or shape of a chimney change the stiffness of the chimney, and these areas have more potential for leaks or cracks in the chimney. The code prohibits these changes within 6 inches (152 mm) of where the chimney passes through the floor, ceiling or roof components.

R1003.7 Offsets. Where a masonry chimney is constructed with a fireclay flue liner surrounded by one wythe of masonry, the maximum offset shall be such that the centerline of the flue above the offset does not extend beyond the center of the chimney wall below the offset. Where the chimney offset is supported by masonry below the offset in an *approved* manner, the maximum offset limitations shall not apply. Each individual corbeled masonry course of the offset shall not exceed the projection limitations specified in Section R1003.5.

❖ Limitations on chimney offsets provide a gradual transition to prevent critical stress concentrations at the bottom of the offset. The maximum offset of the centerline of the flue to the centerline of the wall of the chimney below maintains structural stability for vertical loads. The slope of the offset is limited to that permitted for corbels in Section R1003.5. The offset limitation does not apply in cases where the offset is supported by masonry below the offset and in a manner approved by the building official.

R1003.8 Additional load. Chimneys shall not support loads other than their own weight unless they are designed and constructed to support the additional load. Construction of masonry chimneys as part of the masonry walls or reinforced concrete walls of the building shall be permitted.

❖ Chimneys are subject to considerable stresses resulting from thermal effects and therefore should not support any structural load other than their own weight, unless specifically designed as a supporting member for the additional load. Also, because of its heavy mass, a chimney will tend to settle more than the building structures. As a consequence, the chimney and any part of the building that it supports will settle at a greater rate and to a greater degree than the rest of the building, resulting in damage. If a chimney is subject to structural loads for which it is not designed, the additional stresses created could lead to cracks in the chimney. Thus, the chimney would become a hazard because of the potential of flames from the firebox penetrating the cracks and igniting combustible construction. Moreover, buildups of the products of combustion that leak through the cracks create hazardous conditions inside the building.

R1003.9 Termination. Chimneys shall extend not less than 2 feet (610 mm) higher than any portion of a building within 10 feet (3048 mm), but shall be not less than 3 feet (914 mm) above the highest point where the chimney passes through the roof.

❖ The provisions for the termination height of chimneys above the roof provide for the necessary upward draft in the chimney. Experience has indicated that the required heights produce satisfactory operation of the chimney (see Commentary Figure R1003.2).

R1003.9.1 Chimney caps. Masonry chimneys shall have a concrete, metal or stone cap, a drip edge and a caulked bond break around any flue liners in accordance with ASTM

C1283. The concrete, metal or stone cap shall be sloped to shed water.

❖ The section requires masonry chimneys to have caps and references ASTM C1283, which covers the minimum requirements for installing a clay flue lining for residential concrete or masonry chimneys. A chimney cap protects the top of the masonry surrounding the flue. Although masonry chimneys typically have some type of weatherproof cap, this code section specifically requires a chimney cap and prescribes the minimum criteria for its construction. The cap must be sloped to the outside, overhang the face of the masonry chimney and provide a drip edge. The prescribed caulking of the joint between the masonry and the flue serves as both a sealant and a bond break for any differential movement. The requirements for chimney caps are consistent with the referenced standards ASTM C1283, *Standard Practice for Installing Clay Flue Lining*, and ASTM C 315, *Standard Specification for Clay Flue Liners and Chimney Pots*.

R1003.9.2 Spark arrestors. Where a spark arrestor is installed on a masonry chimney, the spark arrestor shall meet all of the following requirements:

1. The net free area of the arrestor shall be not less than four times the net free area of the outlet of the chimney flue it serves.
2. The arrestor screen shall have heat and corrosion resistance equivalent to 19-gage galvanized steel or 24-gage stainless steel.
3. Openings shall not permit the passage of spheres having a diameter greater than $\frac{1}{2}$ inch (12.7 mm) nor block the passage of spheres having a diameter less than $\frac{3}{8}$ inch (9.5 mm).
4. The spark arrestor shall be accessible for cleaning and the screen or chimney cap shall be removable to allow for cleaning of the chimney flue.

❖ This section contains specifications for spark arrestors, if they are provided. Their use is not mandated by the code, but owners and builders often install them.

R1003.9.3 Rain caps. Where a masonry or metal rain cap is installed on a masonry chimney, the net free area under the cap shall be not less than four times the net free area of the outlet of the chimney flue it serves.

❖ Rain caps are installed a prescribed distance above a chimney flue termination to limit the amount of rain entering the flue. Because an improperly designed chimney rain cap can reduce the draft of a chimney, this section requires the net free area under the rain cap to be at least four times the area of the outlet of the flue opening. Rain caps are also used to keep animals such as rodents and birds from nesting in the chimney or fireplace. As the language indicates, rain caps are not required by the code, but when they are installed

they must have the minimum clearance above the flue termination to provide the minimum net free area required by this section.

R1003.10 Wall thickness. Masonry chimney walls shall be constructed of *solid masonry* units or hollow masonry units grouted solid with not less than a 4-inch (102 mm) nominal thickness.

❖ Masonry chimney walls must have a minimum nominal thickness of 4 inches (102 mm) of either solid masonry units or hollow masonry grouted solid for structural stability.

R1003.10.1 Masonry veneer chimneys. Where masonry is used to veneer a frame chimney, through-flashing and weep holes shall be installed as required by Section R703.

❖ Masonry veneer is a nonstructural facing material that provides ornamentation, protection or insulation. To be considered a veneer, the material cannot act structurally with the backing insofar as the structural strength of the assembly is concerned.

R1003.11 Flue lining (material). Masonry chimneys shall be lined. The lining material shall be appropriate for the type of *appliance* connected, in accordance with the terms of the *appliance* listing and manufacturer's instructions.

❖ Masonry chimneys must be properly lined to allow for the smooth flow of products of combustion. This section regulates specific flue linings.

R1003.11.1 Residential-type appliances (general). Flue lining systems shall comply with one of the following:

1. Clay flue lining complying with the requirements of ASTM C315.
2. Listed and labeled chimney lining systems complying with UL 1777.
3. Factory-built chimneys or chimney units listed for installation within masonry chimneys.
4. Other *approved* materials that will resist corrosion, erosion, softening or cracking from flue gases and condensate at temperatures up to 1,800°F (982°C).

❖ Flue linings must comply with one of the standards listed in this section or be listed for installation within masonry chimneys. Other materials may be used, provided they will resist flue gases and condensate at temperatures up to 1,800°F (982°C) and will not crack, soften or corrode.

R1003.11.2 Flue linings for specific appliances. Flue linings other than these covered in Section R1003.11.1, intended for use with specific types of *appliances*, shall comply with Sections R1003.11.3 through R1003.11.6.

❖ Except as provided in Section R1003.11.1, flue linings for use with specific types of appliances must comply with Sections R1003.11.3 through R1003.11.6.

R1003.11.3 Gas appliances. Flue lining systems for gas *appliances* shall be in accordance with Chapter 24.

❖ Chapter 24 of the code covers flue linings for gas appliances.

R1003.11.4 Pellet fuel-burning appliances. Flue lining and vent systems for use in masonry chimneys with pellet fuel-burning *appliances* shall be limited to the following:

1. Flue lining systems complying with Section R1003.11.1.
2. Pellet vents listed for installation within masonry chimneys (see Section R1003.11.6 for marking).

❖ This section's provisions limit flue lining and vent systems.

R1003.11.5 Oil-fired appliances approved for use with Type L vent. Flue lining and vent systems for use in masonry chimneys with oil-fired *appliances approved* for use with Type L vent shall be limited to the following:

1. Flue lining systems complying with Section R1003.11.1.
2. Listed chimney liners complying with UL 641 (see Section R1003.11.6 for marking).

❖ Flue lining and vent systems for use in masonry chimneys with oil-fired appliances approved for use with a Type L vent are limited to either flue lining systems complying with Section R1003.11.1 or listed chimney liners complying with UL 641.

R1003.11.6 Notice of usage. When a flue is relined with a material not complying with Section R1003.11.1, the chimney shall be plainly and permanently identified by a *label* attached to a wall, ceiling or other conspicuous location adjacent to where the connector enters the chimney. The *label* shall include the following message or equivalent language:

THIS CHIMNEY FLUE IS FOR USE ONLY WITH [TYPE OR CATEGORY OF APPLIANCE] APPLIANCES THAT BURN [TYPE OF FUEL]. DO NOT CONNECT OTHER TYPES OF APPLIANCES.

❖ Flues relined with materials not conforming to Section R1003.11.1 must be permanently identified in a conspicuous location adjacent to the connector's entrance into the building. Thus, current and future occupants of the building will know the type of appliance that may be attached to the flue.

R1003.12 Clay flue lining (installation). Clay flue liners shall be installed in accordance with ASTM C1283 and extend from a point not less than 8 inches (203 mm) below the lowest inlet or, in the case of fireplaces, from the top of the smoke chamber to a point above the enclosing walls. The lining shall be carried up vertically, with a maximum slope not greater than 30 degrees (0.52 rad) from the vertical.

Clay flue liners shall be laid in medium-duty water insoluble refractory mortar conforming to ASTM C199 with tight mortar joints left smooth on the inside and installed to maintain an airspace or insulation not to exceed the thickness of the flue liner separating the flue liners from the interior face

CHIMNEYS AND FIREPLACES

of the chimney masonry walls. Flue liners shall be supported on all sides. Only enough mortar shall be placed to make the joint and hold the liners in position.

❖ Clay flue linings must be installed so there is no leakage through the liner to adjacent spaces, which would result in contaminated air. Flue linings must be installed in accordance with ASTM C1283, beginning at least 8 inches (203 mm) below the lowest inlet and extending to a point above the top of the chimney walls. Masonry chimneys atop masonry fireplaces should have the lining start at the top of the smoke chamber of the fireplace. If the chimney is corbeled, the lining may not slope more than 30 degrees (0.52 rad) from the vertical. A vent space is required around the lining and is not to be obstructed by the mortar used to set the liner. Only the amount of mortar needed to set the liners and hold them in place should be used. The mortar used must be water insoluble since it will be exposed to weather. This airspace will help limit the transfer of the heat buildup in the chimney to the masonry wall. This air space cannot be used for venting other appliances (see Commentary Figure R1003.12).

R1003.12.1 Listed materials. *Listed* materials used as flue linings shall be installed in accordance with the terms of their listings and manufacturer's instructions.

❖ Materials used as flue liners must be installed in accordance with the manufacturer's listing and instructions so the flue gases will be properly removed from the structure and not leak back in.

R1003.12.2 Space around lining. The space surrounding a chimney lining system or vent installed within a masonry chimney shall not be used to vent any other *appliance*.

Exception: This shall not prevent the installation of a separate flue lining in accordance with the manufacturer's instructions.

❖ The open space around a chimney lining system or vent that is installed within a masonry chimney is not to

be used to vent any other appliance. This unused space is not designed or constructed to vent flue gases.

R1003.13 Multiple flues. Where two or more flues are located in the same chimney, masonry wythes shall be built between adjacent flue linings. The masonry wythes shall be not less than 4 inches (102 mm) thick and bonded into the walls of the chimney.

Exception: Where venting only one *appliance*, two flues shall be permitted to adjoin each other in the same chimney with only the flue lining separation between them. The joints of the adjacent flue linings shall be staggered not less than 4 inches (102 mm).

❖ Each separate fireplace should have its own flue. Even outdoor barbecues connected to a chimney should have their own separate flue. Flues in the same chimney must be separated by a 4-inch (102 mm) masonry wythe bonded into the walls of the chimney. Failure to properly separate flues within a common chimney could result in transfer of smoke or other products of combustion from one flue to the other as a result of the downdraft created by interior suction of the inactive flue. The draft could also be created by external wind effects forcing the smoke down the inactive flues as it exhausts the active flue. Two flues in the same chimney venting only one appliance need not be separated from each other; however, the flue joints must be staggered at least 4 inches (102 mm) (see Commentary Figure R1003.12).

R1003.14 Flue area (appliance). Chimney flues shall not be smaller in area than that of the area of the connector from the *appliance* [see Tables R1003.14(1) and R1003.14(2)]. The sizing of a chimney flue to which multiple *appliance* venting systems are connected shall be in accordance with Section M1805.3.

❖ Tables R1003.14(1) and R1003.14(2) determine the sizes of chimney flues for appliances. In no case may

For SI: 1 inch = 25.4 mm.

Figure R1003.12
MULTIPLE FLUES

the flue of the chimney have a smaller area than the area of the connector from the appliance. If the appliance is connected to a flue smaller than the appliance's flue, a backdraft can occur, which will result in the appliance not operating properly and the products of combustion not being vented to the outside.

**TABLE R1003.14(1)
NET CROSS-SECTIONAL AREA OF ROUND FLUE SIZES^a**

FLUE SIZE, INSIDE DIAMETER (inches)	CROSS-SECTIONAL AREA (square inches)
6	28
7	38
8	50
10	78
10 ³ / ₄	90
12	113
15	176
18	254

For SI: 1 inch = 25.4 mm, 1 square inch = 645.16 mm².

a. Flue sizes are based on ASTM C315.

❖ Table R1003.14(1) lists the net cross-sectional area of round flues. The first column provides the interior flue diameter; the second column provides the cross-sectional area. For example, an 8-inch (203 mm) round flue requires a cross-sectional area of at least 50 square inches (32 258 mm²). Flue sizes are based on ASTM C315.

**TABLE R1003.14(2)
NET CROSS-SECTIONAL AREA OF SQUARE AND RECTANGULAR FLUE SIZES**

FLUE SIZE, OUTSIDE NOMINAL DIMENSIONS (inches)	CROSS-SECTIONAL AREA (square inches)
4.5 × 8.5	23
4.5 × 13	34
8 × 8	42
8.5 × 8.5	49
8 × 12	67
8.5 × 13	76
12 × 12	102
8.5 × 18	101
13 × 13	127
12 × 16	131
13 × 18	173
16 × 16	181
16 × 20	222
18 × 18	233
20 × 20	298
20 × 24	335
24 × 24	431

For SI: 1 inch = 25.4 mm, 1 square inch = 645.16 mm².

❖ Table R1003.14(2) lists the net cross-sectional area of rectangular flues. The first column provides the outside nominal dimensions of the flue. The second col-

umn provides the cross-sectional area for the flue. For example, a rectangular flue with an exterior nominal dimension of 12 inches by 16 inches (305 mm by 406 mm) requires a net cross-sectional area of at least 131 square inches (84 516 mm²).

R1003.15 Flue area (masonry fireplace). Flue sizing for chimneys serving fireplaces shall be in accordance with Section R1003.15.1 or R1003.15.2.

❖ There are two methods for determining the flue size for masonry fireplaces. Option 1 uses a fraction of the area of the fireplace opening. Option 2 allows the use of a chart in determining the flue size.

R1003.15.1 Option 1. Round chimney flues shall have a minimum net cross-sectional area of not less than ¹/₁₂ of the fireplace opening. Square chimney flues shall have a minimum net cross-sectional area of ¹/₁₀ of the fireplace opening. Rectangular chimney flues with an *aspect ratio* less than 2 to 1 shall have a minimum net cross-sectional area of ¹/₁₀ of the fireplace opening. Rectangular chimney flues with an *aspect ratio* of 2 to 1 or more shall have a minimum net cross-sectional area of ¹/₈ of the fireplace opening. Cross-sectional areas of clay flue linings are shown in Tables R1003.14(1) and R1003.14(2) or as provided by the manufacturer or as measured in the field.

❖ Option 1 indicates the use of different fractional amounts of the fireplace opening depending on the shape of the flue. Round chimney flues must have a net cross-sectional area of ¹/₁₂ of the fireplace opening, and square flues must have a net cross-sectional area of ¹/₁₂ of the fireplace opening. Rectangular flues need either ¹/₈ or ¹/₁₀ of the net cross-sectional area of the fireplace opening depending on the aspect ratio of the flue. These fractional amounts vary because the effective flue area (EFA) of a square, smooth flue is equal to that of a smooth, round flue where the diameter of the round flue is the same as one side of the square flue (see Commentary Figure R1003.15.1). The cross-hatched areas within the flue of the square or rectangular vent provide no draft.

R1003.15.2 Option 2. The minimum net cross-sectional area of the chimney flue shall be determined in accordance with Figure R1003.15.2. A flue size providing not less than the equivalent net cross-sectional area shall be used. Cross-sectional areas of clay flue linings are shown in Tables R1003.14(1) and R1003.14(2) or as provided by the manufacturer or as measured in the field. The height of the chimney shall be measured from the firebox floor to the top of the chimney flue.

❖ Option 2 entails using the chart in Figure R1003.15.2 to determine the required flue area. The flue must have the equivalent net cross-sectional area as determined by the chart. The cross-sectional area of clay flue linings is given in Tables R1003.14(1) and R1003.14(2) or as provided by the manufacturer. Alternatively, the cross-sectional area of the flue may be field measured.

R1003.16 Inlet. Inlets to masonry chimneys shall enter from the side. Inlets shall have a thimble of fireclay, rigid refractory material or metal that will prevent the connector from

Figure R1003.15.1
MULTIPLE FLUES

pulling out of the inlet or from extending beyond the wall of the liner.

- ❖ Chimney inlet thimbles must not project into the flue. Inlets must have a thimble of fire clay, rigid refractory material or other metal. Thimbles must be installed so they will not dislodge from the inlet opening (see Commentary Figure R1003.16).

R1003.17 Masonry chimney cleanout openings. Cleanout openings shall be provided within 6 inches (152 mm) of the base of each flue within every masonry chimney. The upper edge of the cleanout shall be located not less than 6 inches (152 mm) below the lowest chimney inlet opening. The height of the opening shall be not less than 6 inches (152 mm). The cleanout shall be provided with a noncombustible cover.

Exception: Chimney flues serving masonry fireplaces where cleaning is possible through the fireplace opening.

- ❖ The code requires that cleanout openings be provided within 6 inches (152 mm) of the base of the flue. Additionally, the upper edge of the cleanout opening must be at least 6 inches (152 mm) below the lowest chimney outlet. The cleanout openings should be at least 6 inches (152 mm) high and have a noncombustible cover. The interior of the chimney may become coated with carbonaceous deposits and acids, and as a result the brick in the mortar will be chemically attacked, causing a gradual deterioration. The deposits will fall to the bottom of the chimney, and a cleanout will be necessary to remove them. Additionally, chimney-cleaning operations, which should be done periodically, will result in the accumulation of deposits at the base of the chimney, necessitating a cleanout opening. In the case of a fireplace chimney, the fireplace opening itself provides the cleanout, and no further opening is required.

R1003.18 Chimney clearances. Any portion of a masonry chimney located in the interior of the building or within the exterior wall of the building shall have a minimum airspace

clearance to combustibles of 2 inches (51 mm). Chimneys located entirely outside the exterior walls of the building, including chimneys that pass through the soffit or cornice, shall have a minimum airspace clearance of 1 inch (25 mm). The airspace shall not be filled, except to provide fire blocking in accordance with Section R1003.19.

Exceptions:

1. Masonry chimneys equipped with a chimney lining system listed and *labeled* for use in chimneys in contact with combustibles in accordance with UL 1777 and installed in accordance with the manufacturer's instructions are permitted to have combustible material in contact with their exterior surfaces.
 2. Where masonry chimneys are constructed as part of masonry or concrete walls, combustible materials shall not be in contact with the masonry or concrete wall less than 12 inches (305 mm) from the inside surface of the nearest flue lining.
 3. Exposed combustible trim and the edges of sheathing materials, such as wood siding and flooring, shall be permitted to abut the masonry chimney side walls, in accordance with Figure R1003.18, provided such combustible trim or sheathing is not less than 8 inches (203 mm) from the inside surface of the nearest flue lining.
- ❖ Because of the passage of hot gases and products of combustion, the chimney becomes heated. The code requires that combustibles not be placed directly against the chimney to avoid potential heat transfer and eventual combustion of the combustibles. Masonry chimneys located on the interior of a structure or within an exterior wall require a 2-inch (51 mm) airspace clearance to combustibles. Masonry chimneys located entirely outside of the exterior walls are permitted to have a 1-inch (25 mm) clearance to combustibles (see Figure R1003.18). Three exceptions permit reduced clearances.

For SI: 1 foot = 304.8 mm, 1 square inch = 645.16 mm².

FIGURE R1003.15.2
FLUE SIZES FOR MASONRY CHIMNEYS

R1003.19 Chimney fireblocking. Spaces between chimneys and floors and ceilings through which chimneys pass shall be fireblocked with noncombustible material securely fastened in place. The fireblocking of spaces between chimneys and wood joists, beams or headers shall be self-supporting or be placed on strips of metal or metal lath laid across the spaces between combustible material and the chimney.

❖ As in concealed spaces in wood frame construction, spaces such as floors and ceilings that chimneys pass through must be fireblocked. Section R1003.18 prohibits chimneys from abutting combustible material. Therefore, the 1-inch (25 mm) to 2-inch (51 mm) airspace required to separate the chimney from combustible material must be fireblocked. The fireblocking must be of noncombustible material to a depth of 1

inch (25 mm) and be supported by noncombustible material such as metal lath.

R1003.20 Chimney crickets. Chimneys shall be provided with crickets where the dimension parallel to the ridgeline is greater than 30 inches (762 mm) and does not intersect the ridgeline. The intersection of the cricket and the chimney shall be flashed and counterflashed in the same manner as normal roof-chimney intersections. Crickets shall be constructed in compliance with Figure R1003.20 and Table R1003.20.

❖ Chimney crickets are required when the chimney width parallel to the ridgeline is more than 30 inches (762 mm), provided the chimney does not intersect the ridgeline. The cricket diverts the flow of water from the roof around the chimney. Flashing is required between

the cricket and the chimney, as it is in other roof-chimney intersections.

wide (1219 mm) on a 6:12 roof slope, would need to be 1 foot high (305 mm) (1/4 of 4 feet).

TABLE R1003.20
CRICKET DIMENSIONS

ROOF SLOPE	H
12 - 12	1/2 of W
8 - 12	1/3 of W
6 - 12	1/4 of W
4 - 12	1/6 of W
3 - 12	1/8 of W

❖ Table R1003.20 establishes the height of chimney crickets as depicted in Figure R1003.20. For example, a cricket installed at the face of a chimney that is 4 feet

SECTION R1004
FACTORY-BUILT FIREPLACES

R1004.1 General. Factory-built fireplaces shall be *listed* and *labeled* and shall be installed in accordance with the conditions of the *listing*. Factory-built fireplaces shall be tested in accordance with UL 127.

❖ The code requires that factory-built fireplaces be listed and labeled. In addition, factory-built fireplaces must be tested by an approved testing lab in accordance with UL 127 (see commentary, Section R1005).

For SI: 1 inch = 25.4 mm.

FIGURE R1003.20
CHIMNEY CRICKET

R1004.2 Hearth extensions. Hearth extensions of *approved* factory-built fireplaces shall be installed in accordance with the *listing* of the fireplace. The hearth extension shall be readily distinguishable from the surrounding floor area. Listed and labeled hearth extensions shall comply with UL 1618.

❖ The primary requirements here are that the hearth extension must be installed in accordance with the listing of the fireplace, and it must be easily distinguished from the surrounding floor areas. In lieu of a site-built hearth extension, a listed and labeled hearth extension complying with UL 1618 may be used. UL 1618 includes a comprehensive set of construction and performance requirements for the hearth extension.

R1004.3 Decorative shrouds. Decorative shrouds shall not be installed at the termination of chimneys for factory-built fireplaces except where the shrouds are listed and *labeled* for use with the specific factory-built fireplace system and installed in accordance with the manufacturer's instructions.

❖ These provisions are the same as found in Section R1005.2 (see commentary, Section R1005.2).

R1004.4 Unvented gas log heaters. An unvented gas log heater shall not be installed in a factory-built fireplace unless the fireplace system has been specifically tested, *listed* and *labeled* for such use in accordance with UL 127.

❖ Unvented gas log heaters must not be installed in factory-built fireplaces if the fireplace has not been specifically tested, listed, and labeled for such use. Without such testing, there is no way to know how the unvented gas log heater will function in the fireplace, and it may cause harm to both the appliance and the occupants of the building.

R1004.5 Gasketed fireplace doors. A gasketed fireplace door shall not be installed on a factory-built fireplace except where the fireplace system has been specifically tested, listed and labeled for such use in accordance with UL 127.

❖ The *International Energy Conservation Code*[®] (IECC[®]) has stated that fireplaces must be provided with doors

that prevent air from escaping up the fireplace chimney when the fireplace is not in use. The IECC recognizes that factory-built fireplaces must be listed for use with gasketed glass doors. A substantial energy loss is attributed to such air loss. The intent of the IECC was to prevent air loss by using sealed (gasketed) glass doors on the face of the fireplace. The IECC did not intend for glass doors to be installed where such installation violates the listing of a factory-built fireplace. It is not known what effect glass doors would have on masonry fireplaces, but it is highly suspected that factory-built fireplaces would be affected by the restriction of cooling and dilution airflow, thus producing abnormally high temperatures in and on the fireplace components. UL 127 tests factory-built fireplaces for this situation. Most factory-built fireplaces are not tested for use with tight-fitting (gasketed) doors, but some have been. Tight-fitting doors are considered to be a potential fire hazard if installed on fireplaces that have not been specifically tested and listed to UL127 and found to be safe for use with such doors. The intent to prevent the constant loss of conditioned air up a chimney can also be accomplished with tight-fitting dampers, which are likely to be far more effective than glass doors.

SECTION R1005 FACTORY-BUILT CHIMNEYS

R1005.1 Listing. Factory-built chimneys shall be *listed* and *labeled* and shall be installed and terminated in accordance with the manufacturer's instructions.

❖ Factory-built fireplaces can be used if they are listed and labeled and are installed following the manufacturer's installation instructions. "Listed" and "Labeled" are defined in Chapter 2.

R1005.2 Decorative shrouds. Decorative shrouds shall not be installed at the termination of factory-built chimneys

except where the shrouds are *listed* and *labeled* for use with the specific factory-built chimney system and installed in accordance with the manufacturer's instructions.

- ❖ In general, decorative shrouds are not permitted on top of factory-built chimneys. Installing a shroud on top of a chimney that is not designed for one may result in improper venting of the appliance attached to the chimney. Decorative shrouds are permitted if they are listed and labeled for use with the specific chimney and are installed in accordance with the manufacturers' installation instructions.

R1005.3 Solid-fuel appliances. Factory-built chimneys installed in *dwelling units* with solid-fuel-burning *appliances* shall comply with the Type HT requirements of UL 103 and shall be marked "Type HT and "Residential Type and Building Heating Appliance Chimney."

Exception: Chimneys for use with open combustion chamber fireplaces shall comply with the requirements of UL 103 and shall be marked "Residential Type and Building Heating Appliance Chimney."

Chimneys for use with open combustion chamber *appliances* installed in buildings other than *dwelling units* shall comply with the requirements of UL 103 and shall be marked "Building Heating Appliance Chimney" or "Residential Type and Building Heating Appliance Chimney."

- ❖ Factory-built chimneys must withstand the high temperatures associated with solid fuel burning. For that reason the chimney must be clearly marked as Type HT (High Temperature) with the language "Residential Type and Building Heating Appliance Chimney." Factory-built chimneys for use with solid-fuel-burning appliances must comply with Type HT requirements of UL 103. The exception allows these chimneys to be used with open combustion chamber fireplace stoves that comply with UL 103.

R1005.4 Factory-built fireplaces. Chimneys for use with factory-built fireplaces shall comply with the requirements of UL 127.

- ❖ Chimneys installed and used for factory-built fireplaces must comply with UL 127.

R1005.5 Support. Where factory-built chimneys are supported by structural members, such as joists and rafters, those members shall be designed to support the additional load.

- ❖ Joists and rafters supporting factory-built chimneys must be designed to carry the load of the chimney in addition to other loads that the members carry.

R1005.6 Medium-heat appliances. Factory-built chimneys for medium-heat *appliances* producing flue gases having a temperature above 1,000°F (538°C), measured at the entrance to the chimney, shall comply with UL 959.

- ❖ Factory-built chimneys for medium-heat appliances that produce flue gases with a temperature above 1,000°F (538°C) at the entry to the chimney must comply with UL 959.

Factory-built fireplaces are permitted when they are listed and labeled and are installed in accordance with

the manufacturer's instructions. The word "approved" is defined in Chapter 2. Both factory-built fireplaces and chimneys for solid-fuel-burning appliances must meet the applicable UL standard as listed in the code. Agencies such as UL provide listing services for factory-built fireplaces and chimneys. The listing includes a description of the manufactured unit and requirements for clearance from combustible materials, hearth details if necessary, and other limitations placed on the unit to result in a safe installation. Factory-built fireplaces are installed in conjunction with factory-built chimneys; thus, the complete installation of fireplace and chimney is factory built (see Commentary Figure R1005.6).

R1005.7 Factory-built chimney offsets. Where a factory-built chimney assembly incorporates offsets, no part of the chimney shall be at an angle of more than 30 degrees (0.52 rad) from vertical at any point in the assembly and the chimney assembly shall not include more than four elbows.

- ❖ Section R1005.3 requires factory-built chimneys for solid-fuel-burning appliances to be listed and labeled in accordance with UL 103, *Factory-Built Chimneys for Residential Type and Building Heating Appliances*, and installed in accordance with the manufacturer's instructions. Ideally, factory-built chimneys should be vertical for the entire length from the fireplace to the roof termination; however, offsets often are necessary to avoid structural components or to place the termination in the preferred location. Typically, the manufacturer's installation instructions include limitations on the maximum offset from vertical and the maximum number of elbows in the entire length of the chimney in accordance with UL 103. Section R1005.7 comes directly from UL 103 and intends to make this information readily available to the inspector, who may not have access to the standard or the manufacturer's installation instructions. This section also serves to emphasize that specific limitations apply to factory-built chimneys that are different from common venting systems such as Type B gas vents. To safely vent combustion products, factory-built chimneys must be installed so that no portion of the chimney exceeds an angle of 30 degrees from vertical. The code also limits the number of offsets by setting the maximum number of elbow fittings to four.

SECTION R1006 EXTERIOR AIR SUPPLY

R1006.1 Exterior air. Factory-built or masonry fireplaces covered in this chapter shall be equipped with an exterior air supply to ensure proper fuel combustion unless the room is mechanically ventilated and controlled so that the indoor pressure is neutral or positive.

- ❖ An adequate supply of combustion air must be provided for the fireplace. The code requires that both masonry and factory-built fireplaces have an exterior air supply. The air ducts used in either type of fireplace must be listed.

R1006.1.1 Factory-built fireplaces. Exterior *combustion air* ducts for factory-built fireplaces shall be a *listed* component of the fireplace and shall be installed in accordance with the fireplace manufacturer's instructions.

- ❖ An exterior combustion air supply for factory-built fireplaces must be listed components, and the ducts must be installed in accordance with the manufacturer's instructions.

R1006.1.2 Masonry fireplaces. *Listed combustion air* ducts for masonry fireplaces shall be installed in accordance with the terms of their *listing* and the manufacturer's instructions.

- ❖ If a masonry fireplace uses a listed combustion air duct, the air duct must be installed in accordance with its listing.

R1006.2 Exterior air intake. The exterior air intake shall be capable of supplying all *combustion air* from the exterior of the *dwelling* or from spaces within the *dwelling* ventilated with outdoor air such as nonmechanically ventilated crawl or *attic* spaces. The exterior air intake shall not be located within the garage or basement of the dwelling. The exterior air intake, for other than listed factory-built fireplaces, shall not be located at an elevation higher than the firebox. The exterior air intake shall be covered with a corrosion-resistant screen of $\frac{1}{4}$ -inch (6.4 mm) mesh.

- ❖ The exterior air supply must be capable of providing all of the necessary combustion air. This air must be taken from the exterior of the building or from spaces such as crawl or attic spaces that are adequately ventilated. The crawl or attic spaces cannot be mechanically ventilated. Attic and/or crawl space mechanical

ventilating systems are primarily used to remove air from those areas.

They do this by exhausting the unwanted air or creating a negative pressure in those areas. If an air intake for a fireplace terminates in a crawl or attic space that has a mechanical ventilation system there is a potential for the air intake to perform exactly opposite of its designed intent. The exterior air intake cannot be in the garage or basement of the dwelling unit. For other than listed factory-built fireplaces, the air intake must be lower than the firebox so that the firebox will properly draw in the combustion air. Where combustion air openings are located inside the firebox, the air intake opening on the outside of the dwelling cannot be located higher than the firebox. Such an installation could create a chimney effect, drawing the products of combustion up through the combustion air ducts. These ducts are not generally constructed of materials that can withstand the heat and sparks that could be drawn through them. Interior combustion air openings located outside the firebox are not subject to this requirement. The exterior air intake must be covered with a corrosion-resistant screen of $\frac{1}{4}$ -inch (6.4 mm) mesh.

R1006.3 Clearance. Unlisted *combustion air* ducts shall be installed with a minimum 1-inch (25 mm) clearance to combustibles for all parts of the duct within 5 feet (1524 mm) of the duct outlet.

- ❖ Where masonry fireplaces use unlisted combustion air ducts, the ducts must be installed with a minimum clearance of 1 inch (25 mm) to combustibles for all

CHIMNEYS AND FIREPLACES

parts of the ducts within 5 feet (1524 mm) of the outlets.

R1006.4 Passageway. The *combustion air* passageway shall be not less than 6 square inches (3870 mm²) and not more than 55 square inches (0.035 m²), except that *combustion air* systems for listed fireplaces shall be constructed in accordance with the fireplace manufacturer's instructions.

❖ The combustion air passageway must be a minimum of 6 square inches (3870 mm²) and no more than 55 square inches (0.035 m²). Combustion air systems for listed fireplaces must have combustion air passageways in a size that is established by the manufacturer, which may be different from the dimensions indicated in this section. Air passageways supply combustion air to the firebox without relying on the air within the structure. Without this combustion air, the oxygen in the structure could be depleted to a level unacceptable for the occupants of the building.

R1006.5 Outlet. The exterior air outlet shall be located in the back or side of the firebox chamber or shall be located outside of the firebox, at the level of the hearth and not greater than 24 inches (610 mm) from the firebox opening. The outlet shall be closable and designed to prevent burning material from dropping into concealed combustible spaces.

❖ The combustion air opening may be located in the back or sides of the firebox chamber, or it may be located within 24 inches (610 mm) of the firebox opening on or near the floor. If the opening is on or near the floor, the outlet must be closeable and designed to prevent burning material from dropping into concealed combustible spaces. A noncombustible screen could be used for this purpose, if the mesh is fine enough to prevent burning embers from penetrating the screen.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

ASTM C27–98 (2008), *Specification for Standard Classification of Fireclay and High-Alumina Refractory Brick*. West Conshohocken, PA: ASTM International, 2008.

ASTM C199–84 (2011), *Test Method for Pier Test for Refractory Mortar*. West Conshohocken, PA: ASTM International, 2011.

ASTM C315–07 (2011), *Specification for Clay Flue Linings and Chimney Pots*. West Conshohocken, PA: ASTM International, 2011.

Part IV—Energy Conservation

Chapter 11 [RE]: Energy Efficiency

General Comments

Chapter 11 contains the energy efficiency-related requirements for the design and construction of buildings regulated under the code. The applicable portions of the building must comply with the provisions within this chapter for energy efficiency.

Section N1101 contains the scope and application of the chapter and also regulates material identification and labeling. Section N1102 contains the insulation *R*-value requirements and window *U*-factor requirements for the building envelope, which includes the roof/ceiling, wall and floor assembly. Section N1103 contains the requirements for heating and cooling systems, and includes requirements for equipment efficiency, duct installation, piping insulation and the requirements for

service water heating performance. Section N1104 deals with lighting equipment.

Purpose

This chapter defines requirements for the portions of the building and building systems that impact energy use in new construction and promote the effective use of energy. The provisions in the chapter promote energy efficiency in the building envelope, the heating and cooling system, and the service water heating system of the building. Compliance with this chapter will provide a minimum level of energy efficiency for new construction. Greater levels of efficiency can be installed to decrease the energy use of new construction.

SECTION N1101 GENERAL

N1101.1 Scope. This chapter regulates the energy efficiency for the design and construction of buildings regulated by this code.

Note: The text of the following Sections N1101.2 through N1105 is extracted from the 2015 edition of the International Energy Conservation Code—Residential Provisions and has been editorially revised to conform to the scope and application of this code. The section numbers appearing in parenthesis after each section number are the section numbers of the corresponding text in the International Energy Conservation Code—Residential Provisions.

❖ Chapter 11 applies to portions of the building thermal envelope that enclose conditioned space, as shown in Commentary Figure N1101.1(1). Conditioned space is the area provided with heating or cooling either directly, through a positive heating/cooling supply system (such as registers located in the space), or indirectly through an opening that allows heated or cooled air to communicate directly with the space. For example, a walk-in closet connected to a master bedroom suite may not contain a positive heating supply through a register, but it would be conditioned indirectly by the free passage of heated or cooled air into the space from the bedroom.

A good example of the exception would be an unconditioned garage or attic space. In the case of a garage, if the unconditioned garage area is separated from the conditioned portions of the residence by an assembly that meets the “building envelope” criteria (meaning that the wall between them is insulated), the exterior walls of the garage would not need to be insulated to separate the garage from the exterior climate.

The building thermal envelope consists of the wall, roof/ceiling and floor assemblies that surround the conditioned space. Raised floors over a crawl space or garage, or directly exposed to the outside air are considered to be part of the floor assembly. Walls surrounding a conditioned basement (in addition to surrounding conditioned spaces above grade) are part of the building envelope. The code defines above-grade walls surrounding conditioned spaces as exterior walls. This definition includes walls between the conditioned space and unconditioned garage; roof and basement knee, dormer, gable-end walls; and walls enclosing a mansard roof and basement walls with an average below-grade area that is less than 50 percent of the total basement gross wall area. This definition would not include walls separating an unconditioned garage from the outdoors. The roof/ceiling assembly is the surface where insulation will be installed, typically on top of the gypsum board [see Commentary Figure N1101.1(2)].

For SI: °C = [(°F) - 32]/1.8.

Figure N1101.1(1)
CONDITIONED ENVELOPE

Figure N1101.1(2)
BUILDING ENVELOPE

N1101.2 (R101.3) Intent. This chapter shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each *building*. This chapter is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This chapter is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances.

❖ This chapter is broad in its application, yet specific to regulating the use of energy in buildings where that energy is used primarily for human comfort or heating and cooling to protect the contents. In general, the

requirements of the code address the design of all building systems that affect the visual and thermal comfort of the occupants, including:

- Lighting systems and controls.
- Wall, roof and floor insulation.
- Windows and skylights.
- Cooling equipment (air conditioners, chillers and cooling towers).
- Heating equipment (boilers, furnaces and heat pumps).
- Pumps, piping and liquid circulation systems.

- Supply and return fans.
- Service hot water systems (kitchens and lavatories).

The intent of the chapter is to define requirements for the portions of a building and building systems that affect energy use in new construction and to promote the effective use of energy. Where a code application for a specific situation is in question, the authority having jurisdiction for the building should favor the action that will promote the effective use of energy. The code official may also consider the cost of the required action compared to the energy that will be saved over the life of that action.

This section of the code supports flexibility in application of the code requirements. Although many of the requirements are given in a prescriptive format for ease of use, it is not the intent of the code to stifle innovation—especially innovative techniques that conserve energy. Innovative approaches that lead to energy efficiency should be encouraged, even if the approach is not specifically listed in the code or does not meet the strict letter of the code. This principle should be applied to methods for determining compliance with the code and the building construction techniques used to meet the code.

Any design should first be evaluated to see whether it meets the code requirements directly. If an innovative approach is preferred, the applicant is responsible for demonstrating that the innovative concept promotes energy efficiency. Where the literal code requirements have not been satisfied but the applicant claims to meet the intent, the code official will likely have to exercise professional judgment to determine whether the proposed design meets the intent of the code in the interest of energy efficiency (see commentary, Section R103).

N1101.3 (R101.5.1) Compliance materials. The *building official* shall be permitted to approve specific computer software, worksheets, compliance manuals and other similar materials that meet the intent of this code.

- ❖ The code intends to permit the use of innovative approaches and techniques, provided that they result in the effective use of energy. This section simply recognizes that there are many federal, state and local programs as well as computer software that deal with energy efficiency. Therefore, the code simply states that the code official does have the authority to accept those methods of compliance, provided that they meet the intent of the code. Some of the easiest examples to illustrate this provision are the REScheck™ and COMcheck™ software that are put out by the U.S. Department of Energy (DOE). An example of another program that may be deemed acceptable by the code official is the ENERGY STAR program.

N1101.4 (R102.1.1) Above code programs. The *building official* or other authority having jurisdiction shall be permit-

ted to deem a national, state or local energy-efficiency program to exceed the energy efficiency required by this code. Buildings *approved* in writing by such an energy-efficiency program shall be considered in compliance with this code. The requirements identified as “mandatory” in this chapter, as applicable, shall be met.

- ❖ The purpose of this section is to specifically state that the code official does have the authority to review and accept compliance with another energy program that may exceed that required by the code, as long as the minimum “mandatory” requirements of this code are met. This provision is really a continuation of the provision stated in Section N1101.2 and the fact that the code does intend to accept alternatives as long as the end result is an energy-efficient building that is comparable to or better than that required by the code.

This is also a good section to help reinforce the fact that this code as a model code is a “minimum” code. Therefore, it establishes the minimum requirement that must be met and that anything that exceeds the level is permitted.

While “above code programs” are acceptable because they do exceed the “minimum” requirements of the code, it would not be proper to require compliance with such “above code programs.” Besides the code being the minimum level of acceptable energy efficiency, it is also the maximum efficiency that the code official can require. A building built to the absolute minimum requirement is also the maximum that the code official can demand. It is perfectly acceptable for a designer or builder to exceed the code requirements, but it is not proper for the code official to demand such higher performance.

This section also contains language to ensure that the “mandatory” requirements of the code, such as sealing the building envelope (Section N1102.4) and sealing ducts (Section N1103.3.2), are complied with for all buildings. Since the code has deemed that the mandatory requirements should apply to all buildings, it is reasonable that “above code programs” not be allowed to bypass these requirements.

N1101.5 (R103.2) Information on construction documents. Construction documents shall be drawn to scale upon suitable material. Electronic media documents are permitted to be submitted when *approved* by the *building official*. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed, and show in sufficient detail pertinent data and features of the building, systems and equipment as herein governed. Details shall include, but are not limited to, as applicable:

1. Insulation materials and their *R*-values.
2. Fenestration *U*-factors and SHGCs.
3. Area-weighted *U*-factor and SHGC calculations.
4. Mechanical system design criteria.

5. Mechanical and service water heating system and equipment types, sizes and efficiencies.
 6. Equipment and system controls.
 7. Duct sealing, duct and pipe insulation and location.
 8. Air sealing details.
- ❖ For a comprehensive plan review, all code requirements should be incorporated in the design and construction documents. All of the project information, including specifications, project scope, calculations, and detailed drawings, should be submitted to the code official so that code compliance can be verified. All parties should clearly understand what the project entails. A good plan review is essential to ensure code compliance and a successful project. A statement on the construction documents, such as, “All insulation levels shall comply with the 2012 edition of the *International Energy Conservation Code*® (IECC®)” is not an acceptable substitute for showing the required information. Note also that the code official is authorized to require additional project and code-related information as necessary.

For example, insulation R -values and glazing and door U -factors must be clearly marked on the building plans, specifications or forms used to show compliance. Where two or more different insulation levels exist for the same component (two insulation levels are used in ceilings), the permit applicant must record each level separately on the plans or specifications and clarify where in the building each level of insulation will be installed.

The following discussion is presented for the benefit of both the applicant and the plans examiner. This is not an all-inclusive list, but rather is intended to reflect the minimum scope of information needed to determine energy code compliance:

Permit Applicant’s Responsibilities. At permit application, the goal of the applicant is to provide all necessary information to show compliance with the code. If the plans examiner is able to verify compliance in a single review, the permit can be issued and construction may be started without delay.

Depending on whether the prescriptive or performance methods of compliance are used, the amount and detail of the required information may vary. For example, if using the prescriptive method of compliance, the U -factor and SHGC may be the only information that is needed to verify fenestration compliance. If the “total UA alternative” (Section N1102.1.4) or the performance option (Section N1105) is used, then additional information, such as the fenestration sizes and orientation, may be needed to demonstrate compliance. The envelope information that needs to be on the plans can be presented in a number of ways:

- *On the drawings.* Include elevations that indicate window, door and skylight areas and sections that show insulation position and thickness.

- *On sections and in schedules.* For instance, list R -values of insulation on sections and include U -factors, shading coefficient, visible light transmittance and air infiltration on fenestration and opaque door schedules.
- *Through notes and callouts.* Note that all exterior joints are to be caulked, gasketed, weather-stripped or otherwise sealed.
- *Through supplementary worksheets or calculations.* Provide area-weighted calculations where required, such as for projection factors and heat capacity. The permit applicant may include these calculations on the drawings, incorporate as additional columns in the schedule or submit completed code compliance worksheets provided by the jurisdiction.

Incorrect information may be caused by a lack of understanding of the code. More likely, it indicates that the code has changed since the last project. The applicant can use a correction list as a reminder to update the office specifications to avoid receiving this same correction again in the future.

Plans Examiner’s Responsibilities. The plans examiner must review each permit application for code compliance before a permit is issued. By letting the designer and contractor know what is expected of them early in the process, the building department can increase the likelihood that the approved drawings will comply with the code. This helps the inspector avoid the headache of correcting a contractor who is following drawings that do not meet the code requirements.

The biggest challenge for the plans examiner is often determining where the necessary information is and whether the drawings are complete. The plans examiner should make sure the applicant includes a summary or checklist as part of the submittal package. When building envelope information is provided on the construction documents, it makes the job of the plans examiner easier, generally making for a more thorough review and reducing turnaround time.

A complete building envelope plan review covers all the requirements specific to the architectural building shell, but the electrical drawings may also need to be included and reviewed if the applicant seeks credit for automatic daylighting control for skylights or fenestration.

- Check that duct insulation thickness and conductivity (k -value) are on the drawings and comply with the code.
- Check that the duct insulation R -value is on the drawings and complies with the code.
- Check that there is a note indicating that ducts are to be constructed and sealed in accordance with the *International Mechanical Code*® (IMC®).
- Check that there is a note indicating that operating and equipment maintenance manuals will be supplied to the owner, that air and hydronic sys-

tems will be balanced and that the control system will be tested and calibrated.

N1101.5.1 (R103.2.1) Thermal envelope depiction. The building's thermal envelope shall be represented on the construction drawings.

- ❖ The single most important energy and performance aspect of the home is the buildings thermal envelope and the alignment of the air barrier and thermal barrier systems. It is crucial that the design professional demonstrate an understanding of location of the thermal envelope and that they make an effort to draw its location so that the construction personnel can successfully implement the construction of the building in accordance with the code and the specifications that have been drawn. The air sealing details help make this possible but understanding where the details will be implemented helps ensure better implementation and enforcement.

N1101.6 (R202) Defined terms. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

- ❖ For the purposes of this code, certain abbreviations, terms, phrases, words and their derivatives have the meanings given in Chapter 2 or in this section. The code, with its broad scope of applicability, includes terms used in a variety of construction and energy-related disciplines. These terms can often have multiple meanings, depending on their context or discipline. Therefore, Chapter 2 and this section establish specific meanings for these terms.

ABOVE-GRADE WALL. A wall more than 50 percent above grade and enclosing *conditioned space*. This includes between-floor spandrels, peripheral edges of floors, roof and basement knee walls, dormer walls, gable end walls, walls enclosing a mansard roof and skylight shafts.

- ❖ This definition provides the details of which walls must be treated as above-grade walls. This will help to make the distinction between these walls and basement walls (see definition and commentary, "Basement wall"). These two wall types face a different amount of energy transfer and, therefore, have different insulation requirements. In order to determine the proper insulation requirements for the various walls, both of the definitions should be reviewed. The definition includes any wall that is a part of the building thermal envelope ("enclosing conditioned space") and meets the area requirements. For example, the wall between a dwelling and an unconditioned garage would be included within this definition (see commentary, "Building thermal envelope").

ACCESSIBLE. Admitting close approach as a result of not being guarded by locked doors, elevation or other effective means (see "Readily accessible").

- ❖ Providing access to mechanical equipment and appliances is necessary to facilitate inspection, observation, maintenance, adjustment, repair or replacement. Access to equipment means the equipment can be

physically reached without having to remove a permanent portion of the structure. It is acceptable, for example, to install equipment in an interstitial space that would require removal of lay-in suspended ceiling panels to gain access. Equipment would not be considered accessible if it were necessary to remove or open any portion of a structure other than panels, doors, covers or similar obstructions intended to be removed or opened (see the definition of "Readily accessible"). Access can be described as the capability of being reached or approached for the purpose of inspection, observation, maintenance, adjustment, repair or replacement. Achieving access may first require the removal or opening of a panel, door or similar obstruction, and may require the overcoming of an obstacle such as elevation.

ADDITION. An extension or increase in the *conditioned space* floor area or height of a building or structure.

- ❖ The code uses this term to reflect new construction that is being added to an existing building. This definition is important when determining the applicability of the code provisions (see Section R101.4.3 of the IECC).

AIR BARRIER. Material(s) assembled and joined together to provide a barrier to air leakage through the building envelope. An air barrier may be a single material or a combination of materials.

- ❖ Building tightness against air infiltration is an important aspect of energy conservation. The term "air barrier" is defined to support the provisions of Section N1102.4 regarding air leakage and building tightness. Note that an air barrier is not a single membrane, but rather the system of sealants, seals, insulation and wall sheathing that prevent air infiltration. Although the evaluation and report are prepared by International Code Council® (ICC®), the code official is not obligated to accept or approve the product based on the evaluation report. The term "approved" is always tied to the code official's approval of the product or project. ICC's publishing of an evaluation report does not take away the fact that the approval of the code official is still needed for the material or method described in the report.

ALTERATION. Any construction, retrofit or renovation to an existing structure other than repair or addition that requires a permit. Also, a change in a building, electrical, gas, mechanical or plumbing system that involves an extension, addition or change to the arrangement, type or purpose of the original installation that requires a permit.

- ❖ This definition actually includes two separate definitions: one that applies to building construction and the other to mechanical systems. An alteration is any modification or change made to an existing installation. For example, changing refrigerant types or heat transfer fluids in a system would be considered alterations. This definition specifically excludes additions or repairs and also ties the term to situations where a permit is required. See Chapter 1 of the *International Building Code*® (IBC®) and IMC for the information regarding when a permit is required.

AUTOMATIC. Self-acting, operating by its own mechanism when actuated by some impersonal influence, as, for example, a change in current strength, pressure, temperature or mechanical configuration (see “Manual”).

❖ Operation or control devices or systems operating automatically, as opposed to manually, are designed to operate safely with only periodic human intervention or supervision. A thermostat would be an example of something that is automatic. While a person would set the thermostat to the desired temperature, the thermostat would cycle the heating or cooling system on or off on its own once the temperature hits the established set points.

BASEMENT WALL. A wall 50 percent or more below grade and enclosing *conditioned space*.

❖ Because basement walls are in contact with the ground and ground temperatures differ from air temperatures, the amount of energy transferred through a basement wall is different than the energy transfer through a wall predominantly above grade. Therefore, the code provides different thermal requirements for basement walls and above-grade walls. An individual wall enclosing conditioned space is classified as a “basement wall” where the gross wall area is 50 percent or more below grade and is bounded by soil; otherwise, the wall is classified as an “above-grade wall.” This definition includes a below-grade interior wall separating a basement from a crawl space that meets the percentage requirement. This basement wall classification applies to the whole wall area, even if a portion of the individual wall is not below grade. Therefore, the above-grade portion of the wall is considered as part of the basement wall where the total wall is 50 percent or more below grade. Both sections of the wall (above grade and below grade) are then insulated as a “basement wall.” Likewise, where an exterior wall is less than 50-percent below grade, the whole wall area is classified as an above-grade wall, including the portion underground. For example, the wall of a walk-out basement that is entirely above grade is not considered a basement wall. The wall area of the walk-out wall must be considered as an above-grade wall and compared to the code requirements for above-grade walls. Thus, where the average below-grade depth of the side walls is 50 percent or greater, they are basement walls. If not, they are above-grade walls. The intent of this definition is to apply the provision to each wall enclosing the space. It is not intended to be applied to the aggregate of all of the walls of the basement. Therefore, this classification is done for each individual wall segment and not on an aggregate basis. The basement wall requirements apply only to the opaque basement wall area, excluding windows and doors. For purposes of meeting the code requirements, windows and doors in a basement wall are regulated as any other fenestration opening.

BUILDING. Any structure used or intended for supporting or sheltering any use or occupancy, including any mechanical systems, service water heating systems and electric power and lighting systems located on the building site and supporting the building.

❖ This definition indicates that where this term is used in the code, it means a structure that is intended to provide shelter or support for some activity or occupancy. Though not addressed in the code, it is important to note that the IBC does permit that a fire wall forms a demarcation in between two separate, structurally independent buildings. Therefore, the code provisions could be applied to each building separately or to the structure as a whole. This would be a designer’s decision to make.

BUILDING SITE. A contiguous area of land that is under the ownership or control of one entity.

❖ “Building site” is a key term used throughout this chapter. It is the area of land that is under the ownership of one entity.

BUILDING THERMAL ENVELOPE. The basement walls, exterior walls, floor, roof and any other building elements that enclose *conditioned space* or provide a boundary between *conditioned space* and exempt or unconditioned space.

❖ The “building thermal envelope” is a key term and resounding theme used throughout the code. It defines what portions of the building form a structurally bound conditioned space and are thereby covered by the insulation and infiltration (air leakage) requirements of the code. The building thermal envelope includes all building components separating conditioned spaces (see commentary, “Conditioned space”) from unconditioned spaces or outside ambient conditions and through which heat is transferred. For example, the walls and doors separating an unheated garage (unconditioned space) from a living area (conditioned space) are part of the building thermal envelope. The walls and doors separating an unheated garage from the outdoors are not part of the building thermal envelope. Walls, floors and other building components separating two conditioned spaces are not part of the building thermal envelope. For example, interior partition walls, the common or party walls separating dwelling units in multiple-family buildings and the wall between a new conditioned addition and the existing conditioned space are not considered part of the building thermal envelope. Unconditioned spaces (areas having no heating or cooling sources) are placed outside the building envelope. A space is conditioned if it is heated or cooled directly or where a space is indirectly supplied with heating or cooling through uninsulated walls, floors or uninsulated ducts or HVAC piping. Boundaries that define the building envelope include the following:

- Building assemblies separating a conditioned space from outdoor ambient weather conditions.

- Building assemblies separating a conditioned space from the ground under or around that space, such as the ground around the perimeter of a slab or the soil at the exterior of a conditioned basement wall. Note that the code does not specify requirements for insulating basement floors or underneath slab floors (except at the perimeter edges).
- Building assemblies separating a conditioned space from an unconditioned garage, unconditioned sunroom or similar unheated/cooled area.

The code specifies requirements for ceiling, wall, floor, basement wall, slab-edge and crawl space wall components of the building envelope. In some cases, it may be unclear how to classify a particular part of a building. For example, skylight shafts have properties of a wall assembly but are located in the ceiling assembly. Table 202(1) shows some examples or suggestions of how building envelope components are generally classified and can be used to help determine which code requirement applies to a given building envelope component. Because many of these items are not addressed specifically within the code, the code official should make the determination as to the appropriate classification and construction. When no distinction exists between roof and wall, such as in an A-frame structure, the code official should determine the appropriate classification. Historically, some codes have designated a wall as having a slope of 60 degrees or greater from the horizontal plane. In such situations, if the wall slope is less than 60 degrees, then classification as a “roof” is appropriate. Because the code is silent on this issue, other options such as stating that the roof could be considered to begin at a point 8 feet (2439 mm) above the floor surface of the uppermost story could be used. The reference to “exempted spaces” in the definition of “Building thermal envelope” refers to spaces identified as exempt from this scope of the code.

C-FACTOR (THERMAL CONDUCTANCE). The coefficient of heat transmission (surface to surface) through a building component or assembly, equal to the time rate of heat flow per unit area and the unit temperature difference between the warm side and cold side surfaces ($\text{Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}$) [$\text{W}/(\text{m}^2 \cdot \text{K})$].

- ❖ This definition is included to define a term needed in the provisions of the code for the *U*-factor alternative given in Section N1102.1.2. The term appears in Table N1102.1.2.

CIRCULATING HOT WATER SYSTEM. A specifically designed water distribution system where one or more pumps are operated in the service hot water piping to circulate heated water from the water-heating equipment to fixtures and back to the water-heating equipment.

- ❖ In order to ensure hot water is available immediately at a faucet, circulating hot water systems can be installed

to circulate hot water when the hot water supply system is not in use.

CLIMATE ZONE. A geographical region based on climatic criteria as specified in this code.

- ❖ See the commentary to Section N1101.7.

CONDITIONED FLOOR AREA. The horizontal projection of the floors associated with the *conditioned space*.

- ❖ The conditioned floor area is the total area of all floors in the conditioned space of the building.

CONDITIONED SPACE. An area, room or space that is enclosed within the building thermal envelope and that is directly heated or cooled or indirectly heated or cooled. Spaces are indirectly heated or cooled where they communicate through openings with conditioned spaces, where they are separated from conditioned spaces by uninsulated walls, floors or ceilings, or where they contain uninsulated ducts, piping or other sources of heating or cooling.

- ❖ A conditioned space is typically any space that does not communicate directly to the outside; that is, a space not directly ventilated to the outdoors and meets one of the following criteria:

1. The space has a heating or cooling supply register.
2. The space has heating or cooling equipment designed to heat or cool the space, or both, such as a radiant heater built into the ceiling, a baseboard heater or a wall-mounted gas heater.
3. The space contains uninsulated ducts or uninsulated hydronic heating surfaces.
4. The space is inside the building thermal envelope. For example:
 - A basement with insulated walls but without insulation on the basement ceiling;
 - A closet on a home’s exterior wall that is insulated on the exterior surface of the closet wall;
 - A space adjacent to and not physically separated from a conditioned space (such as a room adjacent to another room with a heating duct but without a door that can be closed between the rooms); or
 - A room completely surrounded by conditioned spaces.

The builder/designer has some flexibility in defining the bounds of the conditioned space as long as the building envelope requirements are met. Spaces that are not conditioned directly but have uninsulated surfaces separating them from conditioned spaces are included within the insulated envelope of the building. For example, an unventilated crawl space below an uninsulated floor is considered part of the conditioned space, even where no heat is directly supplied to the

crawl space area. Where the crawl space is included as a conditioned space, the builder must insulate the exterior crawl space walls instead of the floor above. The task of defining the building envelope is left to the permit applicant.

Examples of unconditioned spaces include garages and basements that are neither heated nor cooled if all duct surfaces running through these spaces are insulated; attached sunrooms that are neither heated nor cooled and have insulated/weatherstripped doors to separate the sun space from the conditioned space; attics and ventilated crawl spaces. Note that the boundary between the conditioned and unconditioned space is subject to the infiltration control requirements of the code (see commentary, Section N1102.4).

Historically, the code tied this definition to “conditioning for human comfort” or by specifying that the conditioning fall within a specific range. Starting with the 2006 edition, the code considers any type of conditioning as creating a “conditioned space.” Therefore, providing heating within a storage building to keep the stock from freezing would still be considered as creating a conditioned space (see Section R101.5.2, Item 2 of the IECC).

CONTINUOUS AIR BARRIER. A combination of materials and assemblies that restrict or prevent the passage of air through the building thermal envelope.

- ❖ This term is used throughout the code and the language was modified to clarify the options for meeting the continuous air-barrier requirements.

CONTINUOUS INSULATION (ci). Insulating material that is continuous across all structural members without thermal bridges other than fasteners and service openings. It is installed on the interior or exterior, or is integral to any opaque surface, of the building envelope.

- ❖ The need for more insulation on exterior walls has created the need to specify continuous insulation on the exterior side of the wall.

CRAWL SPACE WALL. The opaque portion of a wall that encloses a crawl space and is partially or totally below grade.

- ❖ Because exterior crawl space walls may be in contact with the ground, crawl spaces exhibit different heat transfer properties than those of exterior above-grade walls or even basement walls. Thus, the code includes different thermal requirements for exterior crawl space walls.

This definition and distinction is also to help coordinate with Section N1102.2.8. While a basement is defined as a “conditioned space,” crawl spaces may be designed to be either conditioned or unconditioned spaces.

CURTAIN WALL. Fenestration products used to create an external nonload-bearing wall that is designed to separate the exterior and interior environments.

- ❖ This is essential in the code to add a water distribution system that is insulated to retain the heated water upon demand for hot water and conserve energy usage.

DEMAND RECIRCULATION WATER SYSTEM. A water distribution system where pump(s) prime the service hot water piping with heated water upon demand for hot water.

- ❖ This is essential in the code to add a water distribution system that is insulated to retain the heated water on demand for hot water and conserve energy usage.

DUCT. A tube or conduit utilized for conveying air. The air passages of self-contained systems are not to be construed as air ducts.

- ❖ Ducts can be factory manufactured or field constructed of sheet metal, gypsum board, fibrous glass board or other approved materials. Ducts are used in air distribution systems, exhaust systems, smoke control systems and combustion air-supply systems. Air passageways that are integral parts of an air handler, packaged air-conditioning unit or similar piece of self-contained, factory-built equipment are not considered ducts in the context of the code.

DUCT SYSTEM. A continuous passageway for the transmission of air that, in addition to ducts, includes duct fittings, dampers, plenums, fans and accessory air-handling equipment and appliances.

- ❖ Duct systems are part of an air distribution system and include supply, return, transfer and relief/exhaust air systems.

ENERGY ANALYSIS. A method for estimating the annual energy use of the *proposed design* and *standard reference design* based on estimates of energy use.

- ❖ Designs founded on total building performance (see Section N1105) use energy analysis when the design professional requires more flexibility for a sophisticated or innovative design. Using the total-building-performance design methodology, the proposed design is evaluated based on the cost of various types of energy used rather than the units of energy used (Btu, kWh). That cost must be established using an hour-by-hour, full-year (8760 hours) simulation tool capable of simulating the performance of both the proposed and standard designs (see commentary, “Energy simulation tool”). The simulation must be capable of converting calculated energy demand and consumption into utility costs using the actual utility rate schedules rather than the average cost of electricity or gas.

ENERGY COST. The total estimated annual cost for purchased energy for the building functions regulated by this code, including applicable demand charges.

- ❖ The total annual cost for purchased energy includes demand, power and fuel adjustment charges and the impact of special rate programs for large-volume customers. A thorough evaluation of existing tariffs and fee schedules may uncover substantial savings opportunities. In some states, for example, manufacturing customers are exempt from sales taxes for energy. In other states, utilities may have multiple tariff options.

ENERGY SIMULATION TOOL. An *approved* software program or calculation-based methodology that projects the annual energy use of a building.

❖ An energy simulation tool is typically a software package incorporating, among other features, an hour-by-hour, full-year (8760 hours), multiple-zone program to simulate the performance of both proposed and standard design buildings. It is possible to use other types of simulation tools that approximate the dynamics of the hourly energy programs, which can be shown to produce equivalent results for the type of building and HVAC systems under consideration. However, the simulation must be capable of converting calculated energy demand and consumption into utility costs using the actual utility rate schedules (rather than average cost of electricity or gas). Some examples of when an hour-by-hour, full-year type of program is required are:

- When the features intended to reduce energy consumption require time-of-day interactions between weather, loads and operating criteria. Examples include: night ventilation or building thermal storage; chilled water or ice storage; heat recovery; daylighting and water economizer cooling.
- When utility rates are time-of-day sensitive and the proposed design uses time-of-day load shifting between different types of mechanical plant components.

Another distinguishing feature among simulation tools is their sophistication in modeling HVAC systems and plant equipment. Basically, three levels of complexity are used: constant efficiency models; models with simple part-load efficiency adjustment and models with complex part-load efficiency adjustment. Simulation tools in the first category simply calculate hourly equipment input power requirements at part load by applying the full-load efficiency at any given hour. These programs should be avoided for all but constant load applications. Simulated tools with simple part-load efficiency adjustments use a profile of percent-rated input power versus percent-rated load. At each hour, these programs calculate input power to each piece of equipment. These tools are far more accurate than the constant-efficiency models, but still lack accurate compensation for environmental variables.

Building energy simulation tools, available for analyzing daylighting, passive solar design and solar systems, are described in more detail at www.eere.energy.gov/buildings/tools_directory/. This is a portion of the U.S. DOE's Energy Efficiency and Renewable Energy website.

The information includes program uses, computer hardware required, price and contact information. The most sophisticated simulation tools incorporate a number of profiles for each and every piece of equipment. For variable flow fans, this might be as simple as a single profile of percent-rated input power versus

percent-rated airflow. For more complex equipment, such as a cooling tower, the program considers such variables as the wet-bulb temperature, the approach (difference between the condenser water supply temperature and the wet-bulb temperature) and the range (difference between the condenser water entering and leaving temperatures). Each of these variables is used to adjust both the hourly capacity of the tower and the hourly operation (one fan, two fans or no fans). For all but the simplest systems, programs of this category must be used to obtain accurate results. Questions regarding a particular tool's ability to model the building on an hour-by-hour, full-year basis should be addressed to the proprietor or distributor.

ERI REFERENCE DESIGN. A version of the rated design that meets the minimum requirements of the 2006 *International Energy Conservation Code*.

❖ The Energy Rating Index (ERI) compliance alternative utilizes the ERI Reference Design (see Section N1106).

EXTERIOR WALL. Walls including both above-grade walls and basement walls.

❖ Wall insulation requirements defined within the code include almost all opaque exterior construction-bounding conditioned space. Depending on the compliance method, the wall type, glazing percentage and whether the wall is on the exterior or just separating conditioned from unconditioned space can affect the wall insulation requirement. Note also that doors (both glazed and opaque) are considered fenestration (see commentary, "Fenestration").

In earlier editions, the code included the limitation that an exterior wall is vertical or sloped at an angle of 60 degrees (1.1 rad) or greater from the horizontal. This limitation may still be helpful to consider if dealing with unusual situations such as an A-frame building. Where a determination is needed to decide whether the roof or wall provisions are appropriate, this limitation could be helpful.

FENESTRATION. Products classified as either *vertical fenestration* or *skylights*.

❖ The term "fenestration" refers both to opaque and glazed doors and the light-transmitting areas of a wall or roof, but primarily windows and skylights. The code sets performance requirements for fenestration by establishing separate requirements that differ from the wall and roof requirements based on the type of fenestration and, in the case of the prescriptive commercial requirements, by limiting the fenestration area. In some of the compliance options, the fenestration type and area allowed depends on the shading coefficient, the size of overhangs, the thermal performance (*U*-factor) and whether daylighting controls are installed.

Site-built windows, doors, and skylights are exempt from the air leakage testing requirements given in Section N1102.4.3. This definition provides information on what exactly site-built means, to define the scope of the exception given in Section N1102.4.3.

FENESTRATION PRODUCT, SITE-BUILT. A fenestration designed to be made up of field-glazed or field-assembled units using specific factory cut or otherwise factory-formed framing and glazing units. Examples of site-built fenestration include storefront systems, curtain walls, and atrium roof systems.

- ❖ Fenestration products can be site built, not to be confused with field-fabricated fenestration products. This definition is meant to make that distinction.

FENESTRATION, VERTICAL. Windows (fixed or moveable), opaque doors, glazed doors, glazed block and combination opaque/glazed doors composed of glass or other transparent or translucent glazing materials and installed at a slope of a least 60 degrees (1.05 rad) from horizontal.

HEATED SLAB. Slab-on-grade construction in which the heating elements, hydronic tubing, or hot air distribution system is in contact with, or placed within or under, the slab.

- ❖ The space above a heated slab is always conditioned (heated). The definition clarifies that certain slabs are the heating source and, as covered in the code, may require more insulation than unheated slabs. The installation of a radiant heat source in a space does not, in and of itself, qualify a slab as heated.

HIGH-EFFICACY LAMPS. Compact fluorescent lamps, T-8 or smaller diameter linear fluorescent lamps, or lamps with a minimum efficacy of:

1. 60 lumens per watt for lamps over 40 watts;
2. 50 lumens per watt for lamps over 15 watts to 40 watts; and
3. 40 lumens per watt for lamps 15 watts or less.

- ❖ The code contains requirements that a percentage of permanent lighting fixtures have high-efficacy lamps. Therefore, this definition is necessary to indicate what is required to qualify as a high-efficacy lamp.

HISTORIC BUILDING. Any building or structure that is one or more of the following:

1. Listed, or certified as eligible for listing by the State Historic Preservation Officer or the Keeper of the National Register of Historic Places, in the National Register of Historic Places.
2. Designated as historic under an applicable state or local law.
3. Certified as a contributing resource within a National Register-listed, state-designated or locally designated historic district.

- ❖ Historic buildings are given some relief from the requirements of the code (see Section N1107.6).

INFILTRATION. The uncontrolled inward air leakage into a building caused by the pressure effects of wind or the effect of differences in the indoor and outdoor air density or both.

- ❖ Air leakage is random movement of air into and out of a building through cracks and holes in the building envelope. In technical terms, air leakage is called “infiltration” (air moving into a building) or “exfiltration” (air

moving out of a building). In nontechnical terms, air leaks are often referred to as “drafts.” Infiltration may be reduced by either reducing the sources of air leakage (joints, penetrations and holes in the building envelope) or by reducing the pressures driving the airflow.

INSULATED SIDING. A type of continuous insulation with manufacturer-installed insulating material as an integral part of the cladding product having a minimum *R*-value of R-2.

INSULATING SHEATHING. An insulating board with a core material having a minimum *R*-value of R-2.

- ❖ Some exterior hardboard and vinyl siding products are not recommended for use in direct contact with aluminum-foil-faced sheathing products (check with the product manufacturer). Other sheathing products are uniquely designed for use in direct contact with wood, brick, vinyl, aluminum and hardboard-based sidings. To be considered insulating sheathing, the product must have an *R*-value no less than R-2.

LOW-VOLTAGE LIGHTING. Lighting equipment powered through a transformer such as a cable conductor, a rail conductor and track lighting.

- ❖ Track lighting is a form of low-voltage lighting featuring a continuous-powered track that accepts fixtures (called heads) anywhere along its length. The heads and the wide variety of lamps (bulbs) they accept suit virtually every lighting situation and most heads are also adjustable. One-, two-, three- and four-circuit tracks let the lighting design professional mix standard and low-voltage heads or have multiple switching options. Track systems are easily modified or added to as lighting needs change. Although tracks can be recessed flush with a ceiling surface or suspended from posts, they are typically fastened to the surface either directly or with mounting clips. Controls ranging from a simple on/off switch to elaborate programmable dimming devices are widely available, making the system extremely flexible.

MANUAL. Capable of being operated by personal intervention (see “Automatic”).

- ❖ Devices, systems or equipment having manual controls or overrides are designed to operate safely with only human intervention instead of having an automatic operation or control system (see commentary, “Automatic”).

A typical light switch would be an example of a manual device. The lights that the switch controls would stay either off or on until a person took the action of flipping the switch to the appropriate position.

PROPOSED DESIGN. A description of the proposed building used to estimate annual energy use for determining compliance based on total building performance.

- ❖ The proposed design is simply a description of the proposed building that is being used to estimate annual energy costs for determining compliance based on total building performance. The proposed design is effectively the subject building intended to be built. The

performance of the proposed design (the building exactly as it is anticipated to be constructed) is then compared to the standard reference design (a similar building that is assumed to be built to a prescriptive set of minimum code requirements). Although the simulated performance alternative method permits trade-offs in energy use between different systems, the proposed design must still comply with the mandatory requirements. General (“mandatory”) requirements are separately specified in this chapter. For instance, the air-leakage requirements are general requirements that apply, even if the project uses any one of the two performance methods referenced above.

RATED DESIGN. A description of the proposed *building* used to determine the energy rating index.

❖ See Section N1106 for application.

READILY ACCESSIBLE. Capable of being reached quickly for operation, renewal or inspection without requiring those to whom ready access is requisite to climb over or remove obstacles or to resort to portable ladders or access equipment (see “*Accessible*”).

❖ Readily accessible can be described as the capability of being quickly reached or approached for operation, inspection, observation or emergency action. Ready access does not require the removal or movement of any door panel or similar obstruction or overcoming physical obstructions or obstacles, including differential elevation.

REPAIR. The reconstruction or renewal of any part of an existing building for the purpose of its maintenance or to correct damage. For definitions applicable in Chapter 11, see Section N1101.9.

❖ The repair of an item, appliance, energy-using subsystem or other piece of equipment typically does not require a permit. This definition makes it clear that a repair is limited to work on the item and does not include its replacement or other new work.

This definition is important when applying the provisions of Section N1107.1.1 and determining how the code will apply to existing buildings and installations.

REROOFING. The process of recovering or replacing an existing *roof covering*. See “Roof recover” and “Roof replacement.”

RESIDENTIAL BUILDING. For this chapter, includes detached one- and two-family dwellings and multiple single-family dwellings (townhouses) as well as Group R-2, R-3 and R-4 buildings three stories or less in height above grade plane.

❖ The definition of a residential building is important not only for what it does include, but also for what it does not. One of the primary limitations of this definition is the fact that this term will only include the Group R-2 and R-4 occupancies when they are three stories or less in height. Therefore, if a Group R-2 or R-4 occupancy is over three stories in height, it would be defined as a “Commercial building” (see definition, “Commercial

building”) and be required to comply with the requirements of IECC Chapter 4[CE] instead of the residential provisions of IECC Chapter 4[RE]. Detached one and two-family dwellings as well as townhouses are considered Residential Buildings regardless of the number of stories. However, the Group R-3 category as outlined in Section 310.5 includes uses in addition to those containing only one or two dwelling units and townhouses. These other R-3 uses (e.g., boarding houses, congregate living facilities, lodging houses and small care facilities (five or fewer care recipients) if over three stories would fall into the Commercial Building category.

R-1 building is not included within this definition. Therefore, any hotel, motel or similar use classified as a Group R-1 occupancy would need to comply with the Commercial Building requirements. This would apply even if the hotel or motel was three stories or less in height.

Though not specifically addressed within this definition, any building that is built under the provisions of the *International Residential Code*® (IRC®) also would be considered as being a “Residential Building.”

The Group R-2 classification of residential buildings includes apartments and condominiums where three or more units are physically attached. In addition, it includes certain boarding houses, convents, dormitories, fraternities or other such similar facilities. The code defines a dwelling unit as a single housekeeping unit of one or more rooms providing complete independent living facilities, including permanent provisions for living, sleeping, cooking and sanitation (see commentary, “Dwelling unit”). Many of the code provisions address dwelling units specifically. All of the elements listed in the definition must be present for a dwelling unit to exist. Guest rooms (sleeping units) in hotels and motels, patient care rooms in nursing homes and larger group care facilities do not meet these criteria. Therefore, these buildings are considered commercial uses, even if they are three stories or less in height (see the IBC for additional information on dwelling units). Although this definition closely follows the Group R-2 occupancy classification of the IBC, it is important to note there are differences. The main distinction is the three-story limitation, which is found only in the code.

The Group R-4 classification is included in order to coordinate the provisions of the code with the IBC. Group R-4 includes facilities where between 6 and 16 people reside in a supervised residential environment and receive custodial care. This distinction is important because larger facilities are classified by the IBC as Group I occupancies and, therefore, would be considered commercial buildings by the code (see “Commercial building”).

As mentioned earlier, it is important to note the application of the three-story limitation, which is found only in the code. This issue of defining a residential building over three stories in height as a commercial building coordinates the code with ANSI/ASHRAE/IESNA 90.1.

ROOF RECOVER. The process of installing an additional *roof covering* over a prepared existing *roof covering* without removing the existing *roof covering*.

- ❖ Roof recover is considered an alteration to the building. In the application of Section N1109, roof recover is exempt from the code requirements.

ROOF REPAIR. Reconstruction or renewal of any part of an existing roof for the purposes of its maintenance.

- ❖ See Section N1110 for application.

ROOF REPLACEMENT. The process of removing the existing *roof covering*, repairing any damaged substrate and installing a new *roof covering*.

- ❖ This is a form of alteration to a building and may or may not require additional energy conservation measures such as insulation in the roof cavity, depending on the extent of work (see Section N1109).

R-VALUE (THERMAL RESISTANCE). The inverse of the time rate of heat flow through a body from one of its bounding surfaces to the other surface for a unit temperature difference between the two surfaces, under steady state conditions, per unit area ($h \cdot \text{ft}^2 \cdot ^\circ\text{F}/\text{Btu}$) [$(\text{m}^2 \cdot \text{K})/\text{W}$].

- ❖ Thermal resistance measures how well a material or series of materials retards heat flow. Insulation thermal resistance is rated using *R*-values. As the *R*-value of an element or assembly increases, the heat loss or gain through that element or assembly decreases. Thus, a higher *R*-value is considered better than a lower *R*-value.

SERVICE WATER HEATING. Supply of hot water for purposes other than comfort heating.

- ❖ Although the definition makes it clear that the code requirement applies to equipment used to produce and distribute hot water for purposes other than comfort heating, the definition also applies to energy-efficient process water heating systems and equipment. Equipment providing or distributing hot water for uses such as restrooms; showers; laundries; kitchens; pools and spas; defrosting of sidewalks and driveways; carwashes; beauty salons and other commercial enterprises are included. Space-conditioning boilers and distribution systems are not considered service water heating components.

SKYLIGHT. Glass or other transparent or translucent glazing material installed at a slope of less than 60 degrees (1.05 rad) from horizontal. Glazing material in skylights, including unit skylights, solariums, sunrooms, roofs and sloped walls is included in this definition.

- ❖ A skylight is a glazed opening in a roof that admits daylight. Skylights are often the only method of bringing natural light into an interior, enclosed area. Unfortunately, these fixtures often do their job too well. Installing too many skylights or ones too large for the room can lead to overheating during warm-weather months. Also, choosing the most energy-efficient models can compromise light transmission—the reason people buy skylights in the first place.

Skylights are available in a variety of sizes and shapes, though rectangular units are the most common. Although most skylights are fixed or inoperable, others can be opened and shut like a window or have hidden ventilating systems. Large operable skylights designed for the sloping ceilings of attic rooms are even marketed as “roof windows.” These approaches help cool the room in warm weather by venting hot air. The IBC requires either tempered or laminated glass in skylights. Both types are designed to stand up to snow loads and provide protection against falling objects. Tempered glass breaks into small pieces, rather than large shards, if damaged. Laminated glass, which is fused with a thin layer of plastic, stays in place for added safety if broken. Laminated glass is also better at keeping out sound and is slightly more energy efficient, though also slightly more expensive. Skylights are not energy efficient. They collect little heat during the winter, which is when it is needed most—when the sun is low in the sky. Worse yet, because they’re located where the pressure difference between the inside and outside of the house is greatest, skylights are an easy escape route for heated air. Also, in the summer they can heat up the home quickly—when it is not needed.

Like windows, skylights offer a variety of energy-efficient glazing options, including low-E and tinted glass. Green tints are better than bronze tints for reducing solar heat gain while letting in plenty of visible light. And because skylights usually are not visible from the street, tinted glazings are less likely to affect aesthetics.

It is important to note that the term “skylight” can also include glazed roofs and sloped walls. This distinction can affect the proper application of the code requirements. To help determine the appropriate *U*-factor, this definition includes the slope limitation. If the slope of the roof or sloped wall is 60 degrees or less from the horizontal, then the skylight *U*-factor is appropriate. If the slope is greater than 60 degrees, then the glazing would be considered as a fenestration in a wall. As an example using the requirements of Table N1102.1.2 for Climate Zone 1, a skylight would require a *U*-factor of 0.75, while the fenestration in a wall would require a *U*-factor of 1.20. Both the skylight and the more vertical wall fenestration would require an SHGC of 0.30 (see Table N1102.1.2, Note b).

SOLAR HEAT GAIN COEFFICIENT (SHGC). The ratio of the solar heat gain entering the space through the fenestration assembly to the incident solar radiation. Solar heat gain includes directly transmitted solar heat and absorbed solar radiation that is then reradiated, conducted or convected into the space.

- ❖ The SHGC is the fraction of incident solar radiation admitted through a window or skylight. This includes the solar radiation that is both directly transmitted and that which is absorbed and subsequently released inward. Therefore, the SHGC measures how well a window blocks the heat from sunlight. The SHGC is the fraction of the heat from the sun that enters through a window. SHGC is expressed as a number between 0 and 1. The lower a window’s SHGC, the less solar heat it transmits.

In the warmer climate zones, where cooling is the dominant requirement, the code will generally impose a limitation on the amount of solar heat gain permitted. In colder climate zones, the code will generally not place any SHGC requirement on the fenestration. Thus, it will depend upon the climate zone as to whether a higher or lower SHGC is best. While windows with lower SHGC values reduce summer cooling and overheating, they also reduce free winter solar heat gain.

STANDARD REFERENCE DESIGN. A version of the *proposed design* that meets the minimum requirements of this code and is used to determine the maximum annual energy use requirement for compliance based on total building performance.

❖ The standard reference design is simply the same building design as that intended to be built (see commentary, “Proposed design”), except the energy conservation features required by the code (insulation, windows, infiltration, mechanical, lighting and service water heating systems) are modified to meet the minimum prescriptive requirements, as applicable. Note that the standard reference design is not truly a separate building and it is never actually built. It is the baseline against which the proposed design is measured.

The performance of the proposed design (the building exactly as it is anticipated to be constructed) is then compared to the standard reference design (a similar building that is assumed to be built to a prescriptive set of minimum code requirements). Under the performance paths, if the energy efficiency of the proposed design is equal to or better than that of the standard reference design, then the proposed design is acceptable and in compliance with the code requirements.

SUNROOM. A one-story structure attached to a dwelling with a glazing area in excess of 40 percent of the gross area of the structure’s exterior walls and roof.

❖ Sunrooms are unique rooms that create a space that differs in character from that provided by conventional portions of a dwelling. Sunrooms and other highly glazed structures are sometimes called conservatories or solariums. These sunrooms are often added onto an existing building, but there is nothing in the code that would prohibit them from being constructed as a part of a new dwelling.

This definition distinguishes sunrooms from other conventional spaces because they are limited to one story in height and the total glazing area needs to be at least 40 percent of the exterior wall and roof area of the sunroom. This definition and its use in Sections N1102.2.2 and N1102.3.5 are important since most dwellings do not have such large amounts of glazing.

Many of these sunrooms are constructed to be unconditioned spaces and will not have any type of heating or cooling. Other sunrooms may be conditioned either indirectly by openings from the adjacent conditioned space of the dwelling, be provided with a separate space conditioning system or they can be

served as a separate zone from the dwelling’s space-conditioning system. Due to the large amount of glazing and, therefore, the probability that the sunroom will either be hot in the summer or cold in the winter and may be unused during such times, the code provisions address the thermal isolation of these spaces (see definition, “Thermal isolation”).

When addressing the thermal isolation of the sunrooms, the provisions of Sections N1102.2.13 and N1102.3.5 need to be reviewed and code users need to realize how they coordinate with Section N1107.1.1. Section N1102.3.5 will require that “new walls” that separate a sunroom from a conditioned space must comply with the building thermal envelope requirements. Therefore, if a sunroom is built as an addition to an existing dwelling, the existing wall between the sunroom and any conditioned space is not regulated. The same concept applies to the provisions of Section N1102.3.6. Any “new windows and doors” between the sunroom and the dwelling will be regulated, but existing fenestration could remain unchanged.

THERMAL ISOLATION. Physical and space conditioning separation from *conditioned space(s)*. The *conditioned space(s)* shall be controlled as separate zones for heating and cooling or conditioned by separate equipment.

❖ This term is somewhat conceptually similar to the separation provided by the building envelope, but instead of being between the conditioned space and the exterior or conditioned space and unconditioned space, this separation occurs between two conditioned spaces. In this situation it is the separation between the dwelling and the sunroom. Therefore, where the sunroom is an addition, the existing exterior wall of the dwelling will generally provide the thermal isolation between the dwelling and the sunroom at the point where the sunroom addition is attached. If a new door or window opening is added to permit passage between or to provide a connection with the dwelling and the sunroom, that new door or window is required to comply with the fenestration *U*-factor specified in Table N1102.1.2. By requiring the maximum *U*-factor, it ensures a reasonable level of energy conservation between the dwelling and the sunroom so they would not need to be brought into compliance with the *U*-factor specified in the table.

This exemption for the existing doors and windows is based not only on the language in this definition, but also on the scoping requirements found in Sections N1102.3.5. Since these existing doors and windows would be serving as a part of the building envelope for the dwelling prior to the addition of the sunroom, they may be accepted as a part of the thermal isolation between the dwelling and any new sunroom addition (see commentary, “Sunroom” and Section N1102.3.5).

This definition is also important due to the restriction that it places on the heating and cooling system for the various spaces. In order to be thermally isolated, the two spaces are either served by separate systems or as separate zones on a common system.

THERMOSTAT. An automatic control device used to maintain temperature at a fixed or adjustable set point.

- ❖ Thermostats combine control and sensing functions in a single device. Thermostats may signal other control devices to trigger an action when certain temperatures are reached or surpassed. Because thermostats are so prevalent, the various types and their operating characteristics are described here.

The occupied/unoccupied or dual-temperature room thermostat reduces temperature at night. It may be indexed (changed from occupied to unoccupied operation or vice versa) individually from a remote point or in a group by a manual or time switch. Some types have an individual clock and switch built in.

The pneumatic day-night thermostat uses a two-pressure air-supply system, where changing the pressure at a central point from one value to the other actuates switching devices in the thermostat and indexes it.

The heating/cooling or summer/winter thermostat can have its action reversed and its set point changed in response to outdoor and comfort conditions. It is used to actuate controlled devices, such as valves or dampers, that regulate a heating source at one time and a cooling source at another.

The pneumatic heating-cooling thermostat uses a two-pressure air supply similar to that described for occupied/unoccupied thermostats.

Multistage thermostats are arranged to operate two or more successive steps in sequence.

A submaster thermostat has its set point raised or lowered over a predetermined range, in accordance with variations in output from a master controller. The master controller can be a thermostat, manual switch, pressure controller or similar device. For example, a master thermostat measuring outdoor air temperature can be used to readjust the set point of a submaster thermostat that controls the water temperature in a heating system.

A wet-bulb thermostat is often used (in combination with a dry-bulb thermostat) for humidity control. Using a wick or another means of keeping the bulb wet with pure (distilled) water and rapid air motion to ensure a true wet-bulb measurement is essential. Wet-bulb thermostats are seldom used.

A dew-point thermostat is designed to control dew-point temperatures.

U-FACTOR (THERMAL TRANSMITTANCE). The coefficient of heat transmission (air to air) through a building component or assembly, equal to the time rate of heat flow per unit area and unit temperature difference between the warm side and cold side air films ($\text{Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}$) [$\text{W}/(\text{m}^2 \cdot \text{K})$].

- ❖ Thermal transmittance (*U*-factor) is a measure of how well a material or series of materials conducts heat. *U*-factors for window and door assemblies are the reciprocal of the assembly *R*-value:

$$U\text{-factor} = \frac{1}{R\text{-value}}$$

For other building assemblies, such as a wall or roof/ceiling, the *R*-value used in the above equation is the *R*-value of the entire assembly, not just the insulation. This distinction is important and reflects the provisions of Sections N1102.1.4 and N1102.1.5. It also explains why there are differences between the comparable values of Tables N1102.1.2 and N1102.1.4.

The *U*-factors will be used in a number of locations of the code. When using the performance options or the “total UA alternative” (see Section N1102.1.4), the individual thermal transmittance (*U*-factor) of each element is multiplied by the area of each envelope component (walls, floors and ceilings) and the area of each fenestration element (doors, windows and skylights). Therefore, the UA is simply the *U*-factor times the area. For example, a 400-square-foot (37 m²) wall with a *U*-factor of 0.082 would result in a UA of 32.8 (400 × 0.082 = 32.8). The total UA would simply be the sum of all of the individual UAs for each building element (walls, floors, ceilings, doors, windows and skylights).

VENTILATION AIR. That portion of supply air that comes from outside (outdoors) plus any recirculated air that has been treated to maintain the desired quality of air within a designated space.

- ❖ Ventilation air can be used for comfort cooling, control of air contaminants, equipment cooling and replenishing oxygen levels (see commentary, “Ventilation”).

VISIBLE TRANSMITTANCE [VT]. The ratio of visible light entering the space through the fenestration product assembly to the incident visible light, Visible Transmittance, includes the effects of glazing material and frame and is expressed as a number between 0 and 1.

- ❖ The required SHGC rating for glazed fenestration has been continuously lowered such that the amount of light admitted by the glazing is lower. With the advent of requirements for daylighting, the need is for fenestration to admit light; thus, there are opposing needs in the code. The visible transmittance of glazing is now an issue and is therefore defined in the code.

WHOLE HOUSE MECHANICAL VENTILATION SYSTEM. An exhaust system, supply system, or combination thereof that is designed to mechanically exchange indoor air with outdoor air when operating continuously or through a programmed intermittent schedule to satisfy the whole house ventilation rates.

- ❖ Because the construction of buildings is increasingly more air tight, the IMC now requires whole house mechanical ventilation when the measured air leakage rate is lower than a threshold amount. The IECC contains requirements for fan efficacy.

ZONE. A space or group of spaces within a building with heating or cooling requirements that are sufficiently similar so that desired conditions can be maintained throughout using a single controlling device.

- ❖ The simplest all-air system is a supply unit serving a single-temperature control zone. Ideally, this system

responds completely to the space needs and well-designed control systems maintain temperature and humidity closely and efficiently. Single-zone systems can be shut down when not required without affecting the operation of adjacent areas. Thus, the concept of “zoning” for temperature control requires discussion.

Exterior Zoning. Exterior zones are affected by varying weather conditions—wind, temperature and sun—and, depending on the geographic area and season, require both heating and cooling. This variation gives the designer considerable flexibility in choosing a system and results in the greatest advantages. The need for separate perimeter zone heating is determined by:

- Severity of the heating load (i.e., geographic location).
- Nature and orientation of the building envelope.
- Effects of downdraft at windows and the radiant effect of the cold glass surface (type of glass, area, height and *U*-factor).
- Type of occupancy (sedentary versus transient).
- Operating costs (in buildings such as offices and schools that are occupied for considerable periods). Fan-operating costs can be reduced by heating with perimeter radiation during unoccupied periods, rather than operating the main supply fans or local unit fans.

Interior Zoning. Conditions in interior spaces are relatively constant because they are isolated from external influences. Usually, interior spaces require cooling throughout the year. Interior spaces with a roof exposure, however, may require similar treatment to perimeter spaces requiring heat. To summarize, zone control is required when the conditions at the thermostat are not representative of all the rooms or the entire exposure. This situation will almost certainly occur if any of the following conditions exist:

- The building has more than one level.
- One or more spaces are used for entertaining large groups.
- One or more spaces have large glass areas.
- The building has an indoor swimming pool or hot tub.
- The building has a solarium or atrium. In addition, zoning may be required when several rooms or spaces are isolated from each other and from the thermostat.
- The building spreads out in many directions (wings). Some spaces are distinctly isolated from the rest of the building.
- The envelope only has one or two exposures.
- The building has a room or rooms in a basement.
- The building has a room or rooms in an attic space.

- The building has one or more rooms with a slab or exposed floor.
- There are discrete heating/cooling duct systems for each zone requiring control.
- There are automatic zone damper systems in a single heating/cooling duct system.

N1101.7 (R301.1) Climate zones. Climate zones from Figure N1101.7 or Table N1101.7 shall be used in determining the applicable requirements in Sections N1101 through N1111. Locations not in Table N1101.7 (outside the United States) shall be assigned a climate zone based on Section N1101.10.2.

- ❖ Climate involves temperature, moisture, wind and sun and also includes both daily and seasonal patterns of variation of the parameters. To account for these variations, the code establishes climate zones that serve as the basis for the code provisions.

This section serves as the starting point for determining virtually all of the code requirements, especially under the prescriptive compliance paths. Because of their easy-to-understand graphic nature, maps have proven useful over the years as an effective way to enable code users to determine climate-dependent requirements. Therefore, for the United States, the climate zones are shown in the map in Figure N1101.7. Because of the limited size of the map, the code also includes a listing of the climate zones by states and counties in Table N1101.7. Table N1101.7 will allow users to positively identify climate-zone assignments in those few locations for which the map interpretation may be difficult. Whether the map or the county list is used, the climate classification for each area will be the same.

When dealing with the prescriptive compliance paths, the code user would simply look at the map or listing and select the proper climate zone based on the location of the building. When using a performance approach, additional climatic data may be needed.

Virtually every building energy code that has been developed for use in the United States has included a performance-based compliance path, which allows users to perform an energy analysis and demonstrate compliance based on equivalence with the prescriptive requirements. To perform these analyses, users must select appropriate weather data for their given project's location. The selection of appropriate weather data is straightforward for any project located in or around one of the various weather stations within the United States. For other locations, selecting the most appropriate weather site can be problematic. The codes themselves provide little guidance to help with this selection process. During the development of the new climate zones, the developers mapped every county in the United States to the most appropriate SAMSON station (National Climatic Data Center “Solar and Meteorological Surface Observation Network” station) for each county as a whole. This map-

ping is not included within the code but may be used in some compliance software. Designating an appropriate SAMSON station should not be considered to be the only climate data permitted for a given county. It could, however, be used in the absence of better information. Where local data better reflects regional or microclimatic conditions of an area, they would be appropriate to use. For example, elevation has a large impact on climate and can vary dramatically within individual counties, especially in the western United States. Where elevation differences are significant, code officials may require use of sites that differ from the sites designated as being the most appropriate for the county. For additional information on this topic, review the paper “Climate Classification for Building Energy Codes and Standards.”

N1101.7.1 (R301.2) Warm humid counties. Warm humid counties are identified in Table N1101.7 by an asterisk.

❖ Table N1101.7 provides a listing of the counties within the southeastern United States that fall below the white-dashed line that appears in the map in Figure N1101.7. The warm-humid climate designation includes parts of eight states and also covers all of Florida, Hawaii and the U.S. territories. Table N1101.7.2(1) provides the details that were used to determine the classification of the warm-humid designation for the counties.

There currently are very few requirements within the code that are specifically tied to the warm-humid climate criteria. Although not tied directly to the warm-humid designation, many other code sections, such as those addressing moisture control and energy recovery ventilation systems, do take these climatic features into account.

N1101.7.2 (R301.3) International climate zones. The climate zone for any location outside the United States shall be determined by applying Table N1101.7.2(1) and then Table N1101.7.2(2).

❖ Although the code and the new climate zone classifications it includes are predominately used within the United States, they can be used in any location. Because the mapping and decisions that were made during the development of the new climate zones focused primarily on the United States, this section provides the details of how to properly classify the climate zones based upon the thermal criteria [Table N1101.7.2(2)], the major climate types [Table N1101.7.2(1)] and the warm-humid criteria for locations outside of the United States.

N1101.8 (R301.4) Tropical climate zone. The tropical climate zone shall be defined as:

1. Hawaii, Puerto Rico, Guam, American Samoa, US Virgin Islands, Commonwealth of Northern Mariana Islands; and

2. Islands in the area between the Tropic of Cancer and the Tropic of Capricorn.

❖ Tropical areas are quite different from the U.S. mainland in climate, construction techniques, traditional construction and energy prices. Prior to the installation of these new provisions, the IECC treated tropical climates as if they were simply a southern extension of the U.S. mainland. In traditional residences, especially less expensive residences, inexpensive ways to work with the tropical climates have evolved to provide comfortable interior spaces without the need for substantial space conditioning. Tropical electrical prices, usually over 20 cents per kWh, provide a substantial incentive for energy conservation. Solar water heating works particularly well in tropical climates.

This section provides a simple option for a newly defined climate zone, the “tropical zone.” The area between the Tropic of Cancer and the Tropic of Capricorn is the area between 23.5 degrees north and south of the equator.

Traditional construction, especially with solar water heating, is usually more energy efficient than the construction style usually assumed in the IECC, as is shown by an analysis done for Puerto Rico. Using energy-efficient versions of traditional construction saves more energy and is much more cost-effective than pushing those in tropical climates to adopt mainland construction practices. Traditional tropical construction focuses on greatly reducing or eliminating the need for space conditioning by making a living space that is comfortable without space conditioning.

These requirements are based on informal conversations with those who live in tropical regions.

N1101.9 (R302.1) Interior design conditions. The interior design temperatures used for heating and cooling load calculations shall be a maximum of 72°F (22°C) for heating and minimum of 75°F (24°C) for cooling.

❖ While the previous sections of IECC Chapter 3 address outdoor design conditions, this section provides the interior conditions that will be used for properly sizing the mechanical equipment. The proper sizing of mechanical equipment (see Section N1103.7) can vary depending on the selected design conditions. While the code does address oversizing equipment, it is not enforceable without establishing the exact design parameters. This section is included in the code only for system sizing, and it does not affect the interior design temperatures required by other codes such as Section 1204 of the IBC or Section 602.2 of the *International Property Maintenance Code*® (IPMC)®.

The 75°F (24°C) design temperature for cooling was used in the code so that it coordinated with both the ASHRAE *Handbook of Fundamentals* and the Air Conditioning Contractors of America (ACCA) Manuals S and J, established standards that deal with equipment sizing.

**TABLE N1101.7.2(1) [R302.3(1)]
INTERNATIONAL CLIMATE ZONE DEFINITIONS**

MAJOR CLIMATE TYPE DEFINITIONS
<p>Marine (C) Definition—Locations meeting all four criteria:</p> <ol style="list-style-type: none"> 1. Mean temperature of coldest month between -3°C (27°F) and 18°C (65°F). 2. Warmest month mean < 22°C (72°F). 3. At least four months with mean temperatures over 10°C (50°F). 4. Dry season in summer. The month with the heaviest precipitation in the cold season has at least three times as much precipitation as the month with the least precipitation in the rest of the year. The cold season is October through March in the Northern Hemisphere and April through September in the Southern Hemisphere.
<p>Dry (B) Definition—Locations meeting the following criteria: Not marine and $P_{in} < 0.44 \times (TF - 19.5)$ [$P_{cm} < 2.0 \times (TC + 7)$ in SI units] where: P_{in} = Annual precipitation in inches (cm) T = Annual mean temperature in °F (°C)</p>
<p>Moist (A) Definition—Locations that are not marine and not dry.</p>
<p>Warm-humid Definition—Moist (A) locations where either of the following wet-bulb temperature conditions shall occur during the warmest six consecutive months of the year:</p> <ol style="list-style-type: none"> 1. 67°F (19.4°C) or higher for 3,000 or more hours; or 2. 73°F (22.8°C) or higher for 1,500 or more hours.

For SI: °C = [(°F)-32]/1.8, 1 inch = 2.54 cm.

N1101.10 (R303.1) Identification. Materials, systems and equipment shall be identified in a manner that will allow a determination of compliance with the applicable provisions of this code.

- ❖ The intent of this section is to make certain that sufficient information exists to determine compliance with the code during the plan review and field inspection phases. The permittee can submit the required equipment and materials information on the building plans, specification sheets or schedules or in any other way that allows the code official to clearly identify which specifications apply to which portions of the building; that is, which parts of the building are insulated to the levels listed. Materials information includes envelope insulation levels, glazing assembly *U*-factors and duct and piping insulation levels. Equipment information includes heating and cooling equipment and appliance efficiencies where high-efficiency equipment is claimed to meet code requirements.

This section contains specific material, equipment and system identification requirements for the approval and installation of the items required by the code. Although the means for permanent marking (tag, stencil, label, stamp, sticker, bar code, etc.) is often determined and applied by the manufacturer, if there is any uncertainty about the product, the mark is subject to the approval of the code official.

N1101.10.1 (R303.1.1) Building thermal envelope insulation. An *R*-value identification mark shall be applied by the manufacturer to each piece of *building thermal envelope* insulation 12 inches (305 mm) or greater in width. Alternately, the insulation installers shall provide a certification listing the type, manufacturer and *R*-value of insulation installed in each element of the *building thermal envelope*. For blown or sprayed insulation (fiberglass and cellulose), the initial installed thickness, settled thickness, settled *R*-value, installed density, coverage area and number of bags installed shall be *listed* on the certification. For insulated siding, the *R*-value shall be labeled on the product's package and shall be *listed* on

the certification. The insulation installer shall sign, date and post the certification in a conspicuous location on the job site.

- ❖ The thermal performance of insulation is rated in terms of *R*-value. For products lacking an *R*-value identification, the installer (or builder) must provide the insulation performance data. For example, some insulation materials, such as foamed-in-place urethane, can be installed in wall, floor and cathedral ceiling cavities. These products are not labeled, as is batt insulation, nor is it appropriate for them to be evaluated as required in the code for blown or sprayed insulation; however, the installer must certify the type, thickness and *R*-value of these materials.

The *R*-value of loose-fill insulation (blown or sprayed) is dependent on both the installed thickness and density (number of bags used). Therefore, loose-fill insulation cannot be directly labeled by the manufacturer. Many blown insulation products carry a manufacturer's *R*-value guarantee when installed to a designated thickness, "inches = *R*-value." Blown insulation products lacking this manufacturer's guarantee can be subjected to special inspection and testing; what is referred to as "cookie cutting." Cookie cutting involves extracting a column of insulation with a cylinder to determine its density. The insulation depth and density must yield the specified *R*-value according to the manufacturer's bag label specification.

The code and Federal Trade Commission Rule 460 require that installers of insulation in homes, apartments and manufactured housing units report this information to the authority having jurisdiction in the form of a certification posted in a conspicuous location.

N1101.10.1.1 (R303.1.1.1) Blown or sprayed roof/ceiling insulation. The thickness of blown-in or sprayed roof/ceiling insulation (fiberglass or cellulose) shall be written in inches (mm) on markers that are installed at least one for every 300 square feet (28 m²) throughout the attic space. The markers shall be affixed to the trusses or joists and marked with the minimum initial installed thickness with numbers not less than 1 inch (25 mm) in height. Each marker shall face the

TABLE N1101.7.2(2) [R301.3(2)]
INTERNATIONAL CLIMATE ZONE DEFINITIONS

ZONE NUMBER	THERMAL CRITERIA	
	IP Units	SI Units
1	9000 < CDD50°F	5000 < CDD10°C
2	6300 < CDD50°F ≤ 9000	3500 < CDD10°C ≤ 5000
3A and 3B	4500 < CDD50°F ≤ 6300 AND HDD65°F ≤ 5400	2500 < CDD10°C ≤ 3500 AND HDD18°C ≤ 3000
4A and 4B	CDD50°F ≤ 4500 AND HDD65°F ≤ 5400	CDD10°C ≤ 2500 AND HDD18°C ≤ 3000
3C	HDD65°F ≤ 3600	HDD18°C ≤ 2000
4C	3600 < HDD65°F ≤ 5400	2000 < HDD18°C ≤ 3000
5	5400 < HDD65°F ≤ 7200	3000 < HDD18°C ≤ 4000
6	7200 < HDD65°F ≤ 9000	4000 < HDD18°C ≤ 5000
7	9000 < HDD65°F ≤ 12600	5000 < HDD18°C ≤ 7000
8	12600 < HDD65°F	7000 < HDD18°C

For SI: °C = [(°F)-32]/1.8.

attic access opening. Spray polyurethane foam thickness and installed R -value shall be *listed* on certification provided by the insulation installer.

- ❖ To help verify the installed R -value of blown-in or spray-applied insulation, the installer must certify the following information in a signed statement posted in a conspicuous place (see Section N1101.10.1):
 - The type of insulation used and manufacturer.
 - The insulation's coverage per bag (the number of bags required to result in a given R -value for a given area), as well as the settled R -value.
 - The initial and settled thickness.
 - The number of bags installed.

Under circumstances where the insulation R -value is guaranteed, only the initial thickness is required on the certification.

This section helps demonstrate compliance and enforcement of the provisions found in Section N1101.10.1. To assist with application and enforcement, loose-fill ceiling insulation also requires thickness markers that are attached to the framing and face the attic access.

In a large space, markers placed evenly about every 17 feet (5182 mm) (with some markers at the edge of the space) will meet this requirement. For sprayed polyurethane, such markers are not effective. When using this product, the code requires that the measured thickness and R -value be recorded on the certificate.

N1101.10.2 (R303.1.2) Insulation mark installation. Insulating materials shall be installed such that the manufacturer's R -value mark is readily observable upon inspection.

- ❖ For batt insulation, manufacturers' R -value designations and stripe codes are often printed directly on the insulation. Where possible, the insulation must be installed so these designations are readable. Backed floor batts can be installed with the designation against the underfloor, which means it would not be visible. In those cases, the R -value must be certified by the installer or be validated by some other means (see commentary, Section N1101.10.1).

N1101.10.3 (R303.1.3) Fenestration product rating. U -factors of fenestration products (windows, doors and skylights) shall be determined in accordance with NFRC 100.

Exception: Where required, garage door U -factors shall be determined in accordance with either NFRC 100 or ANSI/DASMA 105.

U -factors shall be determined by an accredited, independent laboratory, and labeled and certified by the manufacturer.

Products lacking such a labeled U -factor shall be assigned a default U -factor from Table N1101.10.3(1) or N1101.10.3(2). The solar heat gain coefficient (SHGC) and visible transmittance (VT) of glazed fenestration products (windows, glazed doors and skylights) shall be determined in accordance with NFRC 200 by an accredited, independent

laboratory, and labeled and certified by the manufacturer. Products lacking such a labeled SHGC or VT shall be assigned a default SHGC or VT from Table N1101.10.3(3).

- ❖ Until recently, the buyers of fenestration products received energy performance information in a variety of ways. Some manufacturers described performance by showing R -values of the glass. While the glass might have been a good performer, the rating did not include the effects of the frame. Other manufacturers touted the insulating value of different window components, but these, too, did not reflect the total window system performance. When manufacturers rated the entire product, some used test laboratory measurements and others used computer calculations. Even among those using test laboratory reports, the test laboratories often tested the products under different procedures, making an "apples-to-apples" comparison difficult. The different rating methods confused builders and consumers. They also created headaches for manufacturers trying to differentiate the performance of their products from the performance of their competitors' products.

The NFRC has developed a fenestration energy rating system based on whole-product performance. This accurately accounts for the energy-related effects of all the product's component parts and prevents information about a single component from being compared in a misleading way to other whole-product properties. With energy ratings based on whole-product performance, NFRC helps builders, designers and consumers directly compare products with different construction details and attributes.

Products that have been rated by NFRC-approved testing laboratories and certified by NFRC-accredited independent certification and inspection agencies carry a temporary and permanent label featuring the "NFRC-certified" mark. With this mark, the manufacturer stipulates that the energy performance of the product was determined according to NFRC rules and procedures.

By certifying and labeling their products, manufacturers are demonstrating their commitment to providing accurate energy and energy-related performance information. The code purposely sets the default values fairly high. This helps to encourage the use of products that have been tested and also ensures that products that have little energy-saving values are not used inappropriately in the various climate zones. By setting the default value so high, it will also prevent someone from removing the label from a tested window and then using the default values. Therefore, the default values are most representative of the lower end of the energy-efficient products.

Products that are not NFRC certified and do not exactly match the specifications in Tables N1101.10.3(1) and N1101.10.3(2) must use the tabular specification for the product most closely resembling it. In the absence of tested U -factors, the default U -factor for doors containing glazing can be a combi-

nation of the glazing and door *U*-factor as described in the definition for “*U*-factor” (see commentary, Section 202, “*U*-factor”). The NFRC procedures determine *U*-factor and SHGC ratings based on the whole fenestration assembly [untested fenestration products have default *U*-factors and SHGCs assigned as described in the commentary to Tables N1101.10.3(1) through N1101.10.3(3)]. During construction inspection, the label on each glazing assembly should be checked for conformance to the *U*-factor specified on the approved plans. These labels must be left on the glazing until after the building has been inspected for compliance. A sample NFRC label is shown in Commentary Figure N1101.10.3(1).

Products certified according to NFRC procedures are listed in the *Certified Products Directory*. The directory is published annually and contains energy performance information for over 1.4 million fenestration product options listed by over 450 manufacturers. When using the directory or shopping for NFRC-certified products, it is important to note:

1. A product is considered to be NFRC certified only if it carries the NFRC label. Simply being listed in this directory is not enough.
2. The NFRC-certified mark does not signify that the product meets any energy-efficiency standards or criteria.
3. NFRC neither sets minimum performance standards nor mandates specific performance levels. Rather, NFRC ratings can be used to determine whether a product meets a state or local code or other performance requirement and to compare the energy performance of different products during plan review. For questions about NFRC and its rating and labeling system, more information is available on the organization’s website at www.nfrc.org. NFRC adopted a new energy performance label in 2005. It lists the manufacturer, describes the product, provides a source for additional information and includes ratings for one or more energy performance characteristics.

The IECC offers an alternative to NFRC-certified glazed fenestration product *U*-factor ratings. In the absence of *U*-factors based on NFRC test procedures, the default *U*-factors in Table N1101.10.3(1) must be used. When a composite of materials from two different product types is used, the code official should be consulted regarding how the product will be rated. Generally, the product must be assigned the higher *U*-factor, although an average based on the *U*-factors and areas may be acceptable in some cases.

The product cannot receive credit for a feature that cannot be seen. Because performance features such as argon fill and low-emissivity coatings for glass are not visually verifiable, they do not receive credit in the default tables. Tested *U*-factors for these windows are often lower, so using tested *U*-factors is to the appli-

cant’s advantage. Commentary Figure N1101.10.3(2) illustrates visually verifiable window characteristics, among other various window performance, function and cost considerations.

A single-glazed window with an installed storm window may be considered a double-glazed assembly and use the corresponding *U*-factor from the default table. For example, the *U*-factor 0.80 in Table N1101.10.3(1) applies to a single-glazed, metal window without a thermal break (but with an installed storm window). If the storm window was not installed, the *U*-factor would be 1.20.

**TABLE N1101.10.3(1) [R303.1.3(1)]
DEFAULT GLAZED FENESTRATION *U*-FACTORS**

FRAME TYPE	SINGLE PANE	DOUBLE PANE	SKYLIGHT	
			Single	Double
Metal	1.20	0.80	2.00	1.30
Metal with Thermal Break	1.10	0.65	1.90	1.10
Nonmetal or Metal Clad	0.95	0.55	1.75	1.05
Glazed Block	0.60			

**TABLE N1101.10.3(2) [R303.1.3(2)]
DEFAULT DOOR *U*-FACTORS**

DOOR TYPE	<i>U</i> -FACTOR
Uninsulated Metal	1.20
Insulated Metal	0.60
Wood	0.50
Insulated, nonmetal edge, max 45% glazing, any glazing double pane	0.35

- ❖ Door *U*-factors in Table N1101.10.3(2) should be used wherever NFRC-certified ratings are not available.

There are a few other aspects to note about doors. Opaque door *U*-factors must include the effects of the door edge and the frame. Calculating *U*-factors based on a cross section through the insulated portion is not acceptable. To take credit for a thermal break, the door must have one in both the door slab and in the frame. The values in the table are founded on principles established in the 1997 *ASHRAE Handbook of Fundamentals*.

**TABLE N1101.10.3(3) [R303.1.3(3)]
DEFAULT GLAZED FENESTRATION SHGC AND VT**

	SINGLE GLAZED		DOUBLE GLAZED		GLAZED BLOCK
	Clear	Tinted	Clear	Tinted	
SHGC	0.8	0.7	0.7	0.6	0.6
VT	0.6	0.3	0.6	0.3	0.6

- ❖ This table offers an alternative to NFRC-certified SHGC and visible transmittance (VT) values based on visually verifiable characteristics of the fenestration product. The SHGC is the fraction of incident solar radiation absorbed and directly transmitted by the window area, then subsequently reradiated, conducted or convected inward. SHGC is a ratio, expressed as a number between 0 and 1. The lower a window’s

SHGC, the less solar heat it transmits. The VT is the ratio of visible light entering the space through the fenestration product assembly to the incident visible light. Visible transmittance includes the effects of glazing material and frame and is expressed as a number between 0 and 1.

An SHGC of 0.40 or less is recommended in cooling-dominated climates (Climate Zones 1-3). In heating-dominated climates, a high SHGC increases passive solar gain for the heating but reduces cooling-season performance. A low SHGC improves cooling-season performance but reduces passive solar gains for heating.

N1101.10.4 (R303.1.4) Insulation product rating. The thermal resistance (*R*-value) of insulation shall be determined in accordance with the U.S. Federal Trade Commission *R*-value rule (CFR Title 16, Part 460) in units of $h \times ft^2 \times ^\circ F/Btu$ at a mean temperature of 75°F (24°C).

❖ This section brings two important requirements to the code.

First, the Federal Trade Commission *R*-value rule

details specific test standards for insulation. The test standards are specific to the type of insulation and intended use. This clarifies any questions on the rating conditions to be used for insulation materials.

Second, the text above specifies the rating temperature to be used when evaluating the *R*-value of the product, providing consistency not currently in the code. Insulation products sometimes list several *R*-values based on different test temperatures. This eliminates any question as to which *R*-value to use. The temperature selected is a standard rating condition.

N1101.10.4.1 (R303.1.4.1) Insulated siding. The thermal resistance (*R*-value) of insulated siding shall be determined in accordance with ASTM C1363. Installation for testing shall be in accordance with the manufacturer’s installation instructions.

❖ Insulated siding is a unique product that requires a special test method for determination of *R*-value. This test method is ASTM C1363, *Standard Test Method for Thermal Performance of Building Materials and Envelope Assemblies by Means of a Hot Box Apparatus.*

N1101.11 (R303.2) Installation. All materials, systems and equipment shall be installed in accordance with the manufacturer's instructions and this code.

- ❖ Manufacturer's installation instructions are thoroughly evaluated by the listing agency, verifying that a safe installation is prescribed. When an appliance is tested to obtain a listing and label, the approval agency installs the appliance in accordance with the manufacturer's instructions. The appliance is tested under these conditions; thus, the installation instructions become an integral part of the labeling process. The listing agency can require that the manufacturer alter, delete or add information to the instructions as necessary to achieve compliance with applicable standards and code requirements.

Manufacturers' installation instructions are an enforceable extension of the code and must be in the hands of the code official when an inspection takes place. Inspectors must carefully and completely read and comprehend the manufacturer's instructions in order to properly perform an installation inspection. In some cases, the code will specifically address an installation requirement that is also addressed in the manufacturer's installation instructions. The code requirement may be the same or may exceed the requirement in the manufacturer's installation instructions. The manufacturer's installation instructions could contain requirements that exceed those in the code. In such cases, the more restrictive requirements would apply (see commentary, Section 106).

Even if an installation appears to be in compliance with the manufacturer's instructions, the installation cannot be completed or approved until all associated components, connections and systems that serve the appliance or equipment are also in compliance with the requirements of the applicable *International Codes*[®] (I-Codes[®]) of reference. For example, a gas-fired boiler

installation must not be approved if the boiler is connected to a deteriorated, undersized or otherwise unsafe chimney or vent. Likewise, the same installation must not be approved if the existing gas piping has insufficient capacity to supply the boiler load or if the electrical supply circuit is inadequate or unsafe.

Manufacturer's installation instructions are often updated and changed for various reasons, such as changes in the appliance, equipment or material design; revisions to the product standards and as a result of field experiences related to existing installations. The code official should stay abreast of any changes by reviewing the manufacturer's instructions for every installation.

N1101.11.1 (R303.2.1) Protection of exposed foundation insulation. Insulation applied to the exterior of basement walls, crawlspace walls and the perimeter of slab-on-grade floors shall have a rigid, opaque and weather-resistant protective covering to prevent the degradation of the insulation's thermal performance. The protective covering shall cover the exposed exterior insulation and extend not less than 6 inches (153 mm) below grade.

- ❖ The ultimate performance of insulation material is directly proportional to the workmanship involved in the materials' initial installation, as well as the materials' integrity over the life of the structure. Accordingly, foundation wall and slab-edge insulation materials installed in the vicinity of the exterior grade line require protection from damage that could occur from contact by lawn-mowing and maintenance equipment, garden hoses, garden tools, perimeter landscape materials, etc. In addition, the long-term thermal performance of foam-plastic insulation materials is adversely affected by direct exposure to the sun. To protect the insulation from sunlight and physical damage, it must have a protective covering that is inflexible, puncture resistant, opaque and weather resistant.

N1101.12 (R303.3) Maintenance information. Maintenance instructions shall be furnished for equipment and systems that require preventive maintenance. Required regular maintenance actions shall be clearly stated and incorporated on a readily accessible label. The label shall include the title or publication number for the operation and maintenance manual for that particular model and type of product.

❖ This section establishes an owner's responsibility for maintaining the building in accordance with the requirements of the code and other referenced standards. This section requires, among others, that mechanical and service water heating equipment and appliance maintenance information be made available to the owner/operator. This section does not require that labels be added to existing equipment; having the manufacturer's maintenance literature is usually sufficient to meet this requirement. During final occupancy inspection, the mechanical equipment and water heater should be inspected to verify that the information is taped to each unit or referenced on a label mounted in a conspicuous location on the units.

The code official has the authority to rule on the performance of maintenance work when equipment functions would be affected by such work. He or she also has the authority to require a building and its energy-using systems to be maintained in compliance with the public health and safety provisions required by other I-Codes.

N1101.13 (R401.2) Compliance. Projects shall comply with one of the following:

1. Sections N1101.14 through N1104.
2. Section N1105 and the provisions of Sections N1101.14 through N1104 labeled "Mandatory."
3. An energy rating index (ERI) approach in Section N1106.

❖ This section allows residential buildings to comply with either the prescriptive requirements of Sections N1101 through N1104, the performance options that are provided in Section N1105, or the energy rating index option in Section N1106. Under all options, the building must comply with the mandatory requirements that are found in Sections N1101.3, N1102.4, N1102.5, N1103.1, N1103.1.2, N1103.3.2, N1103.3.3, N1103.3.5, N1103.4, N1103.6, N1103.7, N1103.8, N1103.9 and N1104. A code user may evaluate both options and use the one that fits the project best, as these two differing methods can result in different requirements. Most requirements are given prescriptively. Alternative trade-offs are specified for many requirements, such as the building thermal envelope requirements. For requirements specified by *U*-factors, an overall UA (*U*-factor times the area) can be used to show equivalence. A performance-based annual energy calculation also can be met by showing overall energy equivalence.

The majority of the requirements of this chapter are based on the climate zone where the project is being

built. The appropriate climate zone can be found in Section N1101.7 of the code. Climate Zones 1 through 7 apply to various parts of the continental United States and are defined by county lines. Climate Zones 7 and 8 apply to various parts of Alaska, and Hawaii is classified as Climate Zone 1. The climate zones have been divided into marine, dry and moist to deal with levels of humidity. For more details and background on the development of the new climate zones, see the commentary to Section N1101.7.

N1101.13.1 (R401.2.1) Tropical zone. *Residential buildings* in the tropical zone at elevations below 2,400 feet (731.5 m) above sea level shall be deemed to comply with this chapter where the following conditions are met:

1. Not more than one-half of the *occupied* space is air conditioned.
2. The *occupied* space is not heated.
3. Solar, wind or other renewable energy source supplies not less than 80 percent of the energy for service water heating.
4. Glazing in *conditioned* space has a *solar heat gain coefficient* of less than or equal to 0.40, or has an overhang with a projection factor equal to or greater than 0.30.
5. Permanently installed lighting is in accordance with Section N1104.
6. The exterior roof surface complies with one of the options in Table C402.2.1.1 of the *International Energy Conservation Code*, or the roof/ceiling has insulation with an *R*-value of R-15 or greater. If present, attics above the insulation are vented and attics below the insulation are unvented.
7. Roof surfaces have a minimum slope of $\frac{1}{4}$ inch (6.4 mm) per foot of run. The finished roof does not have water accumulation areas.
8. Operable fenestration provides ventilation area equal to not less than 14 percent of the floor area in each room. Alternatively, equivalent ventilation is provided by a ventilation fan.
9. Bedrooms with exterior walls facing two different directions have operable fenestration on exterior walls facing two directions.
10. Interior doors to bedrooms are capable of being secured in the open position.
11. A ceiling fan or ceiling fan rough-in is provided for bedrooms and the largest space that is not used as a bedroom.

❖ This section provides an alternative for residences in the tropical climates, a simple option for a newly defined climate zone, the "tropical zone." The area between the Tropic of Cancer and the Tropic of Capricorn is the area between 23.5 degrees north and south of the equator. A zone that recognizes the unusually constant and unique climate of this region would help make the I-Codes more of an "international code."

Tropical areas are quite different from the U.S. mainland in climate, construction techniques, traditional construction and energy prices. This chapter, and the IECC heretofore, have treated tropical climates as if they were simply a southern extension of the U.S. mainland. In traditional residences, especially less expensive residences, inexpensive ways to work with the tropical climates have evolved to provide comfortable interior spaces without the need for substantial space conditioning. Tropical electrical prices, usually over 20 cents per kWh, provide a substantial incentive for energy conservation. Solar water heating works particularly well in tropical climates.

Traditional construction, especially with solar water heating, is usually more energy efficient than the construction style assumed in the IECC, as is shown by an analysis done for Puerto Rico. Using energy-efficient versions of traditional construction saves more energy and is much more cost-effective than pushing those in tropical climates to adopt mainland construction practices. Traditional tropical construction focuses on greatly reducing or eliminating the need for space conditioning by making a living space that is comfortable without space conditioning.

The following are explanations, by item:

1. Air conditioning only a portion of the residence is common in some residences and saves energy compared to air conditioning the whole occupied space.
2. Heating is seldom needed.
3. Consistently warm temperatures and high power costs make solar water heating very attractive. Solar water heating is widely used. Water heating is often 35 percent or more of the residential energy use. Substantial energy savings come from solar water heating.
4. Limiting solar gains and providing ventilation is the energy focus for windows. Window *U*-factor has little impact. Window air tightness is of little value when the important feature of the windows is their ability to be operable and provide ventilation.
5. High-efficiency lighting makes sense with tropical energy prices.
6. This references the “cool roof” provisions. This is similar to an option in Hawaii’s code and the Puerto Rico Energy Center’s analysis. Insulation is less valuable in mild climates where the outside temperature is often comfortable as an inside temperature.
7. Even flat roofs need to drain.
8. Ventilation provided by tropical winds makes occupied spaces more comfortable. At least 14 percent of the floor area of the room is an option for unconditioned residences in Hawaii’s new energy code.
9. When bedroom walls facing two directions are available, ventilation on both walls will be more effective.
10. Interior doors should not block bedroom ventilation. This is similar to Hawaii’s new energy code and recommended by the Puerto Rico Energy Center.
11. Ceiling fans increase comfort without conditioning the air. This is similar to Hawaii’s new energy code and recommended by the Puerto Rico Energy Center.

N1101.14 (R401.3) Certificate (Mandatory). A permanent certificate shall be completed by the builder or registered design professional and posted on a wall in the space where the furnace is located, a utility room or an approved location inside the building. Where located on an electrical panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall list the predominant *R*-values of insulation installed in or on ceiling/roof, walls, foundation (slab, *basement wall*, crawl space wall and/or floor) and ducts outside conditioned spaces; *U*-factors for fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing done on the building. Where there is more than one value for each component, the certificate shall list the value covering the largest area. The certificate shall list the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace, or baseboard electric heater is installed in the residence, the certificate shall list “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency shall not be *listed* for gas-fired unvented room heaters, electric furnaces or electric baseboard heaters.

❖ This section is intended to increase the consumer’s awareness of the energy-efficiency ratings for the various building elements in his or her home. The builder or registered design professional has to complete the certificate and place it on or inside the electrical panel (see Commentary Figure N1101.14). The permanent certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels.

The certificate must disclose the building’s *R*-values, fenestration *U*-factors and fenestration SHGC, HVAC equipment types and efficiencies. The energy efficiency of a building as a system is a function of many elements considered as separate parts of the whole. It is difficult to have a proper identification and analysis of a building’s energy efficiency once the building is completed because many of the elements may not be readily accessible.

This information is also valuable for existing structures undergoing alterations and additions to help determine the appropriate sizing for the mechanical systems. This is meant to be a simple certificate that is easy to read. The certificate does not contain all the

information required for compliance and cannot be substituted for information on the required construction documents. Instead, the certificate is meant to provide the housing owner, occupant or buyer with a simple-to-understand overview of the home's energy efficiency. Where there is a mixture of insulation and fenestration values, the value applying to the largest area is specified. For example, if most of the wall insulation was R-19, but a limited area bordering the garage was R-13, the certificate would specify R-19 for the walls. (In contrast, plans and overall compliance would need to account for both *R*-values.)

The code specifies the minimum information on the certificate, but does not prohibit additional information being added so long as the required information is clearly visible. For example, a builder might choose to list energy-efficiency features beyond those required by the code.

Figure N1101.14
CERTIFICATE

SECTION N1102 (R402) BUILDING THERMAL ENVELOPE

N1102.1 (R402.1) General (Prescriptive). The *building thermal envelope* shall meet the requirements of Sections N1102.1.1 through N1102.1.5.

Exception: The following low energy buildings, or portions thereof, separated from the remainder of the building by *building thermal envelope* assemblies complying with this section shall be exempt from the *building thermal envelope* provisions of Section N1102.

1. Those with a peak design rate of energy usage less than 3.4 Btu/h · ft² (10.7 W/m²) or 1.0 watt/ft² of floor area for space conditioning purposes.
 2. Those that do not contain *conditioned space*.
- ❖ The provisions of Section N1102 are the detailed requirements of the levels of insulation, the perfor-

mance of openings (fenestrations) and air-leakage and moisture-control provisions that serve to establish the building's energy efficiency. When combined with the "systems" requirements (Section N1103 and the electrical power requirements in Section N1104), these three sections will provide the total package of energy conservation that the code requires.

The term "building thermal envelope" is defined in Section N1101.6 as being "the basement walls, exterior walls, floor, roof and any other building elements that enclose conditioned spaces. This boundary also includes the boundary between conditioned space and exempt or unconditioned space." Therefore, when combined with the definition of "Conditioned space," the code has defined the boundaries of the building that will be regulated by this section. The building thermal envelope is a key term and resounding theme used throughout the energy requirements. It defines what portions of the building structure bound conditioned space and are thereby covered by the insulation and infiltration (air leakage) requirements of the code. The building thermal envelope includes all building components separating conditioned spaces (see commentary, "Conditioned space") from unconditioned spaces or outside ambient conditions and through which heat is transferred. For example, the walls and doors separating an unheated garage (unconditioned space) from a living area (conditioned space) are part of the building envelope. The walls and doors separating an unheated garage from the outdoors are not part of the building thermal envelope. Walls, floors and other building components separating two conditioned spaces are not part of the building envelope. For example, interior partition walls, the common or party walls separating dwelling units in multiple-family buildings and the wall between a new conditioned addition and the existing conditioned space are not considered part of the building envelope.

Unconditioned spaces (areas having no heating or cooling sources) are considered outside the building thermal envelope and are exempt from these requirements (see Section N1101.6). A space is conditioned if it is heated or cooled directly; communicates directly with a conditioned space or where a space is indirectly supplied with heating, cooling or both through uninsulated walls, floors or uninsulated ducts or HVAC piping. Boundaries that define the building envelope include the following:

- Building assemblies separating a conditioned space from outdoor ambient weather conditions.
- Building assemblies separating a conditioned space from the ground under or around that space, such as the ground around the perimeter of a slab or the soil at the exterior of a conditioned basement wall. Note that the code does not specify requirements for insulating basement floors or underneath slab floors (except at the perimeter edges).

- Building assemblies separating a conditioned space from an unconditioned garage, unconditioned sunroom or similar unheated/cooled area.

The code specifies requirements for ceiling, wall, floor, basement wall, slab-edge and crawl space wall components of the building envelope. In some cases, it may be unclear how to classify a particular part of a building. For example, skylight shafts have properties of a wall assembly but are located in the ceiling assembly. In these situations, a determination needs to be made and approved by the code official prior to construction so that the proper level of insulation can be installed to complete the building thermal envelope. Generally, skylight shafts and other items that are vertical or at an angle of greater than 60 degrees (1.1 rad) from the horizontal would typically use the wall insulation value.

The exception exempts certain buildings from the thermal envelope requirements of Section N1102. The obvious one is any building that does not contain a conditioned space. The other type of building is a low-energy building (design rate of energy usage less than 1 watt/ft²). For these spaces, insulation and rated fenestration are not cost effective.

N1102.1.1 (R402.1.1) Vapor retarder. Wall assemblies in the *building thermal envelope* shall comply with the vapor retarder requirements of Section R702.7.

- ❖ The code provides a pointer to the vapor retarder requirements in either Chapter 14 of the IBC or Chapter 7 of the code. Moisture issues are not directly related to energy issues. However, the materials used for the air infiltration barrier are often capable of serving the vapor barrier requirements. Therefore, this pointer is installed in the code to clarify that the vapor retarder requirements are elsewhere.

N1102.1.2 (R402.1.2) Insulation and fenestration criteria. The *building thermal envelope* shall meet the requirements of Table N1102.1.2 based on the climate zone specified in Section N1101.7.

- ❖ This section serves as the basis for the code's general insulation and fenestration requirements. Therefore, this is the first place to determine what the requirements for the building thermal envelope will be. There are specific requirements for certain assemblies and locations that are addressed in Sections N1102.2 and N1102.3. This section begins by establishing the requirements for the building thermal envelope by requiring compliance with the proper component insulation and fenestration requirements of Table N1102.1.2. However, once that general requirement is established, Sections N1102.1.3, N1102.1.4 and N1102.1.5 will provide three possible means of showing that the building thermal envelope will comply. Any of the three methods may be used at the discretion of the designer. The three options and their advantages are discussed in the commentary with the subsections. In general, the later subsections will provide the designer with more options and flexibility, but they are

also more complex than using Table N1102.1.2 on an individual component basis.

Table N1102.1.2 lists the minimum *R*-value and maximum *U*-factor and SHGC requirements for different portions of the building thermal envelope, including basement and exterior walls, floor, ceiling and any other building elements that enclose conditioned space. Using the table begins with determining the climate zone for the proposed location from Table N1101.7 or Figure N1101.7. Once the climate zone has been determined, each of the *R*-value, *U*-factor or SHGC requirements must be met for the applicable component (e.g., ceilings, walls, floors, etc.).

Maximum fenestration *U*-factor is the first column in Table N1102.1.2 that must be complied with (see definition for "Fenestration" in Chapter 2). Except as modified or exempted by Section N1102.3, each fenestration product in the proposed building must not exceed the maximum *U*-factor requirement presented in the table for a particular climate zone. For example, a single-family residence located in Climate Zone 5 would require installation of glazed fenestration products with a maximum *U*-factor of 0.32. This would include all glazing in the walls of the building thermal envelope (e.g., vertical windows) and skylights in the roof would be limited to a maximum *U*-factor of 0.55. The proposed glazing *U*-factor should be called out in the building plans either on the floor plan or within a window schedule. This will provide the necessary information to the field inspector, who will then need to verify that what is on the plans is installed in the field.

Fenestration products that do not have labels on them must use the default *U*-factors contained in Table N1101.10.3(1) or N1101.10.3(3) (see commentary, Section N1101.10.3). Note that the lowest default *U*-factor included in the table for glazed fenestration is listed at 0.55 for a "nonmetal or metal-clad double-pane window." This *U*-factor will not meet the requirements of the code in Climate Zones 2 and higher.

TABLE N1102.1.2. See page 11-40.

- ❖ Table N1102.1.2 serves as the basis for establishing the building thermal envelope requirements based on the text of Section N1102.1.2 and sets the performance level for each of the individual components listed. See the commentary to Sections N1102.1.2, N1102.2 and N1102.3 for additional discussion related to the components in the table. The simplest compliance approach is to meet these requirements directly. Note that the requirements do not change based on the area of the components of the residence. These same requirements apply to changes in existing buildings; for example, additions.

A few specifics of Table N1102.1.2 may benefit from clarification.

When applying the fenestration requirements of this table, it is important to remember the definition of "Fenestration" and that it does include items such as doors, glass blocks and other items as well as windows. Therefore, any door located in the building thermal

envelope would still be subject to these limitations. Although vertical fenestration (vertical windows and doors) and skylights have a separate column for *U*-factor, the SHGC applies to both. This is reinforced by the provisions of Note b.

The ceiling *R*-value requirements are precalculated for insulation only and already assume a credible *R*-value for other building materials such as air films, interior sheathing and exterior sheathing. The only *R*-value for ceiling insulation that may be used to meet the requirements is that installed between the conditioned space and the vented airspace in the roof/ceiling assembly. This is typically not an issue because most insulation is installed directly on top of the gypsum board ceiling and the ceiling location represents the building thermal envelope. Insulation installed in the ceiling must meet or exceed the required insulation level. The “conditioned attic” requirements of the code may be viewed as an acceptable alternative if approved by the code official. These minimum ceiling *R*-values would still be applicable where the provisions of Section R806.4 of the code were used to create a conditioned attic assembly. In those cases, the location of the insulation and air barrier (building thermal envelope) are simply located at the roof instead of at the ceiling line. See the commentary to Sections N1102.2.1 and N1102.2.2 for additional information regarding ceiling insulation requirements.

The *R*-values presented under the “Walls” column represent the sum of the insulation materials installed

between the framing cavity and, if used, the insulating sheathing. See Section N1102.1.2 regarding how to compute the *R*-value. Insulating sheathing must have an *R*-value of at least R-2 to be considered. The R-2 limitation comes from the definition of “Insulating sheathing.” The *R*-value of noninsulative interior finishes, such as sheet rock, or exterior coverings like wood structural panel siding is not considered when determining whether the proposed wall assembly meets the requirements. For example, in Commentary Figure N1102.1.2, the *R*-value of the cavity insulation installed between framing (R-13) is added to the insulating sheathing installed on the outside of the studs (R-6) resulting in an R-19 wall. The R-19 total insulation value can then be compared to the *R*-value requirement for the specific climate zone in Table N1102.1.2 to determine compliance.

The insulation *R*-value requirement for exterior walls assumes wood framing. Walls framed using steel studs or constructed of materials such as a concrete masonry unit (CMU) are addressed in Sections N1102.2.5 and N1102.2.6. Whenever a residence has more than one type of wall (frame or mass) or more than one type of below-grade wall (conditioned basement or crawl space), the requirement for each component is taken from the appropriate column in Table N1102.1.2.

Mass walls are defined and have additional requirements in Section N1102.2.5. Mass walls are intended to be above-grade walls and do not include basement

TABLE N1102.1.2 (R402.1.2)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT^a

CLIMATE ZONE	FENESTRATION <i>U</i> -FACTOR ^b	SKYLIGHT ^b <i>U</i> -FACTOR	GLAZED FENESTRATION SHGC ^{b, e}	CEILING <i>R</i> -VALUE	WOOD FRAME WALL <i>R</i> -VALUE	MASS WALL <i>R</i> -VALUE ⁱ	FLOOR <i>R</i> -VALUE	BASEMENT ^c WALL <i>R</i> -VALUE	SLAB ^d <i>R</i> -VALUE & DEPTH	CRAWL SPACE ^c WALL <i>R</i> -VALUE
1	NR	0.75	0.25	30	13	3/4	13	0	0	0
2	0.40	0.65	0.25	38	13	4/6	13	0	0	0
3	0.35	0.55	0.25	38	20 or 13 + 5 ^h	8/13	19	5/13 ^f	0	5/13
4 except Marine	0.35	0.55	0.40	49	20 or 13 + 5 ^h	8/13	19	10/13	10, 2 ft	10/13
5 and Marine 4	0.32	0.55	NR	49	20 or 13 + 5 ^h	13/17	30 ^g	15/19	10, 2 ft	15/19
6	0.32	0.55	NR	49	20 + 5 or 13 + 10 ^h	15/20	30 ^g	15/19	10, 4 ft	15/19
7 and 8	0.32	0.55	NR	49	20 + 5 or 13 + 10 ^h	19/21	38 ^g	15/19	10, 4 ft	15/19

For SI: 1 foot = 304.8 mm.

- R*-values are minimums. *U*-factors and SHGC are maximums. When insulation is installed in a cavity which is less than the label or design thickness of the insulation, the installed *R*-value of the insulation shall not be less than the *R*-value specified in the table.
- The fenestration *U*-factor column excludes skylights. The SHGC column applies to all glazed fenestration.
Exception: Skylights may be excluded from glazed fenestration SHGC requirements in Climate Zones 1 through 3 where the SHGC for such skylights does not exceed 0.30.
- “15/19” means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. “15/19” shall be permitted to be met with R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home. “10/13” means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation at the interior of the basement wall.
- R-5 shall be added to the required slab edge *R*-values for heated slabs. Insulation depth shall be the depth of the footing or 2 feet, whichever is less in Zones 1 through 3 for heated slabs.
- There are no SHGC requirements in the Marine Zone.
- Basement wall insulation is not required in warm-humid locations as defined by Figure N1101.10 and Table N1101.10.
- Or insulation sufficient to fill the framing cavity, R-19 minimum.
- The first value is cavity insulation, the second value is continuous insulation, so “13+5” means R-13 cavity insulation plus R-5 continuous insulation.
- The second *R*-value applies when more than half the insulation is on the interior of the mass wall.

walls, which have a separate entry in the table.

Note a reminds the code user which level of performance is required. Therefore, when dealing with R -values, a higher number would be better. When dealing with U -factors, the lower the number, the better the performance.

In accordance with Note c, for basement walls and crawl space walls, the two numbers separated by a “/” represent the values for continuous and cavity insulation; either will meet the code’s requirements. For example, in Climate Zone 6, the wall can either be covered with continuous insulation to a minimum level of R-15 or, if some type of framing is used (such as a wood-frame wall used to finish out a basement), R-19 insulation must be installed within the cavity. This higher level of cavity insulation adjusts for the bridging or reduction in energy efficiency that the framing elements would create.

In accordance with Note d, heated slabs require R-5 insulation in Climate Zones 1, 2 and 3 and R-15 slab edge insulation in Climate Zones 4 and above. This R-15 insulation is the result of R-5 being “added” to the R-10 insulation level specified in the table for Climate Zones 4 through 8.

In accordance with Note g, where R-30 under-floor insulation is required, less insulation may be used if the framing cavity is filled, down to a minimum of R-19. This recognizes that extending the framing solely to hold more insulation can cost more than it is worth.

N1102.1.3 (R402.1.3) R -value computation. Insulation material used in layers, such as framing cavity insulation, or

continuous insulation shall be summed to compute the corresponding component R -value. The manufacturer’s settled R -value shall be used for blown insulation. Computed R -values shall not include an R -value for other building materials or air films. Where insulated siding is used for the purpose of complying with the continuous insulation requirements of Table N1102.1.2, the manufacturer’s labeled R -value for insulated siding shall be reduced by R-0.6.

❖ This section indicates how the R -value in Table N1102.1.2 is to be determined. Table N1102.1.2 specifies the required R -values for the insulation products, the nominal R -value. This is the R -value of the insulation products only. Although other products and features such as finish materials, air films and airspaces may contribute to overall energy efficiency, when determining the R -value in the code, these additional items are not considered and do not contribute to the nominal R -value. For example, if a wall had R-13 cavity insulation, gypsum board with an R -value of almost R-1 and exterior siding that has an R -value of R-1, the overall wall R -value is simply R-13 because the gypsum board and the exterior siding do not contribute to the R -value for purposes of determining code compliance. Where there is more than one layer of insulation, the R -values for the layers are summed. For example, a wall with R-13 batts within the framing cavity and R-4 insulated sheathing would be treated as an R-17 wall ($13 + 4 = 17$). It is only insulation materials that may be summed to determine the component’s R -value.

N1102.1.4 (R402.1.4) U -factor alternative. An assembly with a U -factor equal to or less than that specified in Table N1102.1.4 shall be permitted as an alternative to the R -value in Table N1102.1.2.

❖ For residences built with common insulation products, the most direct method of compliance is often the R -values in Table N1102.1.2. As an alternative, compliance can be demonstrated by calculating the U -factor for a component. Table N1102.1.4 gives U -factors that are deemed to be equivalent to the R -values in the prescriptive tables. Unlike the R -values in Table N1102.1.2, which consider only the insulation, U -factors consider all the parts of the construction. U -factors for a wall might include exterior siding, gypsum board and air films, all of which would be excluded from the R -value computation by Section N1102.1.2; for example, whether wall framing is 16 or 24 inches (406 or 610 mm) on center matters in computing the U -factor. Whether framing is metal or wood can also have a significant impact on U -factor.

U -factors are well suited to several applications. Construction types that limit the amount of framing or include thermal breaks as part of their design may benefit from U -factor calculations. Components with complex or nonuniform geometries can use testing to establish U -factors. Compliance with the “total UA alternative” or tradeoff approach in Section N1102.1.4 requires the use of the U -factor tables.

Example of U -factor calculation in Table N1102.1.4:

WALL COMPONENT	CAVITY	STUDS, PLATES	HEADERS
	R-value	R-value	R-value
Outside air film	0.25	0.25	0.25
Plywood siding	0.59	0.59	0.59
Continuous insulation	5	5	5
Plywood sheathing	0.83	0.83	0.83
Wood studs	—	4.38	4.38
Cavity insulation	13	—	—
1/2" Gypsum board	0.45	0.45	0.45
Inside air film	0.68	0.68	0.68
Sum of thermal resistance	20.8	12.18	12.18

The above table includes the R -values for the cavity and framing (studs, plates and headers). The U -factor is $1/R$ -value. To calculate the U -factor for the combination of the cavity and framing at 16 inches on-center spacing, calculate the U -factor based on the weighting factors of 75-percent cavity, 21-percent studs and plates, and 4-percent headers (78-percent cavity, 18-percent studs and plates and 4-percent headers for 24 inch on-center spacing). An assembly with a U -factor equal to or less than that calculated in this table must be permitted as an alternative to an assembly in Table N1102.1.2.

The U -factor for the above assembly may be calculated as shown below:

$$U = \frac{0.75}{20.8} + \frac{0.21}{12.18} + \frac{0.04}{12.18} = 0.057$$

Example of U -factor alternative:

WALL COMPONENT	CAVITY	STUDS, PLATES	HEADERS
	R-value	R-value	R-value
Outside air film	0.25	0.25	0.25
Plywood siding	0.59	0.59	0.59
Continuous insulation	13.1	13.1	31.1
Plywood sheathing	0.83	0.83	0.83
Wood studs	—	4.38	4.38
Cavity insulation	0.91	—	—
1/2" Gypsum board	0.45	0.45	0.45
Inside air film	0.68	0.68	0.68
Sum of thermal resistance	16.81	20.28	20.28

In the above assembly, the R-13 cavity insulation is removed and a value of 0.91 is assumed for the air-space in the stud cavity. The continuous insulation is increased to 13.1. The framing spacing is increased to 24 inches (610 mm) on center.

The U -factor for the above assembly may be calculated as shown below:

$$U = \frac{0.78}{16.81} + \frac{0.18}{20.28} + \frac{0.04}{20.28} = 0.057$$

The U -factor from the above assembly is equal to or less than that specified in Table N1102.1.4.

It should be noted that the U -factor alternative could be used for all or part of a wall. Thus, the prescriptive R -values in Section N1102.1.2 can be applied to one segment of the wall, and the U -factors in this section can be used to determine the construction of another segment of the wall. One possible combination would be to apply the prescriptive requirements of Table N1102.1.2 for a portion of the exterior wall thermal envelope with structural sheathing and the U -factor alternative (see Table N1102.1.4) for the portion of the exterior wall thermal envelope that does not have structural sheathing. Note h of Table N1102.1.2 could be applied to 40 percent of the wall when structural sheathing is present, allowing a reduction in the R -value of R-3 for this segment.

When approved by the code official based on equivalency and intent of the code in accordance with Section R104.11, alternative methods of construction, materials and insulation systems also may be used as an alternative to the prescriptive R -values of Table N1102.1.2. For example, designers may substitute greater stud spacing, insulated plates and insulated headers in walls as an alternative to the prescribed cavity or continuous insulation.

TABLE N1102.1.4. See page 11-44.

❖ This table provides the equivalent U -factors that may be used under Sections N1102.1.3 and N1102.1.4. See the commentary to Section N1102.1.3 for discussion related to this table.

N1102.1.5 (R402.1.5) Total UA alternative. If the total *building thermal envelope* UA (sum of U -factor times assembly area) is less than or equal to the total UA resulting from using the U -factors in Table N1102.1.4 (multiplied by the same assembly area as in the proposed building), the building shall be considered in compliance with Table N1102.1.2. The UA calculation shall be done using a method consistent with the ASHRAE *Handbook of Fundamentals* and shall include the thermal bridging effects of framing materials. The SHGC requirements shall be met in addition to UA compliance.

❖ This alternative allows one portion of the building to make up for another. It recognizes that there may be reasons for less insulation in some parts of the building, which can be compensated for by more insulation in other parts of the residence. The key concept is that the overall building thermal flow (UA) meets the code. This concept could allow a ceiling to make up for a wall or vice versa. As a practical matter, whether a building will comply with this method can sometimes be esti-

mated quickly. A large area that is significantly over the required R -value will make up for a small area only mildly under the required R -value. Likewise, it will sometimes be obvious that a small area that mildly exceeds the requirement will not make up for a large area well below the requirement.

This section will allow for such tradeoffs but only if the total UA for the proposed building is below the aggregate UA calculation using the required values in Table N1102.1.4 and the same assembly areas as the actual building. In other words, under this alternative, components with varying insulating values can be “traded off” with one another as the builder sees fit just as long as the total UA calculation for the entire building complies with a calculation for that same house that uses the same assembly areas and the maximum UA values from Table N1102.1.4.

The UA is the sum of the component U -factors times each assembly area. The maximum allowable UA is the UA for a proposed design as if it was insulated to meet exactly the individual component U -factor requirements. This tradeoff provision allows the type of insulation and installed fenestration to vary, which permits significant design flexibility. The desire for tradeoffs in construction is common because of unexpected problems or design conflicts, and a UA tradeoff analysis is usually calculated with the assistance of electronic compliance tools, depending on the jurisdiction. (For example, the DOE has online compliance software for the code called REScheck, which can be downloaded from the DOE website at www.energy-codes.gov. REScheck, if approved by the jurisdiction as compliant with the code, can be used to perform a UA tradeoff analysis.)

This section explicitly prohibits the tradeoff of SHGC requirements, requiring that the “SHGC requirements be met in addition to UA compliance.” As a result, glazed fenestration must comply with the SHGC values shown in Table N1102.1.2 even if the U -factor is modified by trading off against some other component.

The requirements of this section establish specific additional requirements for any tradeoff. First, the baseline house must have the same assembly areas as the proposed house (e.g., the same area of each assembly—fenestration, skylights, ceiling, wall and floor). Second, the calculation should be done consistent with the *ASHRAE Handbook of Fundamentals*. Third, the calculation must include the thermal bridging effects of framing materials. To meet these requirements, the calculation method must either specifically combine the actual framing and insulation paths (with their specific areas and U -values) or use framing factors such as those found in the *ASHRAE Handbook of Fundamentals* for all framed building components (Note: this is not necessary for fenestration, which is a whole product value). To illustrate this approach, assume 1,000 square feet (93 m²) of wall, of which 250 square feet (23 m²) is framing (assuming 0.81 U -factor) and 750 square feet (70 m²) is cavity (R-13 insulation).

The baseline (general code requirement) and proposed opaque wall UAs are computed as follows:

- Baseline Opaque Wall for Climate Zone 2 = $(0.082 \times 1000) = 82$. (The 0.082 value used in the calculation is taken from Table N1102.1.4.)
- Proposed Opaque Wall UA = $(0.81 \times 250) + (0.077 \times 750) = 78$. (The 0.81 value used in the calculation was given above as an assumption. The 0.077 value is determined based on the R -value of 13; that is, $1 \div 13 = 0.077$.)

Similar computations would be done for each assembly (such as fenestration or ceilings) and the baseline and proposed values then totaled and compared. If the baseline is greater than or equal to the proposed values, the house satisfies the UA alternative. The home will still need to meet all other prescriptive requirements, including the fenestration SHGC in Table N1102.1.2, the air leakage requirements of Section N1102.4 and the moisture-control requirements of Section N1102.5.

It also should be noted that this alternative is limited to UA tradeoffs for the building’s thermal envelope. The 2015 code does not authorize or establish any basis for HVAC tradeoffs associated with its UA tradeoff option. HVAC performance is simply not addressed under the code prescriptive or UA tradeoff paths. It is addressed only in Section N1105 under the “Simulated Performance Alternative.” As a result, the code elected to limit these simplified tradeoffs to UA envelope tradeoffs and defer any more complex tradeoffs exclusively to the “Simulated Performance Alternative” in Section N1105. If the builder wishes to factor in HVAC performance for tradeoffs, Section N1105 can be used and is permitted based on Section N1101.2, accepting Section N1105 as a compliance option.

Documentation acceptable to the local building department generally must be submitted to the appropriate authority to certify acceptable component UA tradeoffs.

UA alternative example (for calculating standard and proposed designs):

Building areas and U -factors (for single-family, Zone 5 from Table N1102.1.4)

Standard (Code) Design	Proposed Design
Exterior Wall 1050 ft ² $U_w = -0.057$	Exterior Wall 1050 ft ² $U = 0.0451$
Glazed doors and windows 192 ft ² $U_g = 0.32$	Glazed doors and windows 192 ft ² $U = 0.40$
Opaque exterior door 38 ft ² $U_g = 0.32$	Opaque exterior door 38 ft ² $U = 0.35$

ENERGY EFFICIENCY

Roof 1500 ft ² $U_r = 0.026$	Roof 1500 ft ² $U_r = 0.026$
Floor (slab) 1500 ft ² $U = 0.033$	Floor (slab) 1500 ft ² $U_{fe} = 0.033$
$UA_{Standard} = (0.057 \times 1050) + (0.32 \times 192) + (0.32 \times 38) + (0.026 \times 1500) + (0.033 \times 1500) = 222$	
$UA_{Proposed} = (0.0451 \times 1050) + (0.40 \times 192) + (0.35 \times 38) + (0.026 \times 1500) + (0.033 \times 1500) = 225$	

UA Proposed > UA Standard; therefore design fails to meet code requirements.

N1102.2 (R402.2) Specific insulation requirements (Prescriptive). In addition to the requirements of Section N1102.1, insulation shall meet the specific requirements of Sections N1102.2.1 through N1102.2.13.

❖ This section contains specific requirements to be followed for the individual items listed within the subsections. Although Section N1102.1 and Tables N1102.1.2 and N1102.1.4 provide the general basis for complying with the energy requirements of this chapter, Section N1102.2 provides additional details regarding the actual construction of the assemblies or modifications that may affect the general requirements. Relying on the principle that specific requirements apply over general requirements will help ensure that these specific provisions are properly followed.

N1102.2.1 (R402.2.1) Ceilings with attic spaces. Where Section R1102.1.2 would require R-38 insulation in the ceiling, installing R-30 over 100 percent of the ceiling area requiring insulation shall be deemed to satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves. Similarly, where Section R1102.1.2 would require R-49 insulation in the ceiling, installing R-38 over 100 percent of the ceiling area requiring insulation shall be deemed to satisfy the requirement for R-49 insulation wherever the full height of uncompressed R-38 insulation extends over the wall top plate

at the eaves. This reduction shall not apply to the *U*-factor alternative approach in Section R1102.1.4 and the total *UA* alternative in Section R1102.1.5.

❖ The required ceiling *R*-value found in the code is based on the assumption that standard truss or rafter construction was being used. When raised-heel trusses or other methods of framing that would not permit the ceiling insulation to be installed to its full depth over the entire area are used, then the code would permit the installation of a lower *R*-value insulation. The general assumption is that ceiling insulation will be compressed at the edges and, if the special construction techniques are used, that the level of insulation required can be reduced.

Insulation installed in a typical roof assembly will be full height throughout the center portions of the assembly and will taper (be compressed) at the edges as the roof nears the top plate of the exterior wall system [see Commentary Figure N1102.2.1(1)]. The slope of the roof causes this tapering, which is further amplified by any baffling installed to direct ventilation air from the eave vents up and over the insulation. Because of this tapering, the installed *R*-value near the plate lines will be less than the rated *R*-value for the insulation. This is caused by compression (compressed insulation has a lower *R*-value than insulation installed to its full thickness) and the limited space between the floor of the attic and the roof sheathing near the exterior plate line. Thus, a typical installation, on average, will have a lower *R*-value than that of the rated insulation. Because of this, the code will allow installation of a lower insulation value if it can be installed full thickness, to its rated *R*-value, over the plate line of the exterior wall. This allowance recognizes that a partial thermal “bypass” has been made more efficient by using insulation with the full *R*-value at the eaves. The full insulation *R*-value is sometimes achieved by what is termed an “energy truss” or “advanced framing.” This can be achieved by using an oversized truss or raised-heel truss as shown in Commentary Figure N1102.2.1(2). Another way to achieve the full *R*-value would be by use of insulation with a higher *R*-value per inch at the eaves. The use of the options permitted by

**TABLE N1102.1.4 (R402.1.4)
EQUIVALENT *U*-FACTORS^a**

CLIMATE ZONE	FENESTRATION <i>U</i> -FACTOR	SKYLIGHT <i>U</i> -FACTOR	CEILING <i>U</i> -FACTOR	FRAME WALL <i>U</i> -FACTOR	MASS WALL <i>U</i> -FACTOR ^b	FLOOR <i>U</i> -FACTOR	BASEMENT WALL <i>U</i> -FACTOR	CRAWL SPACE WALL <i>U</i> -FACTOR
1	0.50	0.75	0.035	0.084	0.197	0.064	0.360	0.477
2	0.40	0.65	0.030	0.084	0.165	0.064	0.360	0.477
3	0.35	0.55	0.030	0.060	0.098	0.047	0.091 ^c	0.136

5 and Marine 4	0.32	0.55	0.026	0.060	0.082	0.033	0.050	0.055
6	0.32	0.55	0.026	0.045	0.060	0.033	0.050	0.055
7 and 8	0.32	0.55	0.026	0.045	0.057	0.028	0.050	0.055

- a. Nonfenestration *U*-factors shall be obtained from measurement, calculation or an approved source.
- b. When more than half the insulation is on the interior, the mass wall *U*-factors shall be a maximum of 0.17 in Zone 1, 0.14 in Zone 2, 0.12 in Zone 3, 0.087 in Zone 4 except Marine, 0.065 in Zone 5 and Marine 4, and 0.057 in Zones 6 through 8.
- c. Basement wall *U*-factor of 0.360 in warm-humid locations as defined by Figure N1101.10 (R301.1) and Table N1101.10 (R301.1).

this section allows substituting R-30 for R-38 insulation, and R-38 may be substituted for R-49 insulation to meet the requirements of the code. When using the conditioned attic requirements of the code, the same option of using a reduced *R*-value would apply if the insulation was installed directly under the roof deck, rather than on the attic floor (see commentary, Section R806.4). The insulation would be permitted to meet the lesser *R*-value, presuming the full *R*-value was met over the eaves. Of course, this situation would also presume that the attic space beneath the insulation was not vented.

Note that this text applies only to the *R*-value portion of the code; there is no reduction in requirements if the *U*-factor alternative or the total UA alternative is used. In those cases, the reduced thickness must be accounted for in the calculations. In addition, if the res-

idence had more than one separate attic space, it is possible this section could apply to one attic space, but not another.

N1102.2.2 (R402.2.2) Ceilings without attic spaces. Where Section N1102.1.2 would require insulation levels above R-30 and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the minimum required insulation for such roof/ceiling assemblies shall be R-30. This reduction of insulation from the requirements of Section N1102.1.2 shall be limited to 500 square feet (46 m²) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the *U*-factor alternative approach in Section N1102.1.4 and the total UA alternative in Section N1102.1.5.

❖ In situations where the ceiling is installed directly onto the roof rafters and no attic space is created, this sec-

tion will allow a reduced level of ceiling insulation for a limited area. This section addresses the construction of what is typically called “cathedral” or “vaulted” ceilings, which therefore result in that portion of the home not having an attic area above the ceiling. See the definition of “Attic” in Chapter 2 of the code. Based on the use of solid sawn lumber (2 × 8, 2 × 10 or 2 × 12) in conventional construction, as the ceiling *R*-value requirement increases, it may be impossible to install the required ceiling insulation from Table N1102.1.2 within the available cavity depth. In addition, the ventilation requirements of Section R806.3 will further reduce the available space by requiring a minimum space of 1 inch (25 mm) between the insulation and the roof sheathing. Therefore, when the depth of the cavity will not permit the required insulation level, this section permits a reduction to R-30 ceiling insulation instead of the normally required R-38 or R-49 requirement from Table N1102.1.1. This will generally result in reducing the required insulation level instead of having to increase the depth of the framing members. This section in the code recognizes that increases in framing size done only to accommodate higher *R*-values are an expensive way to achieve a limited increase in *R*-value.

It is important to note that this section applies only to areas that have a required insulation level above R-30 (Climate Zones 4 through 8). Further, the reduction is limited to portions of ceiling assemblies that do not exceed 500 square feet (46 m²) or 20 percent of the ceiling area. The intent is that the 500-square-foot (46 m²) or 20-percent limitation be the total aggregate exempted amount of the building’s thermal envelope (ceiling) that can use this reduction. It is not the intent that a home could have multiple areas that were each under the 500-square-foot (46 m²) or 20-percent limit but would aggregate to more than that amount. In situations that cannot meet these limitations [homes in Climate Zones 1 through 3 or homes needing more than 500 square feet (46 m²) of reduced ceiling insulation], the depth of the rafters would have to be increased to meet the table’s required insulation level or other design changes or means of compliance would be necessary. This provision does not apply if the *U*-factor alternative or the total UA alternative is being used. In those cases, the reduced insulation level might be accomplished, but it would be accounted for with additional insulating components in the case of the *U*-factor alternative or with added insulation elsewhere in the case of the total UA alternative.

N1102.2.3 (R402.2.3) Eave baffle. For air-permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. Baffles shall maintain an opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material.

- ❖ For air-permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. This will help prevent wind from degrading the attic insulation performance. Baffles serve to keep vents open,

insulation in place and keep the wind from blowing through the insulation and reducing its effectiveness.

N1102.2.4 (R402.2.4) Access hatches and doors. Access doors from conditioned spaces to unconditioned spaces such as attics and crawl spaces shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access shall be provided to all equipment that prevents damaging or compressing the insulation. A wood-framed or equivalent baffle or retainer is required to be provided when loose-fill insulation is installed, the purpose of which is to prevent the loose-fill insulation from spilling into the living space when the attic access is opened, and to provide a permanent means of maintaining the installed *R*-value of the loose-fill insulation.

Exception: Vertical doors that provide access from conditioned to unconditioned spaces shall be permitted to meet the fenestration requirements of Table R1102.1.2 based on the applicable climate zone specified in Chapter 3.

- ❖ The portion of a ceiling used for an attic access door is a weak part of the building thermal envelope. The purpose of this provision is to ensure that measures are taken to prevent large loss of energy through this opening.

N1102.2.5 (R402.2.5) Mass walls. Mass walls for the purposes of this chapter shall be considered above-grade walls of concrete block, concrete, insulated concrete form (ICF), masonry cavity, brick (other than brick veneer), earth (adobe, compressed earth block, rammed earth) and solid timber/logs, or any other walls having a heat capacity greater than or equal to 6 Btu/ft² × °F (123 kJ/m² × K).

- ❖ The code uses a simple definition for mass walls. Walls made of the specified materials and mass are mass walls. Mass walls may meet the lower mass wall *R*-value (as compared to frame wall values) specified in their respective climate zones because of the energy-conserving characteristics of mass walls. Note that the difference between the wood-frame *R*-value is greatest in southern climates. This recognizes that the thermal “averaging” provided by mass walls is most effective in warmer climates. In the very northern climates where there is almost continual heating during parts of the year, the thermal mass is of limited value. The code simply lists the types of walls that are considered as being “mass” walls. There is no additional limitation or characteristic specified for the walls that would be applicable when using the code.

In general terms, the heat capacity is a measure of how well a material stores heat. The higher the heat capacity, the greater the amount of heat stored in the material. For example, a 6-inch (152 mm) heavyweight concrete wall has a heat capacity of 14 Btu/ft² × °F (620 J/m² × K) compared to a conventional 2 by 4 wood-framed wall with a heat capacity of approximately 3 Btu/ft² × °F (138 J/m² × K). Tables N1102.1.2 and N1102.1.4 are used to determine the insulation or equivalent *U*-factor requirements for mass walls. To use the tables, first consult either Table R301.1 or Figure R301.1 to determine the climate zone of the pro-

posed project. The *R*-value for the assembly is then given for the mass wall in Table N1102.1.2 or the *U*-factor is given in Table N1102.1.4.

When dealing with the mass walls, the insulation location is important. Note i of Table N1102.1.2 indicates that the second *R*-value, which is the higher *R*-value for mass walls in each climate zone, is applicable when more than half of the insulation is on the interior of the mass wall. The first values listed in Table N1102.1.2 are, therefore, based on the installation of the majority of the insulation (“at least 50 percent”) being located on the exterior side of the wall or being integral to the wall. Likewise, Note b of Table N1102.1.4 provides lower maximum *U*-factors for mass walls with more than 50 percent of the insulation on the interior of the wall.

For an example of a wall assembly that has insulation on the exterior of the wall (between the mass wall and the exterior), see Commentary Figure N1102.2.5(1). Concrete masonry units with insulated cores or masonry cavity walls are examples of integral insulation. For mass walls with the insulation installed on the interior (an insulated furred wall located between the conditioned space and the mass wall), see Commentary Figure N1102.2.5(2). As shown, these two figures would be examples of mass walls that meet or exceed the general requirements of this section and Table N1102.1.2 for Climate Zones 1 through 4, except for those in Marine Zone 4.

N1102.2.6 (R402.2.6) Steel-frame ceilings, walls, and floors. Steel-frame ceilings, walls, and floors shall meet the insulation requirements of Table N1102.2.6 or shall meet the *U*-factor requirements of Table N1102.1.4. The calculation of

the *U*-factor for a steel-frame envelope assembly shall use a series-parallel path calculation method.

❖ The insulation requirements of Table N1102.1.2 are based on conventional wood-frame construction methods. Because the code also includes provisions applicable to steel-framing methods, this chapter has been written to include this material. Table N1102.2.6 specifies combinations of cavity and continuous insulation for steel framing that are equivalent to the specified wood-frame component *R*-values in Table N1102.1.2.

Table N1102.1.2 cannot be used directly for steel-frame components. When using Table N1102.2.6, all listed options comply; the code user can choose any option on the list that corresponds to the correct *R*-value in the left-hand column. Steel has a much higher thermal conductivity (ability to transfer heat) than wood. Therefore, steel-frame cavities require a higher *R*-value or include a requirement for insulated sheathing that acts as a thermal break or both.

Instead of using this table, the code user could choose to calculate or measure a *U*-factor for a building component and show compliance based on meeting the *U*-factor requirement in Table N1102.1.4. The code user could use the total UA tradeoff in Section N1102.1.4 or even the performance-based approach in Section N1105 to show compliance based on the overall building, even if the steel-frame wall did not meet the code requirements directly. Other combinations of cavity insulation and continuous insulation not shown in Table N1102.2.6 would also be allowed; however, if a combination from the table is used, no additional calculation is necessary.

TABLE N1102.2.6 (R402.2.6)
STEEL-FRAME CEILING, WALL AND FLOOR INSULATION
(R-VALUE)

WOOD FRAME R-VALUE REQUIREMENT	COLD-FORMED STEEL EQUIVALENT R-VALUE ^a

R-13	R-0 + 9.3 or R-13 + 3.0 or R-15 + 2.4
R-13 + 3	R-0 + 11.2 or R-13 + 4.9 or R-15 + 4.3 or R-19 + 3.5 or R-21 + 3.1
R-20	R-0 + 14.0 or R-13 + 7.7 or R-15 + 7.1 or R-19 + 6.3 or R-21 + 5.9
R-20 + 5	R-13 + 11.5 or R-15 + 10.9 or R-19 + 10.1 or R-21 + 9.7 or R-25 + 9.1
R-21	R-0 + 14.6 or R-13 + 8.3 or R-15 + 7.7 or R-19 + 6.9 or R-21 + 6.5 or R-25 + 5.9
Steel Joist Floor	
R-13	R-19 in 2 × 6, or R-19 + 6 in 2 × 8 or 2 × 10
R-19	R-19 + 6 in 2 × 6, or R-19 + 12 in 2 × 8 or 2 × 10

a. Cavity insulation *R*-value is listed first, followed by continuous insulation *R*-value.

b. Insulation exceeding the height of the framing shall cover the framing.

N1102.2.7 (R402.2.7) Walls with partial structural sheathing. Where Section R1102.1.2 would require continuous insulation on exterior walls and structural sheathing covers 40 percent or less of the gross area of all exterior walls, the continuous insulation *R*-value shall be permitted to be reduced by an amount necessary to result in a consistent total sheathing thickness, but not more than R-3, on areas of the walls covered by structural sheathing. This reduction shall not apply to the *U*-factor alternative approach in Section R1102.1.4 and the total UA alternative in Section R1102.1.5.

❖ The provisions of this section are intended to address a practical situation that occurs when structural sheathing is used over a portion of the outside wall, such as at the corners for horizontal bracing. In those

cases, the thickness of the portion of the wall with structural sheathing could be different than the portion of the wall without sheathing. The code therefore allows a reduction of R-3 in the required insulation of the sheathed portion to facilitate some flexibility in the choice of insulation. This option is only allowed in the application of the prescriptive table, Table N1102.1.2, and not when utilizing the *U*-factor alternative or the UA alternative.

N1102.2.8 (R402.2.8) Floors. Floor framing-cavity insulation shall be installed to maintain permanent contact with the underside of the subfloor decking.

Exception: The floor framing-cavity insulation shall be permitted to be in contact with the topside of sheathing or continuous insulation installed on the bottom side of floor framing where combined with insulation that meets or exceeds the minimum wood frame wall *R*-value in Table 1102.1.2 and that extends from the bottom to the top of all perimeter floor framing members.

❖ Floors that are a part of the building thermal envelope, such as those over a crawl space or an unconditioned garage, are required to meet or exceed the floor *R*-value requirements listed in Table N1102.1.2. The insulation *R*-value requirements range from R-13 in warm climates to R-38 in extremely cold climates. Insulation must be installed between the floor joists and must be well supported with netting, wire, wood strips or another method of support so that the insulation does not droop or fall out of the joist cavities over time. Some floor insulation has a tendency to sag or drop with time. This sag or drop exposes the subfloor directly to the temperature beneath the floor. Sagging also has a tendency to open airflow paths to parts of the floor, producing cold spots and negating the value of the floor insulation in the effected section of the floor. Even small areas that lack insulation or allow air circulation between the floor insulation and the subfloor can have a marked effect on the energy efficiency of the floor. This section specifies that floor insulation must be installed so it will maintain "permanent contact" with the subfloor (meaning over the useful life of the residence).

If a floor of a building extends over outside air, such as over an open carport, the floor is still insulated to the "floor" requirement of Table N1102.1.2 rather than being treated as part of the exterior envelope card meeting the same *R*-value as for ceilings.

The exception provides a specific configuration for insulating a floor. Requiring insulation in floors to be in direct contact with the underside of subfloor decking is one insulating option. Another option is to have an air-space between the floor sheathing and the top of the cavity insulation where this cavity insulation is in direct contact with the topside of sheathing or continuous insulation installed on the underside of the floor framing and is combined with perimeter insulation that meets or exceeds the *R*-value requirements for walls. This second option leads to fewer cold spots yet does not change the heat loss as long as the cavity insula-

tion is in direct contact with a sheathing below it or continuous insulation below it. It also facilitates services to be enclosed within the thermal envelope. An example of this configuration is illustrated in Commentary Figure N1102.2.8.

N1102.2.9 (R402.2.9) Basement walls. Walls associated with conditioned basements shall be insulated from the top of the *basement wall* down to 10 feet (3048 mm) below grade or to the basement floor, whichever is less. Walls associated with unconditioned basements shall meet this requirement unless the floor overhead is insulated in accordance with Sections N1102.1.2 and N1102.2.8.

❖ The walls of conditioned basements must be insulated to meet the requirements of Table N1102.1.2. Each wall of a basement must be considered separately to determine whether it is a basement wall or an exterior wall. It is a basement wall if it has an average below-grade wall area of 50 percent or more. A wall that is less than 50-percent below grade is an exterior wall and must meet the insulation requirements for walls. Most walls associated with basements will be at least 50-percent below grade and, therefore, must meet basement wall requirements.

Walkout basements offer a challenge in determining compliance with the code. A walkout basement [see Commentary Figures N1102.2.9(1) and (2)] may have a back wall that is entirely below grade, a front wall or the walkout portion that is entirely above grade and two sidewalls with a grade line running diagonally. In this case, the back wall must meet the requirements for basement walls, the front wall would need to meet the requirements for walls (either framed wall or mass wall,

as applicable) and the side walls would need to be evaluated to determine whether they were 50 percent or more below grade and, therefore, basement walls.

Basement insulation must extend up to 10 feet (3048 mm) under the ground, or at least as far as the basement wall extends under the ground. Heat flow into the ground occurs all along the buried portion of the wall, as well as along the above-ground portion of the wall. Heat flow below 10 feet (3048 mm) is greatly diminished so the code requires basement insulation only down to 10 feet (3048 mm), or the depth of the basement wall.

The code does not specify whether the insulation is to be placed on the inside or outside of a basement wall. In some localities moisture considerations may suggest the type and location for insulation.

The last part of this section allows insulating unconditioned basement walls as an alternative to insulating the floor above the unconditioned basement. Therefore, it essentially shifts the location of the building thermal envelope from the floor to the basement walls. Although not required, insulating the unconditioned basement walls makes a good deal of sense if a basement is likely to be conditioned at some time after construction.

Because the rim joint between floors is a part of the building envelope, this must be insulated also if the basement is conditioned.

When applying the provisions of this section, it is important to review the definitions for both "Above-grade wall" and "Basement wall" in Section N1101.9. For code users who also deal with commercial buildings, remember that the rule for residential buildings is

Figure N1102.2.8
SLAB INSULATION METHODS

50 percent above or below grade and not the 85-percent minimum below grade with 15-percent maximum above-grade area that is applicable under Section C402.2.2 of the IECC for commercial construction.

N1102.2.10 (R402.2.10) Slab-on-grade floors. Slab-on-grade floors with a floor surface less than 12 inches (305 mm) below grade shall be insulated in accordance with Table N1102.1.2. The insulation shall extend downward from the top of the slab on the outside or inside of the foundation wall.

Insulation located below grade shall be extended the distance provided in Table N1102.1.2 by any combination of vertical insulation, insulation extending under the slab or insulation extending out from the building. Insulation extending away from the building shall be protected by pavement or by not less than 10 inches (254 mm) of soil. The top edge of the insulation installed between the exterior wall and the edge of the interior slab shall be permitted to be cut at a 45-degree (0.79 rad) angle away from the exterior wall. Slab-edge insu-

lation is not required in jurisdictions designated by the *building official* as having a very heavy termite infestation.

- ❖ The perimeter edges of slab-on-grade floors must be insulated to the R -values listed in Table N1102.1.2. These requirements apply only to slabs 12 inches (305 mm) or less below grade. The listed R -value requirements in the table are for unheated slabs. A heated slab must add another R -5 to the required insulation levels based on Note d of Table N1102.1.2.

The insulation must extend downward from the top of the slab or downward to the bottom of the slab and then horizontally in either direction until the distance listed in Table N1102.1.2 is reached. See Commentary Figure N1102.2.8 for examples on how the distance is measured. Most of the heat loss from a slab will occur in the edge that is exposed directly to the outside air. The insulation must be installed to the top of the slab edge to prevent this heat loss. Slab insulation may be installed on the exterior of the slab edge or between the interior wall and the edge of the interior slab as in a nonmonolithic slab. In this type of installation, the exposed insulation could cause problems with tack strips for carpeting. Therefore, the insulation is allowed to be cut at a 45-degree angle away from the exterior of the wall. If a monolithic slab and foundation is being used, the required insulation would obviously need to be installed on the exterior and then either extended to the required depth or turned out to the exterior and be protected by either some type of pavement or a minimum of 10 inches (254 mm) of soil. Insulation that is exposed on or near the surface is easily damaged. This protection method ensures that the insulation remains in place and provides the intended energy savings.

In areas with very heavy termite infestation, slab perimeter insulation need not be installed in accordance with Table N1102.1.2. These areas are identified in Figure R301.2(3) or the jurisdiction may base its

determination on the local history and situation. It is important to understand that this exemption from the slab insulation provisions is for any area with heavy termite infestations. The fact that this is an exemption and does not contain any requirement for a compensating increase of insulation at other locations is important.

The requirements of Section N1102.1.4 could still be used in areas that do not have a heavy termite infestation to eliminate the slab edge insulation if desired. Typically, slab perimeter insulation can be traded off entirely in these climates by increasing the ceiling or wall insulation R -values or by using glazing with a lower U -factor.

N1102.2.11 (R402.2.11) Crawl space walls. As an alternative to insulating floors over crawl spaces, crawl space walls shall be permitted to be insulated when the crawl space is not vented to the outside. Crawl space wall insulation shall be permanently fastened to the wall and extend downward from the floor to the finished grade level and then vertically and/or horizontally for at least an additional 24 inches (610 mm). Exposed earth in unvented crawl space foundations shall be covered with a continuous Class I vapor retarder in accordance with this code. All joints of the vapor retarder shall overlap by 6 inches (153 mm) and be sealed or taped. The edges of the vapor retarder shall extend not less than 6 inches (153 mm) up the stem wall and shall be attached to the stem wall.

- ❖ The code allows for the insulation of crawl space walls in crawl spaces instead of insulating the floor between the crawl space and the conditioned space. In essence, the code user is defining the thermal boundary as either the floor or the crawl space wall. Because the ground under the crawl space is tempered by the thermal mass of the dirt, the temperature of the crawl space is usually more favorable than the outside temperature. This is a popular practice for freeze protection of plumbing pipes in colder climates because it is common to install plumbing in the crawl space. The heat

For SI: 1 inch = 25.4 mm.

Figure N1102.2.10
CRAWL SPACE WALL INSULATION

transferred through the uninsulated floor to the crawl space helps keep the crawl space temperature above freezing when the outside air temperature drops below freezing. To comply with this provision, the crawl space must be mechanically vented or supplied with conditioned air from the living space. Section 1203.3 of the IBC and its subsections address this crawl space ventilation requirement.

The code also requires installation of insulation from the sill plate downward to the exterior finished grade level and then an additional 24 inches (610 mm) either vertically or horizontally (see Commentary Figure N1102.2.10). Under this insulation scenario, the rim joist is considered part of the conditioned envelope and must be insulated to the same level as the exterior wall. The insulation must be attached securely to the crawl space wall so that it does not fall off. The code also requires installing a continuous Class I vapor retarder on the floor of the crawl space to prevent ground-water vapor from entering the crawl space. A Class I vapor retarder is defined in the IBC as a material with a permeance of 0.1 perm or less (see the definition of "Vapor retarder class" in the IBC). The vapor retarder is to be installed with all joints overlapped and sealed or taped to provide continuity. Also, the vapor retarder must extend up the crawl space wall and be secured to the wall with an appropriate attachment, such as either an approved mastic or a treated wood nailer.

N1102.2.12 (R402.2.12) Masonry veneer. Insulation shall not be required on the horizontal portion of the foundation that supports a masonry veneer.

❖ For exterior foundation insulation, the horizontal portion of the foundation that supports a masonry veneer need not be insulated. For slab-edge insulation installed on the exterior of the slab, the code allows the insulation to start at the bottom of the masonry veneer and extend downward. This is essentially a matter of practicality and accommodates the construction of a "brick ledge" without the need for insulating the foundation at the point where the masonry would bear on it.

N1102.2.13 (R402.2.13) Sunroom insulation. *Sunrooms* enclosing conditioned spaces shall meet the insulation requirements of this code.

Exception: For *sunrooms* with *thermal isolation*, and enclosing conditioned spaces, the following exceptions to the insulation requirements of this code shall apply:

1. The minimum ceiling insulation *R*-values shall be R-19 in Zones 1 through 4 and R-24 in Zones 5 through 8.
 2. The minimum wall *R*-value shall be R-13 in all *climate zones*. Walls separating a *sunroom* with a *thermal isolation* from *conditioned space* shall meet the *building thermal envelope* requirements of this code.
- ❖ With the amount of glass in sunrooms, it is imperative the insulation requirements of the code be adhered to ensure minimal current requirements. The exceptions also tighten the requirements per zone to minimize energy usage.

N1102.3 (R402.3) Fenestration (Prescriptive). In addition to the requirements of Section N1102, fenestration shall comply with Sections N1102.3.1 through N1102.3.5.

❖ This section contains specific requirements that affect the requirements for the individual items listed within the subsections. Although Section N1102.1 and Tables N1102.1.1 and N1102.1.5 provide the general basis for complying with the energy requirements of this chapter, Section N1102.3 provides additional details regarding the application of the provisions or modifications that may affect the general fenestration requirements. Relying on the general code policy that specific requirements apply over general requirements will help ensure that these specific provisions are properly applied.

The term "fenestration" in this section refers to opaque doors and the light-transmitting areas of a residential building's wall, floor or roof, generally window, skylight and nonopaque door products (see the definition of "Fenestration" in Chapter 2). Prior to the 2006 edition, the residential energy provisions of the code applied only to buildings with 15 percent or less of glazing areas (fenestration). The code's prescriptive requirements varied depending on the type of residential occupancy, but did include limitations on the amount of fenestration (maximum of 25 percent for one- and two-family dwellings and 30 percent for R-2, R-4 or townhouses). These earlier versions of the code established whole building performance requirements, with fenestration performance requirements as a derivative value dependent on window area, overall envelope area and the performance of other assemblies (e.g., walls, ceilings, floors). The code establishes specific simplified prescriptive requirements (without area considerations) for fenestration products in Table N1102.1.2—specifically, fenestration *U*-factors, skylight *U*-factors and glazed fenestration SHGCs. The elimination of these fenestration area limitations helped to greatly simplify the application of the code's envelope requirements.

The fenestration requirements of the code are critical to the overall energy efficiency of the residence. First, unlike opaque assemblies, glazed fenestration can transmit a substantial amount of heat through the glazing into the living space in both the summer and winter, resulting in a unique concern about solar heat gain (and, as a result, necessitating SHGC requirements). Second, the insulating value (*U*-factor) of typical fenestration is much higher than that of a typical wall. For example, a good low emissivity (low-E), insulated glass wood or vinyl fenestration product will have less than one-fourth the insulating value of an equivalent area of R-13 insulated opaque wall. These issues have an effect not only on energy use, but overall occupant comfort, condensation and other issues.

In accordance with Section N1101.10.3, the *U*-factor and SHGC for each fenestration product must be obtained from a label attached to the product certifying that the values were determined in accordance with

NFRC procedures by an accredited, independent lab or from a limited default table.

N1102.3.1 (R402.3.1) U-factor. An area-weighted average of fenestration products shall be permitted to satisfy the U-factor requirements.

- ❖ Section N1102.3.1 permits using the calculated area-weighted average U-factor of all fenestration products in the building to satisfy the fenestration U-factor requirements set by Table N1102.1.2 or N1102.1.4. As a result, if all fenestration products (window, door or skylight) do not meet the specific value, the user can still achieve compliance if the weighted average of all products is equal to or less than the specified value.

This option permits the use of some windows that have values lower than the prescriptive general requirement, as long as these poorly performing windows are offset by windows with values better than the requirement.

When applying this area-weighted option, it is important to remember that the term “fenestration” includes windows, skylights, doors with glazing and opaque doors, all of which would be included in the average calculation.

Using the U-factor requirement of 0.35 for Climate Zone 6 as an illustration, this section provides two options for compliance. The simplest option is to ensure that all windows and doors have labeled NFRC values of 0.35 or less. This approach is also more likely to ensure adequate performance and comfort throughout the home. Alternatively, a weighted average may be taken of the values from all windows and doors to see if the weighted average is less than or equal to 0.35.

As a simple example, assume 100 square feet (9.3 m²) of 0.32 windows, 100 square feet (9.3 m²) of 0.36 windows and one 20-square-foot (1.8 m²) 0.40 U-factor door [(100 × 0.32) + (100 × 0.36) + (20 × 0.40)] / (100 + 100 + 20) = 0.345 (weighted average U-factor). Therefore, because the weighted average U-factor is less than the required 0.35, the fenestration in this example would be in compliance with the code.

In accordance with Section N1101.10.2, the U-factor for each fenestration product must be obtained from a label attached to the product certifying that the U-factor was determined in accordance with NFRC procedures by an accredited, independent lab. In the absence of an NFRC-labeled U-factor, a value from the limited default tables [Tables N1101.10.3(1) and N1101.10.3(2)] must be used. The provisions of Section N1102.4.5 should be reviewed when using the area-weighted average in the tradeoff options (see commentary, Section N1102.5).

N1102.3.2 (R402.3.2) Glazed fenestration SHGC. An area-weighted average of fenestration products more than 50-percent glazed shall be permitted to satisfy the SHGC requirements.

Dynamic glazing shall be permitted to satisfy the SHGC requirements of Table R1102.1.2 provided the ratio of the higher to lower labeled SHGC is greater than or equal to 2.4,

and the *dynamic glazing* is automatically controlled to modulate the amount of solar gain into the space in multiple steps. *Dynamic glazing* shall be considered separately from other fenestration, and area-weighted averaging with other fenestration that is not dynamic glazing shall not be permitted.

Exception: *Dynamic glazing* is not required to comply with this section when both the lower and higher labeled SHGC already comply with the requirements of Table N1102.1.2.

- ❖ Under Table N1102.1.2, all glazed fenestration products in Climate Zones 1 through 3 must have an SHGC equal to or less than 0.30 (there is no requirement in Climate Zones 4 through 8). This requirement is intended to control unwanted solar gain in cooling-dominated climates to increase comfort, reduce air-conditioning energy and peaks, reduce HVAC sizing and reduce energy costs.

Similar to Section N1102.3.1, Section N1102.3.2 allows some latitude for individual product variability by permitting this performance requirement to be met using an area-weighted average of all of the fenestration products that are more than 50-percent glazed. The 50-percent glazing threshold is established to exclude doors or other fenestration products that are either completely or largely opaque from the equation. The reason for this exclusion is that opaque elements do not allow solar heat gain as glazing does. The area-weighted calculation approach is explained in an example with Section N1102.3.1. An additional example for SHGC is as follows:

Window 1	SHGC - 0.24	200 ft ²
Window 2	SHGC - 0.32	100 ft ²
Window 3	SHGC - 0.30	100 ft ²
Sliding glass door	SHGC - 0.40	40 ft ²

$$[(200 \text{ ft}^2 \times 0.24) + (100 \text{ ft}^2 \times 0.32) + (100 \text{ ft}^2 \times 0.30) + (40 \text{ ft}^2 \times 0.40)] / 440 \text{ ft}^2$$

$$440 \text{ ft}^2 = \text{SHGC} - 0.29 \text{ Average}$$

Using the figures in the example, even though Window 2 and the sliding glass door both have SHGC values that exceed the 0.25 limitation of Table N1102.1.2 for Climate Zones 1 through 3, this design will comply because the weighted average is 0.34.

In accordance with Section R303.1.3, the SHGC for each glazed fenestration product must be obtained from a label attached to the product certifying that the SHGC was determined in accordance with NFRC procedures by an accredited, independent lab. In the absence of an NFRC-labeled SHGC, a value from the limited default table [Table N1101.10.3(1)] must be used.

It is important to note that the SHGC requirement must be met by the fenestration product on a stand-alone basis. The code does not permit the alternative of a “permanent solar shading device” such as eave overhangs or awnings, as was permitted by other

energy codes and previous versions of the code, to assist in code compliance.

N1102.3.3 (R402.3.3) Glazed fenestration exemption. Up to 15 square feet (1.4 m²) of glazed fenestration per dwelling unit shall be permitted to be exempt from *U*-factor and SHGC requirements in Section N1102.1.2. This exemption shall not apply to the *U*-factor alternative approach in Section N1102.1.4 and the total UA alternative in Section N1102.1.5.

❖ In addition to using the area-weighted average approach (Sections N1102.3.1 and N1102.3.2) to allow maximum compliance flexibility for builders, the code allows up to 15 square feet (1.4 m²) of the building's total glazed fenestration area to be exempt from the *U*-factor and SHGC requirements listed in Table N1102.1.1. All other glazing must meet or exceed the designated *U*-factor and SHGC requirements. The exempted glazing area should be designated on the building plan, either on the floor plan or within a window schedule. This will give the necessary information to the field inspector who will then need to verify that what is on the plans is installed in the field. This exemption allows the use of ornate or unique window, skylight or glazed door assemblies in a building without going to another compliance approach. The area, the *U*-factor and SHGC of the exempt product(s) should be excluded from the area-weighted calculations that may be performed under Sections N1102.3.1 and N1102.3.2. In addition, the exception provided by this section would also allow this 15 square feet (1.4 m²) of glazing to be excluded from the limits of Section N1102.5. Note that this exemption does not apply where the basis for the thermal envelope was the *U*-factor alternative in Section N1102.1.4 or the total UA alternative in Section N1102.1.4. In these cases, the amount of insulation does not need to be exempted.

N1102.3.4 (R402.3.4) Opaque door exemption. One side-hinged opaque door assembly up to 24 square feet (2.22 m²) in area is exempted from the *U*-factor requirement in Section N1102.1.2. This exemption shall not apply to the *U*-factor alternative approach in Section N1102.1.4 and the total UA alternative in Section N1102.1.5.

❖ Similar to the exemption provided in Section N1102.3.3 to enhance design flexibility, the code allows one side-hinged opaque door to be exempt from fenestration *U*-factor requirements as contained in Table N1102.1.2, as well as the limitations of Section N1102.5. Although the code does not define it, an opaque door is generally considered to be a fenestration product with an overall glazing area of less than 50 percent. The opaque door exemption allows builders to use an ornate or otherwise *U*-factor noncompliant entrance door assembly in a building without going to another compliance approach. The area and the *U*-factor of the exempt product should be excluded from the area-weighted calculations under Section N1102.4.1.

N1102.3.5 (R402.3.5) Sunroom fenestration. Sunrooms enclosing *conditioned space* shall meet the fenestration requirements of this code.

Exception: For *sunrooms* with *thermal isolation* and enclosing *conditioned space* in *Climate Zones* 2 through 8, the maximum fenestration *U*-factor shall be 0.45 and the maximum skylight *U*-factor shall be 0.70.

New fenestration separating the *sunroom* with *thermal isolation* from *conditioned space* shall meet the *building thermal envelope* requirements of this code.

❖ This section simply reminds the user that sunrooms enclosing conditioned spaces are subject to code requirements. The exception tightens the maximum fenestration *U*-factor for *Climate Zones* 4 through 8. The maximum skylight *U*-factor shall be 0.70. Given the amount of glass in a sunroom, this section of the code tightens up the fenestration requirements and minimizes energy usage.

N1102.4 (R402.4) Air leakage (Mandatory). The *building thermal envelope* shall be constructed to limit air leakage in accordance with the requirements of Sections N1102.4.1 through N1102.4.5.

❖ Sealing the building envelope is critical to good thermal performance of the building. The seal will prevent warm, conditioned air from leaking out around doors, windows and other cracks during the heating season, thereby reducing the cost of heating the residence. During hot summer months, a proper seal will stop hot air from entering the residence, helping to reduce the air-conditioning load on the building. Any penetration in the building envelope must be thoroughly sealed during the construction process, including holes made for the installation of plumbing, electrical and heating and cooling systems (see Commentary Figure N1102.4). The code lists several areas that must be caulked, gasketed, weatherstripped, wrapped or otherwise sealed to limit uncontrolled air movement. Most of the air sealing will be done prior to the installation of an interior wall covering because any penetration will be noticeable and accessible at this time. The code allows the use of airflow retarders (house wraps) or other solid materials as an acceptable method to meet this requirement. To be effective, the building thermal envelope seal must be:

- Impermeable to airflow.
- Continuous over the entire building envelope.
- Able to withstand the forces that may act on it during and after construction.
- Durable over the expected lifetime of the building.

It is unlikely that the same type of barrier will be used on all portions of the building's thermal envelope. Therefore, joints between the various elements, as well as joints or splices within products (such as the overlap in separate pieces of house wrap), must be

effectively addressed to provide the continuity needed to perform as desired.

N1102.4.1 (R402.4.1) Building thermal envelope. The *building thermal envelope* shall comply with Sections N1102.4.1.1 and N1102.4.1.2. The sealing methods between dissimilar materials shall allow for differential expansion and contraction.

❖ Air infiltration is a major source of energy use because the incoming air usually requires conditioning. The uncontrolled introduction of outside air (infiltration) creates a load that varies with time. Ventilation, the controlled introduction of fresh air, is more manageable and provides a more controlled air quality. Uncontrolled infiltration also has a tendency to create or aggravate moisture problems, providing an additional reason to limit infiltration.

N1102.4.1.1 (R402.4.1.1) Installation. The components of the *building thermal envelope* as listed in Table N1102.4.1.1 shall be installed in accordance with the manufacturer's instructions and the criteria listed in Table N1102.4.1.1, as applicable to the method of construction. Where required by the *building official*, an *approved* third party shall inspect all components and verify compliance.

❖ The provisions of this section are intended to reduce the energy loss due to infiltration and to improve insulation installation.

The code allows all materials that are commonly used as sheathing to be part of the thermal envelope, including interior drywall. By the definition of an air barrier, gypsum board should be considered, as should exterior sheathing. The solid sheathing is not enough—for the air barrier to be effective the joints and openings must be sealed. The code does not require the air barrier on the inside of the air permeable insulation.

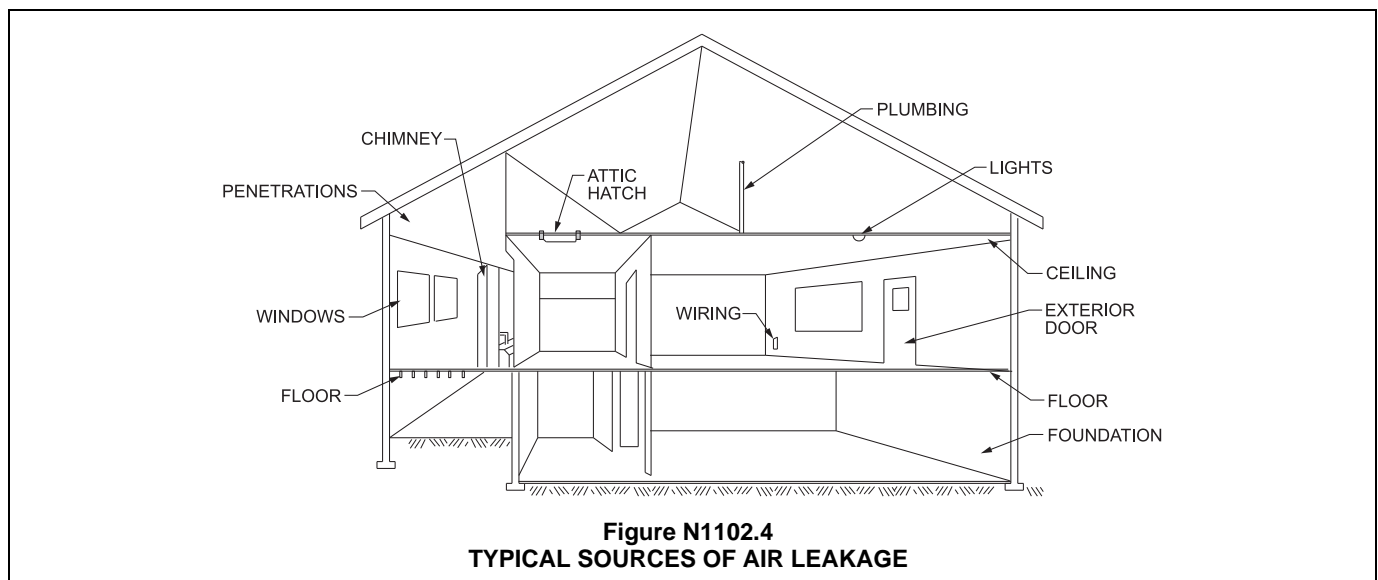

In some cases, inspection of the air barrier is better performed by individuals with more expertise than the staff of the authority having jurisdiction might have. Therefore, the code gives the code official authority to require third-party inspectors.

Note that the line item in the table regarding fireplaces requires gaskets on fireplace doors. All wood-burning fireplaces are a source of air leakage. Loss of energy through these units can be reduced with gasketed doors and a requirement that combustion air be brought directly from the outdoors to the firebox. Gaskets on the fireplace doors will help to minimize air leakage into the firebox. Air that leaks past a poorly gasketed fireplace door, or a door that is simply left open, will flow up the chimney aided by the chimney draft. During the majority of the year the fireplace will not be operating. The combination of well-gasketed doors and a well-sealed flue damper will prevent air leakage through what is effectively an enormous hole in the thermal envelope of the building.

However, it should be noted that the difficulty with this requirement is that most factory-built fireplaces tested in accordance with the code required test standard for factory-built fireplaces, UL127, are not tested and listed with doors. Therefore, there is a significant safety hazard in adding gasketed doors to a factory-built fireplace tested and manufactured in accordance with UL127, without doors. That hazard would be overheating of the unit and high likelihood of causing fires. This provision in Table N1102.4.1.1 for gasketed fireplace doors is a general provision to prevent air leakage and was not intended to prohibit the use of factory-built fireplaces listed for use without doors, in violation of that listing. The specific requirements of the test standard UL127, the product listing and the manufacturer's instructions would prevail for factory-built fireplaces. Keep in mind that Section N1102.4.3 requires tight fitting dampers for all fireplaces as well, which will prevent air leakage.

TABLE N1102.4.1.1. See page 11-56.

❖ This table contains the list of items that are required to be visually inspected if the visual inspection option for demonstrating building air tightness given in Section N1102.4.1.1 is chosen.

**TABLE N1102.4.1.1 (402.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION**

COMPONENT	AIR BARRIER CRITERIA	INSULATION INSTALLATION CRITERIA
General requirements	A continuous air barrier shall be installed in the building envelope. The exterior thermal envelope contains a continuous air barrier. Breaks or joints in the air barrier shall be sealed.	Air-permeable insulation shall not be used as a sealing material.
Ceiling/attic	The air barrier in any dropped ceiling/soffit shall be aligned with the insulation and any gaps in the air barrier sealed. Access openings, drop down stairs or knee wall doors to unconditioned attic spaces shall be sealed.	The insulation in any dropped ceiling/soffit shall be aligned with the air barrier.
Walls	The junction of the foundation and sill plate shall be sealed. The junction of the top plate and the top of exterior walls shall be sealed. Knee walls shall be sealed.	Cavities within corners and headers of frame walls shall be insulated by completely filling the cavity with a material having a thermal resistance of R-3 per inch minimum. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier.
Windows, skylights and doors	The space between window/door jambs and framing, and skylights and framing shall be sealed.	
Rim joists	Rim joists shall include the air barrier.	Rim joists shall be insulated.
Floors (including above garage and cantilevered floors)	The air barrier shall be installed at any exposed edge of insulation.	Floor framing cavity insulation shall be installed to maintain permanent contact with the underside of subfloor decking, or floor framing cavity insulation shall be permitted to be in contact with the top side of sheathing, or continuous insulation installed on the underside of floor framing; and extends from the bottom to the top of all perimeter floor framing members.
Crawl space walls	Exposed earth in unvented crawl spaces shall be covered with a Class I vapor retarder with overlapping joints taped.	Where provided instead of floor insulation, insulation shall be permanently attached to the crawl space walls.
Shafts, penetrations	Duct shafts, utility penetrations, and flue shafts opening to exterior or unconditioned space shall be sealed.	
Narrow cavities		Batts in narrow cavities shall be cut to fit, or narrow cavities shall be filled by insulation that on installation readily conforms to the available cavity space.
Garage separation	Air sealing shall be provided between the garage and conditioned spaces.	
Recessed lighting	Recessed light fixtures installed in the building thermal envelope shall be sealed to the drywall.	Recessed light fixtures installed in the building thermal envelope shall be air tight and IC rated.
Plumbing and wiring		Batt insulation shall be cut neatly to fit around wiring and plumbing in exterior walls, or insulation that on installation readily conforms to available space shall extend behind piping and wiring.
Shower/tub on exterior wall	The air barrier installed at exterior walls adjacent to showers and tubs shall separate them from the showers and tubs.	Exterior walls adjacent to showers and tubs shall be insulated.
Electrical/phone box on exterior walls	The air barrier shall be installed behind electrical or communication boxes or air-sealed boxes shall be installed.	
HVAC register boots	HVAC register boots that penetrate building thermal envelope shall be sealed to the subfloor or drywall.	
Concealed sprinklers	When required to be sealed, concealed fire sprinklers shall only be sealed in a manner that is recommended by the manufacturer. Caulking or other adhesive sealants shall not be used to fill voids between fire sprinkler cover plates and walls or ceilings.	

a. In addition, inspection of log walls shall be in accordance with the provisions of ICC 400.

N1102.4.1.2 (R402.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate of not exceeding five air changes per hour in Climate Zones 1 and 2, and three air changes per hour in Climate Zones 3 through 8. Testing shall be conducted in accordance with ASTM E779 or ASTM E1827 and reported at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures.
 2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures.
 3. Interior doors, if installed at the time of the test, shall be open.
 4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed.
 5. Heating and cooling systems, if installed at the time of the test, shall be turned off.
 6. Supply and return registers, if installed at the time of the test, shall be fully open.
- ❖ The purpose of this code section is to test the building or dwelling unit to demonstrate the building's air tightness. A blower door test, which is a house pressurization test, should be done with a blower door at a pressure of 0.2 inches water gauge [50 Pascals (1psf)]. The building or dwelling unit shall be tested and verified as having an air leakage rate of not exceeding 5 ACH50, or five air changes per hour at 50 Pascals (1 psf) in Climate Zones 1 and 2 and 3 ACH50, or three air changes per hour at 50 Pascals (1 psf), in Climate Zones 3 through 8. The ACH50 is a common measurement made when doing air infiltration tests and, therefore, a reasonable metric for use in the code. Testing can be conducted by an approved third party, if allowed by the code official. Section N1102.4.2.1 requires that HVAC ducts not be sealed during the test. In this context, "sealed" is intended to mean sealed off from the interior of the house. The maximum is 5ACH50, or five air changes per hour at 50 Pascals (1 psf).

N1102.4.2 (R402.4.2) Fireplaces. New wood-burning fireplaces shall have tight-fitting flue dampers or doors, and outdoor combustion air. Where using tight-fitting doors on factory-built fireplaces listed and labeled in accordance with UL 127, the doors shall be tested and listed for the fireplace.

Where using tight-fitting doors on masonry fireplaces, the doors shall be listed and labeled in accordance with UL 907.

❖ All wood-burning fireplaces are a source of air leakage. Loss of energy through these units can be reduced with gasketed doors and a requirement that combustion air be brought directly from the outdoors to the firebox. Gaskets on the fireplace doors will help to minimize air leakage into the firebox. Air that leaks past a poorly fitted fireplace door, or a door that is simply left open, will flow up the chimney aided by the chimney draft. During the majority of times throughout the year, the fireplace will not be in use. The combination of tight-fitting doors; and a tight flue damper will prevent air leakage through what is effectively an enormous hole in the thermal envelope of the building. However, not all factory-built fireplaces are tested for use with doors; therefore, in some cases, installing doors on the fireplace would violate the unit's listing and could create a fire hazard. Doors on factory-built fireplaces are required to be tested and listed for the fireplace in accordance with UL 127. The manufacturer's instructions for factory-built fireplaces should be followed and such instructions could prohibit the installation of doors. Doors on masonry fireplaces are required to be listed and labeled in accordance with UL 907. The code also allows tight-fitting flue dampers for fireplaces to deal with the issue of air loss.

Lastly, this section and Section R1006 of the code require factory-built and masonry fireplaces to be equipped with a direct outdoor combustion supply. The provisions of Section R1006.2 would prevent the installation of a fireplace with the firebox floor below finished grade.

N1102.4.3 (R402.4.3) Fenestration air leakage. Windows, skylights and sliding glass doors shall have an air infiltration rate of no more than 0.3 cfm per square foot (1.5 L/s/m²), and swinging doors no more than 0.5 cfm per square foot (2.6 L/s/m²), when tested according to NFRC 400 or AAMA/WDMA/CSA 101/I.S.2/A440 by an accredited, independent laboratory and *listed* and *labeled* by the manufacturer.

Exception: Site-built windows, skylights and doors.

❖ Windows, skylights and doors should be tested and labeled by the manufacturer as meeting the air infiltration requirements. The intent of this section is to effectively complete the sealing of the building's thermal envelope by providing specific testing and performance criteria for windows, skylights and doors. This testing and labeling requirement provides an easy method for both the builder and the inspector to demonstrate compliance with the code. While "site built" fenestration is exempted from these requirements, units would have to be "durably sealed" to limit infiltration according to the requirements in Section N1102.4.1.

N1102.4.4 (R402.4.4) Rooms containing fuel-burning appliances. In Climate Zones 3 through 8, where open combustion air ducts provide combustion air to open combustion

fuel-burning appliances, the appliances and combustion air opening shall be located outside the building thermal envelope or enclosed in a room, isolated from inside the thermal envelope. Such rooms shall be sealed and insulated in accordance with the envelope requirements of Table N1102.1.2, where the walls, floors and ceilings shall meet a minimum of the basement wall *R*-value requirement. The door into the room shall be fully gasketed and any water lines and ducts in the room insulated in accordance with Section N1103. The combustion air duct shall be insulated where it passes through conditioned space to a minimum of *R*-8.

Exceptions:

1. Direct vent appliances with both intake and exhaust pipes installed continuous to the outside.
 2. Fireplaces and stoves complying with Sections N1102.4.2 and R1006.
- ❖ The entire set of provisions in the code for air leakage are of little value when a combustion air duct is installed, open to the conditioned space, virtually placing a large hole through the thermal envelope. Blower door testing as now required by the code cannot be accomplished with a combustion air opening inside the thermal envelope. Testers regularly block these openings as this is the only way they can pressurize the home, only to be opened after the test is completed. Ideally, direct vent, sealed combustion appliances solve the problem. Where less efficient, open combustion fuel-burning appliances are used, it is reasonable and proper to isolate the appliances and the required combustion air from inside the thermal envelope.

N1102.4.5 (R402.4.5) Recessed lighting. Recessed luminaires installed in the *building thermal envelope* shall be sealed to limit air leakage between conditioned and unconditioned spaces. All recessed luminaires shall be IC-rated and *labeled* as having an air leakage rate not more than 2.0 cfm (0.944 L/s) when tested in accordance with ASTM E283 at a 1.57 psf (75 Pa) pressure differential. All recessed luminaires shall be sealed with a gasket or caulk between the housing and the interior wall or ceiling covering.

- ❖ To correctly apply this provision, it is important to realize that it deals only with recessed lights that are

installed in the building thermal envelope. Therefore, lights that are located so that all sides of the luminaire are surrounded by conditioned space would not fall under this section's requirements. For example, a light located in a soffit would not be regulated if the soffit was below a ceiling that served as the building's thermal envelope. Additionally, a light installed in the floor/ceiling assembly between a first-floor living room and a bedroom above it would be exempted.

Because of their typical location of installation, recessed lighting fixtures pose a potential fire hazard if incorrectly covered with insulation. In addition, the ceiling or a barrier directly above it often serves as the air leakage or moisture barrier for the home.

Therefore, holes cut through the ceiling to install these fixtures also act as chimneys that transfer heat loss and moisture through the building envelope into attic spaces. The heat loss resulting from improperly insulated recessed lighting fixtures can be significant.

Recessed lighting fixtures must be insulation contact (IC)-rated lights, which are typically double-can fixtures, with one can inside another (see Commentary Figure N1102.4.5). The outer can (in contact with the insulation) is tested to make sure it remains cool enough to avoid a fire hazard. An IC-rated fixture should have the IC rating stamped on the fixture or printed on an attached label.

Recessed lights must also be tightly sealed or gasketed to prevent air leakage through the fixture into the ceiling cavity.

N1102.5 (R402.5) Maximum fenestration *U*-factor and SHGC (Mandatory). The area-weighted average maximum fenestration *U*-factor permitted using tradeoffs from Section N1102.1.5 or N1105 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section N1105 in Climate Zones 1 through 3 shall be 0.50.

- ❖ This section is intended to clarify the application of the fenestration performance maximums and to set reasonable performance levels for these products when

using the tradeoffs of Section N1102.1.5 or N1105.

This section does not define the minimum code requirements for fenestration *U*-factors that are set in Table N1102.1.2. Rather, this section sets limits on the tradeoffs allowed based on the total UA calculations (see Section N1102.1.4) or the simulated performance option found in Section N1105. This section is in contrast to the basic principle used in Section N1102.1.5. Although that section will allow a *U*-factor that does not meet the general code requirements offset by the increased efficiency of another part of the residence, this section establishes a limitation on the level of efficiency that can be compensated for.

Note that this section does not set a limit on individual products because Sections N1102.3.1 and N1102.3.2 are not affected. Rather, this section sets an overall limit on the weighted average of those products. These limits are often called “hard limits” or “maximum tradeoff” limits.

In situations where the code is applied to only a portion of the residence, such as only to the addition but not the existing residence, the weighted average could be calculated for just the addition (see commentary, Sections N1102.3.1 and N1102.3.2).

The thermal properties (*U*-factor) of skylights are uniquely different from window products. After installation they perform differently than windows and are, therefore, rated differently. As a result, even the highest rated skylights cannot achieve the same level of *U*-factor performance as windows and glass doors. Therefore, the code provides different values for these “maximum” limits in the tradeoff.

The SHGC provisions are limited in the cooling-dominated climate zones. Therefore, where solar heat gain through the fenestration can affect the cooling load, comfort and efficiency, a “hard limit” of 0.5 would be applied when using Section N1105.

SECTION N1103 (R403) SYSTEMS

N1103.1 (R403.1) Controls (Mandatory). At least one thermostat shall be provided for each separate heating and cooling system.

- ❖ This provision ensures that a separate thermostat is installed for each system. As an example, if separate systems are installed so that one serves the downstairs and one serves the upstairs of a two-story residence, two separate thermostats would be required, one regulating each level. This allows for greater flexibility, control and energy savings than would be possible if both systems were controlled by a single thermostat.

N1103.1.1 (R403.1.1) Programmable thermostat. The thermostat controlling the primary heating or cooling system of the dwelling unit shall be capable of controlling the heating and cooling system on a daily schedule to maintain different temperature set points at different times of the day. This thermostat shall include the capability to set back or temporarily operate the system to maintain *zone* temperatures down to

55°F (13°C) or up to 85°F (29°C). The thermostat shall initially be programmed by the manufacturer with a heating temperature set point no higher than 70°F (21°C) and a cooling temperature set point no lower than 78°F (26°C).

- ❖ This code section provides a requirement that gives each household an opportunity for energy savings by requiring a programmable thermostat that allows changing the temperature setpoints automatically throughout the day.

N1103.1.2 (R403.1.2) Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation when the heat pump compressor can meet the heating load.

- ❖ Heat pump systems must have controls that prevent supplementary electric resistance heater operation when the heating load can be met by the heat pump alone. Typically, these controls will be thermostats that will have a “heat pump” designation on them. The make and model of the thermostat should be called out on the building plans so the inspector can verify that what is installed in the field matches the plans. Because change-outs in the field are common, the instructions that come with the thermostat can also be checked to verify that the thermostat is designed for use with a particular heat pump. To limit the hours of use of the electric-resistance heating unit and provide the most cost-efficient operation of the equipment, the specific control language is included in this section.

N1103.2 (R403.2) Hot water boiler outdoor temperature setback. Hot water boilers that supply heat to the building through one- or two-pipe heating systems shall have an outdoor setback control that lowers the boiler water temperature based on the outdoor temperature.

- ❖ This section provides a requirement that gives each household with a hot water boiler an opportunity for energy savings by requiring a setback that will lower the temperature of the water based on ambient conditions.

N1103.3 (R403.3) Ducts. Ducts and air handlers shall be in accordance with Sections N1103.3.1 through N1103.3.5.

- ❖ The five subsections of Section N1103.3 provide the requirements of this chapter, which apply to the ducts and air handlers used in residential buildings.

N1103.3.1 (R403.3.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to a minimum of R-8 where 3 inches (76.2 mm) in diameter and greater and R-6 where less than 3 inches (76.2 mm) in diameter. Supply and return ducts in other portions of the building shall be insulated to a minimum of R-6 where 3 inches (76.2 mm) in diameter or greater and R-4.2 where less than 3 inches (76.2 mm) in diameter.

Exception: Ducts or portions thereof located completely inside the *building thermal envelope*.

- ❖ HVAC ductwork located outside of the conditioned space must have insulation with minimum *R*-values of R-8 or R-6, depending on the size of the duct. This

includes both supply and return ducts. For areas other than attics, the values are R-6 and R-4.2. Energy losses are less in smaller ducts; therefore, the *R*-value of the insulation is lower for ducts less than 3 inches in diameter.

The exception addresses the fact that ductwork within the thermal envelope is already protected from energy loss by virtue of being within the thermal envelope.

N1103.3.2 (R403.3.2) Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with either the *International Mechanical Code* or Section M1601.4.1 of this code, as applicable.

Exceptions:

1. Air-impermeable spray foam products shall be permitted to be applied without additional joint seals.
 2. For ducts having a static pressure classification of less than 2 inches of water column (500 Pa), additional closure systems shall not be required for continuously welded joints and seams, and locking-type joints and seams of other than the snap-lock and button-lock types.
- ❖ Ducts must be sealed in accordance with the duct sealing requirements of either the IMC or the code. Joints and seams that fail in a duct system can result in increased energy use because the conditioned air will be delivered to an unconditioned space or into a building space where it is not needed, such as a wall or floor assembly, crawl space or attic, instead of to a room or area inside the conditioned envelope. Return-air ductwork installed in basements or concealed building spaces may conduct chemicals or other products that produce potentially harmful fumes. Because the return air operates under negative pressure, any leaks could draw fumes, moisture, soil gases or odors from the surrounding area and direct them into the house. Therefore, sealing of return-air ductwork is also a requirement.

Duct tightness must be checked by leakage testing of the ducts at the end of construction or at the time of rough-in. The pass/fail criteria for leakage rate is more stringent if the rough-in test time is chosen. This is simply because it is probably that some of the ductwork will be disturbed during subsequent construction and, therefore, have a higher leakage rate than what was tested.

N1103.3.2.1 (R403.3.2.1) Sealed air handler. Air handlers shall have a manufacturer's designation for an air leakage of no more than 2 percent of the design air flow rate when tested in accordance with ASHRAE 193.

- ❖ This section of the code requires that air handlers have a manufacturer's designation for an air leakage of no more than 2 percent of the design flow rate when tested in accordance with ASHRAE 193. Energy conservation measures in the air-conditioning industry have driven the manufacturers of systems and compo-

nents to establish compliance with leakage limits in ducts and air-handling units. The standards set by the American Society of Heating, Refrigerating and Air-conditioning Engineers (ASHRAE) form the basis for testing. Establishing an air-handler leakage rate, given the availability of a uniform test procedure, is prudent since any leakage in the air-handling unit contributes to waste of energy. The magnitude of leakage has a direct bearing on energy use and indoor air quality.

N1103.3.3 (R403.3.3) Duct testing (Mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

1. Rough-in test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the system, including the manufacturer's air handler enclosure if installed at the time of the test. All registers shall be taped or otherwise sealed during the test.
2. Postconstruction test: Total leakage shall be measured with a pressure differential of 0.1 inch w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exception: A duct air leakage test shall not be required where the ducts and air handlers are located entirely within the building thermal envelope.

A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*.

- ❖ Duct tightness must be checked by leakage testing at the end of construction or at the time of rough-in. This affords some flexibility to the builder. The test at the end of construction, if failed, could be more difficult to correct; however, the test after rough-in is more stringent as noted in the commentary to Section N1103.3.4.

N1103.3.4 (R403.3.4) Duct leakage (Prescriptive). The total leakage of the ducts, where measured in accordance with Section R403.3.3, shall be as follows:

1. Rough-in test: The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m²) of conditioned floor area.
 2. Postconstruction test: Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m²) of conditioned floor area.
- ❖ The pass/fail criteria for the tested duct leakage rate is more stringent if the rough-in test time is chosen. This is simply because it is probable that some of the ductwork will be disturbed during subsequent construction and, therefore, have a higher leakage rate than what was tested.

N1103.3.5 (R403.3.5) Building cavities (Mandatory). Building framing cavities shall not be used as ducts or plenums.

- ❖ Building framing cavities should not be used as ducts or plenums. Stud bays and other building cavities that are exposed to the differing outside temperatures cannot be used as supply air ducts. In addition, these spaces are limited to use for return air only because the negative pressures within the return air plenum with respect to surrounding spaces will decrease the likelihood of spreading smoke to other spaces via the plenum. In addition, for many of the same reasons that sealing (see Section N1103.2.2) is required, building cavities are a very inefficient means of distributing air.

N1103.4 (R403.4) Mechanical system piping insulation (Mandatory). Mechanical system piping capable of carrying fluids above 105°F (41°C) or below 55°F (13°C) shall be insulated to a minimum of R-3.

- ❖ Heat losses during mechanical fluid distribution impact building energy use both in the energy required to make up for the lost heat and in the additional load that can be placed on the space-cooling system if the heat is released to air-conditioned space. These losses can be effectively limited by insulating the mechanical system piping that conveys fluids at extreme temperatures.

N1103.4.1 (R403.4.1) Protection of piping insulation. Piping insulation exposed to weather shall be protected from damage, including that caused by sunlight, moisture, equipment maintenance and wind, and shall provide shielding from solar radiation that can cause degradation of the material. Adhesive tape shall not be permitted.

- ❖ Proper protection of exposed piping insulation to the weather elements is necessary to protect it from damage, including that due to sunlight, moisture, equipment maintenance and wind.

N1103.5 (R403.5) Service hot water systems. Energy conservation measures for service hot water systems shall be in accordance with Sections N1103.5.1 through N1103.5.4.

- ❖ A review of the definition of “Service water heating” in Chapter 2 is appropriate before applying these requirements. Any time the system is set up to circulate the water through it, the piping is required to be insulated as listed in Section N1103.4.2.

N1103.5.1 (R403.5.1) Heated water circulation and temperature maintenance systems (Mandatory). Heated water circulation systems shall be in accordance with Section R1103.5.1.1. Heat trace temperature maintenance systems shall be in accordance with Section R1103.5.1.2. Automatic controls, temperature sensors and pumps shall be accessible. Manual controls shall be readily *accessible*.

- ❖ When the distribution piping is heated to maintain usage temperatures, such as in circulating hot water systems or systems using pipe heating cable, the system pump or heat trace cable must have conveniently located manual or automatic switches or other con-

trols that can be set to optimize system operation or turn off the system during periods of reduced demand. The simplest of these devices is an automatic time clock. Notice, however, that the code will accept either a readily accessible manual switch or an automatic means to turn off the circulating pump.

N1103.5.1.1 (R403.5.1.1) Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

- ❖ Demand-activated circulation is an efficient energy conservation strategy, given that the *International Plumbing Code*® (IPC®), IECC and IRC require that the hot water piping in automatic temperature maintenance systems in new buildings be insulated with pipe insulation. This means the water in the circulation loop will stay hot for a very long time—up to 45 minutes for 3/4-inch nominal pipe and up to 2 hours for 2-inch nominal pipe—even if the circulating pump is shut off. If this is the case, there is no reason to run the pump when the water is still hot and no reason to run the pump when no one is in the building or when no one is demanding hot water. The only time it makes sense to run the pump is shortly before hot water is needed, hence the requirement that the pump be controlled on demand.

N1103.5.1.2 (R403.5.1.2) Heat trace systems. Electric heat trace systems shall comply with IEEE 515.1 or UL 515. Controls for such systems shall automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.

- ❖ The requirements for heat trace are partly to ensure that the systems can be operated in the most energy-efficient manner consistent with providing heated water to the occupancy. The referenced standards are included to ensure that installed systems are safe for the intended application. The energy consequences of using heat trace are very reasonable. An example is an analysis of a small loop—100 feet long. The energy requirements of keeping the trunk line hot, which is the same as keeping the supply portion of the loop hot in a circulating system, are 701 kWh per year, assuming 12 hours at high temp (115°F) and 12 hours at economy temp (105°F). This is equivalent to operating the loop about 3 hours per day, but with hot water available 24 hours a day/7 days a week in the supply trunk. This is a significant savings when water heating is done electrically or with a similarly expensive fuel. If the branches are also traced, heated water can be delivered even more quickly to the fixtures using only 1,682 kWh per year, which is the same energy as running the loop a little more than 6 hours a day.

N1103.5.2 (R403.5.2) Demand recirculation systems. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a *demand recirculation water system*. Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
 2. The control shall limit the temperature of the water entering the cold water piping to 104°F (40°C).
- ❖ The purpose of this section is to clarify the requirements for installing circulation pumps in applications that use a cold water supply pipe to circulate the water back to the water heater. Demand recirculation water systems are significantly more energy efficient than other recirculation systems and are inherently safer when the cold water supply is used as the return. The greater safety comes from the fact that the controls specified for demand recirculation water systems limit the flow of water from the hot water supply into the cold water supply to only minutes a day and because they limit the temperature of the water that is allowed to go into the cold water supply.

N1103.5.3 (R403.5.3) Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping $\frac{3}{4}$ inch (19 mm) and larger in nominal diameter.
 2. Piping serving more than one dwelling unit.
 3. Piping located outside the conditioned space.
 4. Piping from the water heater to a distribution manifold.
 5. Piping located under a floor slab.
 6. Buried piping.
 7. Supply and return piping in recirculation systems other than demand recirculation systems.
- ❖ This section simply prescribes conditions where hot water piping needs to be provided with a minimum R-3 insulation.

N1103.5.4 (R403.5.4) Drain water heat recovery units. Drain water heat recovery units shall comply with CSA 55.2. Drain water heat recovery units shall be tested in accordance with CSA 55.1. Potable water-side pressure loss of drain water heat recovery units shall be less than 3 psi (20.7 kPa) for individual units connected to one or two showers. Potable water-side pressure loss of drain water heat recovery units shall be less than 2 psi (13.8 kPa) for individual units connected to three or more showers.

- ❖ Drain water heat recovery is often a cost-effective way to add to energy efficiency by recapturing hot water energy that is literally “going down the drain.” The proposed standards have already been in use by design-

ers for 10 years and the resulting ratings are in use by a variety of energy efficiency programs. Commercial (i.e., nonmultiunit residential) applications are engineered systems while multiunit residential applications are nonengineered and straightforward.

CSA B55.2 standard is for fabrication and material quality of DWHR units. CSA B55.1 standard is for testing and labeling of DWHR units efficiency and pressure loss at 2.5 gpm (9.5 lpm).

N1103.6 (R403.6) Mechanical ventilation (Mandatory). The building shall be provided with ventilation that meets the requirements of Section M1507 of this code or the *International Mechanical Code*, as applicable, or with other approved means of ventilation. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

- ❖ Mechanical ventilation is the alternative to having natural ventilation. Both natural and mechanical ventilation can be provided to a space. Unlike natural ventilation, mechanical ventilation does not depend on unpredictable air pressure differentials between the indoors and outdoors to create airflow. The volume of air supplied to a space must be approximately equal to the volume of the air removed from the space. Otherwise, the space will be either positively or negatively pressurized and the actual ventilation flow rate will be equivalent to the lower rate of either the air supply or air exhaust.

The requirements of this section are intended to reduce infiltration into the building when ventilation systems are off. Infiltration speeds up natural cooling or warming of the space during off-hours and can increase the energy use required to maintain normal temperatures.

Any outdoor air inlets or outlets serving fans, boilers and other HVAC systems equipped with an on/off switch that either introduces outside air into a building or exhaust air outside of a building must have dampers that automatically close when the fan is shut off. These dampers may be either gravity type or motorized, regardless of whether the fan is supplying or exhausting air. One of the most common such damper that is seen on homes is the gravity-type backdraft damper on a clothes dryer exhaust duct.

N1103.6.1 (R403.6.1) Whole-house mechanical ventilation system fan efficacy. Mechanical ventilation system fans shall meet the efficacy requirements of Table N1103.6.1.

Exception: Where mechanical ventilation fans are integral to tested and listed HVAC equipment, they shall be powered by an electronically commutated motor.

- ❖ This section of the code is applicable to whole-house mechanical ventilation systems that meet the efficacy requirements of Table N1103.6.1. Findings from a recent study commissioned by the U.S. DOE and the California Energy Commission identified that energy consumption of whole-house mechanical ventilation systems is significant. The study revealed that large

disparities exist in the energy consumption and associated operating costs of whole-house mechanical ventilation systems no matter what the climate is. To reduce the amount of energy consumed by residential mechanical ventilation systems is to address the power consumption of the fans that are powering the system. This is important because these fans will operate many hours per day. The table offers energy efficacy levels for exhaust fans that are the same levels as the current ENERGY STAR ventilation fan specifications.

N1103.7 (R403.7) Equipment sizing and efficiency rating (Mandatory). Heating and cooling equipment shall be sized in accordance with ACCA Manual S based on building loads calculated in accordance with ACCA Manual J or other *approved* heating and cooling calculation methodologies. New or replacement heating and cooling equipment shall have an efficiency rating equal to or greater than the minimum required by federal law for the geographic location where the equipment is installed.

❖ Once the building's thermal envelope is properly insulated and sealed, it will oftentimes allow for the reduction of equipment size from what has typically been installed using a "rule-of-thumb" method or other means of estimating. A properly sized system will operate more efficiently and help to improve the occupant comfort and extend the equipment's service life. Section M1401.3 stipulates that the heating and cooling equipment must be sized based on the building loads calculated in accordance with the ACCA Manual J. This manual contains a simplified method of calculating heating and cooling loads. It includes a room-by-room calculation method that allows the designer to determine the required capacity of the heating and cooling equipment. In addition, it provides a means to estimate the airflow requirements for each of the areas in the house. This estimate can be used in sizing the duct system for the types of heating and cooling units that use air as the medium for heat transfer. Other approved methods may be used with the code official's approval.

Though not required by the code, the calculated airflows would provide a means to evaluate the installation of the mechanical system. By providing the proper airflow to the various portions of the building, the system can operate more efficiently and can help prevent spaces being too hot or too cold.

N1103.8 (R403.8) Systems serving multiple dwelling units (Mandatory). Systems serving multiple dwelling units shall

comply with Sections C403 and C404 of the IECC—Commercial Provisions in lieu of Section N1103.

❖ The criteria in Section N1103 primarily address stand-alone mechanical systems in single-family houses. However, Chapter 11 also includes townhouses up to three stories. Some of these building projects will have more complicated mechanical systems that may consist of a single system serving multiple dwelling units.

N1103.9 (R403.9) Snow melt system controls (Mandatory). Snow- and ice-melting systems, supplied through energy service to the building, shall include automatic controls capable of shutting off the system when the pavement temperature is above 50°F (10°C), and no precipitation is falling and an automatic or manual control that will allow shutoff when the outdoor temperature is above 40°F (4.8°C).

❖ Snow melt equipment is being installed at a greater frequency in residential projects in communities with a high snow accumulation. Previously, the code only required that the building be built to a certain level of efficiency; however, there was no limit placed on the energy use for snow melt, which can be twice the energy use per square foot of the building.

This section does not restrict the use or sizing of snow melt, but it does require that controls be installed on the equipment so that the system will operate more efficiently. The automatic controls provide efficient operation by keeping the system in an idle mode until light snow begins to fall and allowing adequate warm-up before a heavy snowfall. Systems that only use manual controls require the building owner to manually turn on the system when it starts to snow or to leave the system running in the snow-melting mode, using significantly more energy. Chapter 50, Snow Melting and Freeze Protection, 2003 *ASHRAE Applications Handbook* states that using a manual switch to operate snow melt equipment may not melt snow effectively; thus, snow will accumulate. This requirement is also referenced in ANSI/ASHRAE/IESNA Standard 90.1, Section 6.4.3.8, Freeze Protection and Snow/Ice Melting Systems.

N1103.10 (R403.10) Pools and permanent spa energy consumption (Mandatory). The energy consumption of pools and permanent spas shall be in accordance with Sections N1103.10.1 through N1103.10.3.

❖ Because of the heating and filtering operations involved with pools and inground permanently installed spas, they provide a good opportunity to save energy by limiting heat loss or pump operation. This

TABLE N1103.6.1 (R403.6.1)
MECHANICAL VENTILATION SYSTEM FAN EFFICACY

FAN LOCATION	AIR FLOW RATE MINIMUM (CFM)	MINIMUM EFFICACY (CFM/WATT)	AIR FLOW RATE MAXIMUM (CFM)
Range hoods	Any	2.8 cfm/watt	Any
In-line fan	Any	2.8 cfm/watt	Any
Bathroom, utility room	10	1.4 cfm/watt	< 90
Bathroom, utility room	90	2.8 cfm/watt	Any

For SI: 1 cubic foot per minute = 28.3 L/min.

section provides the scoping requirements for the pool and spa heaters, time switches and pool covers that can make the operation more energy efficient. These features would be able to provide energy savings for residential pools if their owners wish to use them. The requirements of this section were added into the code in order to help coordinate with requirements found within ASHRAE 90.1 and to help reduce the energy used by these pools and inground permanently installed spa systems.

N1103.10.1 (R403.10.1) Heaters. The electric power to heaters shall be controlled by a readily *accessible* on-off switch that is an integral part of the heater mounted on the exterior of the heater, or external to and within 3 feet (914 mm) of the heater. Operation of such switch shall not change the setting of the heater thermostat. Such switches shall be in addition to a circuit breaker for the power to the heater. Gas-fired heaters shall not be equipped with continuously burning ignition pilots.

❖ The accessible on-off switch allows the heaters to be completely turned off where there are periods that the heat is not needed or when the pool or spa may not be used for a period of time.

N1103.10.2 (R403.10.2) Time switches. Time switches or other control methods that can automatically turn off and on according to a preset schedule shall be installed for heaters and pump motors. Heaters and pump motors that have built-in time switches shall be in compliance with this section.

Exceptions:

1. Where public health standards require 24-hour pump operation.
 2. Pumps that operate solar- and waste-heat-recovery pool heating systems.
- ❖ The use of a time switch or other control method to control the heater and pumps provides an easy system for pool and spa operations and energy savings. The application of Exception 1 is dependent on the requirements of the local health department in the jurisdiction. Because these are often public pools and spas, the health department may require continuous filtering or circulation. Exception 2 grants a credit for using other systems that help the pool and spa operate more efficiently. Therefore, when solar- and waste-heat recovery systems are used to heat the pool, the exception eliminates the time-switch requirement.

N1103.10.3 (R403.10.3) Covers. Outdoor heated pools and outdoor permanent spas shall be provided with a vapor-retardant cover or other *approved* vapor-retardant means.

Exception: Where more than 70 percent of the energy for heating, computed over an operation season, is from site-recovered energy, such as from a heat pump or solar energy source, covers or other vapor-retardant means shall not be required.

❖ When energy is used to heat a pool or a spa, a cover is required to help hold in the heat and keep it from

being lost to the surrounding air. The level of protection or insulation that the cover must provide depends upon the temperature that the pool is heated to. Any time a pool or spa is heated, the code will require a vapor-retardant pool cover. This type of cover is not required to provide any minimum level of insulation value. It simply will help hold some of the heat in, much like placing a lid on a pot. In situations where the pool is heated above 90°F (32°C), the cover must be insulated to the specified R-12 level. The exception is similar to that found in Section N1103.9.2.

N1103.11 (R403.11) Portable spas (Mandatory). The energy consumption of electric-powered portable spas shall be controlled by the requirements of APSP-14.

❖ This section coordinates this code with the *International Swimming Pool and Spa Code*® (ISPSC®). Both codes rely on ASP-14 for energy conservation requirements for portable spas. The standard addresses efficiency requirements for water heating equipment and water circulation pumps.

N1103.12 (R403.12) Residential pools and permanent residential spas. Residential swimming pools and permanent residential spas that are accessory to detached one- and two-family dwellings and townhouses 3 stories or less in height above grade plane and that are available only to the household and its guests shall be in accordance with APSP-15.

❖ This section coordinates this code with the ISPSC. Both codes rely on ASP-15 for energy conservation requirements for residential pools and permanent residential spas. The standard addresses efficiency requirements for water heating equipment and water circulation pumps.

SECTION N1104 (R404) ELECTRICAL POWER AND LIGHTING SYSTEMS (MANDATORY)

N1104.1 (R404.1) Lighting equipment (Mandatory). Not less than 75 percent of the lamps in permanently installed lighting fixtures shall be high-efficacy lamps or not less than 75 percent of the permanently installed lighting fixtures shall contain only high-efficacy lamps.

Exception: Low-voltage lighting.

❖ Lighting comprises about 12 percent of primary residential energy, making this requirement a substantial energy saver. The overwhelming majority of residential lighting is incandescent—the least energy efficient of all light types. More efficient lighting options are available.

One more efficient lighting option is the compact fluorescent light (CFL). CFLs use about 80 percent less energy than standard incandescent lighting. Limiting this requirement to 75 percent of the lamps in a residence ensures there will be plenty of exceptions for situations where a CFL might not work as well, such as dimmable fixtures.

N1104.1.1 (R404.1.1) Lighting equipment (Mandatory). Fuel gas lighting systems shall not have continuously burning pilot lights.

- ❖ Continuously burning pilots waste energy; therefore, the code does not use them.

SECTION N1105 (R405) SIMULATED PERFORMANCE ALTERNATIVE (PERFORMANCE)

- ❖ Section N1105 describes an alternative way to meet the code's goal of effective use of energy based on showing that the predicted annual energy use of a proposed design is less than or equal to that of the same home if it had been built to meet the prescriptive criteria in Sections N1102 and N1103. Section N1106 does not prescribe a single set of requirements; rather, it provides a process to reach the energy-efficiency goal based on establishing equivalence with the intent of the code. Because of the level of detail required in the analysis, this method of design is not often used for residential buildings; however, with the changes that have been made in Section N1102 and in newer editions of the DOE's REScheck software, Section N1105 may become a more popular means of demonstrating code compliance. This section may allow designers to show that many of their current plans meet the overall code requirements even though individual components of the home fall below the required code compliance levels.

When using this section and other performance options, the term "standard reference design" and "proposed design" are used extensively. These terms can create confusion for some users, but really are very easy to understand. The "proposed design" is exactly that. It is the building as it is proposed to be built, including building size and room configurations, window and wall assemblies, mechanical equipment, orientation, etc. It is essentially the building as it is shown on the construction documents (plans and specifications). The "standard reference design" is the same building configuration and orientation as the proposed design, but instead of matching the plans for the building as it will actually be built, the standard design is shown to only meet the minimum requirements of the code. For example, the standard reference design building in Climate Zone 4 would require that the walls and roof be insulated to a level of R-13 and R-38, respectively, based on the requirements in Table N1102.1.2 (*U*-factors of 0.082 and 0.030 in accordance with Table N1102.1.4). On the other hand, the proposed design may show that the intent is to install R-19 insulation in the walls and R-49 in the roof. Therefore, if everything else in the two buildings was identical, it would be easy to see in this example that the proposed design does exceed what is required by the code in the standard reference design.

There are two fundamental requirements for using this code. First, Section N1105 compliance is based on total estimated annual energy usage across the major energy-using systems in a residential building: envelope, mechanical and service water heating. Note that Section N1105 does not include lighting within the analysis process. Second, Section N1105 compares the energy use of the proposed design to that of a standard reference design. As mentioned above, the standard reference design is the same building design as that proposed, except that the energy features required by the code (insulation, windows, HVAC, infiltration) are modified to meet the minimum prescriptive requirements in Sections N1102 and N1103. The standard reference design is used only for comparison and is never actually built.

Section N1105 sets both general principles and specific guidelines for use in computing the estimated annual energy cost of the proposed and standard reference designs.

These guidelines constitute a large portion of Section N1105 and are easily seen in Table N1105.5.2(1), but are necessary to maintain fairness and consistency between the proposed and standard designs. Although the simulated performance alternative method is the most complex method, it gives the design professional the flexibility to introduce exterior walls, roof/ceiling components, etc., that do not meet the requirements of the prescriptive performance approach in Sections N1102 and N1103, but are considered acceptable where the annual energy use of the proposed building is equal to or less than that of the standard reference design building. Envelope features that lower energy consumption (window orientation, passive-solar features or the use of "cool" reflective roofing products in cooling-dominated climates) and mechanical and service water heating systems that are more efficient than those required by the minimum prescriptive requirements in Sections N1102 and N1103 are used to offset the potentially high thermal transmittance of an innovative exterior envelope design in this instance.

The simulated performance alternative also allows energy supplied by renewable energy sources on the building site to be discounted from the total energy consumption of the proposed design building. Because renewable energy obtained on the site comes from nondepletable sources such as solar radiation, wind, plant byproducts and geothermal sources, its use is not counted as part of the proposed building's energy use. The definition of "Energy cost" in Section N1101.9 and the provisions of Section N1106.3 should be reviewed when dealing with renewable energy. Renewable energy that is purchased from an off-site source cannot be excluded and would be included within the definition of "energy cost."

N1105.1 (R405.1) Scope. This section establishes criteria for compliance using simulated energy performance analysis.

Such analysis shall include heating, cooling and service water heating energy only.

❖ This section simply indicates that the performance analysis can include not only the building envelope performance (as is limited in Section N1102.1.4) but that the tradeoffs can also include the energy that is used for heating, cooling and service water heating. The provisions of this section do not include an allowance for the lighting energy to be included. If a designer wished to include lighting, it would be done under the alternative materials and method provisions of Section R104.11 (see commentary, Section R104.11).

Section N1105.1 establishes the terms of performance-based comparison for residential buildings. Under the Section 1105 Simulated Performance approach, the candidate building (proposed design) is evaluated based on the cost of energy used. In simple terms, Section N1106 states: build the residence any way as long as it is designed to use no more energy than a home built exactly to the minimum requirements in Sections N1102 and N1103.

This performance option can also be used to take advantage of energy-efficiency improvements that are only partly reflected in the total UA (sum of U -factor times the assembly area) of the residence, which is found in Section N1102.1.4. For example, in a cooling climate, reduction in ceiling UA will save more energy than an equal reduction in slab UA. This energy savings occurs because cooling climates have ground temperatures that approach comfortable indoor temperatures, diminishing the value of slab insulation for such climates. In contrast, the ceiling insulation in cooling climates usually receives higher solar loads during the warmest part of the day, increasing the value of ceiling insulation. Therefore, in cooling climates, a change in ceiling UA (perhaps adding more ceiling insulation) may have a substantially greater impact on energy use than the same UA change in slab-edge insulation.

A variety of calculation methods can be used to show compliance under the simulated performance alternative approach. The calculations can be complex; for example, a detailed building energy simulation tool covering all aspects of building energy use. Much of Section N1105 deals with establishing guidelines for defining aspects of the various sophisticated calculations that form the basis of the annual energy-use comparison. Alternatively, the analysis can be a simple calculation or correlation focused on one aspect of energy use. Where a method of analysis does not calculate, model or estimate a specific energy-using feature, it cannot be used for tradeoffs based on that specific feature. For example, software using degree-day-based climate and building envelope calculations does not specifically account for water heater energy use. Therefore, this type of software cannot be used to take credit for a high-efficiency water heater. Note, however, that software using degree-day-based climate and building envelope cal-

culations does account for changes in insulation levels; therefore, it could be used for an insulation tradeoff under the simulated performance approach.

The use of Section N1105 to show compliance is not required by all homes with special features designed to save energy. Very energy-efficient designs may not give credit for all of the design's features to show compliance. For example, a highly energy-efficient, passive solar home may be so well insulated and have such low glazing U -factors that those items alone may be sufficient to show compliance with the energy-related requirements in the code by using only UA computations or by meeting the prescriptive requirements of Sections N1102 and N1103. Because of these very efficient elements, compliance may be shown by using the prescriptive provisions or the easier UA computations instead of a more complex evaluation, which would include the other energy-using subsystems in the building.

N1105.2 (R405.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section N1101.13 be met. All supply and return ducts not completely inside the *building thermal envelope* shall be insulated to a minimum of R-6.

❖ This section serves as a reminder of the requirements found within Section N1101.2. When using Section N1105, compliance with the various mandatory provisions in this chapter is still required. The sections that must be complied with separately include items that often cannot be effectively modeled as well. When using Section N1105, it is important to review the provisions of Section N1102.5, which place "hard limits" on the fenestration U -factors and SHGC that may be used for tradeoffs (see commentary, Section N1102.5).

N1105.3 (R405.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence (*proposed design*) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design*. Energy prices shall be taken from a source *approved* by the *building official*, such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report*. *Building officials* shall be permitted to require time-of-use pricing in energy cost calculations.

Exception: The energy use based on source energy expressed in Btu (J) or Btu per square foot (J/m^2) of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

❖ The general procedure is to show that the annual energy cost for the building is less than the annual energy cost of a building that just meets the prescriptive requirements. The applicant must estimate the annual energy cost for two buildings: the one to be built and the standard reference design building. Because the two are compared on the basis of annual energy

costs, designs that have lower demand charges or use energy when rates are lower may be able to gain an advantage using Section N1105. It is also common to equate energy sources on the basis of cost because energy bills are the principal motivator for energy efficiency. An annual energy analysis could be used to compare a wide variety of energy-using features and conservation opportunities for the candidate building. The annual energy use can be used to trade off insulation; window/door areas; U -factors; HVAC equipment efficiency; water heating efficiency; infiltration control measures; duct insulation and sealing; pipe insulation and renewable energy technologies or new energy technologies. Appliances not regulated by the code (refrigerators, dishwashers, clothes-washing machines, residential lighting) are not eligible for trade-offs under this chapter.

The approach in this section is targeted for use in residences with energy-saving features that are not reflected in the UA or overall U -factor. Examples of features that lower energy consumption but not U -factor include high-efficiency HVAC systems; windows predominantly oriented toward the south; passive solar features; highly reflective (“cool”) roofing products in cooling-dominated climates or renewable energy sources such as photovoltaic, geothermal heat pumps and wind farms.

A building will comply with the requirements of the code and be acceptable when the annual energy cost of the proposed design is less than or equal to the annual energy cost of the standard design. The following sections will provide additional information and guidance related to the standard reference design and the design that it is compared to.

The purpose of the exception is to allow the use of source energy as an alternative metric to energy cost for compliance with the performance provisions.

Adding source energy as an alternative to energy cost offers many benefits to compliance, as follows:

- Using cost will be a liability to the home builder if home buyers do not achieve the savings listed in the compliance documentation.
- Energy cost changes frequently. This means that a home that complies today may not comply a few months from now if costs change.
- Energy cost focuses attention on first-year energy costs, which misses the point of an energy code where features that are generally life-cycle cost effective to the homeowner are added to save energy and make homes more comfortable over the life of the home, not to reduce first cost.

The source multipliers of 3.16 and 1.1 are from the 2002 *DOE Core Databook*. One way to think of this is that electric energy utilized at the site requires 3.16 times the source energy to produce the electricity at power plants and distribute via power lines to homes.

This is because the efficiency of power plants is much less than 100 percent and there are losses in transmission and distribution as well. Other fuels, such as natural gas and fuel oil, have less source energy losses and a lower source energy multiplier.

Standard Reference Design

This section reiterates the simulated performance approach’s strong reliance on principles established in Sections N1102 and N1103 as the foundation for the baseline level of energy efficiency established in the code. Therefore, all tradeoffs are judged against the prescriptive requirements of the standard reference design. Accordingly, insulation levels for the standard design building are set by the prescriptive requirements in Section N1102 and are generally based on the values in Table N1102.1.4. To avoid gaming of the proposed versus standard comparison, general principles and specific guidelines are given for various energy-using systems of the building [see Table N1105.5.2(1)].

The entries in Table N1105.5.2(1) for the envelope and fenestration requirements assist the code user in defining the standard reference design without bias. This is especially true in southern climates, where air-conditioning requirements are significant. In these cooling-dominated climates, where U -factor requirements are relatively high, residences with very large window areas and virtually no wall insulation can comply with the code through the use of windows with very low U -factors. This results in excessive air-conditioning costs in these climates because unshaded windows, dominated by solar heat gain, are required to meet only the code thermal-resistance and solar heat gain requirements. As a result, it is possible to construct residences in these climates with limited wall insulation, as long as windows with high thermal resistance and low SHGC are used.

The Table N1105.5.2(1) entries for the building’s thermal envelope components and fenestration are necessary to pin down the overall energy consumption of the standard design as described in Section N1102. Without the guidance provided by these entries, the areas and U -factors of the windows and building thermal envelope could assume a multitude of different values and still satisfy Section N1102 requirements. Furthermore, different values for these components would result in different overall energy cost levels for the standard design. The annual energy cost of the standard design represents the maximum “budget” the proposed design must meet. Without specific details of the standard reference design’s features and components, this budget becomes a moving target and will result in “gaming”; that is, picking a combination for the standard design that results in a very large energy budget, thus permitting the proposed design to easily comply with Section N1105.

Proposed Design

In general, the proposed design is the building that will be constructed exactly as it is shown in the plans and construction documents. Therefore, most of the entries for Table N1105.5.2(1) will be “as proposed.” There are, however, some sections that must match what is required or used for the standard reference design. The proposed design must be similar in many characteristics to the standard design. Otherwise, it may not provide an “apples-to-apples” comparison, thereby limiting the value of this method in demonstrating that the proposed design truly is more efficient. Some of the items that must be comparable include:

1. The standard and proposed designs must use the same energy sources (fuels) for the same function. For example, a gas-heated standard design cannot be compared to an electrically heated proposed design.
2. The areas of the building components (ceiling, wall and floor), including the building’s shape, configuration and orientation, must all remain the same in both the standard and proposed designs.
3. Both the standard and proposed designs must assume the same outdoor and comfort indoor climate conditions.
4. Both the standard and proposed designs must assume the same occupant diversity and usage patterns; for example, the same thermostat set points, water usage, internal gains, etc.

The exception within Section N1105.3 is important to understand because some jurisdictions may require that comparison be done on the basis of “site energy” versus “annual energy cost.” Because of the fact that the utility charges for various types of energy can change over time, some code officials may prefer that the comparison be made based on the amount of energy delivered to the home instead of the cost of that energy.

The code establishes the effective use of site energy as opposed to primary (a.k.a., source) energy as a goal and then delineates specific criteria, both prescriptive and performance based, for meeting that goal. Primary energy is defined as the amount of energy delivered to a sector adjusted to account for the energy sources used to produce the energy; for example, energy used to generate electricity. Included also is the energy lost in delivering the fuel to a customer; for instance, the electricity lost in the transmission and distribution of electricity. Site (delivered) energy is the amount of energy delivered to a household. Energy generation, transmission and distribution losses are not included. Primary energy is useful to show the ultimate resource impact of sectoral energy demand with respect to global particulate contributions of carbon dioxide, for example. Site energy is necessary if one wants to

know what is going on inside the building. In this case, fuel choice does matter; oil-heated homes may consume more site energy than electrically heated homes, for instance.

From an economist’s perspective, using energy cost instead of primary or site energy is preferable. Deregulation will affect the choice of fuels and households will decide what to consume. This view assumes that competitive pressures will ultimately equalize prices. This primary-versus-site debate centers on electricity, but losses are also associated with other energy sources. For example, one could take distillate fuel oil all the way back to the refinery, even factoring in energy losses in the fuel delivery trucks. So while Section N1105 will generally require the comparison to be based on the annual energy cost for the homeowner, some jurisdictions prefer to know the amount of energy delivered and not the cost. Regardless of which comparison basis is used, it is clearly the intent of Section N1105 to require the effective use of energy.

This exception permits equating different energy sources on the basis of the site energy. Site energy is energy use measured at the building boundary. For designs under Section N1105, site energy is input to the heating, cooling-service and water-heating equipment.

As mentioned earlier, it is common to equate energy sources on the basis of cost because energy bills are the principal motivator for energy efficiency and, over time, the market will move to the more economical energy source. The results of using either energy cost or delivered “site energy” tend to be similar. The use of tradeoffs based on energy costs may be preferable in cooling-dominated climates. The cost of a unit of gas is commonly much less than the same unit of electricity; therefore, equating fossil fuels and electricity in terms of heat content may not reflect the interest of the building owner based primarily on the applicable utility rate structures and tariffs. In southern climates, the use of site-energy-based tradeoffs tends to overcredit changes in heating energy use and undercredit changes in cooling energy use. The intent of the code to “achieve the effective use of energy” (see Section R101.3) can be preserved through the use of an annual energy cost or site-energy-based comparison. The use of site energy, or delivered energy, as the basis for the comparison under Section N1105 requires the approval of the code official.

N1105.4 (R405.4) Documentation. Documentation of the software used for the performance design and the parameters for the building shall be in accordance with Sections N1105.4.1 through N1105.4.3.

- ❖ This section provides a list of the minimum information that is required to demonstrate compliance with the code requirements. The three subsections within Section N1105.4 list the minimum level of information that is needed for this purpose. Because much of the information and software used for the performance option must

be approved by the code official, the jurisdiction should be consulted to see if any additional information may be required (see commentary, Section N1105.6.2).

A review of the code requirements of Section R104 of the IECC should also be included when looking at Section N1105.4. The construction documents must contain the data necessary to confirm that the results of the design have been incorporated into the construction documents and also to allow assessment of compliance. This is of particular importance when coupled with performing a comprehensive plan review given the sometimes very lengthy and sophisticated submittals required by the energy-efficiency method (see commentary, Section R104 of the IECC). Though not listed in the code, some state laws may require that the design of the building construction, and in this case, the development of a comparative building-energy analysis, be done by a registered design professional in accordance with the licensing laws of the state where the work takes place.

In such states, the code official should consider and enforce the requirement to coordinate with state licensing laws that often establish thresholds for when the services of a registered design professional are required.

N1105.4.1 (R405.4.1) Compliance software tools. Documentation verifying that the methods and accuracy of the compliance software tools conform to the provisions of this section shall be provided to the *building official*.

❖ This section is essentially a general requirement that where software is used to demonstrate compliance under Section N1105, the software be shown to provide accurate comparisons and results. Many of the software systems that may be used will be familiar and readily acceptable to the code official. Where a less commonly used software is proposed for use, the code official will need to be shown that the software does perform its intended function and that it is accurately comparing the standard reference and proposed designs.

N1105.4.2 (R405.4.2) Compliance report. Compliance software tools shall generate a report that documents that the *proposed design* complies with Section N1105.3. A compliance report on the *proposed design* shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based on the as-built condition of the building shall be submitted to the *code official* before a certificate of occupancy is issued. Batch sampling of buildings to determine energy code compliance for all buildings in the batch shall be prohibited.

Compliance reports shall include information in accordance with Sections N1105.4.2.1 and N1105.4.2.2. Where the *proposed design* of a building could be built on different sites where the cardinal orientation of the building on each site is different, compliance of the *proposed design* for the purposes of the application for the building permit shall be based on the worst-case orientation, worst-case configuration, worst-case building air leakage and worst-case duct leakage. Such

worst-case parameters shall be used as inputs to the compliance software for energy analysis.

❖ The approved software should be able to demonstrate that the proposed design truly does have an annual energy cost that is either less than or equal to that of the standard reference design. The code requires that a compliance report be submitted on two occasions: 1. At the time of permit application to verify that the proposed design complies with the code; and 2. At the end of the project, before the certificate of occupancy is issued, to verify that the “as-built” building complies with the code.

N1105.4.2.1 (R405.4.2.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include the following:

1. Building street address, or other building site identification.
 2. A statement indicating that the *proposed design* complies with Section N1105.3.
 3. An inspection checklist documenting the building component characteristics of the *proposed design* as indicated in Table N1105.5.2(1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design* with user inputs to the compliance software to generate the results.
 4. A site-specific energy analysis report that is in compliance with Section N1105.3.
 5. The name of the individual performing the analysis and generating the report.
 6. The name and version of the compliance software tool.
- ❖ Providing the address of the project will not only help in the tracking of the project and various permits, but it also ensures that the calculations that were run were for the intended project and are not simply based on a project that may not be applicable. While it may be possible to run a calculation based on a stock set of plans [see orientation provisions in Table N1105.5.2(1)], the best way to provide a truly accurate comparison is to provide a site-specific evaluation, as required in Item 4. Item 2 provides the primary information upon which approval will be granted. A summary must be submitted showing how the annual energy cost of the proposed design compares to the annual energy cost of the standard design. The comparison summary must include, as a minimum, annual energy cost by design (standard versus proposed) and could possibly include the fuel type (electric versus gas versus renewable sources) if it was a part of a tradeoff. Besides showing the actual comparison between the two designs, Item 3 requires an inspection checklist that can be used by the inspector to ensure that the proposed design matches what is actually constructed in the field. This checklist will address the details of the construction upon which the comparison was conducted. See Section N1105.4.3, Item 1, for the equivalent requirement for the standard reference design. These two sections will not only ensure that the accu-

racy of the comparison is fair, but also will provide information so that the comparison can be run again and verified if needed. While it would be best if the checklist did include information for all of the items listed in Table N1105.5.2(1), it is really only necessary that the information is provided for items that are compared or for which trade-offs are based or taken.

Because various versions of software can include different inputs or evaluations, it is important that both the name and version of the software be provided. Changes between the software or various editions of it could often provide different results. Listing the software edition helps the code official evaluate the report and also provides the information to conduct a verification review if necessary.

N1105.4.2.2 (R405.4.2.2) Compliance report for certificate of occupancy. A compliance report submitted for obtaining the certificate of occupancy shall include the following:

1. Building street address, or other building site identification.
 2. A statement indicating that the as-built building complies with Section N1105.3.
 3. A certificate indicating that the building passes the performance matrix for code compliance and listing the energy saving features of the buildings.
 4. A site-specific energy analysis report that is in compliance with Section N1105.3.
 5. The name of the individual performing the analysis and generating the report.
 6. The name and version of the compliance software tool.
- ❖ The items required for the compliance report for obtaining the certificate of occupancy are basically the same as those required for the permit application, except that the report is based on the “as-built” condition of the building. During the course of construction, changes in the windows, type of insulation, equipment or building dimensions are all required to be documented and approved. The changes must be approved based on compliance with the code and the original design. At the end of the day, however, one must verify that the changes made did not have a negative impact on the performance of the building, as analyzed before the permit application.

N1105.4.3 (R405.4.3) Additional documentation. The *building official* shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the *standard reference design*.
 2. A certification signed by the builder providing the building component characteristics of the *proposed design* as given in Table N1105.5.2(1).
 3. Documentation of the actual values used in the software calculations for the *proposed design*.
- ❖ The items in this section are not automatically required as those of Sections N1105.4.1 and N1105.4.2, but are instead only required when the code official wishes

them to be. Item 1 provides information related to the standard reference design similar to what Section N1105.4.2.2, Item 2, provides for the proposed design. Having this information allows the code official or designer to easily replicate the calculations if additional verification reviews or changes are needed.

Item 2 can be useful in a couple of ways. It cannot only be used by the inspector similar to the checklist in Section N1105.2, Item 2, but it helps to ensure that items that may not be seen or visible to the inspector have been installed as proposed. This certification has essentially be considered the same as the builder stating the as-built structure complies with the proposed and originally approved design plans.

Item 3 provides for a possible need to check input values for computer programs utilized. This enables the plan checker to readily verify compliance with the basic requirements of the code.

N1105.5 (R405.5) Calculation procedure. Calculations of the performance design shall be in accordance with Sections N1105.5.1 and N1105.5.2.

- ❖ The provisions of this section simply ensure that the comparisons between the standard reference design and the proposed design are accurate and that it reflects an “apples-to-apples” comparison.

N1105.5.1 (R405.5.1) General. Except as specified by this section, the *standard reference design* and *proposed design* shall be configured and analyzed using identical methods and techniques.

- ❖ Items that are not involved in the tradeoffs must be comparable between the standard reference design and the proposed design. This helps to ensure that the energy savings is truly based on the differences from Table N1105.5.2(1) that are being evaluated. Though it should go without saying, the same calculation method or software must be used to estimate the annual energy usage for space heating and cooling of the standard design and the proposed design. The calculation tool must be approved by the code official. A jurisdiction may want to make known the methods it prefers for comparing annual energy use. The code official retains the authority to determine whether a specific set of computations for a particular residence is acceptable. The use of Section N1105 is optional; therefore, the applicant is free to choose the method for achieving compliance (see commentary, Sections R101.3 and N1101.2). Regardless, whatever calculation procedure is used to evaluate the standard design must also be used to evaluate the proposed design.

N1105.5.2 (R405.5.2) Residence specifications. The *standard reference design* and *proposed design* shall be configured and analyzed as specified by Table N1105.5.2(1). Table N1105.5.2(1) shall include, by reference, all notes contained in Table N1102.1.2.

- ❖ While the majority of Section N1105 addresses the process to evaluate the standard design and proposed design, this section serves as the backbone of Section N1105 and the information upon which the compari-

sons are conducted. Tables N1105.5.2(1) and N1105.5.2(2) provide the list of items that are compared and establish not only the requirements for the standard design but also give a good view of what items may be included and evaluated for tradeoffs. The determination of requirements and application of the various items is fairly easy to follow due to the way the components are listed in separate rows of the table. Under Section N1105, it is only these items that may differ between the proposed and standard reference design. As discussed in the commentary to Section N1105.1, if there are any additional components or features for which a designer wishes to compare and make a tradeoff, the approval of such items would need to be based on Section R104.11.

The information that is determined for Tables N1105.5.2(1) and N1105.5.2(2) would be the type of information that is needed for both Sections N1105.4.2.2, Item 2, and N1105.4.3, Item 1.

TABLE N1105.5.2(1). See page 11-74 through 11-76.

- ❖ As discussed in the commentary to Section N1105.5.2, this table serves as the backbone of the requirements for Section N1105. By comparing the annual energy cost of a standard reference design to that of a proposed design home may trade off the efficiency of one element or component for an increased efficiency in another.

The column dealing with “building components” helps to distinguish what building elements may be considered and included in the performance option of Section N1105. The column labeled “Standard Reference Design” provides the details that are used as the basis for determining the annual energy cost that will serve as the maximum energy cost that the proposed design could use. This column simply states how the standard designed home is to be configured and treated in the simulations that will compare it to the proposed design home. This column simply ensures that comparisons between the two designs truly are based on a plan that meets the intended performance of the code. The “Proposed Design” column simply represents the home for which compliance is trying to be determined. As indicated, most of the items in a proposed design will be “as proposed.” There are a few entries in this column where the proposed design must use the same values as the standard design. These items are restricted so that a fair comparison is provided and so that the design parameters may not simply be changed in an attempt to show improved efficiency. Additional comments about the table or specific component requirements are as follows:

Walls, roofs and fenestration: Similar to Sections N1102.1 and N1102.3, this table separates the impact of solar gains for fenestration such as windows or energy loss through windows and doors from the impact of the wall *U*-factors. The provisions simply ensure that each component of the building’s thermal envelope is evaluated separately.

Walls, floors, ceilings and roofs: To avoid gaming the comparison, the areas of these items must be the same in both designs. No valid comparison of the proposed and standard designs can be made if the size of the two designs is not equal.

Foundations: This section explicitly requires the foundation and on-grade floor type be the same for both designs. Without this provision, the possibility for the designer to select a less energy-efficient foundation or floor type (including modeling a floor system over a heated space) for the standard design and a more energy-efficient foundation type for the proposed design is left open. Under this circumstance, heat loss for the proposed design would be much less significant because of the lower heat loss through the foundation. The resulting loss “credit” results in less insulation being required for the proposed design. This type of credit is prohibited because the designer may not have intended to use the unfavorable foundation in the first place.

Doors: The amount of door area and the orientation for the door are specified. Whether the door is glazed or opaque is not a consideration for the standard design because the area of glazing is dealt with under a separate entry. By requiring the door to be on the north orientation, the effects of SHGC on a glazed door are minimized.

Glazing: This requirement exists in response to strong evidence showing that glazing area and geometry have some impact on the building’s overall thermal transmittance, and that solar heat gain through windows constitutes a large portion of the air-conditioning load (typically 25 percent) in southern climates.

The area limitations help to ensure that the glazing areas are not manipulated to affect the efficiency of the various designs. The proposed glazing area limitation of 18 percent of the conditioned floor area of the residence is identical to the requirement of the Home Energy Rating System Council Guidelines (Version 2) for its standard design, and is equal to the maximum window area that was allowed by ASHRAE Standard 90.2-1993 for its standard design.

The code language, found in Note a, indicating that the glazing area includes the sash, framing and glazing is needed for completeness and clarification. The NFRC guidelines on window labeling require that window performance ratings be based on the full window system product. In other words, the *U*-factor, SHGC, visible light transmittance, air leakage and other properties of the window must be based on the combined impacts of both the glazing and its associated opaque constituents (defined here as “sash”).

Orientation significantly affects the annual energy consumption on a building and is critical to achieving an optimum passive solar design. This section recognizes that building energy consumption is affected by orientation and that an orientation change of the glazing could be a way to manipulate the standard reference design so that it uses an increased amount of

energy or gains an increased advantage by limiting solar heat gain.

Experimental evidence using eight cardinal exposures with equal glazing areas for the standard design as input for simulation programs shows that the procedure is inconvenient with very small increases in accuracy. Due to this, the four cardinal exposures are sufficient for achieving solar neutrality on the standard design. Because the percentage of glass-area facing in a particular orientation can vary significantly on a proposed design, the actual orientations are needed for accuracy. The difference in a large amount of glazing facing directly south, versus southwest, will significantly increase annual energy use, peak loads and the time the peak loads occur. The trend is that the more passive solar techniques are applied to the building, the more important the orientation becomes.

The section establishes an SHGC standard of 0.4 for glazed fenestration products in climates with significant cooling loads. Specifically, this requirement applies to warmer climates (Climate Zones 1 through 3). As a result, this requirement applies throughout much of the southern region of the United States in Oklahoma, Arkansas, Tennessee and North Carolina and extending as far north as the warmer parts of California and Nevada. Although Table N1102.1.2 does not require an SHGC in Climate Zones 4 through 8, this table establishes a requirement of 0.40 for these climate zones. When applying the SHGC provisions of the standard design, remember the application of Note e in Table N1102.1.2 for Climate Zone 3, Marine.

The table addresses interior shading and allows for contribution to the SHGC rating of a window by providing a simple equation to account for interior shading, based on the SHGC of the window's glazing. The "Interior shade fraction" in Section N1105, Performance Compliance Path, is used in simulating the performance of the building as a multiplier to reduce effective SHGC and its impact on the conditioned space. This approach is intended to simulate the effects of interior shades on solar heat gain transmitted through the glazing. As a result, this multiplier is important because it can affect the choice of appropriate fenestration. This section provides a simplified equation for determining interior shading fraction depending on the SHGC of the glazed fenestration product (this equation is based on the assumption of a specific type of interior shade, recognizing that the code has no control over the type of shade ultimately employed). This section is based on the assumption that shades are closed 50 percent of the time throughout the entire year, rather than assuming twice the shade usage in the summer than the winter.

The equation is based on ASHRAE Research Project 1311-RP, that produced a 95-page final report on the effects of various shading devices on building loads resulting from solar heat gain; specifically, Wright, J., et.al., *Improved Cooling Load Calculations for Fenestration with Shading Devices* (dated January 14, 2009).

This report publishes tables of modifiers for 56 glass products and 34 types of interior shading devices. Shade combinations studied in the report included:

1. Louvered shades
 - Three colors (dark, medium, light).
 - Five positions (rotated from closed down to open to closed up).
2. Fabric drape
 - Three colors.
 - Four weave densities (closed, semi-open, open, sheer).
3. Roller shades
 - Three colors.
 - Two densities (opaque, translucent).
4. Insect screen

According to the report, the shading values vary remarkably depending on the type of shade and the type of glass. In fact, one could reasonably conclude that it is impossible to set any meaningful shade fraction without reference to a specific shade and a specific window in each case. Reference to specific shades and window combinations in the code obviously would be complex at best, and would certainly be impractical, since the type of interior shades for each window is typically not controlled by the builder and would require a separate calculation for each window with a different shade. For this section, the equation is based on an assumption to use the most effective drape (from a shade fraction perspective), which is a light-colored tight-weave fabric drape.

Permanent, exterior-mounted shading devices for the standard design are considered atypical and, therefore, are not required or allowed to be included. Where credit is taken in the proposed design for these devices, the code official must approve and confirm the installation of the actual shading device proposed.

Skylights: This intends to reduce the complexity of the design requirements as applied to skylight areas in the standard design. If this section was not included, ceilings and skylights would also require detailed treatment as in Section N1102.3 and the glazing section above to fully specify the standard design.

Air exchange rate: This section establishes conditions under which air-leakage reduction can be claimed reliably. Without using an actual measurement, it often is not practical to document infiltration reduction measures beyond those in the standard design because the code (see Section N1102.4) already assumes a fairly comprehensive air-sealing regimen. Where the test reports that the anticipated building infiltration performance is not achieved as was assumed in the permit application, infiltration must be lowered or some other means must be used to make up the increased energy use attributable to the deficiency in infiltration rates. Note that "tight"

buildings may require mechanical ventilation to improve occupant comfort. Controlling ventilation rates reduces cooking odors, damp musty smells, stale air and elevated levels of carbon dioxide. Ventilation also helps reduce concentrations of air-borne contaminants off-gassed from building materials and related to other household activities.

Internal gains: The calculations for both the standard and proposed designs must assume the same internal loads. Where the simulation tool allows specification of internal gains, the total heat gains (sensible + latent) are to be calculated based on this equation in both the standard and proposed designs (the code does not distinguish between sensible and latent gains). This equation makes internal gains a function of the conditioned area and the number of bedrooms.

Heating systems: This section simply requires that the heating and cooling equipment in the standard design meet the minimum efficiency requirements that are currently required at the time of the evaluation.

This section contains general guidelines for the proposed design for any annual energy analysis under Section N1105. The standard and proposed designs must use the same energy sources (fuels) for the same function. For example, a gas-heated standard design cannot be compared to an electrically heated proposed design. For a fossil-fuel-heated building, the standard design must assume the applicable minimum efficiency as dictated by the code and the National Appliance Energy Conservation Act (NAECA).

Service water heating: Where the simulation tool or calculation models water heating energy, domestic service water-heating calculations must assume a set point of 120°F (49°C), with a daily usage of 30 gallons (113 L) per unit plus 10 gallons (37.8 L) per bedroom.

Thermal distribution systems [see Table N1105.5.2(2)]: Research and practice in the past few years has shown that the major component of heating and cooling system efficiency stems from air leakage in hot and cold air distribution systems (primarily ducts, but also air-handler cabinets). The research has been conducted by ASHRAE; Lawrence-Berkley National Laboratory; Brookhaven National Laboratory; Electric Power Research Institute; Gas Research Institute; Florida Solar Energy Center and numerous other research organizations and national utilities. Many, if not most, utilities in the nation now operate duct-leakage diagnosis and repair efforts as part of their energy conservation and demand side management programs to assist their customers. The Sheet Metal and Air-Conditioning Contractors National Association (SMACNA) has published test proce-

dures in outlining the methods and air distribution systems through duct-system pressurization testing (see the SMACNA *HVAC Air Duct Leakage Test Manual*) and a number of calibrated pressurization test equipment manufacturers are now producing equipment for sale in the market.

Technical questions regarding the specific energy impacts and mechanisms of specific leak types in certain locations remain; however, there is no question the elimination of air leakage results in energy inefficiency in duct systems being limited to conduction gains and losses through the ducts themselves.

The virtual elimination of these leaks also results in much improved heating and cooling system efficiencies (on the order of 95- to 99-percent efficient as opposed to 75- to 80-percent efficient). There is no technical disagreement that, once air leakage is no longer in question, air distribution system efficiency can be determined through straightforward engineering calculations using conduction heat-transfer equations, unencumbered by the complexities of air-leakage flows. A conservative assumption is that the ductwork in the standard design is 50-percent inside and 50-percent outside the conditioned space; however, the arrangement of ductwork in the standard design must be representative of that proposed.

Unless directly heated and cooled, attics and crawl spaces are unconditioned spaces. The specified distribution system efficiency (DSE) is to be used in the standard design where the designer wishes to take advantage of the impacts from improved DSEs in the proposed design and the entire distribution system is substantially leak free. The proposed designs use the specified system efficiencies with the proportion of the ducts inside and outside the conditioned system that is substantially leak free. The proposed designs use the specified system efficiencies with the proportion of the ducts inside and outside the conditioned space determined by the duct length and placement in the proposed design. It is acceptable for the proposed design to use system efficiencies other than those given where such factors result from a code-official-approved, post-construction duct system performance test. [Note that Table N1105.5.2(2) is titled "Default Distribution System Efficiencies" and that Note a of that table indicates that the values are for untested distribution systems.] The provisions in this section are a mechanism that allows builders to take credit for substantially leak-free duct systems where they are installed.

TABLE N1105.5.2(2). See page 11-76.

❖ See the commentary to Section N1105.5.2.

**TABLE N1105.5.2(1) [R405.5.2(1)]
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS**

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Above-grade walls	Type: mass wall if proposed wall is mass; otherwise wood frame.	As proposed
	Gross area: same as proposed	As proposed
	<i>U</i> -factor: as specified in Table N1102.1.4	As proposed
	Solar absorptance = 0.75	As proposed
	Emittance = 0.90	As proposed
Basement and crawl space walls	Type: same as proposed	As proposed
	Gross area: same as proposed	As proposed
	<i>U</i> -factor: from Table N1102.1.4, with insulation layer on interior side of walls	As proposed
Above-grade floors	Type: wood frame	As proposed
	Gross area: same as proposed	As proposed
	<i>U</i> -factor: as specified in Table N1102.1.4	As proposed
Ceilings	Type: wood frame	As proposed
	Gross area: same as proposed	As proposed
	<i>U</i> -factor: as specified in Table N1102.1.4	As proposed
Roofs	Type: composition shingle on wood sheathing	As proposed
	Gross area: same as proposed	As proposed
	Solar absorptance = 0.75	As proposed
	Emittance = 0.90	As proposed
Attics	Type: vented with aperture = 1 ft ² per 300 ft ² ceiling area	As proposed
Foundations	Type: same as proposed	As proposed
	Foundation wall area above and below grade and soil characteristics: same as proposed	As proposed
Opaque doors	Area: 40 ft ²	As proposed
	Orientation: North	As proposed
	<i>U</i> -factor: same as fenestration from Table N1102.1.4	As proposed
Vertical fenestration other than opaque doors	Total area ^h = (a) The proposed glazing area, where the proposed glazing area is less than 15 percent of the conditioned floor area (b) 15 percent of the conditioned floor area, where the proposed glazing area is 15 percent or more of the conditioned floor area	As proposed
	Orientation: equally distributed to four cardinal compass orientations (N, E, S & W).	As proposed
	<i>U</i> -factor: as specified in Table N1102.1.4	As proposed
	SHGC: as specified in Table N1102.1.2 except that for climates with no requirement (NR) SHGC = 0.40 shall be used.	As proposed
	Interior shade fraction: 0.92-(0.21 × SHGC for the standard reference design)	0.92-(0.21 × SHGC as proposed)
	External shading: none	As proposed
	Skylights	None
Thermally isolated sunrooms	None	As proposed
Air exchange rate	Air leakage rate of 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8 at a pressure of 0.2 inches w.g (50 Pa). The mechanical ventilation rate shall be in addition to the air leakage rate and the same as in the proposed design, but no greater than $0.01 \times CFA + 7.5 \times (N_{br} + 1)$ where: <i>CFA</i> = conditioned floor area <i>N_{br}</i> = number of bedrooms Energy recovery shall not be assumed for mechanical ventilation.	For residences that are not tested, the same air leakage rate as the standard reference design. For tested residences, the measured air exchange rate ^a . The mechanical ventilation rate ^b shall be in addition to the air leakage rate and shall be as proposed.

(continued)

TABLE N1105.5.2(1) [R405.5.2(1)]—continued
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Mechanical ventilation	None, except where mechanical ventilation is specified by the proposed design, in which case: Annual vent fan energy use: $\text{kWh/yr} = 0.03942 \times CFA + 29.565 \times (N_{br} + 1)$ where: CFA = conditioned floor area N_{br} = number of bedrooms	As proposed
Internal gains	$IGain = 17,900 + 23.8 \times CFA + 4104 \times N_{br}$ (Btu/day per dwelling unit)	Same as standard reference design.
Internal mass	An internal mass for furniture and contents of 8 pounds per square foot of floor area.	Same as standard reference design, plus any additional mass specifically designed as a thermal storage element ^c but not integral to the building envelope or structure.
Structural mass	For masonry floor slabs, 80 percent of floor area covered by R-2 carpet and pad, and 20 percent of floor directly exposed to room air.	As proposed
	For masonry basement walls, as proposed, but with insulation required by Table R402.1.4 located on the interior side of the walls	As proposed
	For other walls, for ceilings, floors, and interior walls, wood frame construction	As proposed
Heating systems ^{d, e}	As proposed for other than electric heating without a heat pump, where the proposed design utilizes electric heating without a heat pump the standard reference design shall be an air source heat pump meeting the requirements of Section C403 of the IECC-Commercial Provisions. Capacity: sized in accordance with Section N1103.7	As proposed
Cooling systems ^{d, f}	As proposed Capacity: sized in accordance with Section N1103.7.	As proposed
Service water heating ^{d, e, f}	As proposed Use: same as proposed design	As proposed $\text{gal/day} = 30 + (10 \times N_{br})$
Thermal distribution systems	Duct insulation: From Section N1103.2.1 A thermal distribution system efficiency (DSE) of 0.88 shall be applied to both the heating and cooling system efficiencies for all systems other than tested duct systems. For tested duct systems, the leakage rate shall be 4 cfm (113.3 L/min) per 100 ft ² (9.29 m ²) of conditioned floor area at a pressure of differential of 0.1 inches w.g. (25 Pa).	As tested or as specified in Table R405.5.2(2) if not tested. Duct insulation shall be as proposed.
Thermostat	Type: Manual, cooling temperature setpoint = 75°F; Heating temperature setpoint = 72°F	Same as standard reference

For SI: 1 square foot = 0.93 m², 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m², 1 gallon (US) = 3.785 L, °C = (°F-32)/1.8, 1 degree = 0.79 rad.

- Where required by the *code official*, testing shall be conducted by an *approved* party. Hourly calculations as specified in the ASHRAE *Handbook of Fundamentals*, or the equivalent shall be used to determine the energy loads resulting from infiltration.
- The combined air exchange rate for infiltration and mechanical ventilation shall be determined in accordance with Equation 43 of 2001 ASHRAE *Handbook of Fundamentals*, page 26.24 and the “Whole-house Ventilation” provisions of 2001 ASHRAE *Handbook of Fundamentals*, page 26.19 for intermittent mechanical ventilation.
- Thermal storage element shall mean a component not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element must be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or must be connected to such a room with pipes or ducts that allow the element to be actively charged.
- For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.
- For a proposed design without a proposed heating system, a heating system with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.
- For a proposed design home without a proposed cooling system, an electric air conditioner with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.
- For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater with the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For the case of a proposed design without a proposed water heater, a 40-gallon storage-type water heater with the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

(continued)

TABLE N1105.5.2(1) [R405.5.2(1)]—continued
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

h. For residences with conditioned basements, R-2 and R-4 residences and townhouses, the following formula shall be used to determine glazing area:

$$AF = A_s \times FA \times F$$

where:

AF = Total glazing area.

A_s = Standard reference design total glazing area.

FA = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + $0.5 \times$ below-grade boundary wall area).

F = (Above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.

and where:

Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.

Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.

Below-grade boundary wall is any thermal boundary wall in soil contact.

Common wall area is the area of walls shared with an adjoining dwelling unit.

L and CFA are in the same units.

TABLE N1105.5.2(2) [R405.5.2(2)]
DEFAULT DISTRIBUTION SYSTEM EFFICIENCIES FOR PROPOSED DESIGNS^a

DISTRIBUTION SYSTEM CONFIGURATION AND CONDITION	FORCED AIR SYSTEMS	HYDRONIC SYSTEMS ^b
Distribution system components located in unconditioned space	—	0.95
Untested distribution systems entirely located in conditioned space ^c	0.88	1
“Ductless” systems ^d	1	—

For SI: 1 cubic foot per minute = 0.47 L/s, 1 square foot = 0.093m², 1 pound per square inch = 6895 Pa, 1 inch water gauge = 1250 Pa.

a. Default values given by this table are for untested distribution systems, which must still meet minimum requirements for duct system insulation.

b. Hydronic systems shall mean those systems that distribute heating and cooling energy directly to individual spaces using liquids pumped through closed-loop piping and that do not depend on ducted, forced airflow to maintain space temperatures.

c. Entire system in conditioned space shall mean that no component of the distribution system, including the air handler unit, is located outside of the conditioned space.

d. Ductless systems shall be allowed to have forced airflow across a coil but shall not have any ducted airflow external to the manufacturer’s air handler enclosure.

N1105.6 (R405.6) Calculation software tools. Calculation software, where used, shall be in accordance with Sections N1105.6.1 through N1105.6.3.

❖ See the commentary to Section N1105.6.1.

N1105.6.1 (R405.6.1) Minimum capabilities. Calculation procedures used to comply with this section shall be software tools capable of calculating the annual energy consumption of all building elements that differ between the *standard reference design* and the *proposed design* and shall include the following capabilities:

1. Computer generation of the *standard reference design* using only the input for the *proposed design*. The calculation procedure shall not allow the user to directly modify the building component characteristics of the *standard reference design*.
2. Calculation of whole-building (as a single *zone*) sizing for the heating and cooling equipment in the *standard reference design* residence in accordance with Section N1103.6.
3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.
4. Printed *building official* inspection checklist listing each of the *proposed design* component characteristics

from Table N1105.5.2(1) determined by the analysis to provide compliance, along with their respective performance ratings (R -value, U -factor, SHGC, HSPF, AFUE, SEER, EF are some examples).

❖ This section states the general capabilities for the calculation software and its ability to evaluate the effects of building parametrics, system design, climatic factors, operational characteristics and mechanical equipment on annual energy usage.

There are a number of different software programs that are available to perform these calculations. The complexity of the programs will often depend on the amount of parameters that may be varied between the designs. The phrase within the base section that the software must be capable of evaluating the consumption of “all building elements that differ” between the two designs is important because it is the differences between the standard design and the proposed design that determine whether the proposed design is acceptable.

To ensure that the comparisons are made only on the items that are being traded, Item 1 looks to keep the software from allowing any manipulation that would help to reduce the energy costs of the standard design.

N1105.6.2 (R405.6.2) Specific approval. Performance analysis tools meeting the applicable provisions of Section N1105

shall be permitted to be *approved*. Tools are permitted to be *approved* based on meeting a specified threshold for a jurisdiction. The *building official* shall be permitted to approve tools for a specified application or limited scope.

- ❖ Though this section may be viewed as accepting a reduced level of efficiency, the intent is really more in line with the provisions of Section R104.11. An alternative program for evaluating the energy efficiency of a building using performance criteria can be substituted here. However, that alternative must meet the performance criteria of Section N1105.

N1105.6.3 (R405.6.3) Input values. When calculations require input values not specified by Sections N1102, N1103, N1104 and N1105, those input values shall be taken from an *approved* source.

- ❖ This section simply requires that any additional input information that may be required by the calculation software be approved by the code official. Through the use of the phrase “approved source,” the code official would be able to review the source of the information that is being used for inputting information. This will help to ensure that the selected values are reasonable for the situation and not just an estimate.

SECTION N1106 (R406) ENERGY RATING INDEX COMPLIANCE ALTERNATIVE

N1106.1 (R406.1) Scope. This section establishes criteria for compliance using an Energy Rating Index (ERI) analysis.

- ❖ The residential provisions of the IECC allow for varying methods for demonstrating compliance with the code. This includes a prescriptive and simulated performance option in addition to allowing efficiency programs that are designed to go above the minimum code levels, as “deemed to comply” programs. These above code programs must be approved by the code official to be used in the jurisdiction. Alternative programs that depend on an Energy Rating Index (ERI) have been approved as an alternative code or above code program in at least six states and in over 130 jurisdictions. These types of programs typically take the form of a Home Energy Rating System (HERS) program. Under the current code there is no guidance on setting ERI scores, which will lead to inconsistent application of these types of programs based on climate zones.

This section provides an ERI with established rating numbers to allow alternative programs using an ERI to be designed to meet these criteria. The section provides guidelines for the development of the index, requirements for documentation to be provided to

ensure compliance and a requirement that an approved third party verify that the building complies with the applicable ERI.

N1106.2 (R406.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Sections N1101.13 through N1104 identified as “mandatory” and Section N1103.5.3 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficient in Table 402.1.1 or 402.1.3 of the 2009 *International Energy Conservation Code*.

Exception: Supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6.

- ❖ As with Section N1105.2 of the code for the Performance Based Alternative, minimum requirements have been established in the code for all buildings. The sections that must be complied with separately include items that often cannot be effectively modeled as well. When using Section N1106, it is important to review the provisions of Section N1102.5, which place “hard limits” on the fenestration *U*-factors and SHGC that may be used for tradeoffs (see commentary, Section N1102.5).

N1106.3 (R406.3) Energy rating index. The Energy Rating Index (ERI) shall be a numerical integer value that is based on a linear scale constructed such that the *ERI reference design* has an Index value of 100 and a *residential building* that uses no net purchased energy has an Index value of 0. Each integer value on the scale shall represent a 1 percent change in the total energy use of the rated design relative to the total energy use of the *ERI reference design*. The ERI shall consider all energy used in the *residential building*.

- ❖ To avoid confusion in the application of different ERI programs, the parameters for the index are established here. The reason is simple and logical—to allow a clear understanding of the meaning of the index and to be able to uniformly apply the requirements of the code.

N1106.3.1 (R406.3.1) ERI reference design. The *ERI reference design* shall be configured such that it meets the minimum requirements of the 2006 *International Energy Conservation Code* prescriptive requirements.

The proposed *residential building* shall be shown to have an annual total normalized modified load less than or equal to the annual total loads of the *ERI reference design*.

- ❖ The reference house is based on a home built to the 2006 IECC, which is consistent with ERI-based programs that are used today.

N1106.4 (R406.4) ERI-based compliance. Compliance based on an ERI analysis requires that the *rated design* be shown to have an ERI less than or equal to the appropriate

value listed in Table N1106.4 when compared to the *ERI reference design*.

**TABLE N1106.4 (R406.4)
MAXIMUM ENERGY RATING INDEX**

CLIMATE ZONE	ENERGY RATING INDEX
1	52
2	52
3	51
4	54
5	55
6	54
7	53
8	53

❖ Based on the energy conservation levels set by the 2015 IECC, the ERI required for the rated design (i.e., the proposed building) is set as shown.

N1106.5 (R406.5) Verification by approved agency. Verification of compliance with Section N1106 shall be completed by an *approved* third party.

❖ In order to ensure proper application of the parameters of the ERI chosen and the proper use of computer software, this option for energy conservation requires a third party to review the proposed design to ensure compliance with the code. The approved third party should be knowledgeable in the energy code, the ERI system and the use of computer software for design. By stating the agency or individual must be a “third party,” the code is requiring financial independence, with no possible conflicts of interest.

N1106.6 (R406.6) Documentation. Documentation of the software used to determine the ERI and the parameters for the residential building shall be in accordance with Sections N1106.6.1 through N1106.6.3.

❖ See the commentary to Section N1105.4.

N1106.6.1 (R406.6.1) Compliance software tools. Documentation verifying that the methods and accuracy of the compliance software tools conform to the provisions of this section shall be provided to the *code official*.

❖ See the commentary to Section N1105.4.1.

N1106.6.2 (R406.6.2) Compliance report. Compliance software tools shall generate a report that documents that the ERI of the *rated design* complies with Sections N1106.3 and N1106.4. The compliance documentation shall include the following information:

1. Address or other identification of the residential building.
2. An inspection checklist documenting the building component characteristics of the *rated design*. The inspection checklist shall show results for both the *ERI reference design* and the *rated design*, and shall document all inputs entered by the user necessary to reproduce the results.

3. Name of individual completing the compliance report.
4. Name and version of the compliance software tool.

Exception: Multiple orientations. Where an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements in each of the four (north, east, south and west) cardinal orientations.

❖ See the commentary to Section N1105.4.2.

N1106.6.3 (R406.6.3) Additional documentation. The *code official* shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the *ERI reference design*.
2. A certification signed by the builder providing the building component characteristics of the *rated design*.
3. Documentation of the actual values used in the software calculations for the *rated design*.

❖ See the commentary to Section N1105.4.3.

N1106.7 (R406.7) Calculation software tools. Calculation software, where used, shall be in accordance with Sections N1106.7.1 through N1106.7.3.

❖ See the commentary to Sections N1105.6.1 through N1105.6.3.

N1106.7.1 (R406.7.1) Minimum capabilities. Calculation procedures used to comply with this section shall be software tools capable of calculating the ERI as described in Section N1106.3, and shall include the following capabilities:

1. Computer generation of the *ERI reference design* using only the input for the *rated design*.

The calculation procedure shall not allow the user to directly modify the building component characteristics of the *ERI reference design*.

2. Calculation of whole-building, as a single *zone*, sizing for the heating and cooling equipment in the *ERI reference design* residence in accordance with Section N1103.7.
3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.
4. Printed *code official* inspection checklist listing each of the *rated design* component characteristics determined by the analysis to provide compliance, along with their respective performance ratings.

❖ See the commentary to Sections N1105.6.1 through N1105.6.3.

N1106.7.2 (406.7.2) Specific approval. Performance analysis tools meeting the applicable sections of Section N1106 shall be *approved*. Tools are permitted to be *approved* based on meeting a specified threshold for a jurisdiction. The *code*

official shall approve tools for a specified application or limited scope.

- ❖ See the commentary to Sections N1105.6.1 through N1105.6.3.

N1106.7.3 (R406.7.3) Input values. When calculations require input values not specified by Sections N1102, N1103, N1104 and N1105, those input values shall be taken from an approved source.

- ❖ See the commentary to Sections N1105.6.1 through N1105.6.3.

SECTION N1107 (R501) EXISTING BUILDINGS—GENERAL

N1107.1 (R501.1) Scope. The provisions of Sections N1107 through N1111 shall control the *alteration*, repair, addition and change of occupancy of existing buildings and structures.

- ❖ The scope of this chapter is to deal with the specific circumstances related to changes to existing buildings. This chapter provides a roadmap when dealing with different types of projects—alterations, repairs, additions and changes of occupancy.

N1107.1.1 (R501.1.1) Additions, alterations, or repairs: General. Additions, alterations, or repairs to an existing building, building system or portion thereof shall comply with Section N1108, N1109 or N1110. Unaltered portions of the existing building or building supply system shall not be required to comply with this chapter.

- ❖ For commentary on additions, see Section N1108; for alterations, see Section N1109; and for repairs, see Section N1109.

N1107.2 (R501.2) Existing buildings. Except as specified in this chapter, this code shall not be used to require the removal, *alteration* or abandonment of, nor prevent the continued use and maintenance of, an existing building or building system lawfully in existence at the time of adoption of this code.

- ❖ This section addresses the fact that, in general, the code does not affect existing buildings. It will permit an addition to be made to an existing building without requiring the existing building to conform to the code. In such a case, the addition is expected to comply with the current code, but it will not require changes for the existing portion. Therefore, the code does not apply retroactively to existing buildings. When an existing building is modified by an addition, alteration, renovation or repair, Section N1108 or N1109 will provide the guidance and requirements for such changes.

N1107.3 (R501.3) Maintenance. Buildings and structures, and parts thereof, shall be maintained in a safe and sanitary condition. Devices and systems that are required by this code shall be maintained in conformance with the code edition under which installed. The owner or the owner's authorized agent shall be responsible for the maintenance of buildings and structures. The requirements of this chapter shall not provide the basis for removal or abrogation of energy conserva-

tion, fire protection and safety systems and devices in existing structures.

- ❖ The code is designed to regulate new construction and new work and is not intended to be applied retroactively to existing buildings except where existing envelope, lighting, mechanical or service water heating systems are specifically affected by Section N1108, N1109 or N1110. Maintenance of building systems and components is required, but the code does not intend that upgrade or modification to meet this code is applied when maintenance is dealt with.

N1107.4 (R501.4) Compliance. *Alterations, repairs, additions* and changes of occupancy to, or relocation of, existing buildings and structures shall comply with the provisions for *alterations, repairs, additions* and changes of occupancy or relocation, respectively, in this code and the *International Building Code, International Fire Code, International Fuel Gas Code, International Mechanical Code, International Plumbing Code, International Property Maintenance Code, International Private Sewage Disposal Code* and NFPA 70.

- ❖ This code does not intend that compliance with the provisions of other I-Codes, such as the IBC, be ignored. The I-Codes are intended to be a coordinated set of construction codes. This section clarifies the relationship between this chapter of the code and the IRC, IBC, *International Fire Code*[®] (IFC[®]), *International Fuel Gas Code*[®] (IFGC[®]), IMC, IPC, *International Property Maintenance Code*[®] (IPMC[®]), *International Private Sewage Disposal Code*[®] (IPSDC[®]) and NFPA 70.

When alterations and repairs are made to existing mechanical and plumbing systems, the provisions of the I-Codes and NFPA 70 for alterations and repairs must be followed. Those codes indicate the extent to which existing systems must comply with the stated requirements. Where portions of existing building systems, such as plumbing, mechanical and electrical systems, are not being altered or repaired, those systems may continue to exist without being upgraded as long as they are not hazardous or unsafe to the building occupants.

N1107.5 (R501.5) New and replacement materials. Except as otherwise required or permitted by this code, materials permitted by the applicable code for new construction shall be used. Like materials shall be permitted for repairs, provided no hazard to life, health or property is created. Hazardous materials shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

- ❖ There are two options for materials used in repairs to an existing building. Generally, the materials used for repairs should be those that are presently required or permitted for new construction under the I-Codes. It is also acceptable to use materials consistent with those that are already present, except where those materials pose a hazard. This allowance follows the general concept that any repair should not make a building more hazardous than it was prior to the repair. It is generally possible to repair a structure, its compo-

nents and its systems with materials consistent with those materials that were used previously. However, where materials that are now deemed hazardous are involved in the repair work, they may no longer be used. For example, the code identifies asbestos and lead-based paint as two common hazardous building materials that cannot be used in the repair process. Certain materials previously considered acceptable for building construction are now a threat to the health of the occupants.

N1107.6 (R501.6) Historic buildings. No provision of this chapter relating to the construction, *repair*, *alteration*, restoration and movement of structures, and *change of occupancy* shall be mandatory for *historic buildings* provided a report has been submitted to the code official and signed by the owner, a registered *design professional*, or a representative of the State Historic Preservation Office or the historic preservation authority having jurisdiction, demonstrating that compliance with that provision would threaten, degrade or destroy the historic form, fabric or function of the *building*.

❖ In some aspects, this is a bit of a continuation of the “existing building” provisions but it goes even further—historic buildings are exempt. In earlier editions of the code, this exemption applied only to the exterior envelope of such buildings, and to the interior only in those cases where the ordinance explicitly designated elements of the interior. With the current text, historic buildings are exempt from all aspects of the code. This exemption, however, is not without conditions. The most important criterion for application of this section is that the building must be specifically classified as being of historic significance by a qualified party or agency. Usually this is done by a state or local authority after considerable scrutiny of the historical value of the building. Most, if not all, states have authorities, such as a landmark commission, as do many local jurisdictions.

Because of the unique issues involved, historic buildings are exempt from the requirements of the code. This exemption could be extended to include all parts that are “historic,” including additions, alterations and repairs, that would normally be addressed by Section N1108 or N1109. If the proposed addition, alteration or renovation is not “historic,” then the provisions of Section N1108 or N1109 should be applied. Consideration of energy conservation and compliance with the code is still of value in historic buildings. In exempting historic buildings, the code is simply recognizing that energy efficiency may be difficult to accomplish while maintaining the “historic” nature of the building.

SECTION N1108 (R502) ADDITIONS

N1108.1 (R502.1) General. Additions to an existing building, building system or portion thereof shall conform to the provisions of this chapter as they relate to new construction without requiring the unaltered portion of the existing building or building system to comply with this chapter. Additions

shall not create an unsafe or hazardous condition or overload existing building systems. An addition shall be deemed to comply with this chapter where the addition alone complies, where the existing building and addition comply with this chapter as a single building, or where the building with the addition uses no more energy than the existing building. Additions shall be in accordance with Section N1108.1.1 or N1108.1.2.

❖ When an addition is added to an existing building, only the addition is required to comply with the requirements of the code, as outlined in Section N1108.1.1, Prescriptive Requirements. However, this section now provides another option—to use performance requirements on the entire building, with the addition, as stated in Section N1108.1.2. Compliance in this manner was always implicit in the code. This section now provides a roadmap for the available alternatives.

N1108.1.1 (R502.1.1) Prescriptive compliance. Additions shall comply with Sections N1108.1.1.1 through N1108.1.1.4.

❖ The basic premise of this section is that the addition alone, and not the remainder of the building, must comply with the code.

N1108.1.1.1 (R502.1.1.1) Building envelope. New building envelope assemblies that are part of the addition shall comply with Sections N1102.1, N1102.2, N1102.3.1 through N1102.3.5, and N1102.4.

Exception: Where nonconditioned space is changed to conditioned space, the building envelope of the addition shall comply where the UA, as determined in Section N1102.1.5, of the existing building and the addition, and any alterations that are part of the project, is less than or equal to UA generated for the existing building.

❖ The exception is the key to this section. Again, the insulation, sealing and air infiltration barriers required in the code for new construction apply to the addition. However, the exception provides some guidance regarding the circumstance where nonconditioned space becomes conditioned space. A typical example of this would be enclosing an attached garage to become a family room. The baseline for the entire building including the existing building would be the UA of the existing building. That is the sum of the *U*-values for the walls, windows and doors multiplied times the respective areas of each of those components. Accordingly, the total sum of the UA for the completed building including the newly conditioned garage must be less than the UA for the existing building. This ensures that, regardless of how well insulated the existing building is, the addition will not make the building envelope less energy efficient.

Example: An existing house has a total UA of 222. (Using the “Standard” Design as the existing house from the example in commentary Section N1102.1.4. A 20-foot by 10-foot garage is proposed to be converted to a family room. For the example, assume the newly renovated garage has a 20-square-foot window.

EXISTING BUILDING	EXISTING BUILDING PLUS NEW FAMILY ROOM
Exterior Wall: 1050 ft ² $U_w = 0.057$ Glazed doors and windows: 192 ft ² $U_g = 0.32$	Exterior Wall: 1170 ft ² 850 ft ² @ $U_w = 0.057$ 320 ft ² @ $U_w = 0.032$ Glazed doors and windows: 222 ft ² @ $U_g = 0.32$
Opaque Exterior Door: 38 ft ² $U_g = 0.32$ Roof: 1500 ft ² $U_r = 0.026$ Floor (slab): 1500 ft ² $U_s = 0.033$	Opaque Exterior Door: 19 ft ² $U_g = 0.32$ Roof: 1700 ft ² 1500 ft ² @ $U_r = 0.026$ 200 ft ² @ $U_r = 0.022$ Floor: 1700 ft ² 1500 @ $U_s = 0.033$ 200 ft ² @ $U_s = 0.028$

The total UA of the existing building is 222 as calculated in Section N1102.1.4. For the building with the new family room, we are using R-20 wall insulation in the cavity, with R-13 continuous insulation. Floor insulation is increased to R-38. The total UA for that combination of exterior wall values is 234, which is greater than 222. Therefore, some additional insulation will be required in order for the newly created conditioned space to meet the code.

N1108.1.1.2 (R502.1.1.2) Heating and cooling systems. New heating, cooling and duct systems that are part of the addition shall comply with Sections N1103.1, N1103.2, N1103.3, N1103.5 and N1103.6.

Exception: Where ducts from an existing heating and cooling system are extended to an addition, duct systems with less than 40 linear feet (12.19 m) in unconditioned spaces shall not be required to be tested in accordance with Section N1103.2.2.

❖ Heating and cooling systems for additions are required to meet the present day code for additions. The key to this section, again, is the exception that allows relaxation on duct testing requirements. This accommodates a simple addition where there is a short reach with the ductwork in an attic or crawl space to the conditioned spaces in the addition.

N1108.1.1.3 (R502.1.1.3) Service hot water systems. New service hot water systems that are part of the addition shall comply with Section N1103.4.

❖ There is no relaxation of requirements for new construction for service hot water systems provided for additions.

N1108.1.1.4 (R502.1.1.4) Lighting. New lighting systems that are part of the addition shall comply with Section N1104.1.

❖ There is no relaxation of requirements for new construction for lighting systems provided for additions.

N1108.1.2 (R502.1.2) Existing plus addition compliance (Simulated Performance Alternative). Where nonconditioned space is changed to conditioned space, the addition shall comply where the annual energy cost or energy use of the addition and the existing building, and any alterations that are part of the project, is less than or equal to the annual energy cost of the existing building when modeled in accordance with Section N1105. The addition and any alterations that are part of the project shall comply with Section N1105 in its entirety.

❖ Section N1105 provides the performance alternative for compliance with the code. This section simply states that this performance alternative can be used in the design of an addition as well. The difference here is that the “Standard Design” is the existing building, rather than the standard building modeled from compliance with the code as used in Section N1105.

SECTION N1109 (R503) ALTERATIONS

N1109.1 (R503.1) General. *Alterations* to any building or structure shall comply with the requirements of the code for new construction. *Alterations* shall be such that the existing building or structure is no less conforming with the provisions of this chapter than the existing building or structure was prior to the *alteration*.

Alterations to an existing building, building system or portion thereof shall conform to the provisions of this chapter as they relate to new construction without requiring the unaltered portions of the existing building or building system to comply with this chapter. Alterations shall not create an unsafe or hazardous condition or overload existing building systems. *Alterations* shall be such that the existing building or structure uses no more energy than the existing building or structure prior to the *alteration*. Alterations to existing buildings shall comply with Sections N1109.1.1 through N1109.2.

❖ Alterations include renovations, which implies that something is changed in the structure. For example, the removal, rearrangement or replacement of partition walls in an office building is an alteration because, in part, of possible impact on the means of egress, fire resistance or other life safety features of the building. Conversely, the replacement of damaged trim pieces on a door frame is considered a repair, not an alteration.

Basically, alterations are to conform to the requirements for a new structure, except as specifically stated in this section. For example, a new window installed where there was none will be required to have the *U*-factor rating and SHGC rating required for fenestration in the code, even if the insulation in the walls is not in conformance with the code. With this basic intent in

mind, Sections N1109.1.1, N1109.1.2, N1109.1.3, N1109.1.4 and N1109.2 address specific systems in the energy code that could be part of an alteration.

N1109.1.1 (R503.1.1) Building envelope. Building envelope assemblies that are part of the alteration shall comply with Section N1102.1.2 or N1102.1.4, Sections N1102.2.1 through N1102.2.12, N1102.3.1, N1102.3.2, N1102.4.3 and N1102.4.5.

Exception: The following alterations need not comply with the requirements for new construction provided the energy use of the building is not increased:

1. Storm windows installed over existing fenestration.
 2. Existing ceiling, wall or floor cavities exposed during construction provided that these cavities are filled with insulation.
 3. Construction where the existing roof, wall or floor cavity is not exposed.
 4. Roof recover.
 5. Roofs without insulation in the cavity and where the sheathing or insulation is exposed during reroofing shall be insulated either above or below the sheathing.
 6. Surface applied window film installed on existing single pane fenestration assemblies to reduce solar heat gain provided the code does not require the glazing or fenestration assembly to be replaced.
- ❖ The exceptions to this section are the key to these provisions. Alterations involving exterior walls and roofs are required to meet the requirements for a new building unless one of these exceptions apply.

The exceptions address situations where the alteration or repair of a structure or element is not required to comply with the provisions of the code. Some of these situations are typically either a normal part of ongoing maintenance of the building, would improve the performance or would not present an opportunity for improved energy savings. All of these exceptions are tied to the fact that they are permitted, provided “the energy use of the building is not increased.”

Exception 1 is a fairly self-evident provision. Because of the limited nature of the work, there is little opportunity to make additional changes. This helps to reinforce the statement from the main paragraph that the intent is not to make “the unaltered portion(s) of the existing building or building system” comply with the code. In this case, the addition of a storm window over an existing window will only improve performance of the existing fenestration.

Exception 2 is important for a couple of the limitations that it contains. The provision only applies when the ceiling, wall or floor cavity is “exposed during construction.” If the cavity is not opened up, then there is no requirement to do anything. If the cavity is exposed, the requirement will only be to “fill” it with insulation. Therefore, the level of insulation is not required to comply with the building thermal envelope requirements, but is instead only required to be “filled” with any type

of insulation and not to any specific *R*-value.

Exception 3 will exempt the need to make changes to the building thermal envelope because the building cavities are not exposed.

Exception 4 is straightforward. A roof recover is an alteration, but does not impact the building envelope.

Exception 5 applies to roofs that are part of the building envelope and typically would have below-deck or above-deck insulation. The second sentence of Exception 4 permits the code-required insulation to be above or below the deck. For a typical single-family home (with nonconditioned space), the ceiling is the building thermal envelope and the roof is not; therefore, Exception 5 would not apply. However, if during reroofing the existing ceiling cavities are exposed, then Exception 3 would apply.

Exception 6 is straightforward as well. Surface film used to provide a lower SHGC rating is acceptable for windows that do not otherwise need to be replaced.

N1109.1.1.1 (R503.1.1.1) Replacement fenestration. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for *U*-factor and SHGC as provided in Table N1102.1.2.

❖ Replacement windows and doors are required to meet the requirements of the code for new construction, with no exceptions.

Replacing only a glass pane in an existing sash and frame would not fall under this provision if the *U*-factor and SHGC are equal to or lower than the values prior to the replacement. In situations where the existing values are not known or where the replacement is more than just replacing the glass pane, the provisions may be applicable. It is often common practice when fenestration is replaced to remove only the sash and glazing of an existing window and replace them with an entirely new fenestration product. Sometimes the existing frame also is removed but, many times, the new fenestration product is custom made to fit in the existing space left after the sash and glazed portions are removed. In essence, the new fenestration is installed in or over the existing frame. Whether the existing frame is removed or not, these types of replacements are regulated by this section.

Section N1102.3.6 requires that each fenestration unit replaced in a residence not exceed the maximum fenestration *U*-factor and SHGC for the applicable climate zone. This requirement applies to all replacement windows, even if the existing frame is not removed (e.g., the new window is placed inside the old frame), so long as the sash and glazing are replaced. In addition, remember that the definition of “Fenestration” includes doors, which must meet the same *U*-factor requirements as windows. Therefore, the replacement of a door also would have to meet these requirements.

When dealing with replacement fenestration, the code official should be consulted to explain how this requirement will be applied. For simple ease of appli-

cation for both the code official and the installer, the *U*-factor and SHGC requirements could be applied to each fenestration unit. Therefore, the *U*-factor and SHGC required for each unit would be the values listed directly in Table N1102.1.1. However, if acceptable to the code official and additional information is available regarding the performance of the remaining existing windows in the home, it may be reasonable to permit the use of the area-weighted values of Sections N1102.3.1 and N1102.3.2, or even the exemptions of Sections N1102.3.3 and N1102.3.4 to the replaced fenestration unit.

In accordance with Section R102.1, the *U*-factor and SHGC for each replacement fenestration product must be obtained from a label attached to the product certifying that the values were determined in accordance with NFRC procedures by an accredited, independent laboratory. In the absence of an NFRC-labeled *U*-factor or SHGC, a value from the limited default tables [see Tables R303.1.3(1) through R303.1.3(3)] must be used. The NFRC procedures do include applicable methods to test various replacement products.

N1109.1.2 (R503.1.2) Heating and cooling systems. New heating, cooling and duct systems that are part of the alteration shall comply with Sections N1103.1, N1103.2, N1103.3 and N1103.6.

Exception: Where ducts from an existing heating and cooling system are extended, duct systems with less than 40 linear feet (12.19 m) in unconditioned spaces shall not be required to be tested in accordance with Section N1103.3.3.

- ❖ Heating and cooling systems for additions are required to meet the code requirements for new construction for alterations. The key to this section is the exception that allows relaxation on duct testing requirements. This simply accommodates a simple alteration where there is a short reach with the ductwork in an attic or crawl space to the conditioned spaces in the alteration.

N1109.1.3 (R503.1.3) Service hot water systems. New service hot water systems that are part of the alteration shall comply with Section N1103.5.

- ❖ Service hot water systems in an alteration are required to meet the requirements of the code for new construction, with no exceptions.

N1109.1.4 (R503.1.4) Lighting. New lighting systems that are part of the alteration shall comply with Section N1104.1.

Exception: Alterations that replace less than 50 percent of the luminaires in a space, provided that such alterations do not increase the installed interior lighting power.

- ❖ Alterations involving the lighting systems can be relaxed somewhat when fewer than 50 percent of the luminaires are being replaced. However, in keeping with the primary intent of the code for alterations, the

final product cannot use more energy than the building that is being renovated. The code does not allow an increase in lighting power.

N1109.2 (R503.2) Change in space conditioning. Any non-conditioned or low energy space that is altered to become *conditioned space* shall be required to be brought into full compliance with this chapter.

Exception: Where the simulated performance option in Section N1105 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost otherwise allowed by Section N1105.3.

- ❖ The exception recognizes the fact that full compliance with the code for existing buildings is extremely difficult and costly. Conditions such as slab edges, structural thermal bridges and window configurations cannot, in many cases, be practically remedied. Therefore, an alternate compliance path allowing a 10 percent higher total building performance value. This could result in the preservation and adaptive reuse of more existing buildings, which is a significant energy conservation measure.

SECTION N1110 (R504) REPAIRS

N1110.1 (R504.1) General. Buildings, structures and parts thereof shall be repaired in compliance with Section N1107.3 and this section. Work on nondamaged components necessary for the required *repair* of damaged components shall be considered part of the *repair* and shall not be subject to the requirements for *alterations* in this chapter. Routine maintenance required by Section N1107.3, ordinary repairs exempt from *permit*, and abatement of wear due to normal service conditions shall not be subject to the requirements for *repairs* in this section.

- ❖ This section and Section N1110.2 provide details for the user of the code as to what a repair is. A repair is work that would not be required to be in compliance with the alterations provisions of the code. Section N1109.2 provides some specific work that are considered repairs. This is done simply to clarify the code on these specific issues; the list is not intended to be comprehensive—other work could also be considered repairs, as described in this section.

N1110.2 (R504.2) Application. For the purposes of this code, the following shall be considered repairs:

1. Glass-only replacements in an existing sash and frame.
2. Roof repairs.
3. Repairs where only the bulb and/or ballast within the existing luminaires in a space are replaced provided that the replacement does not increase the installed interior lighting power.

- ❖ See the commentary to Section N1110.1.

SECTION N1111 (R505) CHANGE OF OCCUPANCY OR USE

N1111.1 (R505.1) General. Spaces undergoing a change in occupancy that would result in an increase in demand for either fossil fuel or electrical energy shall comply with this code.

- ❖ When a building undergoes a change of occupancy, energy-using systems (envelope, mechanical, service water heating, electrical distribution or illumination) must be evaluated to determine the effect the change of occupancy has on system performance and energy use. For example, if a mercantile building were converted to a restaurant, additional ventilation would be required for the public based on the increased occupant load. If an existing system serves an occupancy that is different from the occupancy it served when the code went into effect, the mechanical system must comply with the applicable code requirements for a mechanical system serving the newer occupancy. Depending on the nature of the previous occupancy, changing a building's occupancy classification could result in a change to the mechanical, service water heating, electrical distribution or illumination systems or any combination of these.

Buildings undergoing a change of occupancy must meet the applicable requirements of the code when peak demand is increased. For example, if a hotel is converted to multiple-family residential use and the conversion results in an increase in the building's peak connected load (space conditioning, lighting or service water heating), the entire building must be brought into compliance.

When the occupancy changes in a portion of an existing building (residential or commercial) and the new occupancy results in an increase in the peak demand for either fossil fuel or electrical energy supply, the portion of the building associated with the new occupancy must meet the code.

When a permittee claims that a change in occupancy will not increase the peak design rate of energy use for the building, it is the applicant's responsibility to demonstrate that the peak load of the converted building will not exceed the peak load of the original building. Without supporting documentation, the peak load generally must be assumed to increase with a change in occupancy.

It is also important that users realize that under the code there can be a difference between the change of occupancy (the way a building is used) and what the IBC deals with when a change of occupancy classification occurs. Therefore, if a storage building that has no heating or cooling is modified so that the building is heated to prevent the stock items from freezing, the IBC would not consider this as a change of occupancy because the occupancy classification would still be Group S-1. This code, however, would consider this a change in occupancy because the way the building is used would change and it would result in an increase in the demand for energy.

N1111.2 (R505.2) General. Any space that is converted to a dwelling unit or portion thereof from another use or occupancy shall comply with this code.

Exception: Where the simulated performance option in Section N1105 is used to comply with this section, the annual energy cost of the proposed design is permitted to be 110 percent of the annual energy cost otherwise allowed by Section N1105.3.

- ❖ This is a specific example of a change in occupancy (see commentary, Section N1111.1).

The exception recognizes the fact that full compliance with the code for existing buildings is extremely difficult and costly. Conditions such as slab edges, structural thermal bridges and window configurations cannot be practically remedied in many cases. Therefore, an alternate compliance path allowing a 10 percent higher total building performance value is needed. This could result in the preservation and adaptive reuse of more existing buildings, which itself is a significant energy conservation measure.

ICC INTERNATIONAL
CODE
COUNCIL®

People Helping People Build a Safer World®

The International Code Council's Training and Education Department

Industry professionals look to ICC to provide the critical knowledge and experiences necessary to excel in today's challenging world. ICC's educational programs cover a broad spectrum of code and construction related topics, offering some of the highest quality instruction direct from the source.

INSTITUTES

Acquire Skills, Share Experiences, Earn CEUs

ICC's training institutes offer a comprehensive education experience and a great way to earn much needed CEUs. Learn best practices from the leading experts in the field, build your network of professional contacts and share experiences. Institutes are held across the country throughout the year. To see the full schedule go to www.iccsafe.org/training.

HIRE ICC TO TEACH

Bring ICC On-Site and Earn CEUs

Give your group the confidence they need to meet tough challenges head-on so they can reach their full potential. ICC's course catalog contains a wide variety of educational topics that are available for contract at a location of your choice. Customized training is also available to fit your needs. For our full course catalogue go to www.iccsafe.org/hireicc.

ICC ONLINE CAMPUS

Earn CEUs at Your Own Pace

Online courses offer access to a comprehensive training and education portal, providing you with an effective and convenient tool to enhance your professional skills. Courses are available anytime for 99 days following registration. Go to www.iccsafe.org/onlinecampus for our full offerings.

For more information about ICC's Training please contact us at
888-ICC-SAFE (422-7233) ext. 33818 or email us at icctraining@iccsafe.org.

2015 I-Code Essentials

This helpful series uses a straightforward, focused approach to explore code requirements with non-code language, allowing readers to gain confidence in their understanding of the material. Each book is an invaluable companion guide to the 2015 IBC, IRC, IFC or IECC for both new and experienced code users.

- Detailed full-color illustrations enhance comprehension of code provisions
- A focused, concise approach facilitates understanding of the essential code provisions
- References to corresponding code sections provide added value as companion guides to the 2015 I-Codes
- Glossary of code and construction terms clarifies their meaning in the context of the code

A. BUILDING CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL BUILDING CODE

Explores those code provisions essential to understanding the application of the IBC in an easy-to-read format. The user-friendly approach of the text simplifies critical concepts so users can achieve a more complete understanding of the code's intent. Full-color illustrations, examples and simplified tables assist the reader in visualizing the code requirements. This up-to-date, step-by-step guide's topic organization reflects the intent of the IBC and facilitates understanding and application of the code provisions.

SOFT COVER #4031S15

PDF DOWNLOAD #8950P596

B. RESIDENTIAL CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL RESIDENTIAL CODE

Explains those code provisions essential to understanding the application of the IRC to the most commonly encountered building practices. The information is presented in a user-friendly manner with an emphasis on technical accuracy and clear non-code language. Full-color illustrations, examples and simplified tables assist the reader in visualizing the code requirements.

SOFT COVER #4131S15

PDF DOWNLOAD #8950P59

ORDER YOUR I-CODE ESSENTIALS TODAY! 1-800-786-4452 | www.iccsafe.org/books

C. FIRE CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL FIRE CODE

Focuses on the essential provisions of the IFC for controlling ignition sources and fire hazards, fire department access to buildings, building uses and processes, fire protection and life safety systems, special processes and uses and hazardous materials.

SOFT COVER #4431S15

PDF DOWNLOAD #8950P59

D. ENERGY CODE ESSENTIALS: BASED ON THE 2015 INTERNATIONAL ENERGY CONSERVATION CODE®

Designed to provide a straightforward, easy-to-read companion guide to the IECC for both beginning and experienced code users. The text provides accurate information on critical energy code applications in the office and in the field for residential and commercial construction. The focused coverage examines those code provisions essential to understanding the application of the IECC to the most commonly encountered building practices and discusses the reasons behind the requirements.

PREFACE

The principal purpose of the Commentary is to provide a basic volume of knowledge and facts relating to building construction as it pertains to the regulations set forth in the 2015 *International Residential Code*[®]. The person who is serious about effectively designing, constructing and regulating buildings and structures will find the Commentary to be a reliable data source and reference to almost all components of the built environment.

As a follow-up to the *International Residential Code*, we offer a companion document, the *International Residential Code*[®] *Commentary—Volume II*. Volume II covers Chapters 12 through Appendix Q of the 2015 *International Residential Code*. The basic appeal of the Commentary is thus: it provides, in a small package and at reasonable cost, thorough coverage of many issues likely to be dealt with when using the *International Residential Code* — and then supplements that coverage with historical and technical background. Reference lists, information sources and bibliographies are also included.

Throughout all of this, strenuous effort has been made to keep the vast quantity of material accessible and its method of presentation useful. With a comprehensive yet concise summary of each section, the Commentary provides a convenient reference for regulations applicable to the construction of buildings and structures. In the chapters that follow, discussions focus on the full meaning and implications of the code text. Guidelines suggest the most effective method of application, and the consequences of not adhering to the code text. Illustrations are provided to aid understanding; they do not necessarily illustrate the only methods of achieving code compliance.

The format of the Commentary includes the full text of each section, table and figure in the code, followed immediately by the commentary applicable to that text. At the time of printing, the Commentary reflects the most up-to-date text of the 2015 *International Residential Code*. Each section's narrative includes a statement of its objective and intent, and usually includes a discussion about why the requirement commands the conditions set forth. Code text and commentary text are easily distinguished from each other. All code text is shown as it appears in the *International Residential Code*, and all commentary is indented below the code text and begins with the symbol ❖. All code figures and tables are reproduced as they appear in the IRC. Commentary figures and tables are identified in the text by the word "Commentary" (as in "see Commentary Figure 704.3"), and each has a full border.

Readers should note that the Commentary is to be used in conjunction with the *International Residential Code* and not as a substitute for the code. **The Commentary is advisory only**; the code official alone possesses the authority and responsibility for interpreting the code.

Comments and recommendations are encouraged, for through your input, we can improve future editions. Please direct your comments to the Codes and Standards Development Department at the Central Regional Office.

Part V—Mechanical

Chapter 12: Mechanical Administration

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

Chapter 12 provides regulations for the administration of the mechanical provisions of the code. Though this may be the smallest chapter in the code, it is very important in that it defines the application of the mechanical provisions to both existing and new construction. It also relates this chapter to the administrative provisions in Chapter 1.

Section M1201 addresses this set of mechanical regulations' relationship with Chapter 1 and the validity of the standards that are referenced. Section M1202 provides the applicability to existing mechanical systems. While the code mainly deals with new systems, this section indicates that some existing situations may fall under the requirements in the chapter.

Purpose

A set of mechanical regulations is intended to be adopted as a legally enforceable document that can safeguard health, safety, property and public welfare. Such regulations cannot be effective without adequate provisions for their administration and enforcement. The official charged with the administration and enforcement of mechanical regulations has a great responsibility, and with this responsibility goes authority. No matter how detailed the mechanical regulations may be, the building official must, to some extent, exercise judgement in determining code compliance. She or he has the responsibility to establish that the homes in which the citizens of the community reside are designed and constructed to be reasonably free from hazards associated with the presence and use of mechanical equipment, appliances and systems.

SECTION M1201 GENERAL

M1201.1 Scope. The provisions of Chapters 12 through 24 shall regulate the design, installation, maintenance, *alteration* and inspection of mechanical systems that are permanently installed and used to control environmental conditions within buildings. These chapters shall also regulate those mechanical systems, system components, *equipment* and *appliances* specifically addressed in this code.

❖ This section lists the chapters in the code that regulate mechanical systems. It indicates that the design, installation, and maintenance of mechanical equipment used to control the environmental conditions within the building are regulated by these chapters. It also states that other mechanical systems specifically addressed within these chapters are so regulated. Other provisions in the code reference the *International Mechanical Code*® (IMC®) and the *International Fuel Gas Code*® (IFGC®). This regulates virtually all mechanical systems and equipment within a dwelling in some form or another.

M1201.2 Application. In addition to the general administration requirements of Chapter 1, the administrative provisions

of this chapter shall also apply to the mechanical requirements of Chapters 13 through 24.

❖ This section makes reference to the administrative requirements of Chapter 1 to include those administrative provisions and make them applicable to the mechanical chapters.

SECTION M1202 EXISTING MECHANICAL SYSTEMS

M1202.1 Additions, alterations or repairs. *Additions, alterations, renovations or repairs* to a mechanical system shall conform to the requirements for a new mechanical system without requiring the existing mechanical system to comply with all of the requirements of this code. *Additions, alterations or repairs* shall not cause an existing mechanical system to become unsafe, hazardous or overloaded. Minor *additions, alterations or repairs* to existing mechanical systems shall meet the provisions for new construction, unless such work is done in the same manner and arrangement as was in the existing system, is not hazardous, and is *approved*.

❖ Major alterations or additions to existing mechanical systems must comply with the provisions of the code.

However, the code does not require existing systems to be upgraded to comply with new requirements unless the alteration or addition renders the existing system unsafe, overloaded or hazardous.

Minor additions, alterations or repairs to existing mechanical systems may be made following the same manner and arrangement as was found for the existing systems, as long as the work does not render the existing and new system unsafe, hazardous or overloaded. The building official has to make a judgement call on the extent of the addition, alteration or repair and determine whether the work is “minor,” thereby allowing the use of the provisions of the old code, or that it is “major,” thereby requiring the new work to be in compliance with the new code. Only when the new work makes the existing system overloaded, unsafe or hazardous does the building official need to require bringing the existing system up to the new provisions of the code.

M1202.2 Existing installations. Except as otherwise provided for in this code, a provision in this code shall not require the removal, *alteration* or abandonment of, nor prevent the continued use and maintenance of, an existing mechanical system lawfully in existence at the time of the adoption of this code.

❖ An existing mechanical system is generally “grandfathered” with code adoption, provided that the system meets a minimum level of safety. Frequently the criteria for determining this level of safety are the regulations (or code) under which the existing building was originally constructed. If there are no previous code criteria that apply, the building official is to apply those provisions of the code that are reasonably applicable to existing buildings. Provisions dealing with hazard abatement in existing buildings and provisions dealing with maintenance, as contained in the property maintenance and fire prevention codes, dictate a specific level of safety.

M1202.3 Maintenance. Mechanical systems, both existing and new, and parts thereof shall be maintained in proper operating condition in accordance with the original design and in a safe and sanitary condition. Devices or safeguards that are required by this code shall be maintained in compliance with the code edition under which installed. The owner or the owner’s designated agent shall be responsible for maintenance of the mechanical systems. To determine compliance with this provision, the *building official* shall have the authority to require a mechanical system to be reinspected.

❖ This section allows the continued use of an existing mechanical system if it was originally lawfully permitted and installed. Periodic adoption of new codes or new provisions that may affect an existing system does not require upgrading the system to comply with the new provisions. However, this is predicated on the system being maintained by the owner in proper operating condition, in accordance with the manufacturer’s requirements. The building official has the authority, as provided for in this section, to require the inspection of a mechanical system to determine whether work was

performed to maintain the equipment in a safe operating condition. If the system becomes hazardous or unsafe, the building official has the authority to require repair, modification or even replacement to render the installation safe.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

IFGC–15, *International Fuel Gas Code*. Washington, DC: International Code Council, 2014.

IMC–15, *International Mechanical Code*. Washington, DC: International Code Council, 2014.

Legal Aspects of Code Administration. Washington, DC: International Code Council, 2002.

Chapter 13: General Mechanical System Requirements

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter contains the provisions that apply to various types of mechanical appliances. The approval of appliances and their proper installation is the main theme. Section M1301 states the scope of the chapter and addresses its relationship with the *International Mechanical Code*® (IMC®) and the *International Fuel Gas Code*® (IFGC®). Section M1302 indicates that all mechanical appliances must be listed and labeled by an approved agency. Section M1303 addresses the information that is needed on the labels. Section M1304 discusses the proper design of appliances considering the appliances' type of fuel and the geographical location of the installed appliance. Section M1305 addresses

access to installed appliances for servicing and potential replacement. Section M1306 contains the allowance for reduced clearances between appliances and combustible construction. Section M1307 contains the criteria for the safe installation of appliances. Section M1308 is a cross reference to the proper sections in the building portion of the code for the drilling and notching of structural members of the building.

Purpose

This chapter contains requirements for the safe and proper installation of mechanical equipment and appliances.

SECTION M1301 GENERAL

M1301.1 Scope. The provisions of this chapter shall govern the installation of mechanical systems not specifically covered in other chapters applicable to mechanical systems. Installations of mechanical *appliances, equipment* and systems not addressed by this code shall comply with the applicable provisions of the *International Mechanical Code* and the *International Fuel Gas Code*.

❖ This section provides general requirements for mechanical systems not specifically covered in other chapters of the code. In addition, it refers to the IMC and the IFGC for regulations governing equipment not addressed by the code.

M1301.1.1 Flood-resistant installation. In flood hazard areas as established by Table R301.2(1), mechanical *appliances, equipment* and systems shall be located or installed in accordance with Section R322.1.6.

❖ The local jurisdiction must fill in Table R301.2(1) upon adoption of the code, including the flood hazards information. Mechanical appliances, equipment, and systems that are located in flood hazard areas must be installed above the design flood elevation or must be designed and installed to prevent the entrance of water into the components and to resist the forces of the flood waters on the components (see commentary, Section R322.1.6).

M1301.2 Identification. Each length of pipe and tubing and each pipe fitting utilized in a mechanical system shall bear the identification of the manufacturer.

❖ The manufacturer is given the option of determining the type of marking for the material. If there is no applicable standard or the applicable standard does not require that the material be identified, identification of the manufacturer is still required by the code. Where the code indicates compliance with an approved standard, the manufacturer must comply with the requirements for marking in accordance with the applicable standard.

M1301.3 Installation of materials. Materials shall be installed in strict accordance with the standards under which the materials are accepted and approved. In the absence of such installation procedures, the manufacturer's instructions shall be followed. Where the requirements of referenced standards or manufacturer's instructions do not conform to minimum provisions of this code, the provisions of this code shall apply.

❖ Mechanical components and materials are to be installed in accordance with the installation requirements of the applicable standard listed in the code. Where a standard is not provided, the manufacturer's instructions must be followed. For example, because there are very few standards available that regulate the installation of valves, the manufacturer's instructions

GENERAL MECHANICAL SYSTEM REQUIREMENTS

must be used to install these components. The code trumps where a referenced standard or manufacturer's instructions are less stringent than the code. It is rare, but the code may contain requirements that are more restrictive than the installation instructions or product listing.

M1301.4 Plastic pipe, fittings and components. Plastic pipe, fittings and components shall be third-party certified as conforming to NSF 14.

❖ Plastic piping, fittings and plastic pipe-related components, including solvent cements, primers, tapes, lubricants and seals used in mechanical systems, must be tested and certified as conforming to NSF 14. This includes hydronic piping and fittings and plastic piping system components including but not limited to pipes, fittings, valves, joining materials, gaskets and appurtenances. This section does not apply to components that only include plastic parts such as brass valves with a plastic stem.

M1301.5 Third-party testing and certification. Piping, tubing and fittings shall comply with the applicable referenced standards, specifications and performance criteria of this code and shall be identified in accordance with Section M1301.2. Piping, tubing and fittings shall either be tested by an approved third-party testing agency or certified by an approved third-party certification agency.

❖ This section requires that all piping, tubing and fittings comply with the referenced standards. However, the provisions contained in Section 104.11 regarding the evaluation and approval of alternative materials, methods and equipment are still applicable (see commentary, Section 104.11). Additionally, the code has been revised to include requirements for third-party certification and testing of such products. "Third-party certified" indicates that the minimum level of quality required by the applicable standard is maintained and the product is often referred to as "listed." "Third-party tested" indicates a product that has been tested by an approved testing laboratory and found to be in compliance with the standard. Although the code does not specifically state the identification or marking requirements, except for the manufacturer's identification, the applicable referenced standard states the minimum information required. The identification or marking requirements typically include the name of the manufacturer, product name or serial number, installation specifications, applicable tests and standards, testing agency and labeling agency.

SECTION M1302 APPROVAL

M1302.1 Listed and labeled. Appliances regulated by this code shall be *listed* and *labeled* for the application in which

they are installed and used, unless otherwise *approved* in accordance with Section R104.11.

❖ Mechanical appliances must be listed and labeled by an approved agency to show that they comply with applicable national standards. The code requires listing and labeling for appliances such as boilers, furnaces, space heaters, cooking appliances and clothes dryers. The code also requires listing for system components. The label is the primary, if not the only, assurance to the installer, the inspector and the end user that a similar appliance has been tested and evaluated by an approved agency and performed safely and efficiently when installed and operated in accordance with its listing.

The label is part of the information that the code official is to consider in the approval of appliances. The only exception to the labeling requirement occurs when the code official approves a specific appliance in accordance with the authority granted in Section R104.11.

The requirement that appliances are to be used only in accordance with their listing is intended to prevent the use of products that have a listing for some application but are being used in a different application for which they have not been tested. An example would be a fan that is listed for use only as a bathroom exhaust fan but is installed for use as a kitchen exhaust hood fan or as a clothes dryer booster fan. Another potential misapplication could be an appliance that has been tested and listed for indoor installation only, but is installed outdoors. Such misapplications have the potential to create hazardous situations.

The code official should exercise extreme caution when considering the approval of unlisted appliances.

Approval of unlisted appliances must be based on some form of documentation that demonstrates compliance with the applicable standards or equivalence with an appliance that is listed and labeled to the applicable standards. Where no product standards exist, documentation must be provided to demonstrate that the appliance is appropriate for the intended use and will provide the same level of performance as would be expected from a similar appliance that is listed and labeled. Sometimes appliances are listed in the field on a case-by-case basis using requirements or outlines of investigation derived from relative appliance standards. One fundamental principle of the code is the reliance on the listing and labeling process to ensure appliance performance. Approvals granted in accordance with Section R104.11 must be justified with supporting documentation. To the code official, installer and end-user very little is known about the performance of an appliance that is not tested and built to an appliance standard.

**SECTION M1303
LABELING OF APPLIANCES**

M1303.1 Label information. A permanent factory-applied nameplate(s) shall be affixed to *appliances* on which shall appear, in legible lettering, the manufacturer's name or trademark, the model number, a serial number and the seal or *mark* of the testing agency. A *label* also shall include the following:

1. Electrical *appliances*. Electrical rating in volts, amperes and motor phase; identification of individual electrical components in volts, amperes or watts and motor phase; and in Btu/h (W) output and required clearances.
2. Absorption units. Hourly rating in Btu/h (W), minimum hourly rating for units having step or automatic modulating controls, type of fuel, type of refrigerant, cooling capacity in Btu/h (W) and required clearances.
3. Fuel-burning units. Hourly rating in Btu/h (W), type of fuel *approved* for use with the *appliance* and required clearances.
4. Electric comfort-heating appliances. The electric rating in volts, amperes and phase; Btu/h (W) output rating; individual marking for each electrical component in

amperes or watts, volts and phase; and required clearances from combustibles.

5. Maintenance instructions. Required regular maintenance actions and title or publication number for the operation and maintenance manual for that particular model and type of product.

❖ This section requires that appliances have a label that is a permanent nameplate. In general, labels other than metal tags or plates usually consist of material that is similar in appearance to a decal, and the label, its adhesive and the printed information are all durable and water resistant. Because of the important information on a label, the label must be permanent, not susceptible to damage and legible for the life of the appliance. The standards appliances are tested to usually specify the required label material, the method of attachment and the required label information. The code requires that the label be affixed permanently and prominently on the appliance or equipment and specifies the information that must appear on the label. The manufacturer may be required by the relevant standard or may voluntarily provide additional information on the label (see Commentary Figure M1303.1).

(Courtesy of The Trane Company and American Standard Company)

SECTION M1304 TYPE OF FUEL

M1304.1 Fuel types. Fuel-fired *appliances* shall be designed for use with the type of fuel to which they will be connected and the altitude at which they are installed. *Appliances* that comprise parts of the building mechanical system shall not be converted for the use of a different fuel, except where *approved* and converted in accordance with the manufacturer's instructions. The fuel input rate shall not be increased or decreased beyond the limit rating for the altitude at which the *appliance* is installed.

❖ An element of information used for the approval of appliances is the label, which ensures that the appliance has been tested in accordance with a valid standard and performed acceptably when installed and operated in accordance with the appliance listing. Manufacturers usually design mechanical appliances to operate on a specific type of fuel. Thus, the fuel used in the appliance test must be the type of fuel specified by the manufacturer on the label. When an appliance is converted to a different type of fuel, the original label that appears on the appliance is no longer valid. Because the original approval of the appliance was based in part on the label, the appliance is no longer approved for use.

Field conversions will more likely allow for the safe operation of the appliance if, as required, the conversion is approved by the code official and done in accordance with the manufacturer's installation instructions. Fuel conversions that are not performed correctly can cause serious malfunctions and hazardous operation. Before a fuel conversion is performed, the manufacturer must be contacted for installation instructions outlining the procedures to follow for proper operation of the appliance. In most cases, conversion kits from the manufacturer are available along with the installation instructions. Once a conversion has been completed, a supplemental label must be installed to update the information contained on the original label, thereby alerting any service personnel of the modifications that have been made.

All fuel-fired appliances are designed to operate with a maximum and minimum British thermal units per hour (Btu/h) input capacity. This capacity is field adjusted to suit the elevation because of the change in air density at different elevations. Alteration of Btu/h input beyond the allowable limits can result in hazardous over-firing or under-firing. Either condition can cause operation problems that include overheating, vent failure, corrosion, poor draft and poor combustion.

SECTION M1305 APPLIANCE ACCESS

M1305.1 Appliance access for inspection service, repair and replacement. *Appliances* shall be accessible for inspection, service, repair and replacement without removing per-

manent construction, other *appliances*, or any other piping or ducts not connected to the *appliance* being inspected, serviced, repaired or replaced. A level working space not less than 30 inches deep and 30 inches wide (762 mm by 762 mm) shall be provided in front of the control side to service an *appliance*.

❖ Because mechanical equipment and appliances require routine maintenance, repair and possible replacement, access is required. Additionally, manufacturer's installation instructions usually contain access recommendations or requirements. As a result, the provisions stated herein supplement the manufacturer's installation instructions.

The provisions of this section specify that access must be provided to components that require observation, inspection, adjustment, servicing, repair or replacement. Access is also necessary for operating procedures such as startup or shutdown. The level working space in front of the control side of the appliance must be 30 inches (762 mm) wide and 30 inches (762 mm) deep to provide adequate space for the technician or inspector to safely perform the work.

The code states that "accessible" means "access that might require the removal of an access panel or similar removable obstruction." An appliance or piece of equipment is not accessible if any portion of the structure's permanent finish materials, such as drywall, plaster, paneling, built-in furniture or cabinets or any other similar permanently affixed building component, must be removed before access is achieved. In addition, removal of all or part of another appliance or the piping or duct or serving other appliances must not be necessary to perform the service, replacement or inspection of an appliance. Such an installation could result in unnecessarily high costs to the homeowner and improper or unsafe reassembly of other appliance and system components. This could also result in service personnel having to perform disassembly and reassembly of appliances and system components that are not within the personnel's area of expertise or licensed work.

The intent is to provide access to all components such as controls, gauges, burners, filters, blowers and motors that require observation, inspection, adjustment, servicing, repair or replacement.

M1305.1.1 Furnaces and air handlers. Furnaces and air handlers within compartments or alcoves shall have a minimum working space clearance of 3 inches (76 mm) along the sides, back and top with a total width of the enclosing space being not less than 12 inches (305 mm) wider than the furnace or air handler. Furnaces having a firebox open to the atmosphere shall have not less than a 6-inch (152 mm) working space along the front combustion chamber side. Combustion air openings at the rear or side of the compartment shall comply with the requirements of Chapter 17.

Exception: This section shall not apply to replacement *appliances* installed in existing compartments and alcoves

where the working space clearances are in accordance with the *equipment* or *appliance* manufacturer's installation instructions.

- ❖ Furnaces and air handlers installed in compartments or alcoves must have clearances from the enclosure so that they can be removed, maintained or repaired as necessary. The minimum clearances specified in the code apply even though the manufacturer's instructions might permit a lesser clearance. Clearances provide access, ventilation, cooling of the appliance and equipment and protection for surrounding combustibles. The front (firebox) clearance helps protect combustibles against flame rollout and allows free movement of combustion air. The exception exempts replacement appliances and equipment installed in existing compartments or alcoves if the installation complies with the manufacturer's instructions. The manufacturer's installation instructions usually contain minimum workspace requirements and minimum clearances to surrounding construction that must be maintained.

M1305.1.2 Appliances in rooms. *Appliances* installed in a compartment, alcove, *basement* or similar space shall be accessed by an opening or door and an unobstructed passageway measuring not less than 24 inches (610 mm) wide and large enough to allow removal of the largest *appliance* in the space, provided there is a level service space of not less than 30 inches (762 mm) deep and the height of the *appliance*, but not less than 30 inches (762 mm), at the front or service side of the *appliance* with the door open.

- ❖ This section specifies an access opening and passageway to afford service personnel reasonable access to appliances and to allow for the passage of system components. Quite often appliances such as furnaces, boilers and water heaters are installed in spaces with little or no forethought about future access for maintenance or replacement.

M1305.1.3 Appliances in attics. *Attics* containing *appliances* shall be provided with an opening and a clear and unobstructed passageway large enough to allow removal of the largest *appliance*, but not less than 30 inches (762 mm) high and 22 inches (559 mm) wide and not more than 20 feet (6096 mm) long measured along the centerline of the passageway from the opening to the *appliance*. The passageway shall have continuous solid flooring in accordance with Chapter 5 not less than 24 inches (610 mm) wide. A level service space not less than 30 inches (762 mm) deep and 30 inches (762 mm) wide shall be present along all sides of the *appliance* where access is required. The clear access opening dimensions shall be not less than of 20 inches by 30 inches (508 mm by 762 mm), and large enough to allow removal of the largest appliance.

Exceptions:

1. The passageway and level service space are not required where the *appliance* can be serviced and removed through the required opening.
2. Where the passageway is unobstructed and not less than 6 feet (1829 mm) high and 22 inches (559 mm)

wide for its entire length, the passageway shall be not more than 50 feet (15 250 mm) long.

- ❖ There is not always sufficient room for mechanical equipment and appliances to be installed in spaces such as basements, alcoves, utility rooms and furnace rooms. In an effort to save floor space or simplify an installation, designers often locate appliances and mechanical equipment on roofs, in attics or in similar remote locations. Access to appliances and equipment could be difficult because of roof slope, stone roof ballast or the lack of a walking surface, such as might occur in an attic or similar space with exposed ceiling joists. The intent of this section is to require a suitable access opening, passageway and workspace that will allow reasonably easy access without endangering the service person (see Commentary Figure M1305.1.3). The longer the attic passageway, the more the service person will be exposed to extreme temperatures and the risk of injury. The attic access opening (typically a scuttle) must be large enough to allow the largest appliance in the attic to pass through such opening. For example, if an attic furnace is the largest appliance, the furnace itself should be able to be removed from the attic without having to disassemble the furnace. Of course, it is understood that ducts, plenums, cooling coil cabinets and other attachments might have to be disconnected from the furnace before removal is possible.

The first exception allows the passageway and level service space to be eliminated if the technician can reach the appliance through the access opening without having to step into the attic. The second exception allows the length of the passageway to be extended to 50 feet (15 250 mm) if there is at least 6 feet (1829 mm) of clear headroom for the entire length of the passageway. This is allowed because there is less danger of lengthy exposure to extreme temperatures if the service personnel can walk erect and unimpeded to the equipment rather than crawling.

Note that some appliances might not be listed for attic installation or might otherwise be unsuitable for such conditions.

M1305.1.3.1 Electrical requirements. A luminaire controlled by a switch located at the required passageway opening and a receptacle outlet shall be installed at or near the *appliance* location in accordance with Chapter 39. Exposed lamps shall be protected from damage by location or lamp guards.

- ❖ An appliance located in an attic is generally not easy to access. A lighting outlet and receptacle outlet encourage and facilitate appliance maintenance. The receptacle will accommodate power tools, drop lights and diagnostic instruments. Also, these provisions negate the need for extension cords, which can be hazardous to service personnel. The lighting outlet is to allow the attic space to be safely navigated and is not intended to provide the necessary lighting for servicing and repair of the appliances. Where exposed lamps (naked light bulbs) are installed as the required lighting outlets, they must be located out of harm's way or must be pro-

GENERAL MECHANICAL SYSTEM REQUIREMENTS

vided with a suitable lamp guard. If service personnel hit and break the lamp with their bodies, tools, parts or other objects, the result could be a shock and/or fire hazard, with the additional hazard of sudden darkness in a dangerous location.

M1305.1.4 Appliances under floors. Underfloor spaces containing *appliances* shall be provided with an unobstructed passageway large enough to remove the largest *appliance*, but not less than 30 inches (762 mm) high and 22 inches (559 mm) wide, nor more than 20 feet (6096 mm) long measured along the centerline of the passageway from the opening to the *appliance*. A level service space not less than 30 inches (762 mm) deep and 30 inches (762 mm) wide shall be present at the front or service side of the *appliance*. If the depth of the passageway or the service space exceeds 12 inches (305 mm) below the adjoining grade, the walls of the passageway shall be lined with concrete or masonry extending 4 inches (102 mm) above the adjoining grade in accordance with Chapter 4. The rough-framed access opening dimensions shall be not less than 22 inches by 30 inches (559 mm by 762 mm), and large enough to remove the largest *appliance*.

Exceptions:

1. The passageway is not required where the level service space is present when the access is open, and the *appliance* can be serviced and removed through the required opening.

2. Where the passageway is unobstructed and not less than 6 feet high (1929 mm) and 22 inches (559 mm) wide for its entire length, the passageway shall not be limited in length.

❖ This section, which applies to crawl spaces, has concepts similar to those of Section M1305.1.3. The more difficult the access to appliances and equipment is, the less likely that the appliance or equipment will be inspected and serviced on a regular basis. Attic and crawl space installations suffer from the “out-of-sight, out-of-mind” syndrome.

The first exception has the same intent as the first exception of Section M1305.1.3. The second exception allows unlimited length of the passageway if there is at least 6 feet (1829 mm) of clear headroom for the entire length of the passageway (see commentary, Section M1305.1.3).

M1305.1.4.1 Ground clearance. *Equipment and appliances* supported from the ground shall be level and firmly supported on a concrete slab or other *approved* material extending not less than 3 inches (76 mm) above the adjoining ground. Such support shall be in accordance with the manufacturer’s installation instructions. *Appliances* suspended from the floor shall have a clearance of not less than 6 inches (152 mm) from the ground.

❖ This section’s requirement provides a buffer from the corrosive effects of an appliance’s contact with the

ground. If supported on the ground, the appliance is to rest on a material that will be a barrier between the appliance and the ground. Concrete is the material that is prescribed, but other approved materials could be used if they provide the same level of protection as the concrete. If the appliance is suspended from the floor assembly above the ground, a minimum separation of 6 inches (152 mm) is called out.

The slab or other support surface must be at least 3 inches (76 mm) above grade so that the appliance being supported will be well above grade and protected from prolonged exposure to moisture and soil. The 3-inch (76 mm) minimum also provides some protection against settling of the slab or support base.

M1305.1.4.2 Excavations. Excavations for *appliance* installations shall extend to a depth of 6 inches (152 mm) below the *appliance* and 12 inches (305 mm) on all sides, except that the control side shall have a clearance of 30 inches (762 mm).

❖ This section allows for appliances to be located below the level of the ground surface in underfloor areas. Again, the concern is to provide a separation from the ground itself. Minimum clearances are provided in this section. The 30-inch-deep (762 mm) workspace is required for adequate access for servicing the appliance.

M1305.1.4.3 Electrical requirements. A luminaire controlled by a switch located at the required passageway opening and a receptacle outlet shall be installed at or near the *appliance* location in accordance with Chapter 39. Exposed lamps shall be protected from damage by location or lamp guards.

❖ This is the same requirement as found in Section M1305.1.3.1. Lighting and a power supply are required for the service of mechanical appliances. Note that Section E3902 requires ground fault circuit interrupter (GFCI) protection for crawl space receptacle outlets. Where exposed lamps (naked light bulbs) are installed as the required lighting outlets, they must be located out of harm's way or must be provided with a suitable

lamp guard. If service personnel hit and break the lamp with their bodies, tools, parts or other objects, the result could be a shock and/or fire hazard, with the additional hazard of sudden darkness in a dangerous location.

**SECTION M1306
CLEARANCES FROM COMBUSTIBLE
CONSTRUCTION**

M1306.1 Appliance clearance. *Appliances* shall be installed with the clearances from unprotected combustible materials as indicated on the *appliance label* and in the manufacturer's installation instructions.

❖ Requirements for clearances to combustibles are emphasized because of the potential fire hazard posed when those clearances are not observed. Maintaining an appropriate distance from the outer surface of an appliance or piece of equipment to combustible materials reduces the possibility of ignition of combustible materials. This section requires appliances to be installed with clearances from unprotected combustibles as indicated on the label for the listed appliance and the manufacturer's installation instructions. The minimum clearances to combustibles are specified in the manufacturer's installation instructions for a labeled appliance. Because an approved agency tests appliances in accordance with these instructions, the clearances required are necessary for the correct installation and operation of the appliance. Note, however, that this section does not include provisions or guidelines for the installation of unlisted appliances. Figure M1306.1 is a graphic image of the reduced clearances allowed by the code. It works in conjunction with Table M1306.2.

FIGURE M1306.1. See below.

❖ Figure M1306.1 is a graphic image of the reduced clearances allowed by the code. It works in conjunction with Table M1306.2.

Note: "A" equals the required clearance with no protection. "B" equals the reduced clearance permitted in accordance with Table M1306.2. The protection applied to the construction using combustible material shall extend far enough in each direction to make "C" equal to "A."

**FIGURE M1306.1
REDUCED CLEARANCE DIAGRAM**

GENERAL MECHANICAL SYSTEM REQUIREMENTS

M1306.2 Clearance reduction. The reduction of required clearances to combustible assemblies or combustible materials shall be based on Section M1306.2.1 or Section M1306.2.2.

❖ See the commentary to Sections M1306.2.1 and M1306.2.2.

TABLE M1306.2. See below.

❖ The column headings of Table M1306.2 list required clearances without protection. The numbers to the right

of each method indicate the permissible reduced clearance measured from the heat-producing appliances to the face of the combustible surface.

The rationale behind the methods of protection listed in Table M1306.2 is based on the ability of the protection to reduce radiant heat transmission from the appliance and equipment to the combustible material so that the temperature rise of the combustible material will remain below the maximum allowed.

TABLE M1306.2
REDUCTION OF CLEARANCES WITH SPECIFIED FORMS OF PROTECTION^{a, c, d, e, f, g, h, i, j, k, l}

TYPE OF PROTECTION APPLIED TO AND COVERING ALL SURFACES OF COMBUSTIBLE MATERIAL WITHIN THE DISTANCE SPECIFIED AS THE REQUIRED CLEARANCE WITH NO PROTECTION (See Figures M1306.1 and M1306.2)	WHERE THE REQUIRED CLEARANCE WITHOUT PROTECTION FROM APPLIANCE, VENT CONNECTOR, OR SINGLE WALL METAL PIPE IS:									
	36 inches		18 inches		12 inches		9 inches		6 inches	
	Allowable clearances with specified protection (Inches) ^b									
	Use column 1 for clearances above an appliance or horizontal connector.									
	Use column 2 for clearances from an appliance, vertical connector and single-wall metal pipe.									
	Above column 1	Sides and rear column 2	Above column 1	Sides and rear column 2	Above column 1	Sides and rear column 2	Above column 1	Sides and rear column 2	Above column 1	Sides and rear column 2
3 ¹ / ₂ -inch-thick masonry wall without ventilated air space	—	24	—	12	—	9	—	6	—	5
1/2-inch insulation board over 1-inch glass fiber or mineral wool batts	24	18	12	9	9	6	6	5	4	3
Galvanized sheet steel having a minimum thickness of 0.0236-inch (No. 24 gage) over 1-inch glass fiber or mineral wool batts reinforced with wire or rear face with a ventilated air space	18	12	9	6	6	4	5	3	3	3
3 ¹ / ₂ -inch-thick masonry wall with ventilated air space	—	12	—	6	—	6	—	6	—	6
Galvanized sheet steel having a minimum thickness of 0.0236-inch (No. 24 gage) with a ventilated air space 1-inch off the combustible assembly	18	12	9	6	6	4	5	3	3	2
1/2-inch-thick insulation board with ventilated air space	18	12	9	6	6	4	5	3	3	3
Galvanized sheet steel having a minimum thickness of 0.0236-inch (No. 24 gage) with ventilated air space over 24 gage sheet steel with a ventilated space	18	12	9	6	6	4	5	3	3	3
1-inch glass fiber or mineral wool batts sandwiched between two sheets of galvanized sheet steel having a minimum thickness of 0.0236-inch (No. 24 gage) with a ventilated air space	18	12	9	6	6	4	5	3	3	3

For SI: 1 inch = 25.4 mm, 1 pound per cubic foot = 16.019 kg/m³, °C = [(°F)-32/1.8], 1 Btu/(h × ft² × °F/in.) = 0.001442299 (W/cm² × °C/cm).

- Reduction of clearances from combustible materials shall not interfere with combustion air, draft hood clearance and relief, and accessibility of servicing.
- Clearances shall be measured from the surface of the heat producing appliance or equipment to the outer surface of the combustible material or combustible assembly.
- Spacers and ties shall be of noncombustible material. Spacers and ties shall not be used directly opposite appliance or connector.
- Where all clearance reduction systems use a ventilated air space, adequate provision for air circulation shall be provided as described. (See Figures M1306.1 and M1306.2.)
- There shall be not less than 1 inch between clearance reduction systems and combustible walls and ceilings for reduction systems using ventilated air space.
- If a wall protector is mounted on a single flat wall away from corners, adequate air circulation shall be permitted to be provided by leaving only the bottom and top edges or only the side and top edges open with not less than a 1-inch air gap.
- Mineral wool and glass fiber batts (blanket or board) shall have a minimum density of 8 pounds per cubic foot and a minimum melting point of 1,500°F.
- Insulation material used as part of a clearance reduction system shall have a thermal conductivity of 1.0 Btu inch per square foot per hour °F or less. Insulation board shall be formed of noncombustible material.
- There shall be not less than 1 inch between the appliance and the protector. The clearance between the appliance and the combustible surface shall not be reduced below that allowed in this table.
- All clearances and thicknesses are minimum; larger clearances and thicknesses are acceptable.
- Listed single-wall connectors shall be permitted to be installed in accordance with the terms of their listing and the manufacturer's instructions.
- For limitations on clearance reduction for solid-fuel-burning appliances see Section M1306.2.3.

Although the materials referred to in Table M1306.2 are common construction materials, confusion often arises over what satisfies the requirement for “insulation board” (Item 6 in the table), sometimes referred to as inorganic insulating board, noncombustible mineral board or noncombustible insulating board. These products are not made of carbon-based compounds.

Carbon-based compounds are those found in cellulose (wood), plastics and other materials manufactured from raw materials that once existed in living organisms. Cement board materials must have a specified maximum “C” (conductance) value in addition to being noncombustible.

Note h specifies a maximum thermal conductivity of Btu/(h · ft · °F). Conductivity is the amount of heat in Btus that will flow each hour through a 1-foot-square (0.0929 m²) slab of material, 1-inch (25 mm) thick with a 1°F temperature difference between both sides and is usually identified by the symbol k. Tables of k values usually do not include the area term in the dimensions for conductivity, and it must be understood that the value must be multiplied by the area to obtain the total Btu value.

Thermal conductance (overall) is the time rate of heat flow through a body not taking thickness into account and is usually identified by the symbol C Btu/(h · ft² · °F).

Thermal resistance (overall) is the reciprocal of overall thermal conductance and is usually identified by the symbol R (hour · ft² · °F/Btu).

This translates into a minimum required insulation R-value of 1.0 (square foot · hour · °F)/Btu per inch of insulating material. The methods in Table M1306.2 control heat transmission by reflecting heat radiation, retarding thermal conductance and providing convective cooling. Where sheet metal materials or metal plates are specified, the effectiveness of the protection can be enhanced by the reflective surface of the metal. Painting or otherwise covering the surface would reduce the metal’s ability to reflect radiant heat and, depending on the color, could increase heat absorption. The airspace between the protected surface and the clearance-reduction assembly allows convection air currents to cool the protection assembly by carrying away heat that has been conducted through the assembly. Where a clearance-reduction assembly must be spaced 1 inch (25 mm) off the wall, the top, bottom and sides of the assembly must remain open as required by Notes d and f to permit unrestricted airflow (convection currents). If the openings were not provided, the air-cooling effect would not take place, and the protection assembly would not be as effective in limiting the temperature rise on the protected surfaces. Ideally, the protection assembly should be open on all sides to provide maximum ventilation.

Spacers must be noncombustible. Spacers should not be placed directly behind the heat source because the location would increase the amount of heat conduction through the spacer, thus creating a “hot spot.” Figure M1306.2 specifically shows a noncombustible spacer arrangement.

The performance of a protective assembly when applied to a horizontal surface, such as a ceiling, will differ substantially from the same assembly placed in a vertical plane. Obviously, temperatures at a ceiling surface will be higher because of natural convection and because the air circulation between the method of protection and the protected ceiling surface will be substantially reduced or nonexistent. It is for these reasons that Table M1306.2 is divided into two application groups.

The manufacturer’s instructions or label for many appliances will state an absolute minimum clearance, regardless of any clearance reduction method used. Those clearance requirements take precedence over Table M1306.2. For example, a typical wood-burning room heater will require in all cases an airspace clearance of at least 12 inches (305 mm), with no further reduction allowed.

The methods in Table M1306.2 are intended to be permanent installations properly supported to prevent displacement or deformation. Movement could adversely affect the performance of the protection method, thus posing a potential fire hazard.

The assemblies in Table M1306.2 are the product of experience and testing. To achieve predictable and dependable performance, the components of the various assemblies cannot be mixed, matched, combined, substituted or otherwise rearranged to comprise new assemblies, and materials cannot be substituted for those prescribed in the table. Any alterations or substitutions could have an effect on the assembly, and its performance would have to be tested and approved.

As stated in Note b to the table, the reduced clearance is measured from the heat source to the combustible material, disregarding any intervening protection assembly.

Note l serves to remind the table user that Section M1306.2.1 puts severe limitations on reducing clearances to solid-fuel appliances.

FIGURE M1306.2. See page 13-10.

❖ See the commentary to Section M1306.2.

M1306.2.1 Labeled assemblies. The allowable clearance shall be based on an approved reduced clearance protective assembly that is listed and labeled in accordance with UL 1618.

❖ Listed and labeled clearance reduction assemblies are available that can be used to reduce clearances based on the testing and listing of the assemblies. Such assemblies may or may not require some field assembly. The manufacturer’s instructions must be closely followed for assembly and installation in order to safely achieve the desired clearance reduction.

M1306.2.2 Reduction table. Reduction of clearances shall be in accordance with the *appliance* manufacturer’s instructions and Table M1306.2. Forms of protection with ventilated air space shall conform to the following requirements:

1. Not less than 1-inch (25 mm) air space shall be provided between the protection and combustible wall surface.

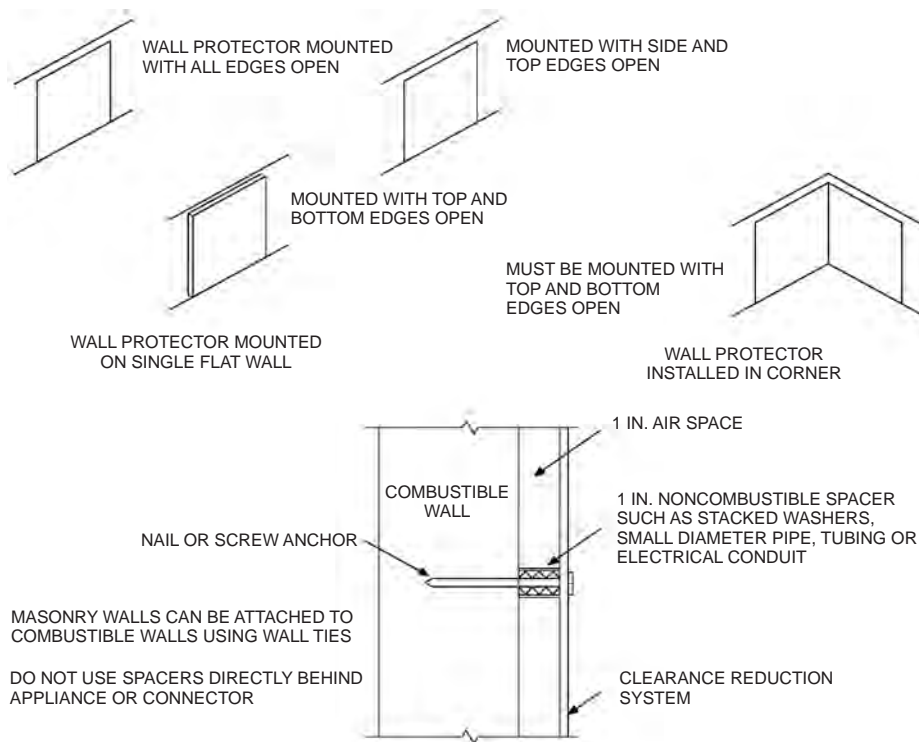

GENERAL MECHANICAL SYSTEM REQUIREMENTS

2. Air circulation shall be provided by having edges of the wall protection open not less than 1 inch (25 mm).
 3. If the wall protection is mounted on a single flat wall away from corners, air circulation shall be provided by having the bottom and top edges, or the side and top edges not less than 1 inch (25 mm).
 4. Wall protection covering two walls in a corner shall be open at the bottom and top edges not less than 1 inch (25 mm).
- ❖ Heat-producing appliances and mechanical equipment must be installed with the required minimum clearances to combustible materials indicated by their listing label. It is not uncommon to encounter practical or structural difficulties in maintaining clearances. Therefore, clearance-reduction methods have been developed to allow, in some cases, reduction of the minimum prescribed clearance distance while achieving equivalent protection. An important understanding is that all prescribed clearances to combustibles are airspace clearances measured from the heat source to the face of the nearest combustible surface, even if that combustible surface is not visible. An example of that would be a wood stud wall located behind a metal panel. If installation of an appliance with the required clearances from combustibles is not possible, this section allows reduction of the clearances in accordance with Table M1306.2 if the appliance manufacturer's instructions allow the reductions to the extent desired. The table includes several forms of protection,

depending on the extent of reduction. This section requires that a 1-inch (25 mm) air space be maintained between the protection and the combustible wall surface to allow unimpeded circulation of convection air needed to keep the temperature rise within acceptable limits. Most of the methods in Table M1306.2 depend on convective cooling as an essential part of the system (see Commentary Figure G2409.2).

When using the assemblies described in Table M1306.2, the clearance is measured as described in Note b. The required clearances are intended to be clear airspace, and therefore the space is not to be filled with insulation or any other material other than an assembly intended to allow clearance reduction. This is especially important where clearances are required from appliances and equipment that rely on the airspace for convection cooling to maintain their proper operating temperature.

The provisions contained in this section are based on the principles of heat transfer. Mechanical equipment or appliances producing heat can become hot, and many appliances have hot exterior surfaces by design. The heat energy is then radiated to objects surrounding the appliances or equipment. When mechanical equipment and appliances are tested, the minimum clearances are established so that radiant and, to a lesser extent, convective heat transfer do not represent an ignition hazard to adjacent surfaces and objects. This distance is called the "required clearance" to combustible materials. Appliance and equip-

For SI: 1 inch = 25.4 mm.

FIGURE M1306.2
WALL PROTECTOR CLEARANCE REDUCTION SYSTEM

ment labels must specify minimum clearances in all directions.

This section permits the use of materials and systems as radiation shields, decreasing the amount of heat energy transferred to surrounding objects and reducing the required clearances between mechanical appliances and equipment to combustibles.

Plaster and gypsum by themselves are classified as noncombustible materials. Under continued exposure to heat, however, these materials will gradually decompose as water molecules are driven out of the material. Plaster on wood lath, plasterboard, sheetrock and drywall are all considered to be combustible materials when the code provisions are applied.

Additionally, gypsum wallboard has a paper face that has a flame spread index that is measurable in the ASTM E84 test. This alone identifies the need to classify gypsum wallboard as a combustible material for the purpose of requiring a separation from heat-producing equipment and appliances.

M1306.2.3 Solid-fuel appliances. Table M1306.2 shall not be used to reduce the clearance required for solid-fuel *appliances* listed for installation with minimum clearances of 12 inches (305 mm) or less. For *appliances listed* for installation with minimum clearances greater than 12 inches (305 mm), Table M1306.2 shall not be used to reduce the clearance to less than 12 inches (305 mm).

- ❖ Because solid-fuel-burning appliances can produce high-intensity radiant heat and have wide variations in heat output, this section restricts the use of Table M1306.2 for types of solid-fuel-burning appliances that are listed for clearances of 12 inches (305 mm) or less. With small clearances, the protection method could be inadequate because of the radiation intensity, reradiation from the protection assembly and inability of the protection method to dissipate the heat energy at the rate received from the appliance. If the listed clearance is greater than 12 inches (305 mm), Table M1306.2 is applicable provided that the clearance is not reduced to less than 12 inches (305 mm). The bottom line is that clearance for solid-fuel appliances can never be less than 12 inches (305 mm).

SECTION M1307 APPLIANCE INSTALLATION

M1307.1 General. Installation of *appliances* shall conform to the conditions of their *listing* and *label* and the manufacturer's instructions. The manufacturer's operating and installation instructions shall remain attached to the *appliance*.

- ❖ Manufacturer's installation instructions are thoroughly evaluated by the listing agency verifying that a safe installation is prescribed. The listing agency can require that the manufacturer alter, delete or add information to the instructions as necessary to achieve compliance with applicable standards and code requirements. Manufacturer's installation instructions are an enforceable extension of the code and must be in the hands of the code official when an inspection

takes place. Without access to the instructions, the code official would be unable to complete an inspection.

When an appliance is tested to obtain a listing and label, the approved agency installs the appliance in accordance with the manufacturer's installation instructions. The appliance is tested under these conditions; thus, the installation instructions become an integral part of the labeling.

The listing and labeling process ensures that the appliance and its installation instructions are in compliance with applicable standards. Therefore, an installation in accordance with the manufacturer's instructions is required, except where the code requirements are more stringent. An inspector must carefully and completely read and comprehend the manufacturer's instructions to properly perform an installation inspection.

In some cases, the code will specifically address an installation requirement that is also addressed in the manufacturer's installation instructions. The code requirements may be the same or may exceed the requirements in the manufacturer's installation instructions or the manufacturer's installation instructions could contain requirements that exceed those in the code. In all cases, the more restrictive requirements would apply.

Even if an installation appears to be in compliance with the manufacturer's instructions, the installation cannot be complete or approved until all associated components, connections and systems that serve the appliance or equipment are also in compliance with the applicable provisions of the code. For example, an oil-fired boiler installation must not be approved if the boiler is connected to a deteriorated, undersized or otherwise unsafe chimney or vent. Likewise, the same installation must not be approved if the existing oil piping is in poor condition or if the electrical supply circuit is inadequate or unsafe.

In the case of replacement installations, the intent of this section is to require new work associated with the installation to comply with the code without necessarily requiring full compliance for the existing, unchanged portions of the related ductwork, piping, electrical, venting and similar mechanical systems. For example, if a furnace is replaced in an existing building, the new work and connections involved with the replacement would be treated as new construction and the existing unaltered system components would be considered as existing mechanical systems. Existing mechanical systems are accepted on the basis that they are free from hazard although not necessarily compliant with current codes. The code is not retroactive except where specifically stated that it applies to existing systems.

Manufacturer's installation instructions are often updated and changed for various reasons, such as changes in the appliance or equipment design, revisions to the product standard and as a result of field experience related to existing installations. The code

GENERAL MECHANICAL SYSTEM REQUIREMENTS

official should stay abreast of any changes by reviewing the manufacturer's instructions for every installation.

Equipment and appliances must be installed in accordance with the manufacturer's installation instructions. The manufacturer's label and installation instructions must be consulted in determining whether or not an appliance or piece of equipment can be installed and operated in a particular hazardous location. The manufacturer's installation instructions must be available on the job site when the equipment is being inspected.

M1307.2 Anchorage of appliances. *Appliances* designed to be fixed in position shall be fastened or anchored in an *approved* manner. In Seismic Design Categories D₀, D₁ and D₂, and in townhouses in Seismic Design Category C, water heaters and thermal storage units shall be anchored or strapped to resist horizontal displacement caused by earthquake motion in accordance with one of the following:

1. Anchorage and strapping shall be designed to resist a horizontal force equal to one-third of the operating weight of the water heater storage tank, acting in any horizontal direction. Strapping shall be at points within the upper one-third and lower one-third of the *appliance's* vertical dimensions. At the lower point, the strapping shall maintain a minimum distance of 4 inches (102 mm) above the controls.
 2. The anchorage strapping shall be in accordance with the appliance manufacturer's recommendations.
- ❖ This section requires the anchorage of fixed appliances to prevent movement or the possible tipping over of the appliance. In areas of high seismic risk,

water heaters must be secured directly to the building. Water heaters can weigh several hundred pounds, and if not properly secured, the water, gas and electrical connections may be damaged or severed, creating a hazardous situation. For example, a 40 gallon water heater will have a total weight that includes the weight of the empty heater plus the weight of the water (40 x 8.333 pounds). Commentary Figure M1307.2 shows a method of anchorage of a residential water heater that is known to have been used. Note that the required strapping must be substantial to resist lateral movement. Water heater manufacturers can provide details for such support and possibly support kits. The use of plumber's perforated hanger strap, also known as "holy iron," is commonly encountered and is probably quite inadequate.

M1307.3 Elevation of ignition source. *Appliances* having an *ignition source* shall be elevated such that the source of ignition is not less than 18 inches (457 mm) above the floor in garages. For the purpose of this section, rooms or spaces that are not part of the *living space* of a *dwelling unit* and that communicate with a private garage through openings shall be considered to be part of the garage.

Exception: Elevation of the ignition source is not required for appliances that are listed as flammable-vapor-ignition resistant.

- ❖ To reduce the hazard of fire or explosion from gasoline and other chemical vapors that are likely to be stored in a garage, appliances having an ignition source must be elevated to keep the ignition source a safe distance above garage floors (see Commentary Figure M1307.3). It is not the intent of this section for the

installer to measure the elevation from the surface of a dedicated appliance stand or other structure built to support the appliance where that stand or structure does not afford room for the storage of flammable liquids. Some flammable and combustible liquids typically associated with hazardous locations give off vapors that are denser than air and tend to collect near the floor. The 18-inch (457 mm) height requirement is intended to reduce the possibility of flammable vapor ignition by keeping the ignition sources elevated above the anticipated level of accumulated vapors. The 18-inch (457 mm) value is a minimum requirement and must be increased when required by the manufacturer's installation instructions.

This section will effectively prohibit the installation of most furnaces, boilers, space heaters, clothes dryers and water heaters directly on the floor of residential garages.

The accumulation of flammable vapors more than 18 inches (457 mm) deep is unlikely in most ventilated locations; therefore, maintaining all possible sources of ignition at least 18 inches (457 mm) above the floor will substantially reduce the risk of explosion and fire [see Commentary Figures G2408.2(1) and G2408.2(2)].

In the context of this section, a source of ignition could be a pilot flame, burner, burner igniter or electrical component capable of producing a spark. The term "ignition source" is defined and can be interpreted as

meaning an intentional source of ignition in a fuel-fired appliance or an unintentional source of ignition for any flammable vapors that may be present in the space (see the definition of "Ignition source").

An appliance installed in a closet or room that is accessible only from the garage must be considered as part of the garage for application of this section. Even though the room may be separated from the garage by walls and a door, there are no practical means of making the door vapor tight nor is there any assurance that the door will remain closed during normal use. An appliance room that is accessed only from the outdoors or only from the living space would not be considered as part of the garage. Rooms such as utility rooms and laundry rooms that communicate with both the garage and the living space and that are part of the living space, are not considered to be part of the garage (see definition of "Living space").

Appliances in the garage must be protected from impact by automobiles and elevation of the appliance may not be sufficient to guard against damage from impact unless the code official determines that the appliance platform is of substantial construction and the necessary height to be capable of protecting the appliance from impact.

The exception recognizes that new technology exists that allows appliances, such as water heaters, to be tested and listed as being flammable-vapor-ignition resistant and suitable for installation without the 18-inch (457 mm) elevation requirement. Note that while new gas-fired water heaters have flammable vapor ignition-resistant technology that allows them to be installed on the floor without the 18-inch (457 mm) elevation (see commentary, Section G2408.2), to the author's knowledge, oil-fired and electric water heaters are not listed as flammable-vapor-ignition resistant.

M1307.3.1 Protection from impact. *Appliances* shall not be installed in a location subject to vehicle damage except where protected by *approved* barriers.

❖ Mechanical appliances installed in garages, carports and any other location where motorized vehicles are present must be protected from vehicular impact.

Although the code does not specify methods of protection, the most apparent method would be to locate the appliance where it could not be struck by a vehicle. A practical method of protection would be to place a formidable and permanent barrier between the motor vehicles and the appliance. This barrier could include such items as an effectively located vehicle wheel stop that is anchored in place, an elevated platform higher than the vehicle's bumpers or one or more concrete-filled steel pipes. Final approval of the method of protection is left to the local code official. See Commentary Figure M1307.3.1 for some commonly used methods of protection.

Figure M1307.3.1
TYPICAL MOTOR VEHICLE IMPACT PROTECTION

M1307.4 Hydrogen generating and refueling operations.

Ventilation shall be required in accordance with Section M1307.4.1, M1307.4.2 or M1307.4.3 in private garages that contain hydrogen-generating *appliances* or refueling systems. For the purpose of this section, rooms or spaces that are not part of the *living space* of a *dwelling unit* and that communicate directly with a private garage through openings shall be considered to be part of the private garage.

- ❖ The use of hydrogen to fuel vehicles and generate electricity in fuel cell appliances to replace petroleum-based fuels is a rapidly developing technology. Key factors in the increased use of hydrogen are the reduced atmospheric emissions associated with hydrogen and the nation's shift to renewable sources of energy.

Typically, the code official will encounter two classes of equipment—those that generate hydrogen for use by other equipment, such as vehicles, and those that use hydrogen as their energy input, such as fuel cell appliances. This section intends to minimize the potential for explosions by limiting the source of hydrogen gas and by requiring sufficient ventilation to dissipate any leakage.

M1307.4.1 Natural ventilation. Indoor locations intended for hydrogen-generating or refueling operations shall be limited to a maximum floor area of 850 square feet (79 m²) and shall communicate with the outdoors in accordance with Sections M1307.4.1.1 and M1307.4.1.2. The maximum rated output capacity of hydrogen-generating *appliances* shall not exceed 4 standard cubic feet per minute (1.9 L/s) of hydrogen for each 250 square feet (23 m²) of floor area in such spaces. The minimum cross-sectional dimension of air openings shall be 3 inches (76 mm). Where ducts are used, they shall be of the same cross-sectional area as the free area of the openings to which they connect. In those locations, *equipment* and *appliances* having an *ignition source* shall be located so that the source of ignition is not within 12 inches (305 mm) of the ceiling.

- ❖ The 850-square-foot (79 m²) maximum floor space used for hydrogen generation or refueling and the maximum rated output capacity of such appliances are intended to limit the amount of hydrogen gas that can accumulate in the space, thus minimizing the potential for explosions.

The location of an ignition source parallels the intent of Section M1307.3, but with respect to the ceiling instead of the floor. This section does not apply to spaces that house only vehicles and that do not contain hydrogen-generating or refueling operations. Because it is more buoyant, hydrogen will dissipate more quickly than natural gas and much more quickly than either propane or gasoline, both of which have vapors that are heavier than air and will linger at an accident site. However, hydrogen and natural gas can both accumulate in unventilated pockets at the top of indoor structures and could represent a risk in such situations.

Similarly, gasoline fumes can accumulate at the floor level in unventilated spaces, posing a different

risk. Thus, ignition sources must be avoided at the top of any unventilated spaces for hydrogen gas. Also, hydrogen is odorless, colorless and burns with a flame that is not generally visible to the human eye. This means that it is unlikely that people will be able to detect unsafe conditions without appropriate instrumentation [similar to carbon monoxide (CO) accumulation in a structure].

M1307.4.1.1 Two openings. Two permanent openings shall be constructed within the garage. The upper opening shall be located entirely within 12 inches (305 mm) of the ceiling of the garage. The lower opening shall be located entirely within 12 inches (305 mm) of the floor of the garage. Both openings shall be constructed in the same exterior wall. The openings shall communicate directly with the outdoors and shall have a minimum free area of 1/2 square foot per 1,000 cubic feet (1.7 m²/1000 m³) of garage volume.

- ❖ The location requirement will prevent the openings from being more than 12 inches (305 mm) tall because the required openings must be entirely within the 12 inches (305 mm) of wall space measured down from the ceiling and up from the floor. The openings must be in the same wall to help create a gravity flow of gases driven by the natural buoyancy of hydrogen gas. The bottom opening is an air inlet and the top opening is an air outlet.

M1307.4.1.2 Louvers and grilles. In calculating free area required by Section M1307.4.1, the required size of openings shall be based on the net free area of each opening. If the free area through a design of louver or grille is known, it shall be used in calculating the size opening required to provide the free area specified. If the design and free area are not known, it shall be assumed that wood louvers will have a 25-percent free area and metal louvers and grilles will have a 75-percent free area. Louvers and grilles shall be fixed in the open position.

- ❖ This section recognizes that louvers and grilles are usually installed over air inlets and outlets to prevent rain, snow and animals from entering the building. When louvers or grilles are used, the solid portion of the louver or grille must be considered when determining the unobstructed (net clear) area of the opening.

Air openings are sized based on a free, unobstructed area for the passage of air. Louvers or grilles placed over these openings reduce the area of the openings because of the area occupied by the solid portions of the grille or louver. The reduction in area must be considered because only the unobstructed area can be credited toward the required opening size.

The reduction in opening area caused by the presence of grilles or louvers will always require openings to be larger than determined from the sizing ratios of this chapter and larger than any duct of the minimum required size that might connect to these openings.

M1307.4.2 Mechanical ventilation. Indoor locations intended for hydrogen-generating or refueling operations shall be ventilated in accordance with Section 502.16 of the *International Mechanical Code*. In these locations, *equip-*

GENERAL MECHANICAL SYSTEM REQUIREMENTS

ment and appliances having an ignition source shall be located so that the source of ignition is below the mechanical ventilation outlet(s).

❖ Section 502.16 of the IMC provides criteria for the design and operation of a mechanical ventilation system in repair garages for natural-gas-fueled and hydrogen-fueled vehicles. This section makes Section 502.16 of the IMC applicable to indoor spaces containing hydrogen-generating and/or refueling operations. Although the IMC does not specify that the outlet must be within 12 inches (305 mm) of the ceiling as is required for natural ventilation, it does require the opening to be located at the high point of the space. This section requires that any ignition source be located below the mechanical exhaust outlet opening.

M1307.4.3 Specially engineered installations. As an alternative to the provisions of Sections M1307.4.1 and M1307.4.2, the necessary supply of air for ventilation and dilution of flammable gases shall be provided by an approved engineered system.

❖ The code is not intended to inhibit innovative ideas or technological advances. A comprehensive regulatory document such as a fuel gas code cannot envision and then address all future innovations in the industry. As a result, a code must be applicable to and provide a basis for the approval of an increasing number of newly developed, innovative materials, systems and methods for which no code text or referenced standards yet exist. The fact that a material, product or method of construction is not addressed in the code is not an indication that prohibition of the material, product or method is intended. The code official is expected to apply sound technical judgment in accepting materials, systems or methods that, while not anticipated by the drafters of the current code text, can be demonstrated to offer equivalent performance. By virtue of its text, the code regulates new and innovative construction practices while addressing the relative safety of building occupants. The code official is responsible for determining whether a requested alternative provides a level of protection of the public health, safety and welfare as required by the code.

M1307.5 Electrical appliances. Electrical appliances shall be installed in accordance with Chapters 14, 15, 19, 20 and 34 through 43 of this code.

❖ Electrical appliances must be installed in accordance with the electrical provisions of Chapters 34 through 43 and the installation requirements for specific appliances in Chapters 14, 15, 19 and 20.

M1307.6 Plumbing connections. Potable water and drainage system connections to equipment and appliances regulated by this code shall be in accordance with Chapters 29 and 30.

❖ Many appliances addressed in the mechanical part of the code have potable water connections and/or drain connections. Chapters 29 and 30 contain provisions for such connections to protect the potable water supply from contamination and to protect the occupants

from health hazards associated with improper connections to the sanitary drainage system.

SECTION M1308 MECHANICAL SYSTEMS INSTALLATION

M1308.1 Drilling and notching. Wood-framed structural members shall be drilled, notched or altered in accordance with the provisions of Sections R502.8, R602.6, R602.6.1 and R802.7. Holes in load-bearing members of cold-formed steel light-frame construction shall be permitted only in accordance with Sections R505.2.6, R603.2.6 and R804.2.6. In accordance with the provisions of Sections R505.3.5, R603.3.4 and R804.3.3, cutting and notching of flanges and lips of load-bearing members of cold-formed steel light frame construction shall not be permitted. Structural insulated panels (SIPs) shall be drilled and notched or altered in accordance with the provisions of Section R610.7.

❖ During mechanical system installation, it is usually necessary to penetrate structural members. The building chapters of the code regulate how these penetrations should be made so as not to weaken the structural members. The provisions of this section refer to those requirements, which are especially strict regarding the cutting and notching of steel members and prohibit the cutting and notching of flanges and lips of cold-formed, steel-framed, load-bearing members. See the commentary to the sections listed in the code text and also to Section P2603.2.

M1308.2 Protection against physical damage. Where piping will be concealed within light-frame construction assemblies, the piping shall be protected against penetration by fasteners in accordance with Sections M1308.2.1 through M1308.2.3.

Exception: Cast iron piping and galvanized steel piping shall not be required to be protected.

❖ This section is intended to minimize the possibility of damage to refrigerant piping and other mechanical system piping from nails, screws or other fasteners. Because nails and screws sometimes miss the stud, rafter joist or top or sole plate, the shield must protect the pipe through the full width of the member and must extend not less than 2 inches (51 mm) above the sole plates and 2 inches (51 mm) below the top plates. Commentary Figure M1308.2 shows typical shield plates. Cast-iron and galvanized steel pipe have wall thicknesses greater than the required thickness of the shield plate, which makes them inherently resistant to nail and screw penetrations. The same requirement exists in Section P2603.2.1 for plumbing piping and Section G2415.7 for gas piping (see commentary, Sections P2603.2.1 and G2415.7). Piping such as refrigerant and gas piping should not be run in close proximity to the underside of roof deck sheathing because there have been cases where roofing nails have penetrated such piping, especially during reroofing. See Section M1411.7.

For SI: 1 inch = 25.4 mm.

M1308.2.1 Piping through bored holes or notches. Where piping is installed through holes or notches in framing members and is located less than 1½ inches (38 mm) from the framing member face to which wall, ceiling or floor membranes will be attached, the pipe shall be protected by shield plates that cover the width of the pipe and the framing member and that extend 2 inches (51 mm) to each side of the framing member. Where the framing member that the piping passes through is a bottom plate, bottom track, top plate or top track, the shield plates shall cover the framing member and extend 2 inches (51 mm) above the bottom framing member and 2 inches (51 mm) below the top framing member.

❖ See the commentary to Section G2415.7.1.

M1308.2.2 Piping in other locations. Where piping is located within a framing member and is less than 1½ inches (38 mm) from the framing member face to which wall, ceiling or floor membranes will be attached, the piping shall be protected by shield plates that cover the width and length of the piping. Where piping is located outside of a framing member and is located less than 1½ inches (38 mm) from the nearest edge of the face of the framing member to which the membrane will be attached, the piping shall be protected by shield plates that cover the width and length of the piping.

❖ See the commentary to Section G2415.7.2.

M1308.2.3 Shield plates. Shield plates shall be of steel material having a thickness of not less than 0.0575 inch (1.463 mm) (No. 16 gage).

❖ See the commentary to Section G2415.7.3.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

- NFPA 70–14, *National Electrical Code*. Quincy, MA: National Fire Protection Association, 2013.

Chapter 14: Heating and Cooling Equipment and Appliances

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter is concerned with the installation and hazards associated with heating and cooling appliances and equipment. These types of appliances and equipment have risks either because of the potential for fire or the accidental release of refrigerants. Both situations are undesirable in dwellings that are covered by the code.

The chapter is a collection of requirements for various heating and cooling appliances, dedicated to single topics by section. The common theme is that all of these types of appliances use energy in one form or another, and the improper installation of the appliances would present a hazard to the occupants of the dwellings.

Section M1401 consists of the general requirements that apply to all such appliances and equipment. Section M1402 contains the provisions for central furnaces. Section M1403 addresses heat pump equipment. Section M1404 refers the reader to Section M1411 for the criteria for refrigeration cooling equipment. Section M1405 contains the provisions for baseboard convectors. Sec-

tion M1406 addresses radiant heating systems. Section M1407 consists of the criteria for duct heaters. Section M1408 contains the provisions for vented floor furnaces. Section M1409 contains provisions for vented wall furnaces. Section M1410 addresses vented room heaters. Section M1411 consists of the provisions for refrigeration cooling equipment. Section M1412 contains the provisions for absorption cooling equipment. Section M1413 addresses evaporative cooling equipment, and Section M1414 contains the provisions for fireplace stoves.

Purpose

This chapter provides, in a simple format, the requirements for heating and cooling appliances and equipment commonly found in dwellings covered by the code. These regulations pertain to the safety of the occupants by establishing minimum requirements for the design, construction, installation and operation of these systems.

SECTION M1401 GENERAL

M1401.1 Installation. Heating and cooling *equipment* and *appliances* shall be installed in accordance with the manufacturer's instructions and the requirements of this code.

❖ As discussed in the commentary to Section M1307.1, the manufacturer's installation instructions are an enforceable extension of the code. The manufacturer's instructions must be available at the job site when the equipment and appliances are being inspected.

M1401.2 Access. Heating and cooling *equipment* and appliances shall be located with respect to building construction and other *equipment* and appliances to permit maintenance, servicing and replacement. Clearances shall be maintained to permit cleaning of heating and cooling surfaces; replacement of filters, blowers, motors, controls and vent connections; lubrication of moving parts; and adjustments.

Exception: Access shall not be required for ducts, piping, or other components approved for concealment.

❖ Because mechanical equipment and appliances require routine maintenance, repairs and possible

replacement, access is required. Additionally, access recommendations or requirements are usually stated in the manufacturer's installation instructions. As a result, the provisions stated here are intended to supplement the manufacturer's installation instructions. The intent is that clearances be sufficient to permit cleaning of the heating and cooling heat exchange surfaces and permit replacement and maintenance of filters, motors, controls, etc. Section M1305.1 contains similar requirements.

The exception recognizes that providing access to some components is not necessary or practical. This is especially true for ducts and piping which are often concealed in walls, floors and ceilings. Components that do not require observation, inspection, adjustment, servicing, repair or replacement are not required to be provided with access when approved by the code official.

M1401.3 Equipment and appliance sizing. Heating and cooling *equipment* and *appliances* shall be sized in accordance with ACCA Manual S or other approved sizing methodologies based on building loads calculated in accordance

with ACCA Manual J or other *approved* heating and cooling calculation methodologies.

Exception: Heating and cooling equipment and appliance sizing shall not be limited to the capacities determined in accordance with Manual S where either of the following conditions applies:

1. The specified equipment or appliance utilizes multi-stage technology or variable refrigerant flow technology and the loads calculated in accordance with the approved heating and cooling calculation methodology are within the range of the manufacturer's published capacities for that equipment or appliance.
 2. The specified equipment or appliance manufacturer's published capacities cannot satisfy both the total and sensible heat gains calculated in accordance with the approved heating and cooling calculation methodology and the next larger standard size unit is specified.
- ❖ The Air Conditioning Contractors of America's Manual J, *Load Calculations for Residential Winter and Summer Air Conditioning*, contains a simplified method of calculating heating and cooling loads. It includes a room-by-room calculation method that allows the designer to determine the required capacity of the heating and cooling equipment. In addition, it provides for an estimate of the airflow requirements for each of the areas in the house. The estimate can be used in sizing the duct system for the types of heating and cooling units that use air as the medium for heat transfer. Other approved methods may be used with the code official's approval.

ACCA Manual S or an approved equivalent is used to accurately choose the size of HVAC equipment after the building's heat gains and losses are determined in accordance with Manual J. Manual S takes into account the varying performance of cooling equipment based on the climate zone it will be installed in. The manual also allows calculation of heating equipment output British thermal units per hour (Btu/h) based on the manufacturer's given input ratings. Fuel-fired heating equipment is typically rated based on Btu/h input, but the input rating cannot be used alone to size the appliance. The actual output rating must be known to match the output to the heat loss of the building. Actual appliance output depends on the efficiency of the appliance and the altitude at which the appliance is installed. For example, an 80 percent efficient appliance with an input rating of 100,000 Btu/h will have an output of 80,000 Btu/h at sea level and that output will decrease as the appliance is elevated above sea level. Appliances must be derated based on the altitude at which they are installed in accordance with the manufacturer's instructions. At higher elevations, the air is less dense and this will affect the fuel and oxygen mixture entering the burners. Some appliances will require adjustments to the burner manifold gas pressure, replacement of orifices and possibly other modifications to the burners, controls and/or venting components. A commonly used derating prescription calls for

the input rating to be reduced 4 percent for each 1,000 feet (304 800 mm) that the appliance is elevated above sea level with no reduction required for an elevation of up to 2,000 feet (609 600 mm) above sea level.

The exception, condition 1 addresses variable capacity equipment and would allow the equipment capacity to exceed the calculated equipment size. The calculated equipment size must fall within the range of the specified (chosen) variable capacity equipment. Condition 2 would allow the next larger standard size of the specified (chosen) equipment where the calculated size of the equipment is inadequate for both the sensible and the sensible and latent heat gains. In other words, if XYZ brand of equipment is specified and the size calculated in accordance with this section won't handle the loads, the next larger size of that specific equipment can be used.

M1401.4 Exterior installations. *Equipment and appliances* installed outdoors shall be *listed and labeled* for outdoor installation. Supports and foundations shall prevent excessive vibration, settlement or movement of the *equipment*. Supports and foundations shall be in accordance with Section M1305.1.4.1.

- ❖ Appliances installed outdoors must be specifically listed and labeled for outdoor installation. The concern is for weather and ambient temperatures. The manufacturer's instructions and listing must be consulted to determine whether a particular appliance is designed for or can be made suitable for outdoor installation. For example, furnaces cannot be installed outdoors in cold climates regardless of any weatherproof enclosure, unless the heat exchanger, burner assemblies and venting system are designed for exposure to temperatures below normal indoor temperatures. Cold ambient temperatures can cause harmful condensation to occur on heat exchanger surfaces of fuel-fired appliances.

Additionally, there may be local ordinances that govern the outdoor installation of appliances. Before installing an appliance outdoors, consult local zoning regulations, ordinances and subdivision covenants. Many of these regulations strictly limit the location of outdoor mechanical equipment and appliances.

Supports and foundations must be adequate for the loads imposed such that there is no movement that could put stress and strains on connections and attachments to the equipment and appliances. Supports and foundations must also comply with the requirements in Section M1305.1.4.1 (see commentary, Section M1305.1.4.1).

M1401.5 Flood hazard. In flood hazard areas as established by Table R301.2(1), heating and cooling *equipment and appliances* shall be located or installed in accordance with Section R322.1.6.

- ❖ Mechanical appliances, equipment and systems for dwellings that are located in flood hazard areas must be installed at or above the elevation required by the code or must be designed and installed to prevent the entry of water into the components and to resist the

forces of the flood waters on the components (see commentary, Section R322.1.6).

SECTION M1402 CENTRAL FURNACES

M1402.1 General. Oil-fired central furnaces shall conform to ANSI/UL 727. Electric furnaces shall conform to UL 1995.

❖ The term “central furnace” refers to a furnace in a central location of the home that heats the air and then distributes it through ducts to the rooms of the home. The term originates from the days when homes were heated by local sources within a room such as a fireplace or a stove. This section requires oil-fired central furnaces to meet the requirements in UL 727, and it requires electric furnaces to meet the requirements of UL 1995. Furnaces can come in many configurations, including upflow, counterflow (downflow), horizontal flow and indoor and outdoor units (see Chapter 24 for gas-fired furnaces).

M1402.2 Clearances. Clearances shall be provided in accordance with the *listing* and the manufacturer’s installation instructions.

❖ The clearances indicated on the equipment label and in the manufacturer’s installation instructions must always be followed, as indicated throughout these mechanical provisions.

M1402.3 Combustion air. *Combustion air* shall be supplied in accordance with Chapter 17. *Combustion air* openings shall be unobstructed for a distance of not less than 6 inches (152 mm) in front of the openings.

❖ This section refers to Chapter 17 for combustion air requirements and specifically requires a minimum 6-inch (152 mm) unobstructed clearance in front of the firebox to ensure adequate distribution of combustion air to the appliance. Fuel-gas-fired furnaces must meet the combustion air requirements in Section G2407.

SECTION M1403 HEAT PUMP EQUIPMENT

M1403.1 Heat pumps. Electric heat pumps shall be listed and labeled in accordance with UL 1995 or UL/CSA/ANCE 60335-2-40.

❖ Heat pumps are central heating units that use the rejection heat from the condenser of a refrigeration circuit to heat the conditioned space. They are often backed up by auxiliary electric resistance heating elements which supplement the heat pump during defrost cycles and during times of very low outdoor ambient temperatures. The source of heat energy is the outdoor air for air-to-air units and bodies of water or wells for water-to-air units. Heat pumps utilize reversing valves that cause the evaporator to become a condenser and vice versa, thus allowing the unit to both heat and cool conditioned spaces.

SECTION M1404 REFRIGERATION COOLING EQUIPMENT

M1404.1 Compliance. Refrigeration cooling *equipment* shall comply with Section M1411.

❖ This section is a cross reference to the actual provisions found in Section M1411.

SECTION M1405 BASEBOARD CONVECTORS

M1405.1 General. Electric baseboard convectors shall be installed in accordance with the manufacturer’s instructions and Chapters 34 through 43 of this code. Electric baseboard heaters shall be listed and labeled in accordance with UL 1042.

❖ Electric baseboard convectors must be listed and labeled in accordance with UL 1042 and be installed in accordance with manufacturers’ installation instructions and with the electrical requirements of the code. The latter are based on the electrical provisions of the *National Electrical Code*, published by the National Fire Protection Association. See Commentary Figure M1405.1 for an illustration of a typical electric baseboard convector.

Figure M1405.1
TYPICAL ELECTRIC BASEBOARD CONVECTOR

SECTION M1406 RADIANT HEATING SYSTEMS

M1406.1 General. Electric radiant heating systems shall be installed in accordance with the manufacturer’s instructions and Chapters 34 through 43 of this code and shall be listed for the application.

❖ Radiant heating systems contain electrical elements that create heat when an electric current passes through them. Radiant heating systems consist of heating cables and radiant heating panels that have been evaluated for contact with specific surfaces. If the system is not installed properly, electricity and the heat emitted could create hazards for the occupants of the dwelling. This section refers to the manufacturer’s instructions and the electrical provisions in Chapters

34 through 43 for safe installations. The manufacturer's installation instructions will have details on the different type of surfaces and the temperature limits for each surface. These requirements are in addition to the requirements found in Sections M1406.2 through M1406.5.

M1406.2 Clearances. Clearances for radiant heating panels or elements to any wiring, outlet boxes and junction boxes used for installing electrical devices or mounting luminaires shall comply with Chapters 34 through 43 of this code.

❖ This section references certain minimum clearances located in the electrical chapters of the code so that the heating elements are not damaged or the electrical circuit continuity is not interrupted, thus rendering portions or all of the radiant heating systems inoperable. This section is also intended to protect the electrical systems, equipment, and components from damage from the heating elements.

M1406.3 Installation of radiant panels. Radiant panels installed on wood framing shall conform to the following requirements:

1. Heating panels shall be installed parallel to framing members and secured to the surface of framing members or mounted between framing members.
 2. Mechanical fasteners shall penetrate only the unheated portions provided for this purpose. Panels shall not be fastened at any point closer than $\frac{1}{4}$ inch (6.4 mm) to an element. Other methods of attachment of the panels shall be in accordance with the panel manufacturer's instructions.
 3. Unless *listed* and *labeled* for field cutting, heating panels shall be installed as complete units.
- ❖ Radiant heat panels mounted on wood framing may act as an ignition source if improperly installed. Because these systems generate heat, they must be mounted to wood framing by fastening through the unheated portions of each panel. Metallic fasteners, such as nails or screws, are excellent conductors of heat as well as electricity; therefore, they must not be driven through any portion of a panel closer than $\frac{1}{4}$ inch (6.4 mm) to a heating element. The manufacturer's installation instructions may contain additional methods that can be used to attach the panels.

M1406.4 Installation in concrete or masonry. Radiant heating systems installed in concrete or masonry shall conform to the following requirements:

1. Radiant heating systems shall be identified as being suitable for the installation, and shall be secured in place as specified in the manufacturer's installation instructions.
 2. Radiant heating panels or radiant heating panel sets shall not be installed where they bridge expansion joints unless protected from expansion and contraction.
- ❖ Fire hazards created by electric radiant heating systems installed in masonry construction are minimal, but these installations require special mounting hard-

ware and must be installed in accordance with the manufacturer's instructions. Radiant panels must be protected from expansion and contraction when mounted over masonry expansion joints to avoid structural damage.

M1406.5 Finish surfaces. Finish materials installed over radiant heating panels or systems shall be installed in accordance with the manufacturer's instructions. Surfaces shall be secured so that nails or other fastenings do not pierce the radiant heating elements.

❖ Finish materials must be carefully installed over electric radiant heating systems so that nails or screws do not penetrate the heating elements. Fasteners that are accidentally driven through these elements could cause short circuits, ground faults, destroy the elements or cause the surfaces to overheat and start a fire. The finish surfaces must be installed in accordance with the instructions supplied by the manufacturer of the radiant heating system.

SECTION M1407 DUCT HEATERS

M1407.1 General. Electric duct heaters shall be installed in accordance with the manufacturer's instructions and Chapters 34 through 43 of this code. Electric duct heaters shall comply with UL 1996.

❖ Electric duct heaters are designed to be installed "in-line" in an air duct system and use electric resistance heating elements to heat the air passing through them. The code requires that their installation comply with the manufacturer's instructions and the electrical provisions in the code.

M1407.2 Installation. Electric duct heaters shall be installed so that they will not create a fire hazard. Class 1 ducts, duct coverings and linings shall be interrupted at each heater to provide the clearances specified in the manufacturer's installation instructions. Such interruptions are not required for duct heaters *listed* and *labeled* for zero clearance to combustible materials. Insulation installed in the immediate area of each heater shall be classified for the maximum temperature produced on the duct surface.

❖ These heaters could be installed in ducts that have combustible components, coverings or insulating materials. This section requires that these heaters be listed for zero clearance to combustible material or that the duct materials be kept at the specified distance from the heaters.

M1407.3 Installation with heat pumps and air conditioners. Duct heaters located within 4 feet (1219 mm) of a heat pump or air conditioner shall be *listed* and *labeled* for such installations. The heat pump or air conditioner shall additionally be *listed* and *labeled* for such duct heater installations.

❖ Heat pumps are typically unable to provide all of the heat required in a building at design temperature and also may have to shut down periodically for a defrost cycle. Thus, they are usually supplemented with elec-

trical resistance heating to meet the occasional periods of peak load requirements and carry the load during defrost.

M1407.4 Access. Duct heaters shall be accessible for servicing, and clearance shall be maintained to permit adjustment, servicing and replacement of controls and heating elements.

❖ Section M1305 has additional criteria for access to the installations of appliances in specific locations.

M1407.5 Fan interlock. The fan circuit shall be provided with an interlock to prevent heater operation when the fan is not operating.

❖ A fan interlock is required to prevent the duct heater from operating when there is no air flow. Without air flow, the duct heater would overheat, possibly creating a fire hazard.

SECTION M1408 VENTED FLOOR FURNACES

M1408.1 General. Oil-fired vented floor furnaces shall comply with UL 729 and shall be installed in accordance with their *listing*, the manufacturer's instructions and the requirements of this code.

❖ Oil-fired floor furnaces are vented appliances that are installed in an opening in the floor. Such units supply heat to the room by gravity convection and direct radiation and typically serve as the sole source of space heating. Such furnaces are common in cottages, small homes, seasonally occupied structures and rural homes. Because the floor grille can become very hot, extreme care must be exercised to prevent occupants, especially children, from contacting the grille by walking or falling on it. Also, care must be taken to avoid a fire hazard caused by placement of materials or furnishings on or near the furnace floor grille.

M1408.2 Clearances. Vented floor furnaces shall be installed in accordance with their listing and the manufacturer's instructions.

❖ Vented floor furnaces must be installed in accordance with the manufacturer's instructions, which are an enforceable extension of the code.

M1408.3 Location. Location of floor furnaces shall conform to the following requirements:

1. Floor registers of floor furnaces shall be installed not less than 6 inches (152 mm) from a wall.
2. Wall registers of floor furnaces shall be installed not less than 6 inches (152 mm) from the adjoining wall at inside corners.
3. The furnace register shall be located not less than 12 inches (305 mm) from doors in any position, draperies or similar combustible objects.
4. The furnace register shall be located not less than 5 feet (1524 mm) below any projecting combustible materials.
5. The floor furnace burner assembly shall not project into an occupied under-floor area.
6. The floor furnace shall not be installed in concrete floor construction built on grade.
7. The floor furnace shall not be installed where a door can swing within 12 inches (305 mm) of the grille opening.

❖ Because of the heat generated in the combustion chamber that is emitted through the floor register, minimum clearances are necessary from the face of the air registers to surrounding walls, overhead projections and other combustible items, such as doors and draperies. See Commentary Figure M1408.3 for required clearances.

**Figure M1408.3
FLOOR FURNACE CLEARANCES**

M1408.4 Access. An opening in the foundation not less than 18 inches by 24 inches (457 mm by 610 mm), or a trap door not less than 22 inches by 30 inches (559 mm by 762 mm) shall be provided for access to a floor furnace. The opening and passageway shall be large enough to allow replacement of any part of the *equipment*.

❖ Either a floor opening (trap door) or a foundation opening must be provided to allow for maintenance or replacement of the furnace. Without such access, appliances are not as likely to receive the maintenance necessary for efficient and safe operation.

M1408.5 Installation. Floor furnace installations shall conform to the following requirements:

1. Thermostats controlling floor furnaces shall be located in the room in which the register of the floor furnace is located.
 2. Floor furnaces shall be supported independently of the furnace floor register.
 3. Floor furnaces shall be installed not closer than 6 inches (152 mm) to the ground. The minimum clearance shall be 2 inches (51 mm), where the lower 6 inches (152 mm) of the furnace is sealed to prevent water entry.
 4. Where excavation is required for a floor furnace installation, the excavation shall extend 30 inches (762 mm) beyond the control side of the floor furnace and 12 inches (305 mm) beyond the remaining sides. Excavations shall slope outward from the perimeter of the base of the excavation to the surrounding *grade* at an angle not exceeding 45 degrees (0.79 rad) from horizontal.
 5. Floor furnaces shall not be supported from the ground.
- ❖ Floor furnaces must have supports independent of the floor register and the ground below. A 6-inch (152 mm) clearance must also be maintained from the ground to protect against moisture, rust and corrosion of the furnace casing. This may be reduced to 2 inches (51 mm) if the unit is sealed against flooding. When the ground must be excavated to provide space for a floor furnace, a 30-inch (762 mm) clearance must be provided for access to the control side and a 12-inch (305 mm) clearance is required on all other sides.

SECTION M1409 VENTED WALL FURNACES

M1409.1 General. Oil-fired vented wall furnaces shall comply with UL 730 and shall be installed in accordance with their *listing*, the manufacturer's instructions and the requirements of this code.

❖ Vented, oil-fired wall furnaces are a type of room heater typically designed to be installed within a 2 × 4 stud cavity in frame construction. Wall furnaces are typically used in cottages, room additions and homes in mild climates. Some units are designed to serve a single room, and others are designed as through-the-wall units to serve adjacent rooms. Wall furnaces are ductless; however, some units are listed for use with a

surface-mounted supply outlet extension. Wall furnaces can be either gravity or forced-air type.

M1409.2 Location. The location of vented wall furnaces shall conform to the following requirements:

1. Vented wall furnaces shall be located where they will not cause a fire hazard to walls, floors, combustible furnishings or doors. Vented wall furnaces installed between bathrooms and adjoining rooms shall not circulate air from bathrooms to other parts of the building.
 2. Vented wall furnaces shall not be located where a door can swing within 12 inches (305 mm) of the furnace air inlet or outlet measured at right angles to the opening. Doorstops or door closers shall not be installed to obtain this clearance.
- ❖ Wall furnaces, like all room heaters, can present a fire hazard if improperly located. The heat discharged or directly radiated from such units can ignite nearby wall or floor surfaces, furniture, trim items, window treatments and doors. A through-the-wall unit serving both a bathroom and an adjacent room must not recirculate air between the two spaces. A combustible door that swings close to a wall furnace could be a fire hazard if at some position the door would be within 12 inches (305 mm) of an air inlet or outlet. A door could also interfere with air-flow through the furnace, thereby causing appliance overheating. Because door closures and doorstops are easily defeated, they must not be depended on to secure the required clearance. If the door swing cannot comply with this section, the door would have to be removed or rehung to change its swing direction.

M1409.3 Installation. Vented wall furnace installations shall conform to the following requirements:

1. Required wall thicknesses shall be in accordance with the manufacturer's installation instructions.
 2. Ducts shall not be attached to a wall furnace. Casing extensions or boots shall be installed only where listed as part of a *listed* and *labeled appliance*.
 3. A manual shut off valve shall be installed ahead of all controls.
- ❖ Most wall furnaces are not designed to force air through ducts, especially the gravity types that do not use fans. Attachment of ducts would add resistance to the flow of air through the furnace, thereby causing abnormally high temperature rises across the heat exchanger and abnormally high temperatures on furnace surfaces. Some wall furnaces are listed and designed for use with supply duct extensions designed for wall mounting that are intended to improve heat distribution. Such duct extensions are factory-built and supplied only by the furnace manufacturer.

The fuel-line connection to every appliance must be equipped with an individual shutoff valve to permit maintenance, repair or replacement of the appliance or its components.

M1409.4 Access. Vented wall furnaces shall be provided with access for cleaning of heating surfaces; removal of burn-

ers; replacement of sections, motors, controls, filters and other working parts; and for adjustments and lubrication of parts requiring such attention. Panels, grilles and access doors that must be removed for normal servicing operations shall not be attached to the building construction.

- ❖ Proper access for servicing and replacement of vented wall furnaces is very important, as it is with the other mechanical appliances regulated by the code (see commentary, Section M1408.4).

SECTION M1410 VENTED ROOM HEATERS

M1410.1 General. Vented room heaters shall be tested in accordance with ASTM E1509 for pellet-fuel burning, UL 896 for oil-fired or UL 1482 for solid fuel-fired and installed in accordance with their *listing*, the manufacturer's installation instructions and the requirements of this code.

- ❖ This section addresses vented space/room heaters, including direct-vent and vent-connected or chimney-connected appliances. As required by the appliance standard, such appliances are equipped with safety controls that will prevent fuel flow to the burners in the event of ignition system failure. UL 896 is the governing standard for oil-fired room heaters, UL 1432 is the standard for solid-fuel heaters and ASTM E1509 is the standard for pellet-fuel-burning heaters. Solid-fuel-burning room heaters in accordance with UL 1482 address solid fuel-burning, free-standing fire chamber assemblies that heat space by direct radiation, circulated heated air or a combination of both. Solid-fuel room heaters are chimney connected, and are designed for operation with the fire chamber (firebox) closed (see commentary, Section M1414.1). Mechanical appliances and equipment must be installed in accordance with the manufacturer's instructions. This is important because the manufacturer's instructions are used by the testing agency when the test installation is constructed. Therefore, a unit tested in compliance with the specified standard and installed in accordance with the manufacturer's instructions is expected to perform the same as the representative sample unit that was tested.

M1410.2 Floor mounting. Room heaters shall be installed on noncombustible floors or *approved* assemblies constructed of noncombustible materials that extend not less than 18 inches (457 mm) beyond the *appliance* on all sides.

Exceptions:

1. *Listed* room heaters shall be installed on noncombustible floors, assemblies constructed of noncombustible materials or floor protectors *listed* and *labeled* in accordance with UL 1618. The materials and dimensions shall be in accordance with the *appliance* manufacturer's instructions.
2. Room heaters *listed* for installation on combustible floors without floor protection shall be installed in

accordance with the *appliance* manufacturer's instructions.

- ❖ Room heaters must be installed on noncombustible floors or approved floor assemblies constructed of noncombustible materials that extend 18 inches (457 mm) beyond the appliance on all sides or installed on assemblies or listed protectors in accordance with the appliance listing and instructions, or they must be listed for installation on combustible floors. They must also be installed following the manufacturer's instructions.

SECTION M1411 HEATING AND COOLING EQUIPMENT

M1411.1 Approved refrigerants. Refrigerants used in direct refrigerating systems shall conform to the applicable provisions of ANSI/ASHRAE 34.

- ❖ The classification of refrigerants is based on ASHRAE 34, which numbers and classifies refrigerants in accordance with their potential hazards. Refrigerants are identified by their number preceded by the letter R, for example, R-134a. Manufacturer trademark names such as "Freon" are not used in the code.

M1411.2 Refrigeration coils in warm-air furnaces. Where a cooling coil is located in the supply plenum of a warm-air furnace, the furnace blower shall be rated at not less than 0.5-inch water column (124 Pa) static pressure unless the furnace is *listed* and *labeled* for use with a cooling coil. Cooling coils shall not be located upstream from heat exchangers unless *listed* and *labeled* for such use. Conversion of existing furnaces for use with cooling coils shall be permitted provided the furnace will operate within the temperature rise specified for the furnace.

- ❖ If a cooling coil is not a part of a listed furnace or air conditioning system and is added to a warm-air furnace, the following requirements must be met:

1. The furnace blower must be rated at 0.5-inch (12.7 mm) of water-column minimum static pressure. The furnace blower must be capable of moving the larger flow rates of air required for cooling.
2. Unless the furnace heat exchanger is corrosion resistant (usually stainless steel), the cooling coil unit must be installed downstream of the heat exchanger.

Moisture in the air could condense on the surface of a heat exchanger that is cooled by being downstream of a cooling coil and such condensation can corrode metal parts.

M1411.3 Condensate disposal. Condensate from cooling coils and evaporators shall be conveyed from the drain pan outlet to an *approved* place of disposal. Such piping shall maintain a minimum horizontal slope in the direction of discharge of not less than $\frac{1}{8}$ unit vertical in 12 units horizontal

(1-percent slope). Condensate shall not discharge into a street, alley or other areas where it would cause a nuisance.

❖ Appliances and equipment containing evaporators or cooling coils, including refrigeration, dehumidification and comfort cooling equipment, can produce condensate from the water vapor in the atmosphere. A drainage system is necessary to dispose of the condensate and prevent damage to the structure. Condensate disposal is a local issue dependent on specific local conditions such as soil conditions, contour of the area, sewer loading and water treatment plant capacity. Because of this, the approval of the disposal place is the responsibility of the local jurisdiction. Some of the locations that could be accepted are storm or sanitary sewers, rooftops, French drains, drainage ditches, collection ponds or simply into the yard, as is typical for most homes.

Some water treatment facilities operate near maximum capacity and do not allow condensate disposal into the sanitary sewer because condensate does not require treatment. If connected to the sanitary sewer, the connection must be indirect in compliance with the plumbing provisions of the code to prevent sewage and gases from entering the equipment or system. French drains, or seepage pits, are effective depending on the permeability of the soil, the rate of discharge and the size of the pit.

The piping conveying the condensate to its disposal point must be properly sloped to ensure drainage just the same as any drainage system. Sagging pipe could trap water and air that would impede the flow of the condensate.

M1411.3.1 Auxiliary and secondary drain systems. In addition to the requirements of Section M1411.3, a secondary drain or auxiliary drain pan shall be required for each cooling or evaporator coil where damage to any building components will occur as a result of overflow from the *equipment* drain pan or stoppage in the condensate drain piping. Such piping shall maintain a minimum horizontal slope in the direction of discharge of not less than $\frac{1}{8}$ unit vertical in 12 units horizontal (1-percent slope). Drain piping shall be not less than $\frac{3}{4}$ -inch (19 mm) nominal pipe size. One of the following methods shall be used:

1. An auxiliary drain pan with a separate drain shall be installed under the coils on which condensation will occur. The auxiliary pan drain shall discharge to a conspicuous point of disposal to alert occupants in the event of a stoppage of the primary drain. The pan shall have a minimum depth of 1.5 inches (38 mm), shall be not less than 3 inches (76 mm) larger than the unit or the coil dimensions in width and length and shall be constructed of corrosion-resistant material. Galvanized sheet steel pans shall have a minimum thickness of not less than 0.0236-inch (0.6010 mm) (No. 24 Gage). Nonmetallic pans shall have a minimum thickness of not less than 0.0625 inch (1.6 mm).
2. A separate overflow drain line shall be connected to the drain pan installed with the *equipment*. This overflow drain shall discharge to a conspicuous point of disposal

to alert occupants in the event of a stoppage of the primary drain. The overflow drain line shall connect to the drain pan at a higher level than the primary drain connection.

3. An auxiliary drain pan without a separate drain line shall be installed under the coils on which condensation will occur. This pan shall be equipped with a water level detection device conforming to UL 508 that will shut off the *equipment* served prior to overflow of the pan. The pan shall be equipped with a fitting to allow for drainage. The auxiliary drain pan shall be constructed in accordance with Item 1 of this section.
4. A water level detection device conforming to UL 508 shall be installed that will shut off the *equipment* served in the event that the primary drain is blocked. The device shall be installed in the primary drain line, the overflow drain line or the *equipment*-supplied drain pan, located at a point higher than the primary drain line connection and below the overflow rim of such pan.

❖ An auxiliary (redundant) drain pan or a secondary drain is required for equipment locations where condensate overflow would cause damage to any building components. The auxiliary drain pan is installed to catch condensate spilling from the primary condensate removal system in the equipment. This backup pan protects the building from structural and finish damage. A secondary (overflow) drain is a second drain connection to the primary pan and is at a higher elevation than the primary drain. These “back-up provisions” help protect the building from structural and finish damage.

Condensate drains are notorious for clogging because of debris (lint, dust) from air-handling systems and the natural affinity to produce slime growths in drain pans and pipes. It is relatively common for condensate overflows to cause damage to buildings. The specified minimum horizontal slope is intended to maintain flow to prevent the blockage of the condensate pipe. However, properly sloping the drain will not ensure that blockage will not occur, therefore, this section provides four options for preventing such damage where the equipment is located in spaces such as attics, above suspended ceilings and furred spaces and locations on upper stories. One of the four methods must be used.

The first method uses an auxiliary drain pan below the coils on which condensate will occur with an independent drain line that discharges to a location that is easily observable to notify the building occupants that a problem with the primary pan exists. The code prescribes the depth of the pan and specific material thicknesses to ensure that the pan will be corrosion resistant and will have sufficient holding capacity and capture ability.

The second method uses an independent overflow drain line connected to the primary drain pan at a point higher than the primary drain line. Most evaporator coil pans are factory provided with an overflow drain tapping that can be used for this purpose. As in the first

method, the point of discharge must be readily observable.

The third method uses a water-level detection device, usually a float switch or electronic sensor that must conform to the requirements of UL 508, located in the auxiliary drain pan [see Commentary Figure M1411.3.1(1)]. These detection devices will shutdown the equipment before the pan can overflow. There is no requirement for a separate drain line for the auxiliary pan in this method; however, there is a requirement for a drain fitting with a plug or cap that can be used to manually drain water from the pan to prevent water from standing in the pan for long periods of time.

The fourth method uses a water-level detection device installed in the primary drain line, in the overflow drain tapping on the primary pan or in the primary drain pan supplied by the manufacturer [see Commentary Figures M1411.3.1(2) and (3)]. This detection device shuts down the equipment before the pan can overflow. It also serves as a very noticeable warning to the homeowner that there is a problem with the HVAC system. Note that Item 4 is an acceptable method of protection, despite the fact that the main paragraph speaks only of secondary drains and auxiliary drain pans and Item 4 is neither.

M1411.3.1.1 Water-level monitoring devices. On down-flow units and other coils that do not have secondary drain or provisions to install a secondary or auxiliary drain pan, a water-level monitoring device shall be installed inside the primary drain pan. This device shall shut off the equipment

served in the event that the primary drain becomes restricted. Devices shall not be installed in the drain line.

- ❖ The intent of this section is to provide adequate overflow protection on all coils that do not have a secondary drain and have no provisions for providing a secondary or auxiliary drain pan. Typical down-flow appliances and equipment used in dwelling units will have cooling

Figure M1411.3.1(3)
CONDENSATE OVERFLOW SHUTOFF SWITCH
INSTALLED IN THE OVERFLOW DRAIN LINE

coil primary drain pans that are equipped with secondary over-flow drain outlets; therefore, this section would rarely have to be applied in residential occupancies. The addition of a water level detection device inside the drain pan [see Commentary Figure M1411.3.1(1)] will prevent overflow caused by stoppages that occur anywhere in the drain, including at the site of the drain opening inside the primary drain pan provided by the manufacturer. When algae, airborne debris and sometimes foreign objects create a stoppage at the drain opening of the primary pan, overflow will not be prevented by a device that is installed externally in the drain line. Devices installed in the drain lines can only monitor stoppages that occur downstream of such devices and are in no way affected by the rising water level from a blockage inside the drain pan provided with the equipment.

When the water overflows from the pan, it typically runs into the duct, causing mold and mildew problems. It will eventually leak out through the joints or seams and cause damage to the building structure.

M1411.3.2 Drain pipe materials and sizes. Components of the condensate disposal system shall be ABS, cast iron, copper, cross-linked polyethylene, CPVC, galvanized steel, PE-RT, polyethylene, polypropylene or PVC pipe or tubing. Components shall be selected for the pressure and temperature rating of the installation. Joints and connections shall be made in accordance with the applicable provisions of Chapter 30. Condensate waste and drain line size shall be not less than 3/4-inch (19 mm) nominal diameter from the drain pan connection to the place of condensate disposal. Where the drain pipes from more than one unit are manifolded together for condensate drainage, the pipe or tubing shall be sized in accordance with an *approved method*.

- ❖ Condensate drains must be constructed of one of the materials listed in this section, which are corrosion resistant. Such drains must be straight runs of pipe without sags or dips that would trap liquid. If coiled

stock tubing is used, it would be difficult to maintain a uniform slope, and the low points (dips) in the tubing would trap water, causing the drain to be air bound, thereby blocking flow. When drains are merged, the piping must be properly sized for the aggregate flow. Note that the minimum size drain is required to be 3/4-inch (19 mm) nominal diameter (I.D.) meaning that the drain line would be referred to or labeled as 3/4-inch size, even though the actual diameter will be slightly more or less than 3/4 inch, depending on the material. The 3/4 inch refers to the trade size of the material, not an actual dimension.

M1411.3.3 Drain line maintenance. Condensate drain lines shall be configured to permit the clearing of blockages and performance of maintenance without requiring the drain line to be cut.

- ❖ Drains that convey condensate water from cooling coils and evaporators are known to develop blockages as a result of debris and biological growth in the system. These drains are commonly cleared of blockages by a compressed gas such as air or nitrogen being forced through the drain. It is inherently hazardous to pressurize plastic piping such as PVC and CPVC with a compressed gas because of the potential for violent rupture and propelled shards of plastic. The drains are seldom large enough to accommodate mechanical drain cleaning (rodding) equipment. The code permits any arrangement that provides access to the drain interior without the drain being severed or cut. This includes capped or plugged tees and cross fittings, unions, removable mechanical couplings and specialty devices made specifically for the attachment of compressed-gas hoses. The intent is to prevent the spillage of condensate that would cause damage to the structure (see Commentary Figure M1411.3.3).

M1411.3.4 Appliances, equipment and insulation in pans. Where *appliances, equipment* or insulation are subject to

water damage when auxiliary drain pans fill, those portions of the *appliances, equipment* and insulation shall be installed above the flood level rim of the pan. Supports located inside of the pan to support the *appliance or equipment* shall be water resistant and *approved*.

❖ If an auxiliary pan receives water and the *appliance/equipment* is sitting directly on the bottom of the pan, water damage can occur to the *appliance/equipment*. Electrical components, metal items subject to corrosion and insulation within the *appliance* are examples of items that are subject to damage when submerged in water. This must be prevented by elevating the *appliance/equipment* above the rim of the pan such that the pan would overflow before any water reached the *appliance/equipment*. The means of elevating the *appliance/equipment* must be unaffected by repeated wettings [see Commentary Figures M1411.3.4(1) and M1411.3.4(2)].

M1411.4 Condensate pumps. Condensate pumps located in uninhabitable spaces, such as attics and crawl spaces, shall be connected to the *appliance or equipment* served such that when the pump fails, the *appliance or equipment* will be prevented from operating. Pumps shall be installed in accordance with the manufacturer's instructions.

❖ Condensate pumps are often located in attics and crawl spaces and above ceilings where they are not readily observable. If they fail, the condensate overflow can cause structural damage to the building, especially

where the overflow will not be noticed immediately. The majority of such pumps are equipped with simple float controls that can be wired in series with the *appliance/equipment* control circuit. When the pump system fails, the float will rise in the reservoir and open a switch before the condensate starts to overflow the reservoir. These float controls are commonly not connected, and in other cases the pump might not be equipped with an overflow switch. This new code section requires the installation of condensate pumps that have this overflow shutoff capability and requires that the *appliance/equipment* served be connected to take advantage of that feature (see Commentary Figure M1411.4).

M1411.5 Auxiliary drain pan. Category IV condensing *appliances* shall have an auxiliary drain pan where damage to any building component will occur as a result of stoppage in the condensate drainage system. These pans shall be installed in accordance with the applicable provisions of Section M1411.3.

Exception: Fuel-fired *appliances* that automatically shut down operation in the event of a stoppage in the condensate drainage system.

❖ Evaporators and cooling coils are not the only *appliances/equipment* that produce condensate. Condensing-type fuel-fired *appliances* such as Category IV furnaces, boilers and condensing water heaters produce water condensate from the combustion of fuel and are considered to be high-efficiency *appliances*.

Figure M1411.3.4(1)
UNACCEPTABLE APPLIANCE AND PAN INSTALLATION

Manufacturers of condensing appliances may recommend that a pan be installed under their appliances; however, this section requires it where leakage would result in damage. The exception allows installation of appliances without an auxiliary drain pan if the appli-

ances will automatically shut down in the event of a condensate drain stoppage. In accordance with the appliance standards, if a drain blockage occurs, some appliances have the option of continuing to operate safely or automatically shutting down.

Figure M1411.3.4(2)
ACCEPTABLE APPLIANCE AND PAN INSTALLATION

Figure M1411.4
CONDENSATE PUMPS IN UNINHABITABLE SPACES

M1411.6 Insulation of refrigerant piping. Piping and fittings for refrigerant vapor (suction) lines shall be insulated with insulation having a thermal resistivity of not less than R-4 and having external surface permeance not exceeding 0.05 perm [2.87 ng/(s · m² · Pa)] when tested in accordance with ASTM E 96.

❖ To improve the efficiency of the refrigeration cycle, to allow for proper compressor cooling and to control the formation of condensation on the piping, the refrigerant vapor (suction) lines must be insulated. Premade refrigerant line sets are commonly used and the suction line is factory insulated. Great care must be taken during installation to prevent the insulation from being torn, ripped or compressed. Damaged insulation will allow condensation to form on the tubing, so the insulation must be repaired or replaced.

M1411.7 Location and protection of refrigerant piping. Refrigerant piping installed within 1½ inches (38 mm) of the underside of roof decks shall be protected from damage caused by nails and other fasteners.

❖ Refrigerant line sets for cooling systems and heat pumps are often routed up exterior walls and into attic spaces, which results in the lines being close to the roof deck at some points. When the roof covering is applied initially or during a reroofing installation, roofing nails and staples have been known to pierce the refrigerant lines. This results in loss of the system's refrigerant charge and results in environmental harm. The system will have to be repaired, evacuated (vacuum pumped) and recharged at significant expense. Protection of such lines is difficult to achieve; therefore, the best approach is to keep the lines away from the roof deck for a distance greater than 1½ inches.

M1411.8 Locking access port caps. Refrigerant circuit access ports located outdoors shall be fitted with locking-type tamper-resistant caps or shall be otherwise secured to prevent unauthorized access.

❖ This provision intends to address a relatively new type and method of substance abuse where people intentionally inhale refrigerant gases for the intoxicating effect. In some cases, this inhalant abuse has resulted in the death of the individual. The typical condensing unit or heat pump unit is located outdoors and is equipped with access ports on the vapor and liquid refrigerant lines. These access ports are necessary for several purposes, such as to allow the connection of diagnostic gauges and to allow refrigerant to be added to or taken from the unit during servicing of the unit. Some of these access ports require back-seated valves to be opened with a wrench to allow refrigerant to escape and many of these access ports are equipped with simple "Schraeder" valves that are similar to the valve cores used on car and truck tires. All access ports are provided with threaded caps to keep out debris and moisture and to also guard against valve leakage. Individuals intent on inhaling refrigerants have found that they can withdraw refrigerant from these units by using simple hand tools or their bare hands to remove the

caps and open the valves.

The purpose of this section is to prevent this dangerous form of substance abuse by making it difficult if not impossible to remove these access port caps. Some of the available locking-type caps are designed such that wrenches, pliers and fingers cannot be used to remove the caps without a special tool/key.

All newly installed equipment, including replacement equipment, must be fitted with locking-type caps as part of such installations or other means must be provided to prevent access to the service ports. Such other means might include locked cages, locked access panels and locating the service access ports where they would be inaccessible to unauthorized persons [see Commentary Figures M1411.8(1) through M1411.8(4)].

REFRIGERANT LOCKING CAPS AND TOOLS

**SECTION M1412
ABSORPTION COOLING EQUIPMENT**

M1412.1 Approval of equipment. Absorption systems shall be installed in accordance with the manufacturer’s instructions. Absorption equipment shall comply with UL 1995 or UL/CSA/ANCE 60335-2-40.

❖ Absorption refrigeration systems use two fluids (an absorbent and a refrigerant) and a heat source to remove heat through evaporation at a lower pressure and then reject the heat through condensation at a higher pressure. Typical absorption systems use

ammonia as the refrigerant and water as the absorbent or lithium bromide as the absorbent and water as the refrigerant.

This section states that absorption systems must be installed in accordance with manufacturers’ installation instructions, which are an enforceable extension of the code. Absorption equipment must be in compliance with UL 1995.

M1412.2 Condensate disposal. Condensate from the cooling coil shall be disposed of as provided in Section M1411.3.

❖ This section and Section M1411.3 provide for the proper and safe disposal of condensate.

M1412.3 Insulation of piping. Refrigerant piping, brine piping and fittings within a building shall be insulated to prevent condensation from forming on piping.

❖ Condensation will deteriorate piping and cause serious damage to other parts of buildings, so the piping must be insulated. Note that insulation alone cannot prevent condensation on piping, because a vapor barrier is necessary to prevent moisture from reaching the pipe surface. Some insulation materials also function as vapor barriers.

M1412.4 Pressure-relief protection. Absorption systems shall be protected by a pressure-relief device. Discharge from the pressure-relief device shall be located where it will not create a hazard to persons or property.

❖ In addition to requiring that the installation of this type of equipment be in compliance with the manufacturer’s instructions, this section specifically requires the installation of pressure-relief devices that are to be discharged to a safe location.

**SECTION M1413
EVAPORATIVE COOLING EQUIPMENT**

M1413.1 General. Evaporative cooling equipment and appliances shall comply with UL 1995 or UL/CSA/ANCE 60335-2-40 and shall be installed:

1. In accordance with the manufacturer’s instructions.
2. On level platforms in accordance with Section M1305.1.4.1.
3. So that openings in exterior walls are flashed in accordance with Section R703.4.
4. So as to protect the potable water supply in accordance with Section P2902.
5. So that air intake opening locations are in accordance with Section R303.5.1.

❖ This section requires installation of exterior equipment on a level platform at least 3 inches (76 mm) above the surrounding grade to protect the equipment from corrosion. This section states that evaporative cooling equipment must be installed in accordance with the manufacturer’s instructions, which are an enforceable extension of the code.

SECTION M1414 FIREPLACE STOVES

M1414.1 General. Fireplace stoves shall be *listed, labeled* and installed in accordance with the terms of the listing. Fireplace stoves shall be tested in accordance with UL 737.

❖ A fireplace stove is a free-standing, chimney-connected, solid-fuel-burning heater designed to be operated with the fire chamber doors in either the open or closed position. The difference between a fireplace stove and a solid-fuel-type room heater is that a room heater is chimney connected and designed for operation with the fire chamber (firebox) closed. A fireplace stove must be tested in accordance with UL 737 whereas a solid-fuel-type room heater is tested in accordance with UL 1482 (see Section M1410). Note that some appliances are listed as both a stove and a room heater and, therefore, can be operated with the fire chamber in either the open or closed position. Fireplace stoves must be installed in accordance with the manufacturer's instructions. Such instructions are an integral part of the product listing since these instructions are used by the testing agency when the test installation is constructed. Therefore, a unit tested in compliance with UL 737 and installed in accordance with the manufacturer's instructions is expected to perform the same as the representative sample unit that was tested.

M1414.2 Hearth extensions. Hearth extensions for fireplace stoves shall be installed in accordance with the *listing* of the fireplace stove. The supporting structure for a hearth extension for a fireplace stove shall be at the same level as the supporting structure for the fireplace unit. The hearth extension shall be readily distinguishable from the surrounding floor area.

❖ Fireplace stoves must be installed in strict accordance with the manufacturer's instructions. These instructions will include specifications for the materials, dimensions and installation of a hearth extension. The hearth extension must be of noncombustible materials and must be supported at the same level as the fireplace stove. The floor supporting the hearth extension can be of combustible construction. Because a fireplace stove is a free-standing heater, in most installations the fireplace stove will be installed on the hearth extension. The dimensions of the hearth extension will be dictated by the manufacturer's installation instructions and will include distances that the hearth extension must extend beyond the sides, back and front of the fireplace stove.

A fireplace stove can be operated with the firebox doors in the open position, similar to a traditional masonry fireplace. The hearth extension will protect the floor structure on all sides from radiant heat, and it will protect the floor structure in front of the stove from sparks, embers, coals and burning solid fuel that might escape from the firebox. The nature of solid fuel can cause burning material to be expelled from the fire box, and large pieces of the fuel can fall from the grate or roll out of the firebox. In addition to the required hearth

extensions, screens should be used as the initial and primary protection against sparks and embers from the firebox.

SECTION M1415 MASONRY HEATERS

M1415.1 General. Masonry heaters shall be constructed in accordance with Section R1002.

❖ Masonry heaters are a type of solid-fuel-burning appliance and are covered in Section R1002, which requires installation in accordance with ASTM E1602 or the terms of the listing. Such heaters are assembled on the job site from locally obtained raw materials or from factory components shipped to the job site. Masonry heaters are designed to be much more efficient than conventional fireplaces by incorporating immense thermal mass (masonry) and multiple pass flueways that provide greater heat exchange surface area and longer combustion gas retention time. Masonry heaters provide heat to the conditioned space by direct radiation of the heat energy stored in the immense thermal mass. In addition to having high thermal efficiencies, masonry heaters have the ability to provide space heating for many hours after the fire has burned out. Some factory-built kits are listed. Clearances to combustibles and convection cooling airflow are extremely important because these heaters store heat at high temperatures for long periods of time.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

NFPA 70–14, *National Electrical Code*. Quincy, MA: National Fire Protection Association, 2013.

Chapter 15: Exhaust Systems

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

As the title states, this chapter is a compilation of all exhaust system-related code requirements applicable to those uses covered by the code. The code regulates the materials used for constructing and installing such duct systems. Air brought into the building for ventilation, combustion or makeup is protected from contamination by the provisions found in this chapter.

Section M1501 requires that all mechanically exhausted air must discharge to the outdoors. Section M1502 pertains to the exhaust ducts from clothes dryers. Section M1503 has the criteria for exhaust ducts for range hoods. Section M1504 requires that microwave ovens be listed and labeled and properly installed. Section M1505 contains the regulations for exhausting domestic open-top broilers, and Section M1506 indicates that if a particular exhaust duct construction is not

found in this chapter, the reader must use the criteria for ducts in Chapter 16. Section M1507 contains the minimum ventilation rates for bathroom and kitchen exhaust systems and some restrictions on recirculation of exhaust air.

The code official must be aware of the effect that exhaust systems can have on space conditioning and ventilation systems. For example, improperly designed exhaust systems can create negative pressure conditions, which can adversely affect the operation of fuel-burning appliances and the operation of other exhaust systems.

Purpose

Chapter 15 presents provisions associated with exhaust systems so hazards associated with exhaust systems and air contaminants can be avoided.

SECTION M1501 GENERAL

M1501.1 Outdoor discharge. The air removed by every mechanical exhaust system shall be discharged to the outdoors in accordance with Section M1506.3. Air shall not be exhausted into an attic, soffit, ridge vent or crawl space.

Exception: Whole-house *ventilation-type attic* fans that discharge into the *attic* space of *dwelling units* having private *attics* shall be permitted.

- ❖ The primary intent of this section is to avoid exhausting contaminants into areas that may be occupied by people or into concealed spaces such as attics and crawl spaces where moisture can damage the building components. To prevent the introduction of contaminants into the ventilation air of a building, exhaust openings must not direct exhaust so that it could be readily drawn in by a ventilating system. To achieve this, the requirement for termination points for exhaust ducts must be in accordance with the location and placement of intake and exhaust openings in accordance with Section M1506.3.

Attics and crawl spaces are not considered to be outdoors. Exhaust ducts cannot terminate in these spaces. Exhaust ducts must connect directly to terminals that pass through the building envelope to the outside atmosphere. Pointing, aiming or similarly directing an exhaust duct at an opening in the envelope of the building such as an attic louver, ridge vent, gable vent,

roof vent, eave vent or soffit vent, in no way ensures that all or any of the exhaust will reach the outdoors. In fact, it is possible that the majority, if not all, of the exhaust vapors and gases will discharge to the attic space rather than to the outdoors (see Commentary Figure M1501.1).

In the case of a duct that terminates in a ventilated soffit, the exhaust can rise into the attic as opposed to falling through the perforated soffit. The flow of air through an opening for attic ventilation is dependent on attic temperature, wind direction, wind speed and opening configuration and location, making attic air movement unpredictable and often in a direction not intended. Additionally, grilles and louvers offer resistance and interfere with the exhaust flow directed at them. This may cause deflection of exhaust back into the attic.

The exception addresses a mechanical alternative to natural ventilation of a dwelling unit. A whole-house ventilation-type attic fan is less source-specific than a dryer, bathroom or kitchen exhaust system. Whole-house ventilation systems are installed to provide a fresh air flow for the occupants either continuously or at timed intervals. The exception is specific to whole-house “ventilation-type” attic fans that create an airflow through open windows. Source-specific fans (bathroom exhaust or kitchen exhaust) would not qualify for the exception because their primary function is to exhaust moisture, odors, vapors or products of com-

EXHAUST SYSTEMS

bustion. The contaminants associated with these functions might be harmful to the occupants, detrimental to the structural integrity of the building or even impact the fire safety performance of the building, and must discharge directly outdoors. The exception applies only to whole-house fans dedicated solely to ventilation and comfort cooling. Within the context of the code, a "private attic" is one in which air discharged from one dwelling unit cannot enter another dwelling unit's attic space. The exception is not related to the whole-house ventilation systems covered in Sections R303.4 and M1507.

SECTION M1502 CLOTHES DRYER EXHAUST

M1502.1 General. Clothes dryers shall be exhausted in accordance with the manufacturer's instructions.

❖ Clothes dryers must be exhausted in compliance with the dryer manufacturer's installation instructions. The manufacturer's installation instructions apply and where the code provisions are more strict, the code applies. Note that some of the provisions in the code are redundant with the appliance installation instructions. Dryers are designed and built to meet industry safety standards. The manufacturer's installation instructions are evaluated by the agency responsible for testing the appliance and, therefore, those instructions will prescribe an installation that is consistent with the appliance installation that was tested. This requirement is consistent with Section M1307.1, which

addresses the installation of all appliances. The correct terminology is "dryer exhaust duct," as the term "vent" is used in a different context elsewhere in the code.

M1502.2 Independent exhaust systems. Dryer exhaust systems shall be independent of all other systems and shall convey the moisture to the outdoors.

Exception: This section shall not apply to *listed* and *labeled* condensing (ductless) clothes dryers.

❖ Clothes dryer exhaust systems are a potential fire hazard because of the combustible lint and debris that can accumulate in the duct and the heat source of the appliance. This combination of combustible lint and elevated temperature has been the cause of fires. The dryer exhaust system must be independent of other systems to prevent the hazard associated with one exhaust entering into or affecting other systems or areas in the building.

Clothes dryer exhaust systems must convey the moisture and any products of combustion directly to the exterior of the building (outdoors); therefore, any devices that allow all or part of the exhaust to discharge to the indoors are in violation of the code. The requirement to convey the exhaust to the outdoors applies to both fuel-fired and nonfuel-fired (i.e., electric) appliances. Clothes dryer exhaust systems cannot terminate in or discharge to any enclosed space, such as an attic or crawl space, regardless of whether or not the space is ventilated through openings to the outdoors. The high levels of moisture in the exhaust air

**Figure M1501.1
PROHIBITED EXHAUST TERMINATION**

can cause condensation to form on exposed surfaces or in insulation materials. Water vapor condensation can cause structural damage, deterioration of building materials and contribute to the growth of mold and fungus. Clothes dryer exhausts that discharge to enclosed spaces will also cause an accumulation of combustible lint and debris, creating a significant fire hazard. An improperly installed clothes dryer exhaust system not only reduces dryer efficiency and increases running time, but also can cause a significant increase in exhaust temperature, causing the dryer to cycle on its high limit control, which is an unsafe operating condition.

The exception specifically excludes condensing clothes dryers from the requirement to exhaust to the outdoors. Condensing dryers are electrically heated and recirculate the same air through the clothes drum. An air-to-air heat exchanger condenses the water vapor in the clothes drum air by using room air as the condensing medium. The condensate is collected in a reservoir that is either manually emptied or automatically emptied by an integral condensate pump. These dryers do not discharge heated air to the outdoors and have the effect of slightly elevating the indoor ambient temperature.

These “ductless” dryers must be listed for this application and installed to comply with the listing. They are commonly installed in applications where a conventional dryer exhaust duct cannot be used because of distance or aesthetics problems.

M1502.3 Duct termination. Exhaust ducts shall terminate on the outside of the building. Exhaust duct terminations shall be in accordance with the dryer manufacturer’s installation instructions. If the manufacturer’s instructions do not specify a termination location, the exhaust duct shall terminate not less than 3 feet (914 mm) in any direction from openings into buildings. Exhaust duct terminations shall be equipped with a backdraft damper. Screens shall not be installed at the duct termination.

- ❖ The clothes dryer exhaust discharge must terminate outdoors because of the high levels of moisture, combustible lint and, for gas-fired units, combustion products in the exhaust. If discharged indoors, such exhaust could present a health and fire hazard, could cause structural damage and deterioration of building material and could contribute to the growth of mold and fungus. The exhaust also contains highly combustible clothes fibers and, in the case of gas-fired units, products of combustion.

The requirement to locate the exhaust outlet at least 3 feet (914 mm) from any openings into the building is intended to minimize the possibility of drawing the dryer exhaust into the house through windows, doors or fresh air intake openings. Note that the dryer installation instructions may specify a greater distance. The 3-foot (914 mm) dimension is consistent with similar requirements in the *International Mechanical Code*® (IMC)® and has been successfully used in the housing industry for years.

Backdraft dampers must be installed in dryer

exhaust ducts to avoid outdoor air infiltration during periods when the dryer is not operating and to prevent the entry of animals. These dampers should be designed and installed to provide an adequate seal when in a closed position to minimize air leakage (infiltration). Backdraft dampers are typically of the gravity type, which are opened by the energy of the exhaust discharge. Some dryer manufacturers prohibit the use of magnetically held backdraft dampers because of the extra resistance that the exhaust flow must overcome.

Exhaust terminal opening size is also governed by the dryer manufacturer’s instructions. Full opening terminals present less resistance to flow and might be mandated by the dryer manufacturer. A “full opening” is considered to be an opening having no dimension less than the diameter of the exhaust duct. Screens are prohibited on the duct termination because lint from the dryer will clog the screen creating flow resistance and eventually a complete blockage. This will result in a fire hazard. Consider that the filter screen integral with the appliance becomes restricted with lint in each cycle of operation. The code does not recognize any type or size of screen as being acceptable. Some dryer exhaust terminals are manufactured with a “basket” type of animal screen and the code makes no exception for such screens. Clothes fibers have the ability to coalesce and clog any screen.

M1502.4 Dryer exhaust ducts. Dryer exhaust ducts shall conform to the requirements of Sections M1502.4.1 through M1502.4.7.

- ❖ See the commentary to subsequent sections.

M1502.4.1 Material and size. Exhaust ducts shall have a smooth interior finish and be constructed of metal having a minimum thickness of 0.0157 inches (0.3950 mm) (No. 28 gage). The duct shall be 4 inches (102 mm) nominal in diameter.

- ❖ This section requires that the diameter of the exhaust duct be 4 inches (102 mm), no larger and no smaller. A 4-inch (102 mm) duct is the basis for the design of the appliance exhaust system. Ducts that are too small would restrict air movement and would cause the dryer to consume more energy because of the longer drying time. They could also cause appliance overheating. Ducts that are too large will cause a decrease in the flow velocity, causing lint and debris to drop out of the exhaust air stream. For example, increasing the duct size from 4 inches to 5 inches (102 mm to 127 mm) will result in a reduction of duct velocity of approximately 37 percent for the typical dryer. The exhaust duct material must be smooth-wall metal with the specified minimum wall thickness. Plastic ducts, corrugated ducts and flexible ducts are all prohibited with the exception of transition ducts in accordance with Section M1502.4.3.

M1502.4.2 Duct installation. Exhaust ducts shall be supported at intervals not to exceed 12 feet (3658 mm) and shall be secured in place. The insert end of the duct shall extend into the adjoining duct or fitting in the direction of airflow. Exhaust duct joints shall be sealed in accordance with Section

M1601.4.1 and shall be mechanically fastened. Ducts shall not be joined with screws or similar fasteners that protrude more than $\frac{1}{8}$ inch (3.2 mm) into the inside of the duct.

- ❖ Clothes dryer ducts must be well supported to prevent deformation and joint separation. The male end of the duct and fittings must point in the direction of airflow to lessen flow resistance, joint leakage and collection of lint. This is common practice for all ducts, regardless of application. Previous editions of the code did not permit duct fasteners to protrude into the inside of the ducts. This created a problem since all ducts have been required by tradition, codes or installation standards to be mechanically fastened at all joints and joint sealing is not equivalent to or a substitute for mechanical fastening (see Section M1601.4.1 applicable to HVAC ducts). This also created a problem when duct cleaning firms attempted to clean dryer exhaust ducts and they would come apart within concealed wall and ceiling spaces. The code permits mechanical fasteners to penetrate up to $\frac{1}{8}$ inch (3.2 mm) into the inside of the dryer exhaust duct. A maximum penetration of $\frac{1}{8}$ inch (3.2 mm) is expected to create only an insignificant amount of lint buildup. The $\frac{1}{8}$ -inch (3.2 mm) limitation was intended to allow the use of short pop-rivets and $\frac{1}{8}$ -inch-long (3.2 mm) screws. Dryer exhaust ducts must be exceptionally well supported and sealed so that the joints will not separate. This is especially important where the ducts are to be concealed within the building construction and where they will be mechanically cleaned by duct cleaning apparatus.

M1502.4.3 Transition duct. Transition ducts used to connect the dryer to the exhaust duct system shall be a single length that is listed and labeled in accordance with UL 2158A. Transition ducts shall be not greater than 8 feet (2438 mm) in length. Transition ducts shall not be concealed within construction.

- ❖ Within the context of this section, a transition duct is a flexible connector used as a transition between the dryer outlet and the connection point to the exhaust duct system. Transition duct connectors must be listed and labeled as transition ducts for clothes dryer application. Transition ducts must be listed to comply with UL 2158A. Such transition ducts are not considered as flexible air ducts or flexible air connectors.

Transition ducts are flexible ducts constructed of a metalized (foil) laminated fabric supported on a spiral wire frame. They are more fire resistant than the typical plastic spiral duct. Transition duct connectors are necessary for domestic dryers because of appliance movement, vibration and outlet location. In many cases, connecting a domestic clothes dryer directly to rigid duct would be difficult.

Transition duct connectors are limited to 8 feet (2438 mm) in length and must be installed in accordance with their listing and the manufacturer's instructions. These duct connectors must not be concealed by any portion of the structure's permanent finish materials, such as drywall, plaster, paneling, built-in furniture or cabinets or any other similar permanently affixed building com-

ponent; they must remain entirely within the room in which the appliance is installed. Transition duct connectors cannot be joined to extend beyond the 8-foot (2438 mm) maximum length limit. Transition ducts are to be cut to length as needed to avoid excess duct and unnecessary bends. Note that in the application of Section M1502.4.5.1, the length of the transition duct is not counted in the overall duct system length, despite the fact that the transition duct does contribute considerable airflow resistance to the exhaust duct system.

M1502.4.4 Dryer exhaust duct power ventilators. Domestic dryer exhaust duct power ventilators shall conform to UL 705 for use in dryer exhaust duct systems. The dryer exhaust duct power ventilator shall be installed in accordance with the manufacturer's instructions.

- ❖ The previous code editions did not recognize dryer exhaust duct power ventilators (DEDPVs) as an option for clothes dryer installations. DEDPVs are loosely referred to as "dryer booster fans" in the marketplace. Prior to the 2015 code, the designer's choices for exhaust duct length were: 1. To limit the duct length to 35 feet; 2. To follow the length limits in the clothes dryer manufacturer's instructions; or, if neither of those choices work, 3. To relocate the dryer. A fourth option was to get the code official to approve the installation of a DEDPV under the alternative approval provision in Section 105. Exhaust ducts that exceed the developed length allowed by the code are a potential fire hazard, create maintenance problems, increase drying times and cause the dryer to be inefficient and waste energy. Dryer exhaust systems are commonly installed improperly with excessive lengths, too many elbows and the wrong duct materials. Because of the high incidence of reported dryer fires, the code strictly regulates the installation. DEDPVs are listed to a revised version of UL 705 that now contains tests and construction requirements that are specific to these devices. DEDPVs have been around for years but until recently were not listed to a national consensus standard that was specific to these devices. The UL 705 standard contains requirements for the construction, testing and installation of DEDPVs and requires them to be equipped with features such as interlocks, limit controls, monitoring controls and enunciator devices to make certain that the dryers or dryer operators are aware of the operating status of the DEDPVs (see Commentary Figure M1502.4.4).

M1502.4.5 Duct length. The maximum allowable exhaust duct length shall be determined by one of the methods specified in Sections M1502.4.5.1 through M1502.4.5.3.

- ❖ The duct length, the number and angle of fittings and the smoothness of the duct interior all contribute to the total friction loss of the airflow. When the friction loss is excessive, a reduction of the air velocity occurs, allowing lint and debris to accumulate in the duct and thus creating a fire hazard. Impeded airflow will also increase drying time, decrease appliance efficiency and raise system temperatures. The manufacturer's instructions and the code limitations concerning duct length,

the number of elbows installed and the type of termination fittings must be adhered to in order to help prevent a fire hazard and allow proper appliance operation.

Note that this section introduces two distinct choices in its two subsections.

M1502.4.5.1 Specified length. The maximum length of the exhaust duct shall be 35 feet (10 668 mm) from the connection to the transition duct from the dryer to the outlet terminal. Where fittings are used, the maximum length of the exhaust duct shall be reduced in accordance with Table M1502.4.5.1. The maximum length of the exhaust duct does not include the transition duct.

- ❖ The maximum exhaust duct length of 35 feet (7620 mm) is the requirement for domestic clothes dryers. The 35-foot (7620 mm) limit is based on the worst case scenario where the dryer is rated for a maximum duct

length of 35 feet (7620 mm). The intent was to ensure that the least capable dryer available would be compatible with a 35-foot (7620 mm) duct system. If the exhaust duct system is designed for worst case, it should work properly in all cases. Note that there may be some dryers on the market that specify a duct length of less than 35 feet (10 668 mm), and the manufacturer's instructions would prevail in such case.

Because the maximum length is based on equivalent length, all fittings must be accounted for in accordance with Table M1502.4.5.1. The length is measured from the point where the transition duct (if used) connects to the rigid exhaust duct system to the terminal outdoors (see Table M1502.4.5.1). The transition duct is excluded from the calculation of equivalent length of the duct system.

**Figure M1502.4.4
DRYER EXHAUST DUCT POWER VENTILATOR**

**TABLE M1502.4.5.1
DRYER EXHAUST DUCT FITTING EQUIVALENT LENGTH**

DRYER EXHAUST DUCT FITTING TYPE	EQUIVALENT LENGTH
4 inch radius mitered 45 degree elbow	2 feet 6 inches
4 inch radius mitered 90 degree elbow	5 feet
6 inch radius smooth 45 degree elbow	1 foot
6 inch radius smooth 90 degree elbow	1 foot 9 inches
8 inch radius smooth 45 degree elbow	1 foot
8 inch radius smooth 90 degree elbow	1 foot 7 inches
10 inch radius smooth 45 degree elbow	9 inches
10 inch radius smooth 90 degree elbow	1 foot 6 inches

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 degree = 0.0175 rad.

Table M1502.4.5.1 assigns an equivalent length to the various types of elbow fittings that are available. The first two rows of the table cover the traditional elbows that the code and dryer manufacturer's installation instructions have always addressed. The other rows in the table cover newer, high-performance elbows that have longer turning radii and smoother walls (i.e., no mitered joints); thus, the equivalent length is substantially reduced. When an installer discovers that the length of an exhaust duct will exceed the limits of the code, he or she may find that using higher performance elbows will keep the length within the allowable limits.

M1502.4.5.2 Manufacturer's instructions. The size and maximum length of the exhaust duct shall be determined by the dryer manufacturer's installation instructions. The code official shall be provided with a copy of the installation instructions for the make and model of the dryer at the concealment inspection. In the absence of fitting equivalent length calculations from the clothes dryer manufacturer, Table M1502.4.5.1 shall be used.

❖ This section allows the 35-foot (7620 mm) limit of the previous section to be exceeded where longer exhaust duct lengths are allowed by the appliance manufacturer's instructions. Today's appliances often, but not always, permit longer distances, therefore this section allows the installer to take advantage of those longer distances where specified by the manufacturer. The make and model of the dryer must be provided to the code official, along with the respective installation instructions, to permit the code official to inspect the duct installation based on the manufacturer's instructions. Because the installation is specific to and dependent on a certain appliance make and model, the code official must follow through to make sure that the appliance did get installed. Remember that the prime objective is to prevent a dangerous mismatch between a dryer and its exhaust system.

Where not otherwise specified by the dryer manufacturer, the flow resistance contributed by fittings installed in the duct system must be in accordance with Table M1502.4.5.1. Each type of fitting and its angle is equated to a certain length of straight duct and this "equivalent length" is added to the actual straight duct length in the system to obtain the total length. The table recognizes newer fitting designs that have smooth bore interiors and much larger turning radii than traditionally used fittings. Such designs greatly reduce friction loss as can be seen by their much smaller equivalent lengths. If an installer is unable to stay within the allowable length on a particular job, he or she may find that substituting better fittings will correct the problem (see Section M1502.4.6).

M1502.4.5.3 Dryer exhaust duct power ventilator. The maximum length of the exhaust duct shall be determined in accordance with the manufacturer's instructions for the dryer exhaust duct power ventilator.

❖ See the commentary to Section M1502.4.4.

M1502.4.6 Length identification. Where the exhaust duct equivalent length exceeds 35 feet (10 668 mm), the equivalent length of the exhaust duct shall be identified on a permanent label or tag. The label or tag shall be located within 6 feet (1829 mm) of the exhaust duct connection.

❖ A point to consider is the situation that will exist when the original dryer is replaced or the original occupant moves out and the new occupant installs a different dryer. In either case, the replacement dryer might not be compatible with the existing duct length. If the duct system equivalent length is not identified in a conspicuous manner, the new resident will be unaware of the potentially hazardous situation that has been created by the dryer and exhaust duct mismatch. It is assumed that the installer will be aware of the equivalent length of exhaust ducts that are entirely exposed and observable (see Commentary Figure M1502.4.6). If the exhaust duct equivalent length is 35 feet or less, there is no point in identifying it because it is assumed to be compatible with all dryers. See Section M1502.4.5.1.

M1502.4.7 Exhaust duct required. Where space for a clothes dryer is provided, an exhaust *duct system* shall be installed. Where the clothes dryer is not installed at the time of occupancy the exhaust duct shall be capped or plugged in the space in which it originates and identified and marked "future use."

Exception: Where a *listed* condensing clothes dryer is installed prior to occupancy of the structure.

❖ Where a space is provided for the future installation of a clothes dryer, an exhaust duct system must be installed so that such system can be inspected and approved (see Commentary Figure M1502.4.7). Otherwise, it is likely that the dryer and exhaust duct system will be installed later without the code official's knowledge and it will not be inspected for proper installation. Note that Section M1502.4.5.2 does not appear to be an option when an exhaust duct system is "roughed-in" for future use because the make, model and exhaust capability of the dryer will be unknown. The code official could approve identifying the equivalent length in accordance with Section M1502.4.6 under the alternative approval provisions of Section R104.11.

The requirement to cap the exhaust duct where a dryer is not installed at the time of occupancy is intended to keep the duct from becoming a conduit for air to travel between the inside of the structure and the outdoors. While a backdraft damper is required at the outdoor termination, capping the duct further reduces the chance of air movement. The capping will also prevent the entry of debris and foreign objects. The cap is required inside at the future dryer's location so that it will be readily apparent when the future dryer is installed. Requiring that a listed condensing dryer be installed prior to occupancy will prevent someone from taking advantage of this exception to avoid installing an exhaust duct system by indicating that a future condensing dryer will be installed (see the commentary for the exception to Section M1502.2).

Sample of typical placard to be placed behind all future dryer installation locations.
 Approximate size 8" x 6" (heavy plastic-like laminate material).
 Type: 0.014" poly carbonate label with area for length display to be punched out with typical hole punch and exhibit a paint-resistant laminate coating.
 Permanent pressure-sensitive 3M adhesive and 4 holes 3/32".
 Provided and installed by HVAC or sheet metal tradesman at trim-out.

Figure M1502.4.6
EXAMPLE OF A DRYER EXHAUST LENGTH LABEL

Figure M1502.4.7
SPACE FOR CLOTHES DRYER INSTALLATION

M1502.5 Protection required. Protective shield plates shall be placed where nails or screws from finish or other work are likely to penetrate the clothes dryer exhaust duct. Shield plates shall be placed on the finished face of framing members where there is less than 1¹/₄ inches (32 mm) between the duct and the finished face of the framing member. Protective shield plates shall be constructed of steel, shall have a minimum thickness of 0.062-inch (1.6 mm) and shall extend not less than 2 inches (51 mm) above sole plates and below top plates.

❖ Protection from nail and screw penetration has been required for wiring, vent systems, plumbing piping, fuel piping, hydronic piping and refrigerant piping for some time in the code, and now it is also required for dryer exhaust ducts (see Commentary Figure M1502.5). Depending on the depth of penetration, a nail or screw could create a serious obstruction problem and potential fire hazard.

SECTION M1503 RANGE HOODS

M1503.1 General. Range hoods shall discharge to the outdoors through a duct. The duct serving the hood shall have a smooth interior surface, shall be air tight, shall be equipped with a back-draft damper and shall be independent of all other exhaust systems. Ducts serving range hoods shall not terminate in an attic or crawl space or areas inside the building.

Exception: Where installed in accordance with the manufacturer's instructions, and where mechanical or natural ventilation is otherwise provided, *listed* and *labeled* ductless range hoods shall not be required to discharge to the outdoors.

❖ A domestic kitchen exhaust system is one that serves appliances typically found in residential occupancies

such as within dwelling units. When compared to commercial cooking operations, residential cooking operations are far less frequent, of shorter duration, have lower heat output and produce fewer grease-laden vapors. However, airborne contaminant control may be even more important in residential cooking operations because of the lower or nonexistent ventilation rates typical of dwelling units. If natural or mechanical ventilation is otherwise provided for a space, this section does not require that the range hoods discharge to the outdoors. This section does not require range hoods to be installed, but regulates their installation. Section M1505.1 does require hoods for open-top broiler units and requires them to exhaust to the outdoors.

By requiring the ducts to have smooth inner walls, this section prohibits the use of flexible and semirigid corrugated ducts for range hood exhaust. As with all exhaust systems, the exhaust must discharge to the outdoors, not to an attic or crawl space or ridge, soffit, gable or roof vent (see commentary, Section M1501.1).

The ducts must be sealed air tight to prevent leakage of air and grease into wall and ceiling cavities. Ducts should be sealed with a material that is suitable for long-term exposure to elevated temperatures. Backdraft dampers prevent the infiltration of outdoor air when the exhaust system is not operating. The hood manufacturer's instructions may require that the ducts be installed with a minimum clearance to combustibles (see commentary, Section M1307.1).

The exception to this section allows the use of listed ductless (recirculating) range hoods as an alternative to the ducted type. However, exhaust to the outdoors would be required if natural or mechanical ventilation was not provided for the kitchen area. Note that many residential-type range hoods are designed to be exhausted to the outdoors and are also designed to be used as recirculating hoods, depending on how they are installed. Ductless residential hoods can remove some grease particulate by means of filters, but otherwise discharge the cooking effluent and combustion products back into the living space.

M1503.2 Duct material. Ducts serving range hoods shall be constructed of galvanized steel, stainless steel or copper.

Exception: Ducts for domestic kitchen cooking *appliances* equipped with down-draft exhaust systems shall be permitted to be constructed of schedule 40 PVC pipe and fittings provided that the installation complies with all of the following:

1. The duct is installed under a concrete slab poured on grade.
2. The underfloor trench in which the duct is installed is completely backfilled with sand or gravel.
3. The PVC duct extends not more than 1 inch (25 mm) above the indoor concrete floor surface.
4. The PVC duct extends not more than 1 inch (25 mm) above grade *outside of the building*.

5. The PVC ducts are solvent cemented.

- ❖ Ducts used for dwelling unit kitchen exhaust must be constructed of noncombustible materials to reduce the potential fire hazard associated with the collection of grease or the absorption of grease into a more porous duct material. This section requires domestic kitchen exhaust ducts to be constructed of galvanized or stainless steel or copper. Section M1503.1 effectively requires rigid ducts.

The exception allows the use of plastic ducts to exhaust the downdraft-type domestic kitchen cooking appliances if all five of the specified installation criteria are met. Plastic ducts are not allowed in above-ground applications because the plastic cannot contain fire within the confines of the duct. This exception allows plastic for the duct material because the duct must be below a slab on grade, and the trench for the duct must be completely backfilled with sand or gravel to: 1. Limit the amount of combustion air available to sustain a duct fire; and 2. Prevent a fire within the duct from spreading to the rest of the building. Additionally, the combustion gases and particulate from the burning plastic will be exhausted to the outdoors, not introduced into the occupied space. The plastic material also has the advantage of corrosion resistance. Metal ducts below a slab are susceptible to deterioration.

M1503.3 Kitchen exhaust rates. Where domestic kitchen cooking *appliances* are equipped with ducted range hoods or down-draft exhaust systems, the fans shall be sized in accordance with Section M1507.4.

- ❖ This section does not require installation of a hood that exhausts to the outdoors for domestic kitchen cooking appliances. It only provides guidance for sizing the exhaust fans for hoods that do exhaust to the outdoors. Mechanical ventilation would be required only where natural ventilation is not provided (see Section R303).

M1503.4 Makeup air required. Exhaust hood systems capable of exhausting in excess of 400 cubic feet per minute (0.19 m³/s) shall be mechanically or naturally provided with makeup air at a rate approximately equal to the exhaust air rate. Such makeup air systems shall be equipped with not less than one damper. Each damper shall be a gravity damper or an electrically operated damper that automatically opens when the exhaust system operates. Dampers shall be accessible for inspection, service, repair and replacement without removing permanent construction or any other ducts not connected to the damper being inspected, serviced, repaired or replaced.

- ❖ It is becoming more common for residential kitchens to resemble commercial kitchens, both aesthetically and functionally. As a result, much larger-capacity range hoods are being installed which aggravates the already existing problem of a lack of adequate makeup air for all exhaust systems in the dwelling. Homes typically suffer multiple ills because of indoor negative pressures caused by an imbalance of exhaust air to makeup air. The typical home relies solely on infiltra-

tion for makeup air and homes are being built much more airtight than in the past. Compounding this issue is the trend for much larger exhaust fans, and the pressure imbalance problem has a very real safety concern. The primary concern is depressurization that can cause chimneys and vents to fail. This section requires a makeup air supply system at the prescribed threshold and further requires it to be tied to the exhaust system controls such that both systems operate simultaneously. The intent is to not allow the homeowner the option of operating the exhaust fan without also operating the makeup air system.

This section states that the makeup air system can be a passive or active system (i.e., natural or mechanical). The makeup air is supposed to be provided “at a rate approximately equal to the exhaust air rate,” which implies an active makeup air system that utilizes a fan; however, the text specifically allows a natural means of providing makeup air. The typical natural means is an opening to the outdoors with a motorized damper that operates in parallel with the exhaust fan. Whether active or passive (mechanical or natural), the makeup supply must have a damper to close the opening when not in use. This section allows a gravity-type damper that opens by the force of air entering the building caused by the negative pressure created by the exhaust fan. In other words, gravity dampers depend on a negative pressure in the building with respect to the outdoors. This negative pressure must overcome the resistance of the inlet opening/duct and also the resistance created by the weight of the damper and its support bearings. The primary concern of this section is that negative pressures in a home invite unwanted infiltration air and can cause natural draft fuel-fired appliances to backdraft and spill combustion products into the home. If the dwelling is allowed to depressurize because of exhaust fans that lack sufficient makeup air, the drafting forces in the vents for natural draft fuel-fired appliances will be overwhelmed and the vents will flow backwards, bringing in makeup air from the outdoors instead of conveying combustion products to the outdoors. Opening a window or relying on infiltration is not an acceptable means of providing makeup air.

M1503.4.1 Location. Kitchen exhaust makeup air shall be discharged into the same room in which the exhaust system is located or into rooms or *duct systems* that communicate through one or more permanent openings with the room in which such exhaust system is located. Such permanent openings shall have a net cross-sectional area not less than the required area of the makeup air supply openings.

- ❖ This section simply clarifies how makeup air is delivered to the kitchen area. Some readers have interpreted the code to require the makeup air to be delivered directly to the kitchen; however, this has never been required by the code. The makeup air can be delivered to any space that freely communicates with the kitchen as well as to the kitchen or any combination of such locations.

SECTION M1504 INSTALLATION OF MICROWAVE OVENS

M1504.1 Installation of a microwave oven over a cooking appliance. The installation of a *listed* and *labeled* cooking appliance or microwave oven over a *listed* and *labeled* cooking appliance shall conform to the terms of the upper appliance's listing and label and the manufacturer's installation instructions. The microwave oven shall conform to UL 923.

- ❖ A cooking appliance or microwave oven installed above other cooking appliances must be listed for use above the lower appliance. This section addresses the fire hazard created by having hot surfaces, open flames and, possibly, a cooking fire located under a cooking appliance or microwave oven. Installation clearances must comply with the manufacturer's instructions for the upper appliance. UL 923 is the standard applicable to microwave ovens. Combination units consisting of an oven with an integral exhaust hood are commonly installed above ranges and cook-tops.

SECTION M1505 OVERHEAD EXHAUST HOODS

M1505.1 General. Domestic open-top broiler units shall have a metal exhaust hood, having a minimum thickness of 0.0157-inch (0.3950 mm) (No. 28 gage) with $\frac{1}{4}$ -inch (6.4 mm) clearance between the hood and the underside of combustible material or cabinets. A clearance of not less than 24 inches (610 mm) shall be maintained between the cooking surface and the combustible material or cabinet. The hood shall be not less than the width of the broiler unit, extend over the entire unit, discharge to the outdoors and be equipped with a backdraft damper or other means to control infiltration/exfiltration when not in operation. Broiler units incorporating an integral exhaust system, and *listed* and *labeled* for use without an exhaust hood, need not have an exhaust hood.

- ❖ The surface material of the hood must not come in direct contact with combustible material, therefore, a $\frac{1}{4}$ -inch (6.4 mm) clearance between the hood and the underside of combustible material and cabinets is required. Otherwise, a grease fire or hot gases from the broiler unit may heat the hood to temperatures that could cause ignition of combustible material mounted above the hood.

A clearance of at least 24 inches (610 mm) must be maintained between the cooking surface and overhead cabinets constructed of combustible materials. These clearances help ensure that combustible material will not be ignited in the event of a fire on the broiler. Note that this section mandates that the hood exhaust to the outdoors and there is no option for recirculating-type hoods.

SECTION M1506 EXHAUST DUCTS AND EXHAUST OPENINGS

M1506.1 Duct construction. Where exhaust duct construction is not specified in this chapter, construction shall comply with Chapter 16.

- ❖ This section refers the reader to Chapter 16 for any exhaust duct construction not specified in Chapter 15. For example, clothes dryer exhaust duct construction is specified in this chapter, but toilet/bathroom exhaust duct construction is addressed only in Chapter 16.

M1506.2 Duct length. The length of exhaust and supply ducts used with ventilating equipment shall not exceed the lengths determined in accordance with Table M1506.2.

Exception: Duct length shall not be limited where the duct system complies with the manufacturer's design criteria or where the flow rate of the installed ventilating equipment is verified by the installer or approved third party using a flow hood, flow grid or other airflow measuring device.

- ❖ Commonly, exhaust fans, especially bathroom exhaust fans, are installed and ducts are run from the fans to the outlet terminals with little regard for the pressure losses in the duct run. A fan rated at 100 cfm, for example, will not move 100 cfm of air if the exhaust duct creates a static pressure drop greater than that for which the fan was rated. Flexible duct offers greater flow resistance than smooth-wall duct, making the problem worse in many cases. The use of duct fittings greatly adds to the flow resistance. Section M1507.4 sets the required exhaust rates and fans are chosen to satisfy that section, however, poorly designed exhaust ducts can prevent the systems from complying with the intent of Section M1507.4 because the fans cannot deliver the required airflow through poorly designed ducts. The exception allows the ducts to be designed by the fan manufacturer, where such information is provided. Often the manufacturer of the fan is silent on the allowable length of duct and number of fittings. Compliance can also be achieved by field testing the installed system and verifying the actual airflow rates.

The table addresses smooth-wall and flexible ducts and sets the maximum duct length based on the diameter of the duct. Looking at the table, one can quickly see that many commonly installed fan and duct combinations are substandard and will not perform as intended. For example, the common 50 cfm fan can never utilize 3-inch flex duct and can use 3-inch smooth-wall duct only in 5-foot runs with no elbows. The size of the fan outlet cannot dictate the size of the duct as, quite often, the duct will have to be larger than the fan outlet. Note c in Table M1506.2 explains how duct fittings are addressed in the table. For example, a 4-inch flexible duct with an 80 cfm fan could not have

any elbows, and a 4-inch smooth-wall duct with an 80 cfm fan could have only two elbows and 1 foot of duct, or one elbow and 16 feet of duct.

Note that Table M1506.2 states that the fans were rated with an assumed static pressure loss of 0.25 inch water column in the duct. Some fans might be rated with an assumed static pressure of 0.10 inch w.c. and if they are, the table would allow ducts that are too long for such fans, resulting in fans not meeting their design airflow rate. When using the table, the static pressure at which the fan was tested should be taken into consideration.

M1506.3 Exhaust openings. Air exhaust openings shall terminate not less than 3 feet (914 mm) from property lines; 3 feet (914 mm) from operable and nonoperable openings into the building and 10 feet (3048 mm) from mechanical air intakes except where the opening is located 3 feet (914 mm) above the air intake. Openings shall comply with Sections R303.5.2 and R303.6.

- ❖ These provisions for termination points are for air that is exhausted from a dwelling unit. Such air will include kitchen exhaust, bathroom exhaust and clothes dryer exhaust and these exhaust terminations would be required to be 3 feet (914 mm) from operable openings into a building (i.e., windows and doors). The exhaust terminations that penetrate through the exterior walls or roof will need to be located 3 feet (914 mm) from windows that are providing the natural ventilation to the dwelling unit. Considering that the exhaust from a dwelling unit is not considered to be hazardous or noxious and is of low volume, the 3-foot (914 mm) separation from windows is deemed to be reasonable. Mechanical air intakes must be located not less than 10 feet (3048 mm) from exhaust from a bathroom, kitchen and domestic clothes dryer. In the case where the required 10-foot (3048 mm) separation cannot be met, the intake must be located at least 3 feet (914 mm) below the exhaust termination. It is assumed that the

exhaust that is present will be buoyant in air because of its temperature or specific gravity and such exhaust will rise above and away from the intake opening.

SECTION M1507 MECHANICAL VENTILATION

M1507.1 General. Where local exhaust or whole-house mechanical ventilation is provided, the equipment shall be designed in accordance with this section.

- ❖ Mechanical ventilation can consist of either local exhaust or whole-house mechanical ventilation. Local exhaust is defined as an exhaust system that uses one or more fans to exhaust air from a specific room or rooms within a dwelling. Examples of local exhaust include bathroom and kitchen exhaust. Section R303 requires either natural or mechanical ventilation of toilet rooms and bathrooms. This section brings mechanical ventilation into the exhaust chapter for convenience. It should be noted that the choice of using either natural or mechanical ventilation is one the designer must make except as required by Section R303.4.

Whole-house mechanical ventilation is defined as an exhaust system, supply system or combination thereof, that is designed to mechanically exchange indoor air for outdoor air. The system can either operate continuously or it can be programmed to operate intermittently.

M1507.2 Recirculation of air. Exhaust air from bathrooms and toilet rooms shall not be recirculated within a residence or to another *dwelling unit* and shall be exhausted directly to the outdoors. Exhaust air from bathrooms and toilet rooms shall not discharge into an *attic*, crawl space or other areas inside the building.

- ❖ This section prohibits the recirculation of exhaust air from toilet rooms and bathrooms within a dwelling or to another dwelling. In some cases, installers connect the outlets of bathroom exhaust fans together to a com-

**TABLE M1506.2
DUCT LENGTH**

DUCT TYPE	FLEX DUCT								SMOOTH-WALL DUCT							
	50	80	100	125	150	200	250	300	50	80	100	125	150	200	250	300
Fan airflow rating (CFM @ 0.25 inch wc ^a)																
Diameter ^b (inches)	Maximum length ^{c, d, e} (feet)															
3	X	X	X	X	X	X	X	X	5	X	X	X	X	X	X	X
4	56	4	X	X	X	X	X	X	114	31	10	X	X	X	X	X
5	NL	81	42	16	2	X	X	X	NL	152	91	51	28	4	X	X
6	NL	NL	158	91	55	18	1	X	NL	NL	NL	168	112	53	25	9
7	NL	NL	NL	NL	161	78	40	19	NL	NL	NL	NL	NL	148	88	54
8 and above	NL	NL	NL	NL	NL	189	111	69	NL	NL	NL	NL	NL	NL	198	133

For SI: 1 foot = 304.8 mm.

- a. Fan airflow rating shall be in accordance with ANSI/AMCA 210-ANSI/ASHRAE 51.
- b. For noncircular ducts, calculate the diameter as four times the cross-sectional area divided by the perimeter.
- c. This table assumes that elbows are not used. Fifteen feet of allowable duct length shall be deducted for each elbow installed in the duct run.
- d. NL = no limit on duct length of this size.
- e. X = not allowed. Any length of duct of this size with assumed turns and fittings will exceed the rated pressure drop.

mon duct to avoid multiple roof, wall or soffit penetrations. This will result in some exhaust air flowing backwards through the fan that is not running because the backdraft dampers in such fans will allow some leakage. This problem is much worse where the common duct serves fans that are located in different dwelling units, such as for a duplex. The code does not expressly prohibit the discharge side of exhaust fans from being connected to a common duct, but the fan manufacturer might prohibit such installations. Recirculating (ductless) exhaust fans are not allowed if mechanical ventilation of a space is required, but such fans are allowed in naturally ventilated spaces.

Recirculation to other dwelling units is prohibited because odors, disease-causing organisms, tobacco smoke, moisture and other contaminants could be transported from one dwelling unit to another.

The requirement for directing air exhausted from bathrooms directly to the outdoors is the same fundamental requirement as expressed in Section M1501 (see commentary, Section M1501.1).

M1507.3 Whole-house mechanical ventilation system.

Whole-house mechanical ventilation systems shall be designed in accordance with Sections M1507.3.1 through M1507.3.3.

❖ All habitable rooms are required by Section 303.1 to be provided with natural ventilation through windows, doors or other approved openings, with an option for mechanical ventilation in accordance with this section. For years natural ventilation has been used which relied on the occupants to open windows and doors to provide ventilation to dwellings. While natural ventilation is still allowed, concerns over indoor air quality have raised questions over the effectiveness of naturally ventilating a dwelling. There are provisions in the code that allow mechanical ventilation to be provided instead of natural ventilation, and, in some cases, require mechanical ventilation to be provided. Section R303.4 will require a dwelling to be provided with whole-house mechanical ventilation when natural ventilation alone is not sufficient for dwellings that are tightly sealed such that their infiltration rate is 5 or fewer air changes per hour at an indoor/outdoor pressure differential of 50 Pa (ACH_{50}) (see commentary, Section R303.4).

In the case where the air infiltration is 5 ACH or greater, these provisions are not mandatory, but they can be used by the designer as another tool or option to provide ventilation for a home in lieu of using natural ventilation.

M1507.3.1 System design. The whole-house ventilation system shall consist of one or more supply or exhaust fans, or a combination of such, and associated ducts and controls. Local exhaust or supply fans are permitted to serve as such a system. Outdoor air ducts connected to the return side of an air handler shall be considered as providing supply ventilation.

❖ The proponent of the change that is responsible for the whole-house mechanical ventilation requirements indicated that these provisions came from the 2004 edition of ASHRAE 62.2. The intent was to reduce the standard

down to the nuts and bolts of mechanical ventilation and provide requirements that are simple and straight forward. Therefore, if a mechanical ventilation system is installed in a dwelling, the designer or builder will have prescriptive requirements on which the system can be based and the code official has provisions on which he or she can evaluate the system for compliance.

The system is made up of supply or exhaust fans or a combination of supply and exhaust fans along with associated ducts and controls for the system. Local bathroom exhaust fans and kitchen fans can be used as part of the system and outdoor air can be brought in through passive openings, dedicated supply fans or outdoor air ducts connected to the return side of the air-handling unit. Note that if the dwelling's air-handling unit or furnace is used to supply outdoor air, the unit must run continuously or have controls to operate intermittently in accordance with Section M1507.3.3. If the outdoor air duct is connected to the air-handler return air duct system and exhaust fans are used as the whole-house mechanical ventilation system (WHMVS), it would not matter if the airhandler is running because the outdoor air will be able to move through the duct system because of the negative pressure created by the exhaust fans. This scenario has the advantage of mixing the outdoor air with indoor air and distributing it in a manner that will not cause discomfort for the occupants.

There are generally three types of whole-house exhaust systems consisting of exhaust ventilation, supply ventilation and balanced ventilation. Exhaust ventilation systems are better suited for cold climates since they work by depressurizing the dwelling. Positively pressurizing a dwelling in a cold climate can force moist air into wall cavities causing condensation to occur in the wall assemblies. In warmer climates with high humidity, reducing the inside pressure will cause air to migrate from the outdoors to inside the dwelling units' wall cavities, which can cause moisture damage if it condenses. Exhaust fans are used to remove air from the dwelling, usually in bathrooms and the kitchen where the most contaminants are located, and then makeup air replaces the air that is exhausted. While infiltration might account for some of the makeup air, outdoor air connections to the return side of the air-handling unit can be used to supply the outdoor makeup air. Since the dwelling is under negative pressure, extreme care must be taken to make sure that fuel-fired appliances and appliance vents are not affected (see Sections M1503.4 and G2407.4).

Supply ventilation systems are better suited for warmer climates since they work by pressurizing the dwelling. In colder climates, when the dwelling is pressurized, warm air can migrate from inside the dwelling into the building cavities which could cause condensation and structural damage to the dwelling. Supply fans are used to supply air to the dwelling with outdoor air into areas of the dwelling which are usually occupied (i.e., family rooms and bedrooms). For this reason, the air should be located so that it mixes with the condi-

tioned air so that it does not create drafts and make the occupants uncomfortable. Relief vents and kitchen and bath fan ducts are used to relieve air from the dwelling.

Balanced ventilation systems consist of supply and exhaust fans which provide approximately equal amounts of outdoor air and exhaust air. Exhaust is usually taken from bathrooms and kitchen areas and the outdoor air is usually supplied to the occupied areas of the dwelling, like family rooms and the bedrooms. A balanced ventilation system using supply and exhaust fans in combination is well suited for an energy recovery ventilation system, thus allowing the energy penalty associated with ventilation to be minimized.

M1507.3.2 System controls. The whole-house mechanical ventilation system shall be provided with controls that enable manual override.

- ❖ The whole-house mechanical ventilation system must run continuously or have controls to operate intermittently in accordance with Section M1507.3.3. A manual override switch/control must be provided to allow the occupants an option to override the system. Note that an override function could mean manually turning off the system or manually turning on the system. Many systems are also designed with a “vacation” setting which allows the occupants to shut down the system when they will be away. See Section M1507.3.3 for more discussion on system control schemes.

M1507.3.3 Mechanical ventilation rate. The whole-house mechanical ventilation system shall provide outdoor air at a continuous rate of not less than that determined in accordance with Table M1507.3.3(1).

Exception: The whole-house mechanical ventilation system is permitted to operate intermittently where the system has controls that enable operation for not less than 25-percent of each 4-hour segment and the ventilation rate pre-

scribed in Table M1507.3.3(1) is multiplied by the factor determined in accordance with Table M1507.3.3(2).

- ❖ The amount of continuous outdoor air required for a WHMVS is indicated in Table M1507.3.3(1). The rates in this table are based on ASHRAE 62.2 and are tied to the area of the conditioned space and the number of bedrooms. Basements, utility areas, laundry rooms, and similar rooms would be considered as part of the dwelling unit’s floor area if these spaces are conditioned. For example, a 2,500-square-foot dwelling with four bedrooms would require 75 cfm of continuous outdoor airflow based on Table M1507.3.3(1).

Intermittent operation is permitted in accordance with the exception. The exception permits intermittent operation based on the run time percentage in each 4-hour time segment. When there is anything less than 100-percent continuous operation, the amount of outdoor air required in Table M1507.3.3(1) is multiplied by the factors in Table M1507.3.3(2). The factors are based on the percentage of time that the system runs in every 4-hour segment of a day. While intermittent operation is permitted, the tradeoff is that more outdoor air is required. For example, in the 2,500-square-foot dwelling with four bedrooms, 75 cfm of continuous outdoor air is required. If intermittent operation was used and 50 percent operation during a 4-hour period was chosen, then the amount of airflow would have to be multiplied by a factor of 2. That would mean that in each 4-hour segment of a day, the ventilation system must run for 2 hours (50 percent of 4 hours) and the amount of airflow provided would be 150 cfm (75 cfm × 2). The minimum run time permitted is 25 percent or 1 hour of run time, which would require the amount of outdoor air to be multiplied by 4. In the above example, for 1 hour of operation in a 4-hour period, 300 cfm of outdoor air is required. The only option to having a

TABLE M1507.3.3(1)
CONTINUOUS WHOLE-HOUSE MECHANICAL VENTILATION SYSTEM AIRFLOW RATE REQUIREMENTS

DWELLING UNIT FLOOR AREA (square feet)	NUMBER OF BEDROOMS				
	0 – 1	2 – 3	4 – 5	6 – 7	> 7
	Airflow in CFM				
< 1,500	30	45	60	75	90
1,501 – 3,000	45	60	75	90	105
3,001 – 4,500	60	75	90	105	120
4,501 – 6,000	75	90	105	120	135
6,001 – 7,500	90	105	120	135	150
> 7,500	105	120	135	150	165

For SI: 1 square foot = 0.0929 m², 1 cubic foot per minute = 0.0004719 m³/s.

TABLE M1507.3.3(2)
INTERMITTENT WHOLE-HOUSE MECHANICAL VENTILATION RATE FACTORS^{a, b}

RUN-TIME PERCENTAGE IN EACH 4-HOUR SEGMENT	25%	33%	50%	66%	75%	100%
Factor ^a	4	3	2	1.5	1.3	1.0

a. For ventilation system run time values between those given, the factors are permitted to be determined by interpolation.

b. Extrapolation beyond the table is prohibited.

EXHAUST SYSTEMS

timed control system is to run the fans continuously.

Where fans are designed to run continuously, such fans should not be controlled by the typical wall switch to which all occupants are accustomed because the occupants will inadvertently turn off the fans when they leave the room, as they have done most of their lives. For example, bathroom/toilet room exhaust fans can be used as a component of the WHMVS in a dwelling. The occupants of such dwelling would turn off the fans when they left the bathroom if they were provided with the typical wall switch that they are accustomed to using, thus disabling the WHMVS. Although not explicitly stated in the code, the implied intent is to require the WHMVS to have controls that the occupants will recognize as being part of a WHMVS. For example, a wall switch can be located and labeled such that it is obviously not intended to be turned off unless an occupant purposely intends to shut off the WHMVS. Alternatively, the fans could be controlled solely by the branch circuit breaker that supplies them, with the circuit identified as bath fans for the WHMVS.

M1507.4 Local exhaust rates. *Local exhaust* systems shall be designed to have the capacity to exhaust the minimum air flow rate determined in accordance with Table M1507.4.

- ❖ The mechanical ventilation rates for kitchens, toilet rooms and bathrooms are specified in Table M1507.4. See Section G2407.4 regarding required makeup air where appliance operation can be affected by negative building pressures.

TABLE M1507.4
MINIMUM REQUIRED LOCAL EXHAUST RATES FOR
ONE- AND TWO-FAMILY DWELLINGS

AREA TO BE EXHAUSTED	EXHAUST RATES
Kitchens	100 cfm intermittent or 25 cfm continuous
Bathrooms-Toilet Rooms	Mechanical exhaust capacity of 50 cfm intermittent or 20 cfm continuous

For SI: 1 cubic foot per minute = 0.0004719 m³/s.

- ❖ The exhaust rates specified in this table are identical to those in Table 403.3.1.1 of the IMC. The continuous rates are lower than the intermittent rates, reflecting the fact that an exhaust fan that runs continuously will provide some degree of overventilation during periods in which contaminants are not being produced. An intermittent exhaust fan will run for short periods of time only, requiring a higher exhaust rate to effectively control odors, cooking effluent and moisture.

Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code:

IMC–15, *International Mechanical Code*. Washington, DC: International Code Council, 2014.

NFPA 70–14, *National Electrical Code*. Quincy, MA: National Fire Protection Association, 2013.

Chapter 16: Duct Systems

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter addresses duct systems by instituting requirements for the protection of the occupants of the building and the building itself. This chapter regulates the materials and methods of construction. Duct construction affects the performance of the entire air distribution system.

Section M1601 contains the material requirements that are generally applied to all duct construction and installation. Section M1602 contains regulations for return air.

Purpose

Chapter 16 contains requirements for the installation of supply, return and exhaust air systems. The chapter contains no information on the design of these systems from the standpoint of air movement, but it is concerned with the structural integrity of the systems and the overall impact of the systems on the fire-safety performance of the building. Design considerations such as duct sizing, maximum efficiency, cost effectiveness, occupant comfort and convenience are the responsibility of the designer.

SECTION M1601 DUCT CONSTRUCTION

M1601.1 Duct design. *Duct systems* serving heating, cooling and *ventilation equipment* shall be installed in accordance with the provisions of this section and ACCA Manual D, the appliance manufacturer's installation instructions or other *approved* methods.

❖ Material and construction requirements for duct systems can be divided into two major categories: those for above-ground ducts and those for underground ducts. The demands placed on each of these types of duct systems are different; therefore, they are treated separately in the code and in the following commentary.

Adequately sized supply air and return air ductwork is essential for efficient and proper circulation of conditioned air. Ducts must be large enough to allow sufficient airflow through appliances to satisfy refrigerant coil airflow demands and to avoid excessive temperature rise. As a practical matter, restriction of the supply duct system is an infrequently encountered problem. However, inadequately sized return systems are often found in the field, particularly on heat pump installations. The code does not provide specific requirements for sizing duct systems, but relies on ACCA *Manual D*, the appliance manufacturer or other sizing criteria approved by the code official.

M1601.1.1 Above-ground duct systems. Above-ground *duct systems* shall conform to the following:

1. *Equipment* connected to *duct systems* shall be designed to limit discharge air temperature to not greater than 250°F (121°C).
2. Factory-made ducts shall be listed and labeled in accordance with UL 181 and installed in accordance with the manufacturer's instructions.

3. Fibrous glass duct construction shall conform to the SMACNA *Fibrous Glass Duct Construction Standards* or NAIMA *Fibrous Glass Duct Construction Standards*.
4. Field-fabricated and shop-fabricated metal and flexible duct constructions shall conform to the SMACNA *HVAC Duct Construction Standards—Metal and Flexible* except as allowed by Table M1601.1.1. Galvanized steel shall conform to ASTM A653.
5. The use of gypsum products to construct return air ducts or plenums is permitted, provided that the air temperature does not exceed 125°F (52°C) and exposed surfaces are not subject to condensation.
6. *Duct systems* shall be constructed of materials having a flame spread index of not greater than 200.
7. Stud wall cavities and the spaces between solid floor joists to be used as air plenums shall comply with the following conditions:
 - 7.1. These cavities or spaces shall not be used as a plenum for supply air.
 - 7.2. These cavities or spaces shall not be part of a required fire-resistance-rated assembly.
 - 7.3. Stud wall cavities shall not convey air from more than one floor level.
 - 7.4. Stud wall cavities and joist-space plenums shall be isolated from adjacent concealed spaces by tight-fitting fireblocking in accordance with Section R602.8.
 - 7.5. Stud wall cavities in the outside walls of building envelope assemblies shall not be utilized as air plenums.

❖ Metal ducts are usually constructed of galvanized sheet steel. Duct size is based on required airflow, sys-

tem pressure, flow velocity and pressure losses caused by friction. Duct material thickness is determined by duct size, static pressure of the system, distance between supports and whether the duct is reinforced. Metal ducts must be constructed with the minimum thicknesses specified in Table M1601.1.1, which bases the minimum required duct thickness on the geometry of the duct, the material used and the major dimension of the duct (the diameter for round ducts and the widest side for rectangular ducts).

Metallic ducts must be constructed to comply with the requirements contained in SMACNA *HVAC Duct Construction Standards - Metal and Flexible*. This standard contains information on duct reinforcement, joints, fittings, hangers and supports and other pertinent design information needed to achieve a stable, efficient and durable installation of ductwork. While this standard contains the minimum required thickness of duct materials, ducts that are installed within a single dwelling are allowed to be constructed with the minimum thicknesses specified in Table M1601.1.1.

Factory-made ducts must be tested and classified in accordance with the provisions of UL 181. Only Class 0 and Class 1 are recognized by UL 181. Class 0 indicates flame spread and smoke-developed indices of zero; Class 1 indicates a flame spread index not greater than 25 and a smoke-developed index not greater than 50, when tested to ASTM E84. The exception to the 25 flame spread index for nonmetallic ducts is Item 6 of this section, which is intended to allow the installation of plastic ducts above ground where such ducts have a flame spread index of 200 or less. However, it should be noted that there is an ICC committee formal interpretation that opines that plastic ducts are allowed to be installed above ground only if they meet the Class I flame spread index requirement of 25 and smoke development index of 50. Plastic rigid ducts are typically made of PVC that cannot meet a smoke development index of 50.

UL 181 requires that a nonmetallic duct be tested to determine its fire-performance characteristics, corrosion resistance, mold-growth resistance, humidity resistance, leakage resistance, temperature resistance, erosion resistance and structural performance. Air ducts that conform to the requirements of UL 181 are identified by the manufacturer's or vendor's name, rated velocity, negative and positive pressure classification and duct material class.

Fibrous ducts are constructed of a composite material of rigid (high-density) fiberglass board and a factory-applied facing, typically reinforced aluminum. The surface of the fibrous duct that is exposed to the airflow is sealed with a fiber-bonding adhesive that prevents erosion of the fiberglass material. The factory-applied exterior duct-board facing contributes to the strength and rigidity of the composite material, acts as a heat reflector, serves as a vapor barrier and is an integral component of the joining method used to construct fibrous ducts. The material is available in board form for shop or field fabrication into rectangular sections or into

10-sided duct form, which approximates a circular cross section. Factory-built round fibrous glass ducts are also available.

Fibrous ducts take advantage of the inherent insulating qualities of the glass fiber material. The air friction factors for fibrous ducts are higher than those for sheet metal because of the relatively rough surface finish of the former.

Construction of fibrous glass ducts must conform to the requirements of the SMACNA Fibrous Glass Duct Construction Standards or NAIMA Fibrous Glass Duct Construction Standards, which provides details for the design and fabrication of air distribution systems using fibrous glass ducts. The SMACNA and NAIMA standards referenced in this section and the previous section are enforceable extensions of the code.

The maximum discharge temperature permitted by industry standards for warm-air heating systems is 250°F (121°C). This section prohibits nonmetallic ducts from being used in applications in which the air temperature would exceed this maximum because the material has not been tested to withstand higher temperatures, and high temperatures will cause accelerated aging of the duct material.

Gypsum board is a composite material commonly used for the construction of air plenums and shafts. Gypsum board can reduce construction costs because it is a common component of building construction assemblies. By serving a dual purpose, gypsum board eliminates the need for independent duct construction. The use of gypsum board to form ducts and plenums is specifically regulated to prevent deterioration of the gypsum board material. Air temperatures that exceed 125°F (52°C) will, over time, dry both the paper facing and the gypsum of the gypsum board, leading to deterioration of the panel.

Gypsum board can also deteriorate when exposed to moisture, which will happen if the surface temperature of the gypsum board is lower than the airstream dew-point temperature, causing water to condense on the surface of the gypsum board. For these reasons, gypsum board cannot be used for air distribution systems using evaporative cooling equipment. It is further restricted to return-air system applications only, a maximum airstream temperature of 125°F (52°C) and an airstream dew-point temperature continuously below the temperature of the gypsum board surface. Evaporative cooling equipment, such as "swamp coolers," uses water as a refrigerant. The resulting addition of moisture to the airstream could cause deterioration of the gypsum board.

Stud spaces and joist spaces have commonly been used as plenums in residential construction (see Section N1103.3.5). These spaces are limited to return air plenums because the negative pressures within the return air plenum with respect to surrounding spaces will decrease the likelihood of spreading smoke to other spaces via the plenum. Also, the temperature and moisture content of heated, cooled and conditioned supply air could cause a fire hazard or deterioration of

the construction materials exposed in the spaces.

Note that Section N1103.3.5 prohibits the use of all framing cavities as ducts or plenums.

The space must not be a part of a fire-resistance-rated assembly because the ASTM E119 test does not consider the impact of air movement within the assembly on the fire-resistance rating. This restriction is a concession to the convenience and cost-saving potential of this method of moving air. The use of stud spaces inherently means the interconnection of different floor levels by the concealed space. Because of the hazard of such an interconnection, the use of this type of plenum is limited to return air from one floor level only for each independent stud cavity. All cavities not used for air movement must be isolated from the plenum by fire-blocking constructed and installed in accordance with the code. The use of stud wall cavities as a plenum in outside walls is prohibited due to the difficulty in sealing the space to prevent outdoor air from infiltrating the cavity, which would increase the heating and cooling loads on the system. Note that Section N1103.3.5 prohibits the use of all framing cavities as ducts or plenums.

Commentary Figure M1601.1.1(1) shows an example of an acceptable stud and joist space installation. The bottom plate of the wall is cut away for the plenum to function, and fireblocking is installed in the joist and stud space to limit communication of the plenum with other spaces. The stud cavity shown is being used to return air from one floor level only, conducting it to the space below, where the air-handling equipment is

located. Commentary Figure M1601.1.1(2) shows an example of an unacceptable stud and joist space installation.

Whether viewed as a shaft or as a duct, a stud-cavity plenum penetrates floor assemblies and is, therefore, subject to the floor penetration protection requirements of Section R302.4.1.

Because air is returned from more than one floor level through the same stud cavity, this section prohibits this type of installation because it creates a direct connection from one floor level to another by means of a concealed cavity. Such direct connections would act as a chase or chimney, allowing fire and smoke to spread quickly upward through the building. Thus, stud-cavity return-air plenums are subject to the same restrictions and requirements as floor openings and penetrations regulated by Section R302.4. Stud-space and joist-space plenums must be viewed as an exception to the fireblocking provisions of Section R302.11 because one or more fireblocks (wall plates) must be removed or relocated to construct the plenums. The code does not mention the type of materials allowed for “panning” the bottom of open joists to create joist-space plenums. Traditionally, sheet metal has been used; however, composite materials are also used. The building official must determine what materials are acceptable for joist panning.

TABLE M1601.1.1.

- ❖ The minimum thicknesses indicated are the low end of the tolerance range for the nominal thicknesses of

**TABLE M1601.1.1
DUCT CONSTRUCTION MINIMUM SHEET METAL THICKNESS FOR SINGLE DWELLING UNITS^a**

19 to 20	0.024	0.034	0.024	0.034

For SI: 1 inch = 25.4 mm, 1 inch water gage = 249 Pa.

- a. Ductwork that exceeds 20 inches by dimension or exceeds a pressure of 1 inch water gage (250 Pa) shall be constructed in accordance with SMACNA *HVAC Duct Construction Standards—Metal and Flexible*.

commonly available sheet materials according to SMACNA *HVAC Duct Construction Standards*. The minimum thickness allows the code official to verify that the proper nominal thickness of material is being used. The dimension indicated for rectangular sizes is the largest dimension. The indicated thicknesses for aluminum sheet are for aluminum alloy 3003-H 14. Note a was added to the table to indicate that for ducts having static pressures greater than 1-inch water gauge, and for ducts with a dimension greater than 20 inches (508 mm), the ducts must be designed in accordance with the material thickness and reinforcing requirements of the SMACNA *HVAC Duct Construction Standard*.

M1601.1.2 Underground duct systems. Underground duct systems shall be constructed of approved concrete, clay, metal or plastic. The maximum duct temperature for plastic ducts shall not be greater than 150°F (66°C). Metal ducts shall be protected from corrosion in an approved manner or shall be completely encased in concrete not less than 2 inches (51 mm) thick. Nonmetallic ducts shall be installed in accordance with the manufacturer’s instructions. Plastic pipe and fitting materials shall conform to cell classification 12454-B of ASTM D1248 or ASTM D1784 and external loading properties of ASTM D2412. Ducts shall slope to an accessible point for drainage. Where encased in concrete, ducts shall be sealed and secured prior to any concrete being poured. Metallic ducts having an approved protective coating and nonmetallic ducts shall be installed in accordance with the manufacturer’s instructions.

- ❖ Ducts installed underground must be able to resist the forces imposed on them by the materials that encase them, the forces created by floodwaters in and around

them and corrosion. The ASHRAE *Handbook of HVAC Systems and Equipment* recommends that all underground ducts and fittings be round to provide optimum structural performance. Unlike round ducts, square or rectangular ducts offer little resistance to deformation or collapse caused by the structural loads associated with burial.

Metal ducts must have either a protective coating to resist corrosion or be completely encased in concrete a minimum of 2 inches (52 mm) thick all around. Concrete-encased ducts may eventually corrode; however, the air passageway will be maintained because of the remaining concrete enclosure. All nonmetallic ducts and metallic ducts with factory-applied protective coatings must be approved, and all such duct installations must be in accordance with the manufacturer’s installation instructions. Application of any field-applied protective coating must be approved. Great care must be taken to protect underground ducts from damage prior to placing the concrete or installing the permanent structure above them. Plastic duct and fitting systems designed for underground applications are available and allow corrosion-resistant and waterproof installations.

Plastic ducts have the advantage of being corrosion resistant. The required external loading properties of ASTM D2412 ensure that the pipe has the ability to resist deformation from the loads associated with direct burial. Plastic ducts rapidly lose strength as their temperature approaches their maximum service temperature. At temperatures above 150°F (65.5°C), PVC pipe is substantially weakened and deformation/collapse is possible.

Figure M1601.1.1(1)
ACCEPTABLE STUD AND JOIST-SPACE INSTALLATION

Underground ducts must be sloped to drain to an accessible point in the event that water enters the duct through duct openings or from the subsoil. Water can cause corrosion, deterioration of duct materials and duct blockages; therefore, sloping the duct to drain to a collection point will allow removal of water. The code does not require that ducts be watertight. This section requires that the duct be sealed before the concrete is poured to prevent concrete from entering the duct.

M1601.2 Vibration isolators. Vibration isolators installed between mechanical *equipment* and metal ducts shall be fabricated from *approved* materials and shall not exceed 10 inches (254 mm) in length.

- ❖ Isolators must be built from materials that will withstand the temperatures and pressures of typical conditioned air passing through the duct. The 10-inch (254 mm) length limitation prevents installation of long lengths of nonrigid duct material, which could adversely affect the integrity of the duct system.

M1601.3 Duct insulation materials. Duct insulation materials shall conform to the following requirements:

1. Duct coverings and linings, including adhesives where used, shall have a flame spread index not higher than 25, and a smoke-developed index not over 50 when tested in accordance with ASTM E84 or UL 723, using the specimen preparation and mounting procedures of ASTM E2231.

Exception: Spray application of polyurethane foam to the exterior of ducts in attics and crawl spaces shall be permitted subject to all of the following:

1. The flame spread index is not greater than 25 and the smoke-developed index is not greater than 450 at the specified installed thickness.
 2. The foam plastic is protected in accordance with the ignition barrier requirements of Sections R316.5.3 and R316.5.4.
 3. The foam plastic complies with the requirements of Section R316.
2. Duct coverings and linings shall not flame, glow, smolder or smoke when tested in accordance with ASTM C411 at the temperature to which they are exposed in service. The test temperature shall not fall below 250°F (121°C). Coverings and linings shall be listed and labeled.
 3. External reflective duct insulation shall be legibly printed or identified at intervals not greater than 36 inches (914 mm) with the name of the manufacturer, the product *R*-value at the specified installed thickness and the flame spread and smoke-developed indices. The installed thickness of the external duct insulation shall include the enclosed air space(s). The product *R*-value for external reflective duct insulation shall be determined in accordance with ASTM C1668.
 4. External duct insulation and factory-insulated flexible ducts shall be legibly printed or identified at intervals not longer than 36 inches (914 mm) with the name of the manufacturer, the thermal resistance *R*-value at the specified installed thickness and the flame spread and smoke-developed indexes of the composite materials. Spray polyurethane foam manufacturers shall provide the same product information and properties, at the nominal installed thickness, to the customer in writing at the time of foam application. Nonreflective duct insulation product *R*-values shall be based on insulation only, excluding air films, vapor retarders or other duct components, and shall be based on tested *C*-values at 75°F (24°C) mean temperature at the installed thickness, in accordance with recognized industry procedures. The installed thickness of duct insulation used to determine its *R*-value shall be determined as follows:

- 4.1. For duct board, duct liner and factory-made rigid ducts not normally subjected to compression, the nominal insulation thickness shall be used.
- 4.2. For ductwrap, the installed thickness shall be assumed to be 75 percent (25-percent compression) of nominal thickness.

4.3. For factory-made flexible air ducts, The installed thickness shall be determined by dividing the difference between the actual outside diameter and nominal inside diameter by two.

4.4. For spray polyurethane foam, the aged *R*-value per inch measured in accordance with recognized industry standards shall be provided to the customer in writing at the time of foam application. In addition, the total *R*-value for the nominal application thickness shall be provided.

- ❖ Because duct systems connect most rooms in a building, they can provide a path for fire and smoke to travel throughout that building. Duct coverings and linings are exposed to the surrounding environment and to the airstream in the duct. To reduce the possible spread of fire and smoke, duct coverings and linings must be tested to ASTM E84 or UL 723. These materials are limited to a maximum flame spread index of 25 and a smoke-developed index of 50, which correspond to Class 1 material. In addition, duct coverings and linings must be rated for the air temperatures expected; this avoids degradation of these materials.

An exception to the requirement for meeting the flame spread and smoke-developed indices was added to allow spray polyurethane insulation to be applied on the exterior of ducts in attics and crawl spaces as long as all of the requirements of the exception are met. Although the exception requires this foam plastic to be protected by an ignition barrier, Sections 316.5.3 and 316.5.4 allow for deletion of the ignition barrier if the foam plastic material is specifically approved in accordance with Section 316.6.

To verify that duct coverings and linings will not present a fire hazard, these materials must be tested in the form in which they will be installed at their rated temperatures but to not less than 250°F (121°C) in accordance with the procedures of ASTM C411. This minimum temperature for testing represents the maximum temperature that industry standards will permit in the airstream of a warm-air heating appliance. It is important that the duct coverings and linings are tested in their composite form rather than having tests conducted on each component that comprises the product (i.e., the insulation, the facing and the adhesive). Each component could pass the ASTM E84 or UL 723 tests individually, but could fail when combined into the final assembly to be installed in the field. Requiring the product to be listed and labeled ensures that the product installed is the same one that was tested.

ASTM E84 and UL 723 indicate the test methods required for duct coverings and linings, including a requirement for testing of systems representative of the actual field installation. ASTM E2231 was added to the code because it contains the specimen preparation and mounting procedures necessary to ensure that the specimen tested in the laboratory is as close as possible to the actual field installation. This will result in a safer field installation where the actual performance of the material can be more accurately predicted.

To assist inspectors, the code requires that duct insulation have a label with the manufacturer's name, thermal resistance (R), and the flame/smoke indexes. However, because labeling of the exterior of spray polyurethane insulation is not feasible, the code requires that the same information be given, in writing, to the customer at the time of application.

A third-party agency must provide quality control inspections at the manufacturer's facility in accordance with the requirements for labeling. Testing performed by an independent agency must determine the insulating R -value, the flame spread index and the smoke-developed index. The 36-inch (914 mm) label intervals are intended to increase the likelihood that every cut piece of insulation and flexible duct will have a label.

Reflective duct insulation is a defined term in Chapter 2. It is typically constructed of aluminum foil or metalized film membranes having closed air cells sandwiched between the membranes. The air cells provide R -value and the foil or metalized film acts as a reflector of radiant energy. *Reflective duct insulation* is often installed with spacers that create an airspace (not to be confused with air films) between the duct surface and the inside surface of the insulation, thereby increasing the overall R -value of the assembly. Items 4.1 through 4.4 of Item 4 do not apply to *reflective duct insulation*.

The thermal performance of duct insulation is dependent on its "installed" condition including the compressed condition, as is the case for duct wrap insulations other than *reflective duct insulation*. This section is intended to provide manufacturers, installers and inspectors with specific guidance for meeting the intent of the code. For example, installed fiberglass duct wrap is assumed to have a thickness of 75 percent of the nominal uninstalled thickness. The R -value reduction for the product will account for the decreased thermal resistance caused by compression of the product.

M1601.4 Installation. Duct installation shall comply with Sections M1601.4.1 through M1601.4.10.

❖ See Sections M1601.4.1 through M1601.4.10.

M1601.4.1 Joints, seams and connections. Longitudinal and transverse joints, seams and connections in metallic and nonmetallic ducts shall be constructed as specified in SMACNA HVAC *Duct Construction Standards—Metal and Flexible* and NAIMA *Fibrous Glass Duct Construction Standards*. Joints, longitudinal and transverse seams, and connections in ductwork shall be securely fastened and sealed with welds, gaskets, mastics (adhesives), mastic-plus-embedded-fabric systems, liquid sealants or tapes. Tapes and mastics used to seal fibrous glass ductwork shall be *listed* and *labeled* in accordance with UL 181A and shall be marked "181A-P" for pressure-sensitive tape, "181 A-M" for mastic or "181 A-H" for heat-sensitive tape.

Tapes and mastics used to seal metallic and flexible air ducts and flexible air connectors shall comply with UL 181B and shall be marked "181 B-FX" for pressure-sensitive tape or "181 BM" for mastic. Duct connections to flanges of air distribution system equipment shall be sealed and mechanically fastened. Mechanical fasteners for use with flexible

nonmetallic air ducts shall comply with UL 181B and shall be marked 181B-C. Crimp joints for round metallic ducts shall have a contact lap of not less than 1 inch (25 mm) and shall be mechanically fastened by means of not less than three sheet-metal screws or rivets equally spaced around the joint.

Closure systems used to seal all ductwork shall be installed in accordance with the manufacturers' instructions.

Exceptions:

1. Spray polyurethane foam shall be permitted to be applied without additional joint seals.
2. Where a duct connection is made that is partially inaccessible, three screws or rivets shall be equally spaced on the exposed portion of the joint so as to prevent a hinge effect.
3. For ducts having a static pressure classification of less than 2 inches of water column (500 Pa), additional closure systems shall not be required for continuously welded joints and seams and locking-type joints and seams of other than the snap-lock and but-ton-lock types.

❖ Duct sealing is commonly overlooked or poorly performed. The U.S. Environmental Protection Agency (EPA) estimates that 20 percent of the energy efficiency of heating and cooling systems can be lost due to duct air leaks located outside of the conditioned space. With the increased focus on lowering energy use in all types of buildings, substantial gains in energy efficiency can be obtained by making sure that ducts are "substantially" airtight. While approved duct materials have low permeability, the joints in these materials to fittings/equipment must be carefully sealed to achieve a "substantially" air-tight condition.

Field experience has shown that poor workmanship and failure to follow manufacturer's instructions has resulted in a high incidence of joint failure in attics and crawl spaces. It is not uncommon to find that air is supplied to or air is returned from an attic because of a separated duct joint. This is obviously a tremendous waste of energy.

In general, joints must be sealed using tapes, mastics, liquid sealants, gasketing or other approved closure systems. A "closure system" consists of the materials and an installation method used to make the joint substantially airtight. This section specifically addresses sealing for three types of duct material which can be accomplished as follows:

- Rigid fibrous glass ductwork must be sealed in accordance with UL 181A. Where pressure-sensitive tape is used, the exterior of the tape must be factory marked with the designation "181 A-P." Where mastic is used, the container label must indicate "181 A-M." Where heat-sensitive tape is used, the exterior of the tape must be factory marked with the designation "181 A-H."
- Metallic ducts, flexible air ducts and flexible air connectors must be sealed in accordance with

UL 181B. Where pressure-sensitive tape is used, the exterior of the tape must be factory marked with the designation “181B F-X.” Where mastic is used, the container label must indicate “181 B-M.”

In addition to sealing, joints must also be mechanically fastened. In other words, sealing by itself is not a substitute for the mechanical fastening of a duct joint. Two examples are taping a flexible air duct to a fitting and “gluing” a round metal duct joint with caulking. Both practices are not acceptable fastening methods. Mechanical fasteners must be used. This section specifically addresses the mechanical fastening of three types of duct material as follows:

- Rigid fibrous glass ductwork must be mechanically attached to flanges of air distribution equipment or sheet metal fittings. For example, where a rigid fibrous glass duct connects to a sheet metal flange of an air handler, sheet metal screws (with flat washers) can be used to attach the duct board to the metal flange. Where fittings for other ducts must attach to the duct, a “spin in,” “twist lock” or “tabbed” collar provides for the required mechanical fastening of the joint.
- Flexible air ducts and flexible air connectors must be fastened to collar stubs or duct connector sleeves. Worm gear band clamps and plastic cable ties are most commonly used for fastening. Where cable ties are used, they must comply with UL 181B and be marked “181-C.” The collar stubs should have a convex bead formed on the circumference of the fitting to prevent the flexible duct from being pulled off of the connector. Commentary Figure M1601.4.1 shows installation guidelines for flexible air ducts and flexible air connectors.
- Round metal duct with crimp joints must have an overlap of at least 1 inch (25.4 mm). At least three sheet metal screws or rivets must be installed, equally spaced around the duct, for mechanical fastening of the joint. A minimum of 3 fasteners creates a rigid joint that will not allow a hinge movement.

Exception 1 allows spray polyurethane foam insulation to serve as a duct joint sealing method. Spray foam insulation has strong adhesive properties and low porosity such that its application provides an equivalent air-tight condition as compared to other closure systems. Exception 2 allows the spacing of the screws or rivets on round metal ducts to be equally spaced on the portion of duct joint that can be accessed, if the entire perimeter of the joint cannot be accessed. The installation of duct work in close quarters such as in joint spaces and chases, often limits access to the complete circumference of the joint. The installation of three screws or rivets in the portion of joint that can be accessed is a reasonable accommo-

ation for such conditions. For air systems with a static pressure of less than 2 inches water column (0.50 kPa), Exception 3 allows for longitudinal (including spiral-type) welded joints and locking-type joints and seams to not be sealed. A welded or locking-type (e.g., Pittsburgh lock) joint is sufficiently air tight at low pressures such that joint sealing would be of limited value. Snap-lock and button-lock type joints do not fall under Exception 3 and must be sealed because such joints will leak. Note that some duct manufacturers provide snap-lock joints that contain a factory-applied sealant in the locking groove that serves to seal the joint when assembled. S-slip joints and lap joints must always be sealed.

M1601.4.2 Duct lap. Crimp joints for round and oval metal ducts shall be lapped not less than 1 inch (25 mm) and the male end of the duct shall extend into the adjoining duct in the direction of airflow.

❖ The crimped end of a round duct is the male end and it points in the direction of flow. The minimum required lap creates joint stability and allows for proper mechanical fastening. Crimped joints can be exceptionally leaky depending on the length of lap. Section M1601.4.1 requires such joints to be sealed.

M1601.4.3 Plastic duct joints. Joints between plastic ducts and plastic fittings shall be made in accordance with the manufacturer’s installation instructions.

❖ Plastic ducts are typically installed underground. If plastic ducts are installed, this section requires the installer to follow the duct manufacturer’s instructions for making joints in the duct. Some manufacturers require joints to be solvent cemented while others require the joints to be caulked. Section M1601.4.1 does not address plastic ducts.

M1601.4.4 Support. Factory-made ducts listed in accordance with UL 181 shall be supported in accordance with the manufacturer’s installation instructions. Field- and shop-fabricated fibrous glass ducts shall be supported in accordance with the SMACNA *Fibrous Glass Duct Construction Standards* or the NAIMA *Fibrous Glass Duct Construction Standards*. Field- and shop-fabricated metal and flexible ducts shall be supported in accordance with the SMACNA *HVAC Duct Construction Standards—Metal and Flexible*.

❖ These material requirements and the 10-foot (3048 mm) maximum spacing requirement prescribe structural support for metal ductwork to limit deflection and maintain alignment. Nonmetallic ducts must be supported in accordance with the manufacturer’s installation instructions because these ducts are produced in various configurations. See Commentary Figure M1601.4.1 for information on nonmetallic duct support.

M1601.4.5 Fireblocking. Duct installations shall be fire-blocked in accordance with Section R602.8.

❖ Section R602.8 refers to Section R302.11 and requires that all openings around ducts at ceiling and floor levels must be fireblocked. Fireblocking retards the spread of fire to other areas in the dwelling.

Installation Guidelines

4.1 Code Reference

The "authority having jurisdiction" should be referenced to determine what law, ordinance or code shall apply in the use of flexible duct.

Ducts conforming to NFPA 90A or 90B shall meet the following requirements:

- a. Shall be tested in accordance with Sections 5-21 of Underwriters Laboratories Standard for Factory-Made Air Ducts and Air Connectors, UL 181.
- b. Shall be installed in accordance with the conditions of their listing.
- c. Shall be installed within the limitations of the applicable NFPA 90A or 90B Standard.

4.2 General

The routing of flexible duct, the number of bends, the number or degrees in each bend and the amount of sag allowed between support joints will have serious effects on system performance due to the increased resistance each introduces. Use the minimum length of flexible duct to make connections. It is not recommended that excess length of ducts be installed to allow for possible future relocations of air terminal devices.

Avoid installations where exposure to direct sunlight can occur, e.g. turbine vents, sky lights, canopy windows, etc. Prolonged exposure to sunlight will cause degradation of the vapor barrier. Direct exposure to UV light from a source lamp installed within the HVAC system will cause degradation of some inner core/liner materials.

Terminal devices shall be supported independently of the flexible duct.

Repair torn or damaged vapor barrier/jacket with duct tape listed and labeled to Standard UL 181B. If internal core is penetrated, replace flexible duct or treat as a connection.

4.3 Installation and Usage

Install duct fully extended, do not install in the compressed state or use excess lengths. This will noticeably increase friction losses.

Figure 6

Figure 7

**Figure M1601.4.1
INSTALLATION INSTRUCTIONS FOR FLEXIBLE AIR DUCTS AND AIR CONNECTORS
(Courtesy of Air Diffusion Council)**

(continued)

Installation Guidelines . . . continued

Avoid bending ducts across sharp corners or incidental contact with metal fixtures, pipes or conduits. Radius at center line shall not be less than one duct diameter.

Figure 8

Do not install near hot equipment (e.g. furnaces, boilers, steam pipes, etc.) that is above the recommended flexible duct use temperature.

Figure 9

4.4 Connecting, Joining and Splicing Flexible Ducts

All connections, joints and splices shall be made in accordance with the manufacturer's installation instructions.

For flexible ducts with plain ends, standardized installation instructions conforming to this standard are shown in Sections 4.5 "Nonmetallic With Plain Ends" (uses tape and clamp to seal/secure the core to the fitting), 4.6 "Alternate Nonmetallic With Plain Ends" (uses mastic and clamp to seal/secure the core to the fitting), and 4.7 "Metallic With Plain Ends" (optional use of tape or mastic and metal screws to seal/secure the core to the fitting).

Due to the wide variety of ducts and duct assemblies with special end treatments, e.g. factory installed fittings, taped ends, crimped metal ends, etc., no standardized installation instructions are shown. Reference manufacturer's installation instructions.

All tapes, mastics, and nonmetallic clamps used for field installation of flexible ducts shall be listed and labeled to Standard UL 181B - Closure Systems for Use With Flexible Air Ducts and Air Connectors.

Sheet metal fittings to which flexible ducts with plain ends are attached shall be beaded and have a minimum of 2 inches [50 mm] collar length. Beads are optional for fittings when attaching *metallic* flexible ducts.

Sheet metal sleeves used for joining two sections of flexible duct with plain ends shall be a minimum of 4 inches [100 mm] in length and beaded on each end. Beads are optional for sleeves when joining *metallic* flexible ducts.

Flexible ducts secured with nonmetallic clamps shall be limited to 6 inches w.g. [1500 Pa] positive pressure.

Figure M1601.4.1—continued
INSTALLATION INSTRUCTIONS FOR FLEXIBLE AIR DUCTS AND AIR CONNECTORS
 (Courtesy of Air Diffusion Council)

(continued)

Installation Guidelines . . . continued

4.5 Installation Instructions for Air Ducts and Air Connectors - Nonmetallic with Plain Ends

Connections

1. After desired length is determined, cut completely around and through duct with knife or scissors. Cut wire with wire cutters. Fold back jacket and insulation.

2. Slide at least 1" [25 mm] of core over fitting and past the bead. Seal core to collar with at least 2 wraps of duct tape. Secure connection with clamp placed over the core and tape and past the bead.

3. Pull jacket and insulation back over core. Tape jacket with at least 2 wraps of duct tape. A clamp may be used in place of or in combination with the duct tape.

Splices

1. Fold back jacket and insulation from core. Butt two cores together on a 4" [100 mm] length metal sleeve.

2. Tape cores together with at least 2 wraps of duct tape. Secure connection with 2 clamps placed over the taped core ends and past the beads.

3. Pull jacket and insulation back over cores. Tape jackets together with at least 2 wraps of duct tape.

NOTES:

1. For uninsulated air ducts and air connectors, disregard references to insulation and jacket.
2. Use beaded sheet metal fittings and sleeves.
3. Use tapes listed and labeled in accordance with Standard UL 181B and marked "181B-FX".
4. Nonmetallic clamps shall be listed and labeled in accordance with Standard UL 181B and marked "181B-C". Use of nonmetallic clamps shall be limited to 6 in. w.g. [1500 Pa] positive pressure.

Installation Guidelines . . . continued

4.6 Alternate Installation Instructions for Air Ducts and Air Connectors - Nonmetallic with Plain Ends

Connections and Splices

Step 1

After desired length is determined, cut completely around and through duct with knife or scissors. Cut wire with wire cutters. Pull back jacket and insulation from core.

Step 2

Apply mastic approximately 2" [50 mm] wide uniformly around the collar of the metal fitting or over the ends of a 4" [100 mm] metal sleeve. Reference data on mastic container for application rate, application thickness, cure times and handling information.

Step 3

Slide at least 2" [50 mm] of core over the fitting or sleeve ends and past the bead.

Step 4

Secure core to collar with a clamp applied past the bead. Secure cores to sleeve ends with 2 clamps applied past the beads.

Step 5

Pull jacket and insulation back over core ends. Tape jacket(s) with at least 2 wraps of duct tape. A clamp may be used in place of or in combination with the duct tape.

NOTES:

1. For uninsulated air ducts and air connectors, disregard references to insulation and jacket.
2. Use beaded sheet metal fittings and sleeves.
3. Use mastics listed and labeled in accordance with Standard UL 181B and marked "181B-M" on container.
4. Use tapes listed and labeled in accordance with Standard UL 181B and marked "181B-FX".
5. Nonmetallic clamps shall be listed and labeled in accordance with standard UL 181B and marked "181B-C". Use of nonmetallic clamps shall be limited to 6 in. w.g. [1500 Pa] positive pressure.

(continued)

Installation Guidelines . . . continued

4.7 Installation Instruction for Air Ducts and Air Connectors - Metallic with Plain Ends

Connections and Splices

1. After cutting duct to desired length, fold back jacket and insulation exposing core. Trim core ends squarely using suitable metal shears. Determine optional sealing method (Steps 2 or 5) before proceeding.

4. Secure to collar/sleeve using #8 sheet metal screws spaced equally around circumference. Use 3 screws for diameters under 12" [300 mm] and 5 screws for diameters 12" [300 mm] and over.

2. When mastics are required and for pressures 4" w.g. [1000 Pa] and over, seal joint with mastic applied uniformly to the outside surface of collar/sleeve. (Disregard this step when not using mastics and proceed to Step 3).

5. For pressures under 4" w.g. [1000 Pa] seal joint using 2 wraps of duct tape applied over screw heads and spirally lapping tape to collar/sleeve. (Disregard this step when using mastics per Step 2).

3. Slide at least 1" [25 mm] of core over metal collar for attaching duct to take off or over ends of a 4" [100 mm] metal sleeve for splicing 2 lengths of duct.

6. Pull jacket and insulation back over core. Tape jacket with 2 wraps of duct tape. A clamp may be used in place of or in combination with the duct tape.

NOTES:

1. For uninsulated air ducts and air connectors, disregard references to insulation and jacket.
2. Use mastics listed and labeled to Standard UL 181B and marked "181B-M" on container.
3. Use tapes listed and labeled to Standard UL 181B and marked "181B-FX".
4. Nonmetallic clamps shall be listed and labeled in accordance with Standard UL 181B and marked "181B-C".

16 | ADC Flexible Duct Performance & Installation Standards, 4th Edition

Figure M1601.4.1—continued
INSTALLATION INSTRUCTIONS FOR FLEXIBLE AIR DUCTS AND AIR CONNECTORS
 (Courtesy of Air Diffusion Council)

(continued)

Installation Guidelines . . . continued

4.8 Supporting Flexible Duct

Flexible duct shall be supported at manufacturer's recommended intervals, but at no greater distance than 5' [1.5 m]. Maximum permissible sag is 1/2" per foot [42 mm per meter] of spacing between supports.

A connection to rigid duct or equipment shall be considered a support joint. Long horizontal duct runs with sharp bends shall have additional supports before and after the bend approximately one duct diameter from the center line of the bend.

Figure 10

Hanger or saddle material in contact with the flexible duct shall be of sufficient width to prevent any restriction of the internal diameter of the duct when the weight of the supported section rests on the hanger or saddle material. In no case will the material contacting the flexible duct be less than 1 1/2" [38 mm] wide.

Figure 11

Figure 12

ADC Flexible Duct Performance & Installation Standards, 4th Edition

Figure M1601.4.1—continued
INSTALLATION INSTRUCTIONS FOR FLEXIBLE AIR DUCTS AND AIR CONNECTORS
 (Courtesy of Air Diffusion Council)

(continued)

Installation Guidelines . . . continued

Factory installed suspension systems integral to the flexible duct are an acceptable alternative hanging method when manufacturer's recommended procedures are followed.

Figure 13

Flexible ducts may rest on ceiling joists or truss supports. Maximum spacing between supports shall not exceed the maximum spacing per manufacturer's installation instruction.

Figure 14

Support the duct between a metal connection and bend by allowing the duct to extend straight for a few inches before making the bend. This will avoid possible damage of the flexible duct by the edge of the metal collar.

Figure 15

Vertically installed duct shall be stabilized by support straps at a max. of 6' [1.8 m] on center.

Figure 16

Note:
Factory-made air ducts may not be used for vertical risers in air duct systems serving more than two stories.

**Figure M1601.4.1—continued
INSTALLATION INSTRUCTIONS FOR FLEXIBLE AIR DUCTS AND AIR CONNECTORS
(Courtesy of Air Diffusion Council)**

M1601.4.6 Duct insulation. Duct insulation shall be installed in accordance with the following requirements:

1. A vapor retarder having a maximum permeance of 0.05 perm [2.87 ng/(s · m² · Pa)] in accordance with ASTM E96, or aluminum foil with a minimum thickness of 2 mils (0.05 mm), shall be installed on the exterior of insulation on cooling supply ducts that pass through unconditioned spaces conducive to condensation except where the insulation is spray polyurethane foam with a maximum water vapor permeance of 3 perm per inch [1722 ng/(s · m² · Pa)] at the installed thickness.
 2. Exterior *duct systems* shall be protected against the elements.
 3. Duct coverings shall not penetrate a fireblocked wall or floor.
- ❖ Where a duct is installed outdoors or in an unconditioned area (such as an attic or crawl space), it can be exposed to humidity and temperature differentials that can create condensation on the outside of the duct. A vapor retarder must be installed on the exterior of the duct to protect the duct and/or insulation from damage caused by moisture. Duct insulation and coverings must not penetrate fireblocked assemblies. If the exterior insulation and vapor retarder burn in a fire, a pathway will open for the fire to spread through the penetration in the structure for the duct.

The exterior of cooling supply ducts that are insulated with spray polyurethane foam which has a maximum water vapor permeance of 3 perm per inch does not require a vapor retarder or aluminum foil. Spray polyurethane foam has been successfully used without a vapor barrier in other applications, such as exterior walls. The natural low permeance of the installed material makes a vapor barrier over the spray foam insulation redundant.

M1601.4.7 Factory-made air ducts. Factory-made air ducts shall not be installed in or on the ground, in tile or metal pipe, or within masonry or concrete.

- ❖ Factory-made air ducts must be listed and labeled for underground installations. Ducts not listed for in-ground installations might not have sufficient strength to withstand the loads applied by these types of installations and might not be suitable for high-moisture areas.

M1601.4.8 Duct separation. Ducts shall be installed with not less than 4 inches (102 mm) separation from earth except where they meet the requirements of Section M1601.1.2.

- ❖ A physical separation from earth is the best method of protecting metallic and nonmetallic ducts from the effects of corrosion and moisture.

M1601.4.9 Ducts located in garages. Ducts in garages shall comply with the requirements of Section R302.5.2.

- ❖ Ducts in garages and ducts penetrating separation walls or ceilings between garages and living spaces must be designed to prevent fire and smoke from easily entering the living spaces (see commentary, Sections R302.5.2 and M1601.6). Section R302.5.2 is intended to protect the penetration of the fire separa-

tion between a dwelling and an attached garage. The code assumes that the 26-gage steel ductwork and the furnace/air-handler casing will offer a significant impediment to the spread of fire from the garage to the dwelling interior. Placing furnaces, airhandlers and ductwork in unconditioned spaces is becoming less common because of energy saving efforts. Concern has been expressed by some that having a furnace/air-handler with nonmetallic access doors to the blower or filter compartments creates a weak spot in the steel duct barrier. The code official can approve materials other than steel in accordance with Sections R302.5.2 and R104.11.

M1601.4.10 Flood hazard areas. In flood hazard areas as established by Table R301.2(1), *duct systems* shall be located or installed in accordance with Section R322.1.6.

- ❖ In buildings and structures located in flood hazard areas, ducts must be installed above the design flood elevation or must be capable of preventing water from entering the ducts and capable of withstanding the forces of buoyancy and moving water (see commentary, Section R322.1.6).

M1601.5 Under-floor plenums. Under-floor plenums shall be prohibited in new structures. Modification or repairs to under-floor plenums in existing structures shall conform to the requirements of this section.

- ❖ New structures must not be designed to use crawl spaces as plenums. This practice is quite rare and such arrangements can waste energy and negatively affect indoor air quality. Because some existing structures might still utilize under-floor plenums, this section allows those arrangements to continue to exist even if modifications or repairs are performed to those systems. See Commentary Figure M1601.5 for an example of an under-floor plenum system.

M1601.5.1 General. The space shall be cleaned of loose combustible materials and scrap, and shall be tightly enclosed. The ground surface of the space shall be covered with a moisture barrier having a minimum thickness of 4 mils (0.1 mm). Plumbing waste cleanouts shall not be located within the space.

Exception: Plumbing waste cleanouts shall be permitted to be located in unvented crawl spaces that receive *conditioned air* in accordance with Section R408.3.

- ❖ Loose combustible scrap must be removed from an under-floor space used as a plenum. The space must be substantially air tight because the furnace will place the plenum under a slight positive pressure to force conditioned air out of the registers into the rooms above. If there are leaks in the plenum walls, the conditioned air will escape to the outdoors and result in energy loss and the creation of negative pressure in the living space.

Efforts to rod drains through cleanouts located in under-floor plenums could create spills and splashes of sewage in the plenum and cleanout openings might be carelessly left open allowing sewer gases to enter the plenum. Because this would create an insanitary

air condition for the building occupants, plumbing cleanouts are prohibited in these spaces. An issue that often comes up is whether fuel gas piping is prohibited in under-floor plenums. Chapter 24 contains the requirements for fuel-gas piping and does not prohibit gas piping in such spaces.

M1601.5.2 Materials. The under-floor space, including the sidewall insulation, shall be formed by materials having flame spread index values not greater than 200 when tested in accordance with ASTM E84 or UL 723.

❖ The enclosing materials of an under-floor plenum, including the sidewall insulation, are limited to materials having a flame spread index less than or equal to 200 because the plenum space could introduce smoke and fire to the living space.

M1601.5.3 Furnace connections. A duct shall extend from the furnace supply outlet to not less than 6 inches (152 mm) below the combustible framing. This duct shall comply with the provisions of Section M1601.1. A noncombustible receptacle shall be installed below any floor opening into the plenum in accordance with the following requirements:

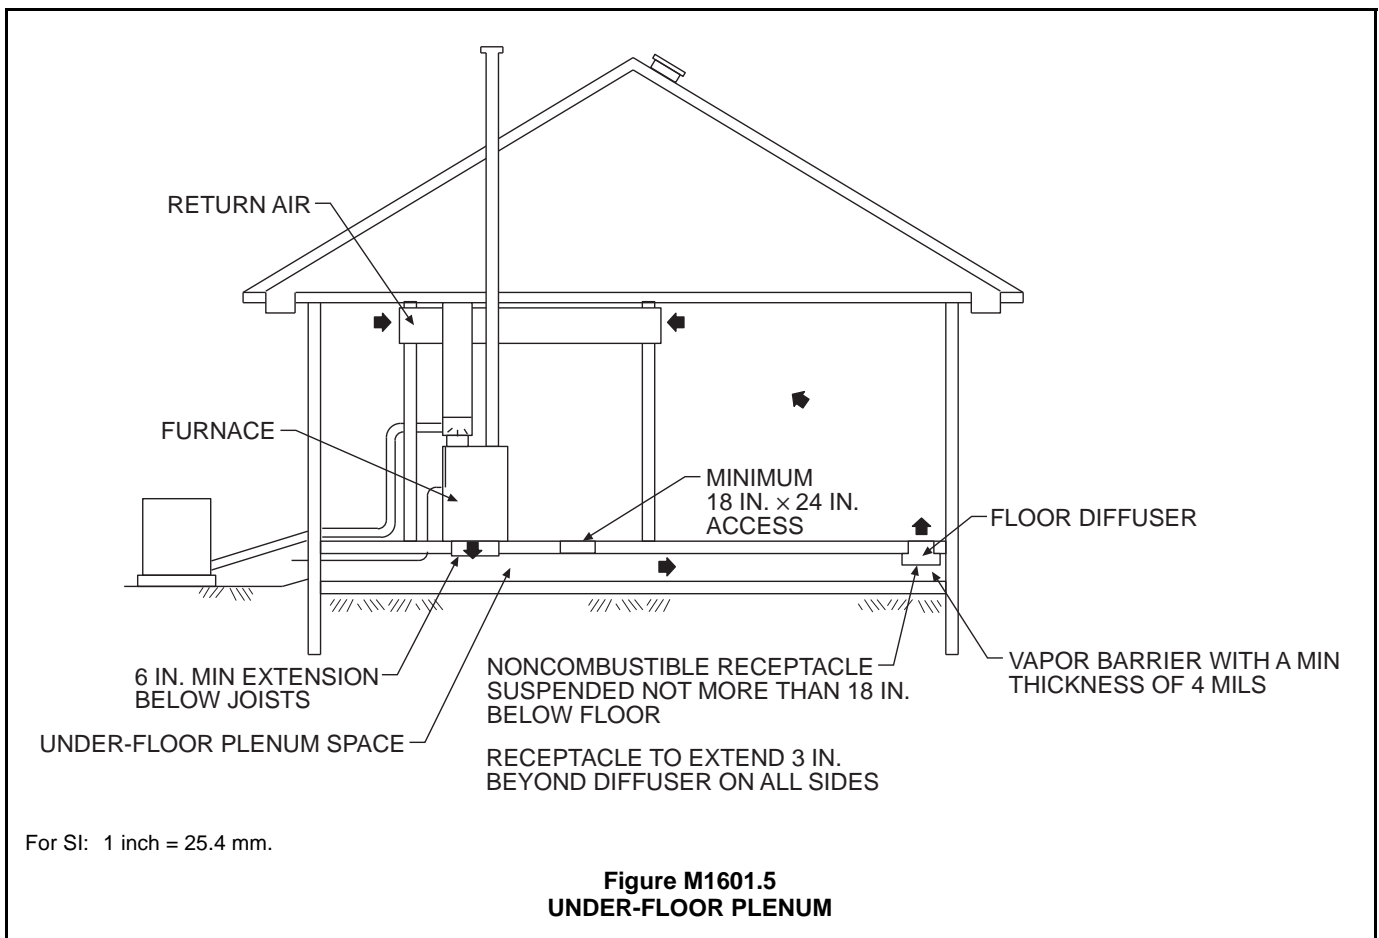

1. The receptacle shall be securely suspended from the floor members and shall be not more than 18 inches (457 mm) below the floor opening.

2. The area of the receptacle shall extend 3 inches (76 mm) beyond the opening on all sides.
3. The perimeter of the receptacle shall have a vertical lip not less than 1 inch (25 mm) in height at the open sides.

❖ A noncombustible receptacle, (i.e., a pan) must be installed below each of the supply openings in the floor. This receptacle (pan) must be suspended from the floor members and must be located not greater than 18 inches (457 mm) below the floor opening so that items and debris dropped into floor openings can be easily retrieved by reaching down through the opening. The receptacle (pan) must extend 3 inches (76 mm) beyond the opening on all sides and have a vertical lip at least 1-inch (25 mm) high to keep items from sliding or rolling off the edges of the pan. The requirement for the pan material to be noncombustible anticipates the potential for burning material being dropped into the opening.

M1601.5.4 Access. Access to an under-floor plenum shall be provided through an opening in the floor with minimum dimensions of 18 inches by 24 inches (457 mm by 610 mm).

❖ An 18-inch by 24-inch (457 mm by 610 mm) or larger opening in the floor is required to provide access to the under-floor plenum to permit maintenance and repairs in the crawl space.

**Figure M1601.5
UNDER-FLOOR PLENUM**

DUCT SYSTEMS

M1601.5.5 Furnace controls. The furnace shall be equipped with an automatic control that will start the air-circulating fan when the air in the furnace bonnet reaches a temperature not higher than 150°F (66°C). The furnace shall additionally be equipped with an *approved* automatic control that limits the outlet air temperature to 200°F (93°C).

❖ Because exposed wood joists and flooring often form under-floor plenums, the outlet air temperature from the furnace must be limited to 200°F (93°C).

Furnaces must also be equipped with an automatic control that starts the air circulation fan before the air temperature in the furnace at the heat exchanger exceeds 150°F (66°C). This requirement serves to limit plenum air temperature. Note that replacement furnaces will not likely be available that can meet these control requirements and altering the furnaces would violate the listing of the appliance.

M1601.6 Independent garage HVAC systems. Furnaces and air-handling systems that supply air to living spaces shall not supply air to or return air from a garage.

❖ This section prohibits a furnace or air-handler from serving both living spaces and garages. If a garage is conditioned, it must be done so by an independent system. For example, if a furnace supplies air to a garage and also to a dwelling interior, the air to the garage will be lost because return air cannot be taken from a garage. The result will be negative pressure in the dwelling with respect to the garage, and the condition will cause contaminants in the garage to migrate into the dwelling (see M1602.2, Item 4).

Garages could contain contaminants that would negatively affect air quality in the living spaces. Pressure differentials and duct leakage could cause contaminants to migrate into the living space. Requiring that the living space system be completely separate ensures that contaminants will not be introduced into the living spaces.

SECTION M1602 RETURN AIR

M1602.1 Outdoor air openings. Outdoor intake openings shall be located in accordance with Section R303.5.1. Opening protection shall be in accordance with Section R303.6.

❖ See Sections R303.5.1 and R303.6.

M1602.2 Return air openings. Return air openings for heating, ventilation and air conditioning systems shall comply with all of the following:

1. Openings shall not be located less than 10 feet (3048 mm) measured in any direction from an open combustion chamber or draft hood of another appliance located in the same room or space.
2. The amount of return air taken from any room or space shall be not greater than the flow rate of supply air delivered to such room or space.
3. Return and transfer openings shall be sized in accordance with the appliance or equipment manufacturers'

installation instructions, Manual D or the design of the registered design professional.

4. Return air shall not be taken from a closet, bathroom, toilet room, kitchen, garage, mechanical room, boiler room, furnace room or unconditioned attic.

Exceptions:

1. Taking return air from a kitchen is not prohibited where such return air openings serve the kitchen only, and are located not less than 10 feet (3048 mm) from the cooking appliances.
 2. Dedicated forced-air systems serving only the garage shall not be prohibited from obtaining return air from the garage.
 5. Taking return air from an unconditioned crawl space shall not be accomplished through a direct connection to the return side of a forced-air furnace. Transfer openings in the crawl space enclosure shall not be prohibited.
 6. Return air from one dwelling unit shall not be discharged into another dwelling unit.
- ❖ Return air is defined and is typically partially or completely recirculated, thus it is important to control the locations from which return air is taken to prevent contamination. Item 1 expresses the concern for drawing combustion products into the return air intakes. Item 4 addresses locations where contaminants would be expected to be present. Item 2 is intended to prevent the creation of negative pressures that would interfere with the function of vents, chimneys and fuel-fired appliances. Such interference can cause appliance malfunction, unsafe operation and spillage of combustion products into the space served by the return air system. Item 3 defers the sizing of return air openings and transfer openings to the design professional, the appliance manufacturer or the ACCA *Manual D* for residential duct systems. The aggregate area of all ducts or openings that convey return air back to the furnace must be adequate to allow the required airflow through the furnace. A furnace that is "starved" for return air will produce an abnormal temperature rise across the heat exchanger, which is a fire hazard and likely detrimental to the furnace. Item 6 prohibits a return system from serving more than one dwelling unit. Any arrangement in which dwelling units share all or part of an air distribution system would allow a communication of atmospheres in the units. This communication would spread odors, smoke, contaminants and disease-causing organisms from one dwelling unit to another and therefore must be avoided. Item 5 addresses the practice of indirectly conditioning a crawl space to the extent that it is considered to be within the thermal envelope of the building. Transfer openings are allowed for this purpose, but locating a ducted return air opening in the crawl space is prohibited because of the potential for contaminants such as moisture, dust, radon, mold, etc., to be present in such space. Item 4 addresses potential sources of air contaminants, and the creation of pressure differentials that can draw

combustion products and contaminants from garages, chimneys, vents and appliances. Return air openings might interfere with the ability of exhaust systems and hoods to capture the target contaminants or effluent. Taking return air from an unconditioned attic would also cause significant energy waste.

Exception 1 recognizes that return air could be necessary for conditioning a kitchen and contamination of the return air is avoided by the required minimum separation from cooking appliances. Exception 2 recognizes that return air from a garage cannot be avoided where the return system is part of a space conditioning system that serves the garage.

Chapter 17: Combustion Air

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

Complete combustion of fuel is essential for the proper operation of appliances, for control of harmful emissions and for achieving maximum fuel efficiency. Combustion air supplies, among other things, the oxygen necessary for the complete and efficient burning of fuel. If insufficient quantities of oxygen are supplied, the combustion process will be incomplete, creating dangerous byproducts and wasting energy in the form of unburned fuel (hydrocarbons). The byproducts of incomplete combustion are poisonous, corrosive and combustible and can cause serious appliance or equipment malfunctions that pose fire or explosion hazards.

Combustion air also serves other purposes in addition to supplying oxygen. It ventilates and cools appliances and the rooms or spaces that enclose them, and it plays an important role in producing and controlling draft in vents and chimneys. An insufficient combustion air supply could cause an appliance to overheat and discharge combustion byproducts into the building.

A combustion air supply is also necessary to prevent oxygen depletion, which threatens the safety of the building occupants. Both building-occupant respiration and the combustion process of fuel-burning appliances consume the available oxygen in a room or space. The depletion of available oxygen promotes incomplete fuel combustion.

Adequate combustion air supply is extremely important, but it is one aspect of mechanical installation that is often overlooked, ignored or compromised. Depending on the appliance type, location and building construction, supplying combustion air can be easy, or it can involve complex designs and extraordinary methods. In any case, the importance of a proper combustion air supply cannot be overemphasized.

This chapter does not actually contain any combustion air requirements. It was recognized in previous editions of the code that the requirements in this chapter were based on combustion air requirements that were developed for fuel-gas burning appliances. Liquid and solid fuel-burning appliances do not have the same requirements for combustion air. Therefore, all of the requirements in this chapter were deleted and replaced with instructions on where to find fuel-specific combustion air requirements for solid, liquid and fuel gas-fired appliances. Chapter 24 covers gas appliances.

Purpose

This chapter directs the reader to appropriate combustion air requirements provided in other publications or chapters of the code.

SECTION M1701 GENERAL

M1701.1 Scope. Solid fuel-burning *appliances* shall be provided with *combustion air* in accordance with the *appliance* manufacturer's installation instructions. Oil-fired *appliances* shall be provided with *combustion air* in accordance with NFPA 31. The methods of providing *combustion air* in this chapter do not apply to fireplaces, fireplace stoves and direct-vent *appliances*. The requirements for combustion and dilution air for gas-fired *appliances* shall be in accordance with Chapter 24.

❖ Combustion air is necessary for complete fuel combustion. In some situations, air is necessary for ventilation of the appliance enclosure. A lack of combustion air results in incomplete fuel combustion, which causes soot production, increased carbon monoxide production, serious appliance malfunction and the risk of fire or explosion. Incomplete fuel combustion and improper draft and venting compound each other and

greatly increase the risk of the release of carbon monoxide, thereby endangering the occupants of the space or building. Lack of the air necessary for ventilation of the appliance enclosure can result in excessive temperatures in that enclosure, thus introducing the risks of overheating the appliance and fire.

Potential sources of combustion air are (1) the indoor atmosphere in which the appliance is located, (2) outdoor openings and ducts, (3) a combination of the two and (4) any other approved arrangement for the dependable introduction of outdoor air into the building or directly to the fuel-burning appliance.

Combustion air requirements for a fuel-burning appliance are dependent on the type of fuel burned by the appliance. As such, this section directs the reader to other publications or Chapter 24 of the code for the requirements specific to the type of fuel that the appliance burns.

As stated in the general comments at the beginning of this chapter, this combustion air chapter in previous code editions did not specifically address the combustion air requirements for solid and liquid fuel burning appliances as this chapter was originally developed long ago (1992 CABO, *One- and Two-family Dwelling Code*) based on the combustion air requirements for gas-fired appliances. Up until the 2000 edition (first edition) of the code, this chapter was applicable to liquid, solid and gas-fired appliances. In the 2000 edition of the code, a new fuel gas chapter was introduced which included combustion air requirements for gas-fired appliances. With the introduction of the new fuel gas chapter, it was intended that the combustion air chapter be applicable only to liquid and solid fired appliances. Even though the first section of Chapter 17 from the 2000 edition forward did attempt to redefine the scope of the chapter to be only for liquid and solid fuel-fired appliances, many users of the code continued to apply this chapter to gas-fired appliance installations. As subsequent revisions to Chapter 24 occurred (and those same revisions were not carried over into Chapter 17), the requirements of the two chapters began to diverge creating confusion for code users who attempted to apply both chapters to gas-fired appliances. Replacing all of the combustion air requirements in Chapter 17 with instructions on where to find combustion air requirements for the specific type of fuel-burning appliance eliminated the confusion about gas-fired appliance combustion air requirements and provided the location for appropriate combustion air requirements for solid and liquid fuel-fired appliances.

Because of the unique configurations and variety of solid fuel-burning appliances (e.g., wood, pellet, biomass), no one set of combustion air requirements could adequately cover all solid fuel-fired appliance installations. Therefore, the best information must be obtained from the manufacturer's installation instructions for the specific appliance.

NFPA 31, *Installation of Oil-burning Equipment*, has long been recognized for many aspects of oil-fired appliance installations that were not covered by the code. Because NFPA 31 has combustion air requirements, the standard is the appropriate source for this information. The reader is advised to consult NFPA 31 directly.

M1701.2 Opening location. In flood hazard areas as established in Table R301.2(1), *combustion air* openings shall be located at or above the elevation required in Section R322.2.1 or R322.3.2.

- ❖ Appropriately locating ventilation and combustion air openings in buildings that are subject to flooding will substantially reduce the amount of damage to appliances as well as to the building structure in the event of flooding.

Chapter 18: Chimneys and Vents

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

Chapter 18 regulates the design, construction, installation, maintenance, repair and approval of chimneys, vents and their connections to fuel-burning appliances. A properly designed chimney or vent system is needed to conduct the flue gases produced by a fuel-burning appliance to the outdoors. In the case of natural draft appliances, the chimney or vent system serving the appliance is expected to produce a draft at the appliance connection. This chapter does not cover venting requirements for fuel gas-fired appliances (see Chapter 24).

Draft is produced by the temperature difference between combustion gases (flue gases) and the ambient atmosphere. It is measured as pressure in inches of water column (kPa) and is a negative pressure—meaning that it is less than the atmospheric pressure at the point of measurement. Because hotter gases are less dense, they are buoyant and will rise in the chimney, causing negative pressures to develop that are directly proportional to the height of the chimney or vent and directly proportional to the temperature difference between the flue gases and the ambient air. Draft produced by a chimney or vent is the motivating force that conveys

combustion products from natural draft appliances to the outside atmosphere.

The type of vent or chimney used in a given installation is generally based on the type of fuel burned by the appliance, the temperature of the flue gases produced by the combustion process and the appliance category. Because the code classifies appliances into three temperature categories (low, medium and high heat), the fuel type and characteristics of the flue gas must be analyzed for the design of a chimney or vent system. Higher efficiency appliances continue to produce lower flue gas temperatures, and the diversity of mechanical venting systems continues to expand.

Because of new technology and higher efficiency appliances/equipment, venting means are becoming increasingly diversified and complex. Many of today's appliances are designed to be vented by more than one type of venting system.

Purpose

This chapter contains provisions that would minimize the hazards associated with the products of combustion from fuel-burning appliances.

SECTION M1801 GENERAL

M1801.1 Venting required. Fuel-burning *appliances* shall be vented to the outdoors in accordance with their *listing* and *label* and manufacturer's installation instructions except *appliances* listed and *labeled* for unvented use. Venting systems shall consist of *approved* chimneys or vents, or venting assemblies that are integral parts of *labeled appliances*. Gas-fired *appliances* shall be vented in accordance with Chapter 24.

❖ Every fuel-burning appliance must be vented by a chimney or vent, unless the appliance is listed and labeled for unvented use. This chapter does not apply to unvented fuel gas-fired appliances or vented fuel gas-fired appliances. Quite often there is confusion resulting from users of the code trying to apply this chapter to gas-fired appliances. This chapter does not apply to gas-fired appliances.

M1801.2 Draft requirements. A venting system shall satisfy the draft requirements of the *appliance* in accordance with the manufacturer's installation instructions, and shall be con-

structed and installed to develop a positive flow to convey combustion products to the outside atmosphere.

❖ Every fuel-burning appliance must be vented by a chimney or vent unless the appliance is direct vented, integrally vented or mechanically vented. Although chimneys and vents share a basic purpose, they are different creatures with different code requirements. Some code sections pertain to chimneys only, some to vents only and some to both. The code is frequently misapplied because people refer to vents as chimneys and vice versa.

The combustion byproducts produced by the burning of fuels consist primarily of carbon dioxide; nitrogen; water vapor and small amounts of carbon monoxide, nitric oxide, nitrogen dioxide and other compounds that vary with the type and purity of the fuel. Some of the compounds, especially carbon monoxide (CO), are poisonous, and some are corrosive. The amount of carbon monoxide in combustion gases varies with the type of fuel, the type of burner and the condition and adjustment of the burner.

Carbon monoxide poisoning as a result of malfunctioned

tioning fuel-burning appliances or malfunctioning chimneys or vents, or the lack thereof, has caused many fatalities. The products of combustion must be conducted to the outdoors so that operation of the appliance does not pose a threat to the building occupants. Fuel-burning appliances have widely varying operating characteristics; the method of venting the combustion byproducts must therefore be designed for the particular type of appliance served. Flue gases produced by appliances differ primarily in temperature and chemical composition. Methods of venting differ in the temperature and pressure ranges over which they operate and whether or not they can accommodate condensation.

A mismatch between an appliance and a chimney or vent can result in a hazardous operating condition. For example, an appliance that produces high-temperature flue gases can cause vent material to degrade or melt. It can also cause excessively high temperatures on the outer surface of the vent. On the other hand, an appliance that produces low-temperature flue gases can cause vent material to corrode and deteriorate because of condensation.

M1801.3 Existing chimneys and vents. Where an *appliance* is permanently disconnected from an existing chimney or vent, or where an *appliance* is connected to an existing chimney or vent during the process of a new installation, the chimney or vent shall comply with Sections M1801.3.1 through M1801.3.4.

❖ Existing chimneys and vents must be reevaluated for continued suitability whenever the “conditions of use change.” A “condition of use change” is the permanent removal of one appliance or the installation of an appliance (either an additional appliance or the replacement for an existing appliance). Such changes could result in failure of the venting system to produce adequate draft for the appliances and could also cause the venting system to produce harmful condensation. The chimney or vent reevaluation must be in accordance with the following four code sections. First, the size of the existing chimney or vent must be verified (see Section M1801.3.1). Second, if the existing chimney or vent is of the proper size, the exterior of the chimney or vent must be inspected to verify that there is proper clearance to combustibles (see Section M1801.3.4). Third, the internal flue passageway must be inspected and cleaned (see Section M1801.3.2). Finally, masonry chimneys that are to be reused must have a cleanout installed if one does not already exist (see Section M1801.3.3).

M1801.3.1 Size. The chimney or vent shall be resized as necessary to control flue gas condensation in the interior of the chimney or vent and to provide the *appliance*, or *appliances* served, with the required draft. For the venting of oil-fired *appliances* to masonry chimneys, the resizing shall be done in accordance with NFPA 31.

❖ The combined input from multiple appliances, especially older lower efficiency appliances, can maintain chimney or vent temperatures that are high enough to

provide the necessary draft and avoid harmful condensation. Changing an existing configuration by disconnecting and eliminating an appliance or by substituting a higher efficiency appliance can cause a decrease in flue gas temperature, resulting in poor draft and/or condensation. The elimination of one or more draft hood equipped appliances will reduce the amount of dilution air in a venting system, increasing the likelihood of condensation.

The requirements of the code for the design of a new chimney or vent must be used to determine the required chimney/vent size to serve all of the appliances that will be connected. If the required size is different (either smaller or larger) than the existing system, the dimensions of the chimney or vent will likely need to be changed. If the required size is smaller, a liner system complying with UL 1777 could be installed in an existing chimney or vent (see the exception for Section M1801.3.4). If the required size is larger, the existing chimney or vent must be replaced with one of the proper size; or abandoned, if a new chimney or vent system is to be installed in another location.

Where a masonry chimney vents an oil-fired appliance, the requirements of NFPA 31 must be followed when resizing a masonry chimney.

A common scenario involves removing a chimney-vented furnace or boiler and leaving a water heater as the only appliance vented to the chimney. In such cases, the chimney is grossly oversized for the water heater which typically results in poor draft and the production of continuous condensation within the chimney. This scenario has received much attention and has caused those in the industry to use the phrase “orphaned water heater” to describe the arrangement.

M1801.3.2 Flue passageways. The flue gas passageway shall be free of obstructions and combustible deposits and shall be cleaned if previously used for venting a solid or liquid fuel-burning *appliance* or fireplace. The flue liner, chimney inner wall or vent inner wall shall be continuous and free of cracks, gaps, perforations, or other damage or deterioration that would allow the escape of combustion products, including gases, moisture and creosote.

❖ The chimney or vent must be inspected, cleaned (if needed), reinspected (if cleaned), and repaired or replaced (if needed). Where a chimney or vent previously conveyed flue gases from solid or liquid fuel, the inside surfaces of the flue gas passageway must be cleaned regardless of what an initial inspection reveals. Cleaning after solid or liquid fuel flue gas exposure is the only way to ensure proper conditions for a thorough examination of the flue gas passageway. The cleaning also eliminates fuel deposits that might cause a chimney or vent fire, reduces frictional resistance to flow and prevents any residual deposits from falling into lower parts of the venting system.

Use of a chimney or vent without proper inspection (and cleaning, if required) is a code violation. If the inspection shows that the flue gas passageway of the vent or chimney is incapable of preventing leakage of

combustion gases and liquids, the chimney or vent must be either repaired or relined (see commentary, Section M1801.3.1). Where an oil-fired appliance is vented through the chimney, flue repairs must comply with the requirements of NFPA 31.

M1801.3.3 Cleanout. Masonry chimneys shall be provided with a cleanout opening complying with Section R1003.17.

- ❖ If an existing masonry chimney is to be reused but is found to not have a cleanout, a cleanout must be installed.

M1801.3.4 Clearances. Chimneys and vents shall have air-space clearance to combustibles in accordance with this code and the chimney or vent manufacturer's installation instructions.

Exception: Masonry chimneys equipped with a chimney lining system tested and *listed* for installation in chimneys in contact with combustibles in accordance with UL 1777, and installed in accordance with the manufacturer's instructions, shall not be required to have a clearance between combustible materials and exterior surfaces of the masonry chimney. Noncombustible firestopping shall be provided in accordance with this code.

- ❖ An existing chimney or vent that is to be reused must be inspected to verify that proper external clearances to combustibles exist for the entire length of the chimney or vent, as required by the code for a new chimney or vent installation. If proper clearances do not exist, either the building structure (within allowable structural limitations) must be altered to provide the required clearances or the chimney/vent system realigned to provide the required clearances. Where proper clearances cannot be provided by either method, the chimney/vent system must be replaced with a system installed with the proper clearances. Note that where a chimney/vent system passes through floors or ceilings of a building, the code requires the installation of noncombustible fireblocking between the exterior of the chimney/vent system and the structure (see Chapter 10).

Clearances for vents and factory-built chimneys are typically indicated on the exterior of the vent or chimney. If the required clearances are not indicated on the vent or chimney, the manufacturer must be contacted and the original installation instructions consulted.

Existing masonry chimneys commonly do not have the proper external clearances to combustibles required by the code, especially if the structure is fairly old. The exception allows for listed chimney lining systems to be installed in masonry chimneys. Listed chimney liners are designed to provide insulation value to compensate for the lack of clearance of the masonry chimney to combustibles. Such chimney liner systems must comply with the requirements of UL 1777.

M1801.4 Space around lining. The space surrounding a flue lining system or other vent installed within a masonry chimney shall not be used to vent any other *appliance*. This shall not prevent the installation of a separate flue lining in accor-

dance with the manufacturer's installation instructions and this code.

- ❖ When a chimney lining system is installed within a chimney, an annular space will be created between the liner and the chimney. Such a space usually has an irregular shape and is not conducive to the proper flow of flue gases. Also, vent gases could degrade the lining system.

M1801.5 Mechanical draft systems. A mechanical draft system shall be used only with *appliances listed and labeled* for such use. Provisions shall be made to prevent the flow of fuel to the *equipment* when the draft system is not operating. Forced draft systems and portions of induced draft systems under positive pressure during operation shall be designed and installed to prevent leakage of flue gases into a building.

- ❖ Commonly used chimney and vent systems are not designed for positive pressure (above atmospheric pressure). Such chimneys and vents are intended to produce a draft and thus operate with negative (below atmospheric) internal pressures. Specialized vents and chimneys are available that are designed for positive pressure applications. The misapplication of chimney and venting materials can result in leakage of combustion gases and can cause chimney or vent deterioration due to condensation corrosion.

M1801.6 Direct-vent appliances. Direct-vent *appliances* shall be installed in accordance with the manufacturer's instructions.

- ❖ Direct-vent appliances must be listed and labeled and installed in accordance with the manufacturer's instructions. These appliances are designed to draw combustion air through a duct that is connected directly to the outdoors and expel combustion products through another duct to the outdoors. Some direct vent systems operate by natural draft while others are blower assisted. The vent and intake pipes are often terminated outdoors in a single vent/air intake assembly constructed in a concentric arrangement.

M1801.7 Support. Venting systems shall be adequately supported for the weight of the material used.

- ❖ Vent manufacturers supply support parts, and manufacturers' instructions provide detailed requirements for support of vent systems. Improper support can cause strain on vent components, appliance connectors and fittings resulting in vent, appliance or connector damage and loss of required clearance to combustibles and proper pitch. Frequently, venting installations suffer from lack of or improperly installed supports, brackets and hangers (see Commentary Figure M1801.7).

M1801.8 Duct penetrations. Chimneys, vents and vent connectors shall not extend into or through supply and return air ducts or plenums.

- ❖ In residential construction, stud and joist spaces are sometimes used instead of ducts for return air and combustion air. Areas under a floor are sometimes

used as plenums. A combustion products vent, vent connector or exhaust duct is not permitted to extend into or through an air plenum or space used as an air duct. The combustion vent could leak flue gases into the circulating air, creating a health hazard. The restriction does not apply to a space that is being used to convey combustion air.

M1801.9 Fireblocking. Vent and chimney installations shall be fireblocked in accordance with Section R602.8.

❖ Fireblocking with noncombustible materials must be installed in wood-frame construction at all openings around vents, pipes, ducts, chimneys and fireplaces at ceiling and floor levels. See the commentary to Section R602.8 (R302.11).

M1801.10 Unused openings. Unused openings in any venting system shall be closed or capped.

❖ Unused openings in chimneys or vents can allow vent gases to escape into the building, cause loss of draft or allow the entry of birds and rodents. The method used to close an unused opening must not create a protrusion that can restrict flow through the vent or chimney passageway.

M1801.11 Multiple-appliance venting systems. Two or more *listed* and *labeled appliances* connected to a common natural draft venting system shall comply with the following requirements:

1. *Appliances* that are connected to common venting systems shall be located on the same floor of the *dwelling*.

Exception: Engineered systems as provided for in Section G2427.

2. Inlets to common venting systems shall be offset such that no portion of an inlet is opposite another inlet.

3. Connectors serving *appliances* operating under a natural draft shall not be connected to any portion of a mechanical draft system operating under positive pressure.

❖ If there is more than one opening into a single chimney or vent passageway, the openings must be located at different heights or otherwise be arranged so that the flow of combustion products from one connector cannot enter another connector instead of going up the flueway. This provision intends to prevent the flow or spilling of flue gases back into the building through an adjacent appliance flue connection.

Each solid-fuel-burning appliance or fireplace must have a dedicated independent chimney or vent. Solid-fuel appliances cannot share a common chimney with any other appliance or fireplace. Solid-fuel-burning appliances produce creosote deposits on the interior walls of chimney liners. The creosote is highly combustible. In the event of a chimney fire, other connections to the chimney could allow fire to break out of the chimney and into the building. Also, chimney passageways can become partially blocked by creosote formation, thus forcing vent gases from other appliances to discharge back into the building.

M1801.12 Multiple solid fuel prohibited. A solid fuel-burning *appliance* or fireplace shall not connect to a chimney passageway venting another *appliance*.

❖ Each solid-fuel-burning appliance or fireplace must have a dedicated independent chimney or vent. Solid-fuel appliances cannot share a common chimney with any other appliance or fire-place. Solid-fuel-burning appliances produce creosote deposits on the interior walls of chimney liners. The creosote is highly combus-

tible. In the event of a chimney fire, other connections to the chimney could allow fire to break out of the chimney and into the building. Also, chimney passageways can become partially blocked by creosote formation, thus forcing vent gases from other appliances to discharge back into the building.

SECTION M1802 VENT COMPONENTS

M1802.1 Draft hoods. Draft hoods shall be located in the same room or space as the *combustion air* openings for the *appliances*.

❖ Draft hoods are installed in gas-venting systems to regulate the draft intensity and to prevent downdrafts from entering gas appliances. Draft hoods also allow dilution air to be drawn into the vents, inhibiting the formation of moisture condensed from the flue gases. Air drawn into the venting system must be replaced to prevent a negative pressure that could produce spillage of vent gases into the dwelling. Draft hoods must therefore be located in the same room or space as combustion air openings. This provision will ensure that the venting system will be in the same pressure zone as the combustion chamber.

M1802.2 Vent dampers. Vent dampers shall comply with Sections M1802.2.1 and M1802.2.2.

❖ Dampers control the rate of combustion by regulating the amount of draft. When the appliance is not operating, they allow flue gas passageways to be closed to reduce the loss of conditioned air through the chimney. This section addresses the use of both manually operated and automatic dampers.

M1802.2.1 Manually operated. Manually operated dampers shall not be installed except in connectors or chimneys serving solid fuel-burning *appliances*.

❖ Manual dampers can be installed only in solid-fuel-burning appliances. Such dampers control the rate of combustion by regulating the amount of draft and also reduce the loss of conditioned air through the vent or chimney when the appliance is not operating by allowing the vent or chimney to be closed. The damper is usually opened manually during the process of starting a fire. If the damper is not opened, smoke will spill back into the room, alerting the user. For gas- or liquid-fuel-fired appliances, however, the user may not be aware of a partially or completely closed damper, and a hazardous condition could develop. The code therefore prohibits the use of manual dampers for all but solid-fuel-burning appliances. Note that this section does not prohibit the use of fixed baffles that are components of approved appliance venting systems.

M1802.2.2 Automatically operated. Automatically operated dampers shall conform to UL 17 and be installed in accordance with the terms of their *listing* and *label*. The installa-

tion shall prevent firing of the burner when the damper is not opened to a safe position.

❖ Automatic dampers can be used with gas- or liquid-fuel-fired natural draft appliances. Because damper failure can result in a hazardous condition, automatic dampers must be listed and labeled, and installed in strict accordance with the manufacturer's installation instructions and the terms of the listing. An improperly installed or malfunctioning damper can cause the appliance to malfunction and discharge the combustion products back into the building. Automatic dampers are designed to prove that they are in the open position before allowing the appliance burners to fire.

M1802.3 Draft regulators. Draft regulators shall be provided for oil-fired *appliances* that must be connected to a chimney. Draft regulators provided for solid fuel-burning *appliances* to reduce draft intensity shall be installed and set in accordance with the manufacturer's installation instructions.

❖ Oil-fired appliances must be fitted with a draft regulator unless the appliance is listed and labeled for use without the draft regulator. Draft regulators may be installed on solid-fuel-burning appliances to reduce the draft intensity. When required, draft regulators must be installed in the same room or enclosure as the appliance so that no difference in pressure between the air at the regulator and the combustion air supply will exist. Draft regulators are of the barometric type and are somewhat comparable to the draft hood used with gas appliances. See Commentary Figure M1802.3 for illustrations of draft hoods and draft regulators.

M1802.3.1 Location. Where required, draft regulators shall be installed in the same room or enclosure as the *appliance* so that a difference in pressure will not exist between the air at the regulator and the *combustion air* supply.

❖ See the commentary to Section M1802.1.

SECTION M1803 CHIMNEY AND VENT CONNECTORS

M1803.1 General. Connectors shall be used to connect fuel-burning *appliances* to a vertical chimney or vent except where the chimney or vent is attached directly to the *appliance*.

❖ Unless the chimney or vent is connected directly to the appliance, a connector is necessary. A connector is piping or a factory-built assembly that is used to connect a fuel-burning appliance to a vent or chimney, including any necessary fittings to make the connection or a change in direction.

M1803.2 Connectors for oil and solid fuel appliances. Connectors for oil and solid fuel-burning *appliances* shall be constructed of factory-built chimney material, Type L vent material or single-wall metal pipe having resistance to corro-

CHIMNEYS AND VENTS

sion and heat and thickness not less than that of galvanized steel as specified in Table M1803.2.

- ❖ Connectors for oil- and solid-fuel-burning appliances must be constructed of the materials listed in this section to ensure that they are capable of tolerating the high temperatures and corrosive nature of the vent gases being conveyed.

TABLE M1803.2
THICKNESS FOR SINGLE-WALL METAL PIPE CONNECTORS

DIAMETER OF CONNECTOR (inches)	GALVANIZED SHEET METAL GAGE NUMBER	MINIMUM THICKNESS (inch)
Less than 6	26	0.019
6 to 10	24	0.024
Over 10 through 16	22	0.029

For SI: 1 inch = 25.4 mm.

M1803.3 Installation. Vent and chimney connectors shall be installed in accordance with the manufacturer's instructions and within the space where the *appliance* is located. *Appliances* shall be located as close as practical to the vent or chimney. Connectors shall be as short and straight as possible and installed with a slope of not less than $\frac{1}{4}$ inch (6 mm) rise per foot of run. Connectors shall be securely supported and joints shall be fastened with sheet metal screws or rivets. Devices that obstruct the flow of flue gases shall not be installed in a connector unless *listed* and *labeled* or *approved* for such installations.

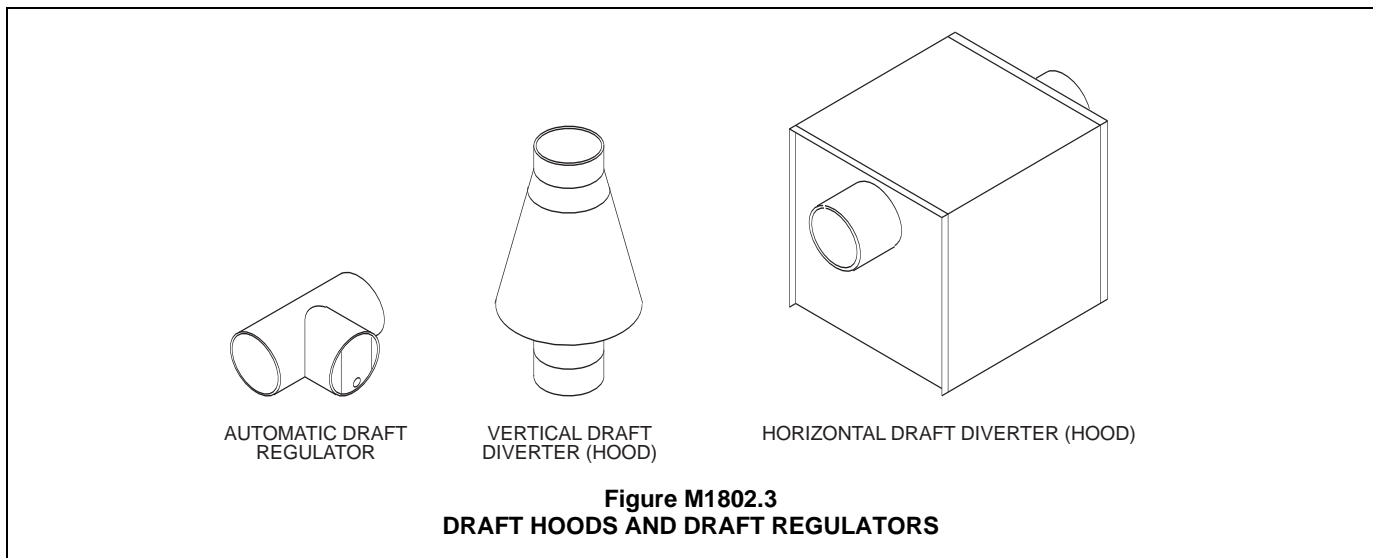

- ❖ A connector must be supported for the design and weight of the material used. Proper support is necessary to maintain the clearances required by Section M1803.3.4, to maintain the required pitch, and to prevent physical damage and separation of joints. The joints between connectors and appliance draft hood outlets and flue collars must be secured with screws, rivets or other approved means. The joints between pipe sections also must be secured with screws, rivets or other approved means. Some connectors are available with a proprietary-type fastening method. The

special proprietary joints do not require screws, rivets or other fasteners if they provide equivalent resistance to disengagement or displacement. This section addresses connectors, not chimneys and vents, and most chimney and vent manufacturers do not require or might even prohibit the use of screws or rivets for securing joints for chimney and vent pipe sections and fittings.

The ideal chimney or vent configuration is a vertical system, even though it is not always practical. This section requires all portions of a chimney or vent connector to rise vertically a minimum $\frac{1}{4}$ inch per each foot (0.02 mm/m) of its horizontal length. The connector slope is intended to induce the flow of flue gases by taking advantage of the natural buoyancy of the hot gases. Connector slope can promote the priming of a cold venting system and can partially compensate for short connector vertical rise.

M1803.3.1 Floor, ceiling and wall penetrations. A chimney connector or vent connector shall not pass through any floor or ceiling. A chimney connector or vent connector shall not pass through a wall or partition unless the connector is *listed* and *labeled* for wall pass-through, or is routed through a device *listed* and *labeled* for wall pass-through and is installed in accordance with the conditions of its *listing* and *label*. Connectors for oil-fired *appliances listed* and *labeled* for Type L vents, passing through walls or partitions shall be in accordance with the following:

1. Type L vent material for oil *appliances* shall be installed with not less than *listed* and *labeled* clearances to combustible material.
 2. Single-wall metal pipe shall be *guarded* by a ventilated metal thimble not less than 4 inches (102 mm) larger in diameter than the vent connector. A minimum 6 inches (152 mm) of clearance shall be maintained between the thimble and combustibles.
- ❖ Walls and partitions in dwellings are often constructed of combustible materials and must be protected from exposure to high temperatures from venting compo-

vents. Type B and Type L vents must be installed with clearances to combustibles in accordance with their listing and label. Because single-wall metal pipe does not have the insulating qualities of Type B and Type L vents, it must be installed within a ventilated metal thimble when passing through combustible walls and partitions. The thimble must be at least 4 inches (102 mm) larger in diameter than the connector. Note that this section prohibits all penetrations of ceilings and floors.

M1803.3.2 Length. The horizontal run of an uninsulated connector to a natural draft chimney shall not exceed 75 percent of the height of the vertical portion of the chimney above the connector. The horizontal run of a *listed* connector to a natural draft chimney shall not exceed 100 percent of the height of the vertical portion of the chimney above the connector.

❖ The appliance and its chimney or vent should be located in close proximity to keep the connector length to a minimum. A connector must be limited in length because of flow resistance of the connector and heat loss through the connector wall. A listed connector is assumed to be an air insulated double-wall type, therefore a longer length is permitted because it will help maintain sufficiently high vent gas temperatures to produce draft.

M1803.3.3 Size. A connector shall not be smaller than the flue collar of the *appliance*.

Exception: Where installed in accordance with the *appliance* manufacturer's instructions.

❖ Unless otherwise specified in the manufacturer's instructions, the size of the connector must be at least equal to the diameter of the appliance flue collar. A lesser size could restrict the flow of flue gases and result in spillage of flue gases into the dwelling.

M1803.3.4 Clearance. Connectors shall be installed with clearance to combustibles as set forth in Table M1803.3.4. Reduced clearances to combustible materials shall be in accordance with Table M1306.2 and Figure M1306.1.

❖ Connectors, vents and chimneys must be installed with minimum clearances to combustibles. These clearances can be reduced if the combustible material is protected by one of the methods of protection given in Table M1306.2. The clearance requirements in Table M1803.3.4 apply to unlabeled single-wall connectors serving a listed appliance. Connectors that are listed and labeled must be installed with the clearance to combustibles required by the connector manufacturer's installation instructions. If the appliance or connector manufacturer's installation instructions specify larger clearances than those prescribed by this section, the manufacturer's installation instructions govern.

**TABLE M1803.3.4
CHIMNEY AND VENT CONNECTOR CLEARANCES
TO COMBUSTIBLE MATERIALS^a**

TYPE OF CONNECTOR	MINIMUM CLEARANCE (inches)
Single-wall metal pipe connectors: Oil and solid-fuel appliances Oil appliances listed for use with Type L vents	18 9
Type L vent piping connectors: Oil and solid-fuel appliances Oil appliances listed for use with Type L vents	9 3 ^b

For SI: 1 inch = 25.4 mm.

- These minimum clearances apply to unlisted single-wall chimney and vent connectors. Reduction of required clearances is permitted as in Table M1306.2.
- Where listed Type L vent piping is used, the clearance shall be in accordance with the vent listing.

M1803.3.5 Access. The entire length of a connector shall be accessible for inspection, cleaning and replacement.

❖ Because connectors are exposed to high temperatures and possible condensation, the entire length of the connector must be accessible to allow observation of any degradation of the connector or lack of clearances and to allow replacement.

M1803.4 Connection to fireplace flue. Connection of *appliances* to chimney flues serving fireplaces shall comply with Sections M1803.4.1 through M1803.4.4.

❖ This section regulates installations where fireplace chimneys are used to vent appliances, such as room heaters and fireplace-insert heaters.

M1803.4.1 Closure and accessibility. A noncombustible seal shall be provided below the point of connection to prevent entry of room air into the flue. Means shall be provided for access to the flue for inspection and cleaning.

❖ Without an air-tight connection between the chimney flue and the appliance chimney connector, chimney draft will draw room air into the flue, thus weakening the draft drawn through the appliance. Because the chimney flue is no longer open to the fireplace firebox, the chimney connection must be designed to provide access to the chimney for inspection and cleaning.

M1803.4.2 Connection to factory-built fireplace flue. A different *appliance* shall not be connected to a flue serving a factory-built fireplace unless the *appliance* is specifically *listed* for such an installation. The connection shall be made in conformance with the *appliance* manufacturer's instructions.

❖ Factory-built fireplaces may or may not be tested for uses other than as a traditional fire-place. Connecting an appliance or fireplace-insert heater could result in abnormally high fire-place or chimney temperatures, leading to component deterioration and hazardous

operation. The fireplace manufacturer will provide specific details stating what appliance connections are allowed. Usually, the manufacturer's instructions will prohibit any modifications and any use of the fireplace other than that for which it was designed.

M1803.4.3 Connection to masonry fireplace flue. A connector shall extend from the *appliance* to the flue serving a masonry fireplace to convey the flue gases directly into the flue. The connector shall be accessible or removable for inspection and cleaning of both the connector and the flue. *Listed* direct-connection devices shall be installed in accordance with their *listing*.

- ❖ The appliance chimney connector must extend up through the fireplace damper and smoke chamber and terminate in the chimney flue. This helps produce an adequate draft and reduces the possibility of combustible creosote deposits forming within the fireplace throat and smoke chamber.

M1803.4.4 Size of flue. The size of the fireplace flue shall be in accordance with Section M1805.3.1.

- ❖ The size of the connector must be equal to the diameter of the appliance to prevent a restriction in the flow of the flue gases. See the commentary to Section M1805.3.1.

**SECTION M1804
VENTS**

M1804.1 Type of vent required. *Appliances* shall be provided with a *listed* and *labeled* venting system as set forth in Table M1804.1.

- ❖ Vents and chimneys are distinct systems. The provisions of this section apply only to vents. The vents addressed in this section are natural draft venting systems that produce draft using the same principles that produce draft in chimneys.

Vents regulated by this section are factory fabricated and must be listed and labeled. The labeling requirement applies to all components of the system, including the sections of pipe, fittings, terminal caps, supports and spacers.

A vent system can be used only with oil-burning and pellet-burning appliances that are listed and labeled for use with a vent. Solid-fuel-burning appliances must not be connected to a vent system, because such appliances produce flue gas temperatures that are much higher than the temperatures for which vents are designed. The burning of solid fuels also produces creosote. Creosote formation leaves a combustible deposit on the surface of the flue passageway that, if ignited, can produce a fire with temperatures higher than 2,000°F (1093°C). Such temperatures far exceed the maximum safe temperature of a vent system.

Type L vents and pellet vents must be tested in accordance with UL 641 and are designed to vent oil-burning and pellet-fuel-burning appliances. Oil-burning appliances produce a higher flue gas temperature than gas-fired appliances. Type L vents are typically double-

wall, air-insulated vent piping systems constructed of galvanized and stainless steel. They are designed for natural draft applications only and must not be used to convey combustion gases under a positive pressure. For example, a Type L vent must not be used with Category III or IV gas-fired appliances and must not be used on the discharge side of an exhaustor or power-vented appliance. Positive pressures will cause a Type L vent to leak combustion gases into the building, and the leakage can cause condensation to form within the vent system pipe, fittings and joints, resulting in corrosion damage to the vent and eventual vent failure.

**TABLE M1804.1
VENT SELECTION CHART**

VENT TYPES	APPLIANCE TYPES
Type L oil vents	Oil-burning appliances listed and labeled for venting with Type L vents
Pellet vents	Pellet fuel-burning appliances listed and labeled for use with pellet vents

M1804.2 Termination. Vent termination shall comply with Sections M1804.2.1 through M1804.2.6.

- ❖ The standards for vents and appliances require that venting instructions be supplied by the manufacturer of the appliance and the manufacturer of the vent system. Such instructions are part of the labeling requirements. Any deviation from them is a violation of the code.

The clearance to combustibles for a vent system is determined by the testing agency and stated on the component labels and in the manufacturer's instructions. Not all vents have the same required clearances to combustibles. The clearances are determined by vent performance during testing in accordance with the applicable standard. Different vent materials and designs impact the vent's ability to control the amount of heat transmitted to surrounding combustibles. Installation of the vent system in accordance with the clearances listed on the vent's label and in the manufacturer's installation instructions is critical.

The termination of a natural draft vent must comply with the requirements of the manufacturer's installation instructions and Sections M1804.2.1 through M1804.2.5. A vent used in conjunction with a mechanical exhaustor must meet the termination requirements established in Section M1804.2.6.

The vent system must be physically protected to prevent damage to the vent and to prevent combustibles from coming into contact with or being placed too close to the vents. This protection is usually provided by enclosing the vent in chases, shafts or cavities during building construction. Physical protection is not required in the room or space where the vent originates (at the appliance connection) and is not required in such locations as attics that are not occupied or used for storage. For example, assume that a vent is installed in an existing building and that it extends from the basement, through a first-floor closet, through the attic and through the roof. The portion of the vent passing through the closet must be protected from damage.

The means of physical damage protection must also be designed to maintain separation between the vent and any combustible storage. To prevent the passage of fire and smoke through the annular space around a vent penetration through a floor or ceiling, the vent must be fireblocked with a noncombustible material in accordance with the code. Vent manufacturers provide factory-built components and installation instructions for fireblocking penetrations.

M1804.2.1 Through the roof. Vents passing through a roof shall extend through flashing and terminate in accordance with the manufacturer’s installation requirements.

- ❖ Manufacturers’ installation instructions contain the requirements for the termination of vents through the roof (see Commentary Figure M1804.2.1).

M1804.2.2 Decorative shrouds. Decorative shrouds shall not be installed at the termination of vents except where the shrouds are *listed* and *labeled* for use with the specific venting system and are installed in accordance with the manufacturer’s instructions.

- ❖ Decorative shrouds have become a popular architectural feature that, in some cases, have proven to be a

fire hazard. They are designed to be aesthetically pleasing and to hide chimney and vent terminations. These shrouds have caused fires resulting from overheated combustible construction and the accumulation of debris and animal nesting. Shrouds can also interfere with the function of a chimney or vent system. Shrouds are allowed only where they are listed and labeled for use with a specific factory-built chimney system. Unlisted, field-constructed shrouds are prohibited.

M1804.2.3 Natural draft appliances. Vents for natural draft *appliances* shall terminate not less than 5 feet (1524 mm) above the highest connected *appliance* outlet, and natural draft gas vents serving wall furnaces shall terminate at an elevation not less than 12 feet (3658 mm) above the bottom of the furnace.

- ❖ To develop and maintain adequate venting action (draft), the termination of gravity vents must be at least 5 feet (1524 mm) above the vent collar of the appliance and at least 12 feet (3658 mm) above the bottom of a wall furnace.

For SI: 1 degree = 0.0175 rad.

Figure M1804.2.1
VENT TERMINATION THROUGH A ROOF

M1804.2.4 Type L vent. Type L venting systems shall conform to UL 641 and shall terminate with a *listed* and *labeled* cap in accordance with the vent manufacturer's installation instructions not less than 2 feet (610 mm) above the roof and not less than 2 feet (610 mm) above any portion of the building within 10 feet (3048 mm).

- ❖ The termination heights are consistent with the requirements of NFPA 31.

Consideration must be given to vent location in the design/installation phase of a building so that the vent termination will not require long extensions of vent pipe exposed to the outdoors. Vent piping exposed to the outdoors encourages condensation in cold weather, could require guy wires or braces depending on height, and is considered aesthetically unattractive. Another good reason to plan for vent location during the design phase of a building is to allow straight vertical runs of vent and avoid difficult offsets. Good planning can also prevent vents from passing through the roof on the street side of the building. Quite often, difficult vent offsets in attics are needed for vents to penetrate the roof on the back side of a building.

M1804.2.5 Direct vent terminations. Vent terminals for direct-vent *appliances* shall be installed in accordance with the manufacturer's instructions.

- ❖ Direct-vent appliances include appliances that have a closed combustion chamber and a conduit for bringing all combustion air directly from the outdoors. Direct-vent appliances are often referred to as "sealed combustion" or "separated combustion" appliances.

The code does not provide prescriptive termination requirements for these appliances and relies on the manufacturer's installation instructions.

M1804.2.6 Mechanical draft systems. Mechanical draft systems shall comply with UL 378 and shall be installed in accordance with their *listing*, the manufacturer's instructions and, except for direct-vent *appliances*, the following requirements:

1. The vent terminal shall be located not less than 3 feet (914 mm) above a forced air inlet located within 10 feet (3048 mm).
2. The vent terminal shall be located not less than 4 feet (1219 mm) below, 4 feet (1219 mm) horizontally from, or 1 foot (305 mm) above any door, window or gravity air inlet into a *dwelling*.
3. The vent termination point shall be located not closer than 3 feet (914 mm) to an interior corner formed by two walls perpendicular to each other.
4. The bottom of the vent terminal shall be located not less than 12 inches (305 mm) above finished ground level.
5. The vent termination shall not be mounted directly above or within 3 feet (914 mm) horizontally of an oil tank vent or gas meter.

6. Power exhauster terminations shall be located not less than 10 feet (3048 mm) from *lot lines* and adjacent buildings.

7. The discharge shall be directed away from the building.

- ❖ Mechanical draft systems must be listed to UL 378 which contains a comprehensive set of construction and performance requirements that are used to evaluate and list draft equipment. The appliance installations addressed in this section use auxiliary or integral fans and blowers to force the flow of combustion products to the outdoors. This section applies to nonintegral power exhausters, integrally power-exhausted appliances, and venting systems equipped with draft inducers. This section does not address direct-vent appliances.

The seven requirements in this section provide guidance in locating the vent terminal to prevent drawing the vented products of combustion back into the building and creating a hazardous condition.

M1804.3 Installation. Type L and pellet vents shall be installed in accordance with the terms of their *listing* and *label* and the manufacturer's instructions.

- ❖ The standards for vents and appliances require that venting instructions be supplied by the manufacturer of the appliance and the manufacturer of the vent system. Such instructions are part of the labeling requirements. Any deviation from them is a violation of the code.

The clearance to combustibles for a vent system is determined by the testing agency and stated on the component labels and in the manufacturer's instructions. Not all vents have the same required clearances to combustibles. The clearances are determined by vent performance during the testing in accordance with the applicable standard. Different vent materials and designs impact the vent's ability to control the amount of heat transmitted to surrounding combustibles. Installation of the vent system in accordance with the clearances listed on the vent's label and in the manufacturer's installation instructions is critical.

Physical protection of the vent system is required to prevent damage to the vent and to prevent combustibles from coming into contact with or being placed too close to the vents. This protection is typically provided by enclosing the vent in chases, shafts or cavities in the building construction. Physical protection is not required in the room or space where the vent originates (at the appliance connection) and would not be required in locations such as attics that are not occupied or used for storage. For example, assume that a vent is installed in an existing building and that it extends from the basement, through a first-floor closet, through the attic and through the roof. The portion of the vent passing through the closet must be protected from damage. The means of physical damage protection must also be designed to maintain separation between the vent and any combustible storage. To

prevent the passage of fire and smoke through annular space around a vent penetration through a floor or ceiling, the vent must be fireblocked with a noncombustible material in accordance with the code. Vent manufacturers provide installation instructions and factory-built components for fireblocking penetrations.

M1804.3.1 Size of single-appliance venting systems. An individual vent for a single *appliance* shall have a cross-sectional area equal to or greater than the area of the connector to the *appliance*, but not less than 7 square inches (4515 mm²) except where the vent is an integral part of a *listed* and *labeled appliance*.

❖ This section sets the minimum vent area allowed on gravity vent appliances at 7 square inches (4515 mm²) [which calculates to a minimum 3-inch (76 mm) diameter vent]. Obviously, if the vent is an integral part of the listed appliance, lesser sizes may be accepted. Section M1803.3.3 requires that the size of the vent or connector be not less than the appliance flue collar. Therefore, when the appliance flue collar is larger than 3 inches (76 mm) in diameter, the connector and vent must be increased in size accordingly.

M1804.4 Door swing. Appliance and equipment vent terminals shall be located such that doors cannot swing within 12 inches (305 mm) horizontally of the vent terminals. Door stops or closers shall not be installed to obtain this clearance.

❖ Vent terminals for sidewall-vented appliances (such as direct-vent gas fireplaces and fireplace heaters, direct-vent room heaters, direct-vent water heaters, furnaces and boilers and also nondirect-vent appliances) are sometimes located where a side-swinging door can impact the vent terminal or swing close to the terminal. The results can be damage to the vent terminal, a fire hazard and interference with the appliance venting and combustion air intake. Also, if the door blocks or deflects the vent discharge such that the combustion products are pulled back into the combustion air intake, the result would be excessive CO production and serious appliance malfunction and sooting.

A damaged vent terminal could cause appliance malfunction and carbon monoxide poisoning. It could also cause damage to nearby combustible surfaces and create a fire hazard. Door stops and closer devices cannot be depended on because they are easily defeated or removed [see Commentary Figures G1804.4(1) and G1804.4(2)].

Figure G1804.4(2)
DOOR SWING

SECTION M1805 MASONRY AND FACTORY-BUILT CHIMNEYS

M1805.1 General. Masonry and factory-built chimneys shall be built and installed in accordance with Sections R1003 and R1005, respectively. Flue lining for masonry chimneys shall comply with Section R1003.11.

❖ See Sections R1003, R1003.11 and R1005.

M1805.2 Masonry chimney connection. A chimney connector shall enter a masonry chimney not less than 6 inches (152 mm) above the bottom of the chimney. Where it is not possible to locate the connector entry at least 6 inches (152 mm) above the bottom of the chimney flue, a cleanout shall be provided by installing a capped tee in the connector next to the chimney. A connector entering a masonry chimney shall extend through, but not beyond, the wall and shall be flush with the inner face of the liner. Connectors, or thimbles where used, shall be firmly cemented into the masonry.

❖ The 6-inch space below the bottom of the chimney connector serves as a trap to collect debris from within the chimney that falls into the chimney. Connectors must not extend beyond the inner face of the chimney liner to prevent complete or partial obstruction of the chimney. Connectors must be sealed and attached to the chimney to prevent leakage and dislocation of the connector.

M1805.3 Size of chimney flues. The effective area of a natural draft chimney flue for one *appliance* shall be not less than the area of the connector to the *appliance*. The area of chimney flues connected to more than one *appliance* shall be not less than the area of the largest connector plus 50 percent of the areas of additional chimney connectors.

Exception: Chimney flues serving oil-fired *appliances* sized in accordance with NFPA 31.

❖ This section requires a chimney or vent serving a single appliance to have a minimum cross-sectional area equal to the cross-sectional area of the appliance outlet connection. The maximum size of a chimney or vent is also an important design consideration. Oversized chimneys and vents can fail to produce sufficient draft and can cause condensation of the flue gases. Existing chimneys and vents might become oversized if an appliance that was previously connected is removed. In excessively large chimneys and vents, the flue gases are cooled by expansion and because of increased heat loss through the larger flue passage surface area. The cooling effect reduces the temperature differences necessary to produce draft and can cause the flue gases to reach the dew point temperature. The resulting condensation is highly corrosive and can cause deterioration of the chimney, vent, connected appliances and the building.

For connection to more than one appliance, this section requires that the area of the flue be increased by 50 percent of the area of the additional connector. The reason is based on a diversity factor arising from the fact that all appliances are not likely to be firing simultaneously at their maximum rate. Any design conflicting with the sizing criteria of this section must be considered as an engineered system. Note that this sizing rule does not apply to gas-fired appliances, however, an extremely limited version of the rule is found in Sections G2427.5.4 and G2427.6.8.1.

M1805.3.1 Size of chimney flue for solid-fuel appliance.

Except where otherwise specified in the manufacturer's installation instructions, the cross-sectional area of a flue connected to a solid-fuel-burning *appliance* shall be not less than the area of the flue collar or connector, and not larger than three times the area of the flue collar.

- ❖ So that flue gases exhaust properly, the cross-sectional area of the flue connected to a solid-fuel-burning appliance must not be less than the area of the flue collar or connector. For proper draft, and to allow the chimney to be heated sufficiently to produce and maintain this draft, this section puts a maximum size limitation on the chimney, not to exceed three times the area of the flue collar (see commentary, Section M1805.3). As with all chimneys and all vents, they can fail from being too small and from being too big. In either case, the chimney or vent can fail to convey the combustion products to the outdoors and can fail to prevent condensation damage within the chimney or vent.

Chapter 19: Special Appliances, Equipment and Systems

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter regulates the installation of fuel-burning appliances that are not covered in other chapters. Section M1901 covers the installation of and clearances to ranges and ovens. Section M1902 addresses the proper installation and controls necessary for safe operation of sauna heaters. Section M1903 addresses the testing and installation of stationary fuel cell power plants. Section M1904 directs the reader to the sections of the code and other *International Codes*® (I-Codes®) that have installation requirements for hydrogen systems.

The chapters of the code are dedicated to single sub-

jects, however, because the two subjects in this chapter do not contain the volume of text necessary to warrant individual chapters, they have been combined into a single chapter. This chapter is a collection of requirements for various appliances. The only commonality is that the subjects use energy to perform some task or function.

Purpose

This chapter provides regulations for the proper installation of ranges, ovens, fuel cells and sauna heaters. The intent is to provide a reasonable level of protection for the occupants of the dwelling.

SECTION M1901 RANGES AND OVENS

M1901.1 Clearances. Freestanding or built-in ranges shall have a vertical clearance above the cooking top of not less than 30 inches (762 mm) to unprotected combustible material. Reduced clearances are permitted in accordance with the *listing* and *labeling* of the range hoods or *appliances*. The installation of a listed and labeled cooking appliance or microwave oven over a listed and labeled cooking appliance shall be in accordance with Section M1504.1. The clearances for a domestic open-top broiler unit shall be in accordance with Section M1505.1.

❖ Freestanding and built-in ranges must be located for required clearances to unprotected combustible materials. Cooking range tops can produce intense heat. The vertical clearance called out will help prevent the ignition of any unprotected combustible materials that are commonly found in residential kitchens. A cooking appliance or microwave oven and an open top broiler unit have additional requirements found in Sections M1504.1 and M1505.1, respectively (see commentary, Sections M1503, M1507, M1504.1, M1505.1 and G2447.5).

Ducted or ductless range hoods are often installed over ranges. Note, however, that the code does not require such hoods. When installed, range hoods must conform to the manufacturer's installation instructions. Reduced clearances to these hoods are allowed if the hoods are listed and labeled for such.

M1901.2 Cooking appliances. Cooking *appliances* shall be *listed* and *labeled* for household use and shall be installed in

accordance with the manufacturer's instructions. The installation shall not interfere with *combustion air* or access for operation and servicing. Electric cooking appliances shall comply with UL 1026 or UL 858. Solid-fuel-fired fireplace stoves shall comply with UL 737.

❖ This section requires the listing and labeling of all cooking appliances and installation in accordance with the manufacturer's installation instructions. Cooking appliances listed only for commercial use must not be installed in residential kitchens. Sections G2447.2 and G2447.3 prohibit gas-fired commercial cooking appliances from being installed in dwelling units, except where the appliances are listed as both commercial and domestic (household) types. Commercial cooking appliances do not have the same safety features as residential appliances, such as push-to turn safety knobs and insulated doors. Commercial appliances allow much higher surface temperatures on the enclosure components, have higher energy output, higher effluent output and higher clearances to combustibles, all of which can be unsuitable or unsafe for domestic environments. There are cooking appliances on the market that have the size, features and appearance of commercial appliances, but they are listed for domestic/residential installation or are listed for both commercial and domestic use. The referenced standards listed contain a comprehensive set of construction and performance requirements that are used to evaluate and list cooking equipment specifically for use in dwelling units.

SECTION M1902 SAUNA HEATERS

M1902.1 Locations and protection. Sauna heaters shall be protected from accidental contact by persons with a guard of material having a low thermal conductivity, such as wood. The guard shall not have a substantial effect on the transfer of heat from the heater to the room.

- ❖ Sauna heaters produce steam by evaporating water that passes through or over a heating element. Guards must be installed around the source of steam because occupants of the space of the sauna are usually unclothed. These guards must be made of a material that has low thermal conductivity, such as wood, to protect the occupants from burns.

M1902.2 Installation. Sauna heaters shall be installed in accordance with the manufacturer's instructions. Sauna heaters shall comply with UL 875.

- ❖ Sauna heaters must be listed, labeled and installed in accordance with the manufacturer's installation instructions. The listing and label must indicate compliance with UL 875, which contains construction and performance requirements that are used to evaluate sauna heaters.

M1902.3 Combustion air. *Combustion air* and venting for a nondirect vent-type heater shall be provided in accordance with Chapters 17 and 18, respectively.

- ❖ Combustion air for fuel-burning appliances must not be taken from within the sauna room itself. Sauna rooms are usually very small, confined spaces that do not contain an adequate volume of combustion air. For other than direct vent appliances, combustion air must be supplied in accordance with Chapter 17.

M1902.4 Controls. Sauna heaters shall be equipped with a thermostat that will limit room temperature to not greater than 194°F (90°C). Where the thermostat is not an integral part of the heater, the heat-sensing element shall be located within 6 inches (152 mm) of the ceiling.

- ❖ The room must be kept at a temperature not to exceed 194°F (90°C). This temperature has been determined to be the maximum safe level, beyond which occupants can be injured. So that the thermostat will measure the highest temperature of the room and thus maintain an acceptable and safe temperature range throughout the space, the thermostat for the appliance must either be integral with the heater or be installed within the top 6 inches (76 mm) of the room.

SECTION M1903 STATIONARY FUEL CELL POWER PLANTS

M1903.1 General. Stationary fuel cell power plants having a power output not exceeding 1,000 kW, shall comply with ANSI/CSA America FC 1 and shall be installed in accordance with the manufacturer's instructions and NFPA 853.

- ❖ The private generation of electricity for commercial and residential use is an emerging technology that is expected to gain widespread acceptance as future

technological improvements result in lower costs. Fuel cells have been included in the code to provide guidance to the building community for those future installations.

The code requires that fuel cell power plants with an output of 1,000 kW or less be listed in accordance with ANSI/CSA America FC 1, and requires that the units be installed in accordance with the manufacturer's instructions and NFPA 853. NFPA 853 provides guidance on location of the power plants, fuel system supplies, ventilation and exhaust of the space containing the unit and fire protection requirements. Although fuel cell technology has been available since the 1800s, its first practical use was by NASA to generate electricity and water for the Gemini and Apollo spacecraft and the space shuttles. Because the installation of fuel cells in privately owned buildings is relatively new, the following discussion of the fuel cell process is included to provide a basic understanding of the technology.

A fuel cell is an electrochemical device that converts the chemical energy of a hydrocarbon fuel (hydrogen, natural gas, coal-bed methane, methanol, gasoline, etc.) and an oxidant (air or oxygen) into useable electricity. The fuel cell consists of a fuel electrode (anode) and an oxidant electrode (cathode) separated by an ion-conducting membrane (electrolyte). When a hydrocarbon fuel is introduced into the fuel cell, the catalyst surface of the membrane converts the hydrogen gas molecules into hydrogen ions and electrons. The hydrogen ions pass through the membrane to react with oxygen and electrons to form water as a reaction byproduct. The electrons, which cannot pass through the membrane, must travel around it through an external circuit, thereby creating direct current (dc) electricity [see Commentary Figure M1903.1(1)].

When fueled by pure hydrogen, the only byproducts of the fuel cell process are heat and water. Low levels of CO₂ are produced when other fuels are used. Unlike traditional fossil-fuel electric generating stations that burn the fuels, the electrochemical fuel cell process produces no particulate matter, nitrogen oxides or sulfur oxides.

When the waste heat is captured for use in heating water or a cogeneration process, fuel cell efficiency can reach 80 percent.

A typical fuel cell consists of three sections: a fuel processor, a fuel stack (power generator) and a power conditioner [see Commentary Figure M1903.1(2)].

The fuel processor section has two components: (1) the fuel reformer, which processes a hydrocarbon fuel, such as methane, into a hydrogen-rich formate gas and (2) a carbon monoxide cleanup system to reduce CO concentrations to acceptable levels.

The fuel cell stack consists of many individual fuel cells that operate as previously described to generate electricity and usable heat. The power output of the unit increases based on the number and arrangement of individual cells stacked in series and/or in parallel in the unit. There are several types of fuel cell technologies, including phosphoric acid (PA), molten carbonate

(MC), solid oxide (SO) and proton exchange membrane (PEM), which are named based on the type of electrolyte used in the membrane section of the cell.

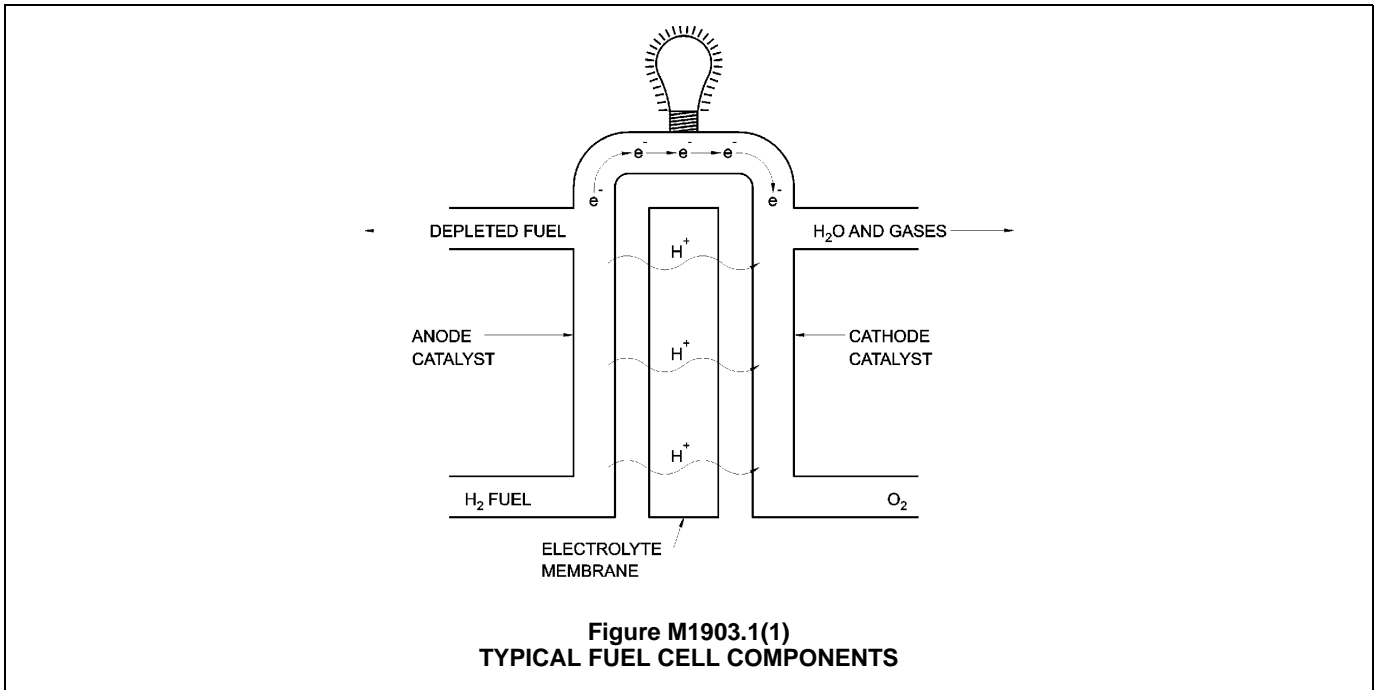

The power conditioner (inverter) section converts the direct current (dc) produced in the fuel cell stack into alternating current (ac). Batteries are used to smooth out power surge demands, such as HVAC start-ups, and to supply additional power when demand exceeds the peak out-put of the cell stack.

Although currently available, fuel cell units are not cost competitive with established electricity suppliers, but the initial and operating costs are expected to decrease as more manufacturers enter the market. Where there are constraints on transmission expansion, in remote locations or in areas where reduced emission of pollutants is critical, fuel cells could be seriously considered as an energy source. Fuel cells can also be attractive where the quality and dependability of commercial power is a concern.

**SECTION M1904
GASEOUS HYDROGEN SYSTEMS**

M1904.1 Installation. Gaseous hydrogen systems shall be installed in accordance with the applicable requirements of Sections M1307.4 and M1903.1 and the *International Fuel Gas Code*, the *International Fire Code* and the *International Building Code*.

- ❖ Systems that use or produce hydrogen gas can create potentially explosive situations where installation and ventilation instructions are not adhered to properly. Chapter 7 of the *International Fuel Gas Code*® (IFGC®) is the primary source of regulations related to gaseous hydrogen systems, but the *International Building Code*® (IBC®), the *International Fire Code*® (IFC®) and Sections M1307.4 and M1903.1 of this code also contain code requirements. Chapters 4 and 5 of the IBC state requirements for hydrogen cut-off rooms and Chapter 23 of the IFC provide requirements for hydrogen fueling stations.

Chapter 20: Boilers and Water Heaters

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter applies to all boilers and water heaters. A water heater is any appliance that heats potable water and supplies it to the plumbing hot water distribution system. However, some water heaters are also used for space heating. These are listed for combination potable water heating and space heating applications. A boiler

either heats water or generates steam for space heating and is generally a closed system.

Purpose

This chapter regulates the installation of boilers and water heaters. Its purpose is to protect the occupants of the dwelling from the potential hazards associated with such appliances.

SECTION M2001 BOILERS

M2001.1 Installation. In addition to the requirements of this code, the installation of boilers shall conform to the manufacturer's instructions. The manufacturer's rating data, the nameplate and operating instructions of a permanent type shall be attached to the boiler. Boilers shall have their controls set, adjusted and tested by the installer. A complete control diagram together with complete boiler operating instructions shall be furnished by the installer. Solid and liquid fuel-burning boilers shall be provided with *combustion air* as required by Chapter 17.

❖ This section governs the installation and commissioning of boilers and their control systems. The mechanical equipment requirements for approval, labeling, installation, maintenance, repair and alteration are regulated by Chapters 12 and 13.

A durable copy of the complete operating instructions must be attached to the boiler upon completion of installation by the contractor. Boiler systems can be complex and generally require coordinated operation among several pieces of equipment. The proper operating procedures, set points, etc., must be specified in the operating instructions. The control system design documentation in the operating instructions typically includes diagrams, system schematics and control sequence descriptions.

M2001.1.1 Standards. Packaged oil-fired boilers shall be listed and labeled in accordance with UL 726. Packaged electric boilers shall be listed and labeled in accordance with UL 834. Solid fuel-fired boilers shall be listed and labeled in accordance with UL 2523. Boilers shall be designed, constructed and certified in accordance with the ASME *Boiler and Pressure Vessel Code*, Section I or IV. Controls and safety devices for boilers with fuel input ratings of 12,500,000 Btu/hr (3 663 388 watts) or less shall meet the

requirements of ASME CSD-1. Gas-fired boilers shall conform to the requirements listed in Chapter 24.

❖ The history of boiler accidents shows that they are potentially dangerous if not properly designed, constructed and installed. Along with the code, several industry standards are referenced for the design and construction of boilers, and equipment manufacturers produce boilers in accordance with these referenced standards. The design and construction of boilers are regulated by these references. ASME CSD-1 specifies what safety devices and controls are required for boilers, such as pressure and temperature limit controls and low-water cutoffs. Design and construction requirements for specific types of boilers are found in the applicable sections of these referenced standards.

M2001.2 Clearance. Boilers shall be installed in accordance with their *listing* and *label*.

❖ Because boilers, related appliances and mechanical equipment require inspection, observation, routine maintenance, repairs and possible replacement, working clearance around such equipment and appliances is required. The manufacturer's installation instructions state the access requirements and clearances to combustibles. See Commentary Figure M2001.2 for an illustration of a typical installation.

M2001.3 Valves. Every boiler or modular boiler shall have a shutoff valve in the supply and return piping. For multiple boiler or multiple modular boiler installations, each boiler or modular boiler shall have individual shutoff valves in the supply and return piping.

Exception: Shutoff valves are not required in a system having a single low-pressure steam boiler.

❖ Shutoff valves are required to facilitate maintenance and repairs by isolating a boiler from the system that it serves. Without isolation valves, the entire system of

piping and components would have to be taken out of service, relieved of pressure and drained before a boiler or water-side/steam-side component could be removed for servicing, repair or replacement. Where systems have multiple boilers, isolation valves permit one or more boilers to be removed from service without affecting the remaining units, thus preserving partial system operation. A modular boiler unit is a field-assembled boiler composed of multiple interdependent modules. Modular units are designed to permit close matching of boiler capacity to building loads and to allow for future expansion of capacity by the addition of modules to a boiler "package." Each independent boiler or modular boiler, whether single or in groups, must have individual shutoff valves (see Commentary Figure M2001.3).

The exception states that shutoff valves are not required for systems with a single low-pressure steam boiler. Shutoff valves would not be of value for a single

low-pressure steam boiler installation because of a negligible amount of heat transfer medium to relieve from the system. Also, maintaining a partial capacity system operation is impossible with only a single unit.

M2001.4 Flood-resistant installation. In flood hazard areas established in Table R301.2(1), boilers, water heaters and their control systems shall be located or installed in accordance with Section R322.1.6.

❖ The local jurisdiction must fill in Table R301.2(1) upon adoption of the code, including the flood hazards information. Boilers, water heaters and associated control systems that are located in flood hazard areas must be installed above the design flood elevation or must be designed and installed to prevent the entrance of water into the components and to resist the forces of the flood waters on the components (see commentary, Section R322.1.6).

**SECTION M2002
OPERATING AND SAFETY CONTROLS**

M2002.1 Safety controls. Electrical and mechanical operating and safety controls for boilers shall be *listed* and *labeled*.

❖ This section requires the listing and labeling of electrical and mechanical operating and safety controls to help ensure their safety and dependability.

M2002.2 Hot water boiler gauges. Every hot water boiler shall have a pressure gauge and a temperature gauge, or combination pressure and temperature gauge. The gauges shall indicate the temperature and pressure within the normal range of the system's operation.

❖ All boilers operate within certain pressure and temperature limitations. Problems and hazards can develop if these limitations are exceeded. Pressure and temperature gauges are necessary to allow boiler owners and service technicians to check and monitor system operating conditions. Gauges indicate hazardous conditions and causes of problems or malfunctions. They also help prevent future hazards or problems from developing by signaling the need for system repairs and service. To allow reasonably accurate readings, gauges must have a range and scale of values that are proportioned to the boiler's normal operating range. For example, a pressure gauge with a range of 0 to 250 psi (0 to 1724 kPa) would barely deflect the needle when installed on a 10-psi (69 kPa) system, and pressure readings are inaccurate and not readily discerned at the extreme ends of a gauge's range. The gauges must have the resolution and increments to allow an accurate reading to be taken. Hot water boiler gauges are often equipped with combina-

tion pressure and temperature gauges (see Commentary Figure M2002.2).

M2002.3 Steam boiler gauges. Every steam boiler shall have a water-gauge glass and a pressure gauge. The pressure gauge shall indicate the pressure within the normal range of the system's operation. The gauge glass shall be installed so that the midpoint is at the normal water level.

❖ All steam boilers operate within certain pressure and water level limits that must be observed. However, unlike with hot water boilers, water temperature is not a concern for steam systems. Whenever steam is present, the water temperature in a steam boiler will be a function of steam pressure and is easily determined when the steam pressure is known. A steam pressure gauge indicates both normal and abnormal operating conditions and the presence of a hazardous condition and is necessary to observe and monitor boiler opera-

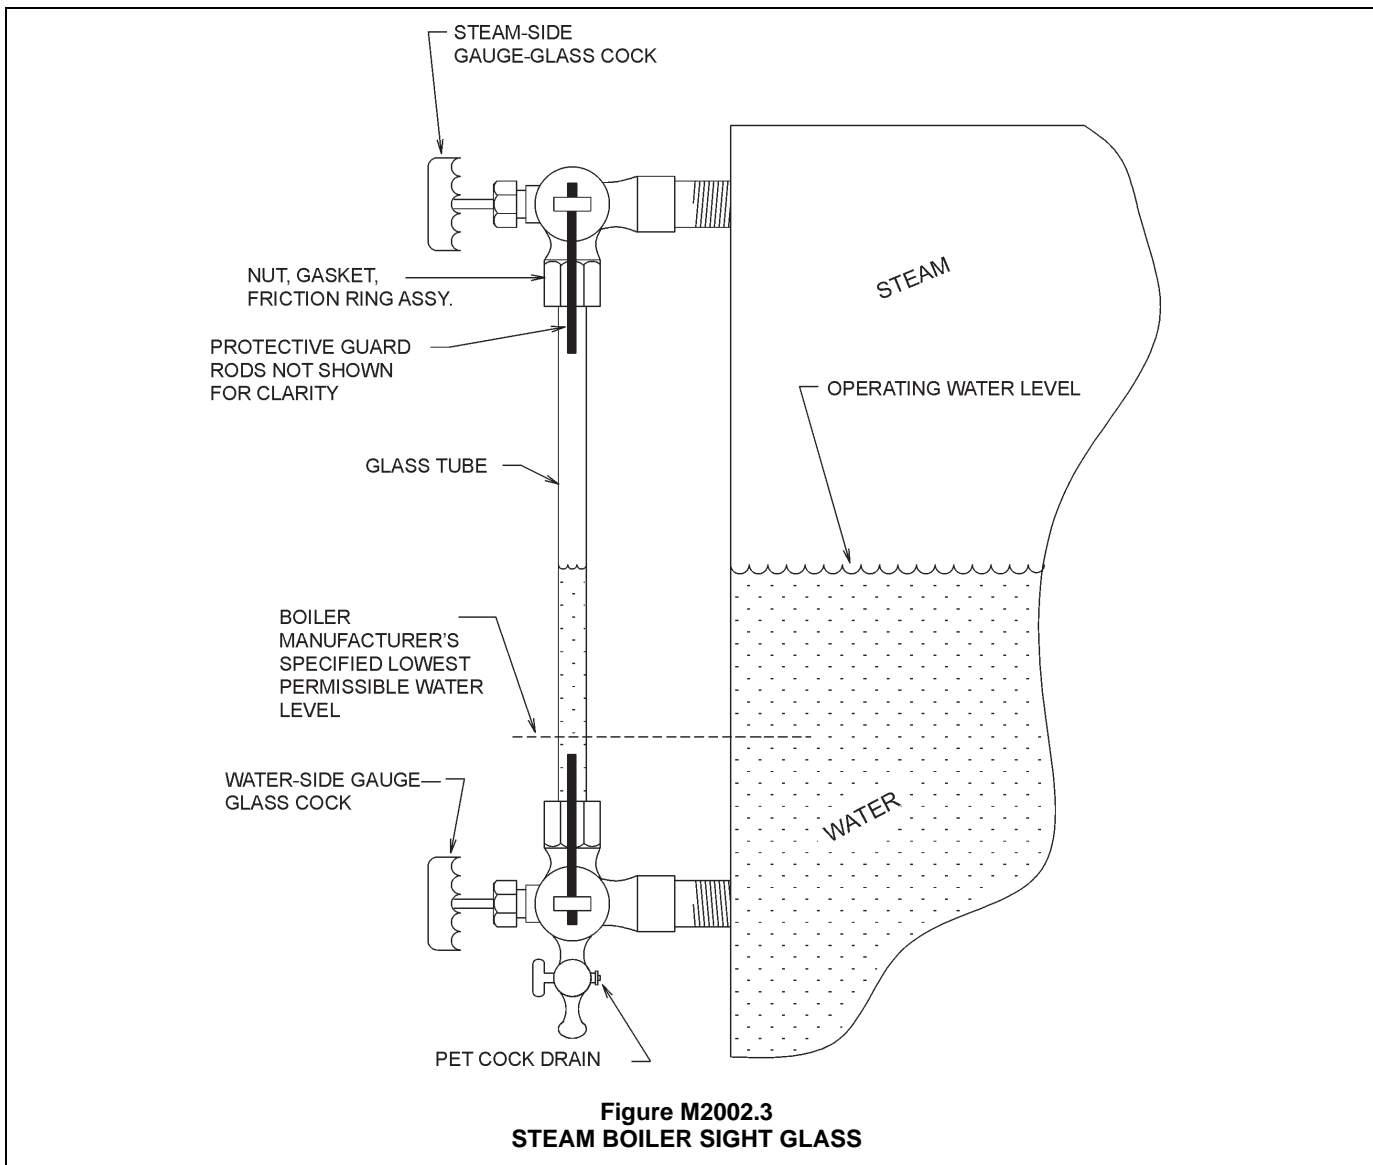

tion. The water level in a boiler fluctuates within a narrow margin between too low and too high. Because proper boiler operation is dependent on the water level being maintained within the high and low parameters, a water-gauge glass is necessary to visually indicate the actual water level in the boiler.

A water-gauge glass, commonly referred to as a “sight glass,” indicates the following: boiler flooding, low water conditions, condensate return operation, unstable water levels resulting from foaming and surging, boiler water condition and the amount of automatic or manual makeup water feed (see Commentary Figure M2002.3). If either or both of the gauge-glass cocks are closed, the water-level reading will be erroneous, and the boiler could be empty even though the gauge glass reads “normal.”

Ideally, a steam boiler pressure gauge should indicate the normal system operating pressure at approximately the first quarter to midpoint of the scale. For example, a 0 to 100 psi (0 to 690 kPa) pressure gauge

would be a very poor indicator for a low-pressure [15 psi (103 kPa) or less] steam heating boiler (see commentary, Section M2002.2). Low-pressure steam gauges are often designed to read both pressure and vacuum because some steam systems will develop a partial vacuum as steam condenses in the distribution system.

A water-gauge glass is always installed on a boiler with the bottom of the glass connected below the normal water level and the top of the glass connected above the normal water level. When connected in this manner, the boiler water level will be accurately represented in the column of water in the gauge glass. It has been an industry tradition to equate the midpoint of a gauge glass with the “normal” water level in a boiler. The coincidence of the gauge-glass mid-point and normal water level also allows the greatest amount of indicator range above and below normal, thus allowing clear indication of abnormal water levels.

**Figure M2002.3
STEAM BOILER SIGHT GLASS**

M2002.4 Pressure-relief valve. Boilers shall be equipped with pressure-relief valves with minimum rated capacities for the *equipment* served. Pressure-relief valves shall be set at the maximum rating of the boiler. Discharge shall be piped to drains by gravity to within 18 inches (457 mm) of the floor or to an open receptor.

❖ Boilers must be protected from overpressure by one or more relief valves. A relief valve is designed to open in direct proportion to the boiler pressure force acting on its closure disk. The higher the pressure, the greater the force, and the wider the valve opens. Boilers installed without a relief valve can produce devastating explosions and have been responsible for loss of life and damage to property. Relief valves also play an important role in protecting aging equipment that may have deteriorated or weakened because of prolonged use. Relief valves must be installed directly into the openings provided for that purpose by the boiler manufacturer and must be discharged to a safe location. The discharge is a threat to the occupants and the building because of the high temperature produced when the valves discharge. Because relief valve discharge is a symptom of a boiler malfunction, the discharge must be observable to provide a warning to initiate remedial action. Relief valve discharge piping must never be located where it is subject to freezing or installed in a such a way that it functions as a “trap” by allowing discharge water to remain in the pipe.

M2002.5 Boiler low-water cutoff. Steam and hot water boilers shall be protected with a low-water cutoff control.

Exception: A low-water cutoff is not required for coil-type and water-tube type boilers that require forced circulation of water through the boiler and that are protected with a flow sensing control.

❖ If a steam or hot water boiler is operated (fired) without water or with water below the minimum level, overheating and severe boiler damage can occur. In addition to damage or destruction of the boiler, a severe fire or explosion hazard can result from the overheating or failure of the combustion chamber enclosure. Burner malfunction can also occur as a result of leakage and destruction of the boiler heat exchange surfaces. The heat exchange surfaces of fuel-fired boilers absorb radiated heat from the flames and, by conduction, absorb heat from the combustion gases produced by the combustion of fuel. This heat is conducted to the water at a rate that prevents the temperature of the heat exchanger material from exceeding the maximum for which it was designed. As the water level drops in a boiler, a greater area of heat exchange surface becomes dry and thus subject to overheating. All boiler manufacturers specify and mark on the unit the minimum water level to be maintained in the boiler, below which damage would be possible. All boilers are subject to a loss of water. A leak anywhere in the piping system or in the boiler itself can result in a dangerous condition caused by water loss. This is especially true for steam boilers because they are dependent on the timely return of condensate water and the proper oper-

ation and sequencing of controls for the return and makeup water feed systems.

A low-water cutoff is an essential control device designed to prevent boiler operation when the water level is too low. Because steam boilers (as opposed to hot water boilers, which are completely filled) maintain a water level, a low-water condition is much more likely to occur in a steam system. However, the hazards resulting from low water levels are the same for both boilers. Also, a flash steam explosion can occur if makeup water is introduced into an over-heated steam or hot water boiler. For these reasons, hot water boilers are also required to be protected by a low-water cutoff control. This section requires low-water cutoffs without regard to heat energy input. Some low-water cutoff controls are intended to be field installed as part of the boiler “trim” (appurtenances), and others are factory installed directly into tapped openings provided on the boiler.

Traditional low-water cutoff controls use float-actuated mechanisms. Electronic probe-type controls, which are commonly used for hot water boiler protection, detect the water level with an electrode that relies on the slight conductivity of the boiler water to complete a relay circuit (see Commentary Figure M2002.5). In the case of coil-type (water-tube) boilers requiring forced circulation to prevent coil or tube overheating, a flow-sensing device, which detects flow and verifies that the boiler and system are full of water, is required. Low-water cutoff controls do not sense flow and, therefore, cannot protect a forced circulation coil-type/water-tube boiler from overheating caused by loss of circulation.

Photo courtesy of the Hydro Level Company

Figure M2002.5
BOILER LOW-WATER CUTOFF CONTROL DEVICE

Electric boilers are generally protected with factory-installed water-level sensing devices to prevent heating element failure, which could occur if the elements were not submerged.

The sole purpose of a low-water cutoff control is to stop (cut off) the heat input to the boiler whenever the water level is dangerously low. These devices automatically interrupt the power supply to the burner controls or heating elements to cause boiler shutdown. For forced-circulation boilers, such as hot water, water-tube-type boilers, the flow-sensing control must shut off the energy input when circulation has stopped or is less than the required flow rate as established by the manufacturer of the boiler.

M2002.6 Operation. Low-water cutoff controls and flow sensing controls required by Section M2002.5 shall automatically stop the combustion operation of the appliance when the water level drops below the lowest safe water level as established by the manufacturer or when the water circulation flow is less than that required for safe operation of the appliance, respectively.

❖ See the commentary to Section M2002.5.

**SECTION M2003
EXPANSION TANKS**

M2003.1 General. Hot water boilers shall be provided with expansion tanks. Nonpressurized expansion tanks shall be securely fastened to the structure or boiler and supported to carry twice the weight of the tank filled with water. Provisions shall be made for draining nonpressurized tanks without emptying the system.

❖ Hot water heating systems are closed systems that are completely filled with water. When the water is heated, it expands and, because it is in a closed system, quickly develops hydrostatic pressure. Expansion tanks are used to absorb additional system water volume caused by expansion, thus avoiding wide variation in system pressure and possible discharge of pressure relief valves. Expansion tanks are either open tank reservoirs (nonpressurized) or sealed vessels (pressurized).

M2003.1.1 Pressurized expansion tanks. Pressurized expansion tanks shall be consistent with the volume and capacity of the system. Tanks shall be capable of withstanding a hydrostatic test pressure of two and one-half times the allowable working pressure of the system.

❖ Because they are subjected to the same pressures as the boiler system, closed-type expansion tanks must have a pressure rating equal to or exceeding that of the boiler system operating pressure. The code requires that pressurized tanks withstand a hydrostatic test pressure of 2½ times the allowable working pressure of the system. Closed-type expansion tanks contain a cushion of air that compresses as water expands into the tank. The pressure in a hot water system will increase several pounds per square inch as the temperature increases. However, the compression of the

air in a properly sized expansion tank will prevent the pressure from exceeding the maximum system operating pressure. Open-type expansion tanks are elevated reservoirs holding the expanded hot water at atmospheric pressure.

M2003.2 Minimum capacity. The minimum capacity of expansion tanks shall be determined from Table M2003.2.

❖ The capacity of nonpressurized and pressurized expansion tanks is very important to the proper operation of the boiler system. Refer to the table showing minimum capacities of expansion tanks as they relate to the hot water system volume. Note that the system volume in gallons includes the volume of the water in the boiler, piping, radiators and convectors. The volume of expansion tanks is not included in the system volume.

**TABLE M2003.2
EXPANSION TANK MINIMUM CAPACITY^a
FOR FORCED HOT-WATER SYSTEMS**

SYSTEM VOLUME ^b (gallons)	PRESSURIZED DIAPHRAGM TYPE	NONPRESSURIZED TYPE
10	1.0	1.5
20	1.5	3.0
30	2.5	4.5
40	3.0	6.0
50	4.0	7.5
60	5.0	9.0
70	6.0	10.5
80	6.5	12.0
90	7.5	13.5
100	8.0	15.0

For SI: 1 gallon = 3.785 L, 1 pound per square inch gauge = 6.895 kPa, °C = [(°F)-32]/1.8.

- a. Based on average water temperature of 195°F (91°C), fill pressure of 12 psig and a maximum operating pressure of 30 psig.
- b. System volume includes volume of water in boiler, convectors and piping, not including the expansion tank.

❖ This table gives the minimum capacities of two types of expansion tanks. One is the pressurized diaphragm type, which is described in Section M2003.1.1. The other is the nonpressurized type. The capacities of the tanks vary depending on the volume of the system under consideration.

**SECTION M2004
WATER HEATERS USED FOR SPACE HEATING**

M2004.1 General. Water heaters used to supply both potable hot water and hot water for space heating shall be installed in accordance with this chapter, Chapter 24, Chapter 28 and the manufacturer’s instructions.

❖ Water heaters serving the dual purpose of supplying potable hot water and being a heat source for a hot water space-heating system must be listed and labeled for that dual application. This section does not address water heaters used solely for space-heating applications, but rather addresses water heaters that

serve a primary purpose of domestic water heating and a secondary purpose of space heating. Water heater labels indicate whether or not the appliance is suitable for space heating. Water heaters are listed and labeled as water heaters which are defined in Chapter 2. A water heater used solely for space heating applications would not meet the definition of a water heater and would likely violate the conditions of its listing.

Chapter 28 contains additional requirements for the proper installation of such water heaters.

SECTION M2005 WATER HEATERS

M2005.1 General. Water heaters shall be installed in accordance with Chapter 28, the manufacturer's instructions and the requirements of this code. Water heaters installed in an attic shall comply with the requirements of Section M1305.1.3. Gas-fired water heaters shall comply with the requirements in Chapter 24. Domestic electric water heaters shall comply with UL 174. Oiled-fired water heaters shall comply with UL 732. Thermal solar water heaters shall comply with Chapter 23 and UL 174. Solid fuel-fired water heaters shall comply with UL 2523.

❖ This section recognizes that water heaters and hot water storage tanks must be considered as both mechanical appliances (equipment) and plumbing appliances; therefore, they must comply with both the mechanical and plumbing sections of this code. Manufacturer's installation instructions are thoroughly evaluated by the listing and labeling agency to establish that a safe installation is prescribed. The listing and labeling agency can require the manufacturer to alter, delete or add information in the installation instructions as necessary to achieve compliance with the applicable standards and code requirements.

When a water heater is tested to obtain a listing and label, the approved agency installs the water heater in accordance with the manufacturer's installation instructions. The water heater is then tested under these conditions; thus, the installation instructions become an integral part of the listing and labeling process.

The manufacturer's installation instructions must be available to the code official because they are an enforceable extension of the code and are necessary for determining that the water heater has been properly installed. Simply put, the listing and labeling process indicates that the water heater and its installation instructions are in compliance with applicable standards. Therefore, an installation in accordance with the manufacturer's installation instructions is required, except where the code requirements are more stringent. It is necessary for an inspector to carefully and completely read and comprehend the manufacturer's instructions in order to properly perform an installation inspection.

Even if an installation appears to be in compliance with the manufacturer's instructions, the installation cannot be complete or approved until all associated components, connections and systems that serve the water heater are also in compliance with the applicable code provisions.

A water heater installation is complex in that it has a fuel or power supply; a chimney or vent connection, if fuel fired; a combustion air supply, if fuel fired; connections to the plumbing potable water distribution system; and controls and devices to prevent a multitude of potential hazards from conditions such as excessively high temperatures, pressures and ignition failure. In addition to the requirements of Section M1305.1.3, the structural provisions of the code must be observed for attic installations because of the large point load contributed by the water heater. The typical 40-gallon water heater will weigh over 400 pounds when filled with water.

M2005.2 Prohibited locations. Fuel-fired water heaters shall not be installed in a room used as a storage closet. Water heaters located in a bedroom or bathroom shall be installed in a sealed enclosure so that *combustion air* will not be taken from the living space. Installation of direct-vent water heaters within an enclosure is not required.

❖ The intent of this section is to prevent fuel-fired appliances from being installed in rooms and spaces where the combustion process could pose a threat to the occupants. Potential threats include depleted oxygen levels; elevated levels of carbon dioxide, nitrogen oxides and carbon monoxide, and other combustion gases; ignition of combustibles; and elevated levels of flammable vapors. See Section G2406.2 for the same concerns regarding gas-fired water heaters.

In small rooms such as bedrooms and bathrooms, the doors are usually closed when the room is occupied, and combustion gases could build up to life-threatening levels. Occupants would not be aware of impending danger. The last sentence of this section relates only to the second sentence.

M2005.2.1 Water heater access. Access to water heaters that are located in an *attic* or underfloor crawl space is permitted to be through a closet located in a sleeping room or bathroom where *ventilation* of those spaces is in accordance with this code.

❖ Mechanical equipment and appliances require regular maintenance. Proper access to enable repairs or replacement of equipment is a must. See Sections M2005.2 and G2406.2.

All water heaters have a far shorter working life than the building in which they are located; therefore, they must be replaced one or more times during the lifetime of the building. This future need has often been overlooked, and water heaters have been installed in locations that would necessitate the dismantling or destruction of a permanent portion of the structure to install a new water heater.

BOILERS AND WATER HEATERS

M2005.3 Electric water heaters. Electric water heaters shall also be installed in accordance with the applicable provisions of Chapters 34 through 43.

- ❖ This section refers the user back to the electrical chapters in the code for electric water heaters.

M2005.4 Supplemental water-heating devices. Potable water heating devices that use refrigerant-to-water heat exchangers shall be *approved* and installed in accordance with the manufacturer's instructions.

- ❖ Waste heat from refrigeration systems can be used to heat potable water and can provide substantial energy savings overtime. This section allows the use of such systems if the equipment is approved and installed in accordance with the manufacturer's installation instructions. Heat pump water heaters are becoming more common and provide a high coefficient of performance and also provide the beneficial side effect of free space cooling in the location of the heat pump appliance.

SECTION M2006 POOL HEATERS

M2006.1 General. Pool and spa heaters shall be installed in accordance with the manufacturer's installation instructions. Oil-fired pool heaters shall comply with UL 726. Electric pool and spa heaters shall comply with UL 1261.

- ❖ This section addresses specialized types of water heaters used with swimming pools, recreational or therapeutic spas and hot tubs. Pool and spa heaters are similar in design to hot water boilers. Usually, these heaters are of the water-tube type, are open nonpressurized systems and are designed for either indoor or outdoor installation.

M2006.2 Clearances. The clearances shall not interfere with *combustion air*, draft hood or flue terminal relief, or accessibility for servicing.

- ❖ The manufacturer's installation instructions can contain recommendations that are either more or less restrictive than the code for combustion air requirements, draft hood or terminal relief and accessibility for servicing the appliance. In either case, the more restrictive requirement governs.

M2006.3 Temperature-limiting devices. Pool heaters shall have temperature-relief valves.

- ❖ Temperature relief devices must be installed on pool heaters to protect against the development of high temperatures that could cause scalding injuries. Pool heaters are defined by ANSI Z2.56 as "An appliance designed for heating non-potable water stored at atmospheric pressure, such as water in swimming pools, spas, hot tubs and similar applications." This section is not specific as to the type of pool heater, thus it would appear to apply to electric, fuel-fired and heat pump type pool heaters. The code is silent on the set-

point of the relief device, therefore such temperature needs to be approved by the code official and also be consistent with the heater manufacturer's instructions.

M2006.4 Bypass valves. Where an integral bypass system is not provided as a part of the pool heater, a bypass line and valve shall be installed between the inlet and outlet piping for use in adjusting the flow of water through the heater.

- ❖ Unless a similar system is integrated within the heater, a bypass line and valve must be installed to allow control of the flow rate of water through the heater, which in turn allows control of the temperature rise of the water circulated through the unit.

Chapter 21: Hydronic Piping

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

Hydronic piping includes piping, fittings and valves used in building space conditioning systems. Applications include hot water, chilled water, steam, steam condensate, brines and water/antifreeze mixtures. This chapter regulates installation, alteration and repair of all hydronic piping systems.

Section M2101 contains the installation requirements that apply to all hydronic systems. Section M2102 discusses baseboard convectors. Section M2103

addresses floor heating systems. Section M2104 covers low temperature piping applications. Section M2105 contains the provisions for ground source heat pump system loop piping.

Purpose

The requirements herein are intended to affect the reliability, serviceability, energy efficiency and safety of hydronic systems.

SECTION M2101 HYDRONIC PIPING SYSTEMS INSTALLATION

M2101.1 General. Hydronic piping shall conform to Table M2101.1. *Approved* piping, valves, fittings and connections shall be installed in accordance with the manufacturer's instructions. Pipe and fittings shall be rated for use at the operating temperature and pressure of the hydronic system. Used pipe, fittings, valves or other materials shall be free of foreign materials.

- ❖ Table M2101.1 lists the piping materials that are permitted for use in hydronic systems. This section does not prohibit the use of other materials that provide equivalent performance as approved by the building official. Materials that have previously been used for other than hydronic applications can contain residual contaminants that are harmful to the hydronic system. Before any used pipe, fitting, valve or other material is used, it must be examined to determine that its performance will be equivalent to that required for new materials for the intended application.

M2101.2 System drain down. Hydronic piping systems shall be installed to permit draining of the system. Where the system drains to the plumbing drainage system, the installation shall conform to the requirements of Chapters 25 through 32 of this code.

Exception: The buried portions of systems embedded underground or under floors.

- ❖ To facilitate system repairs and maintenance, hydronic piping systems must be sloped and arranged to allow the transfer-medium fluids or condensate to be drained from the system. Each trapped section of the system piping must be fitted with drain cocks, unions or some other means of opening the system for draining. Drainage discharge to the plumbing system must be by indi-

rect connection in accordance with the code.

Where portions of hydronic systems are buried below grade or installed below floors, such as a slab on grade, for which there is no access to drain piping by gravity, an exception allows those portions to not have a gravity drain point. System fluid can be removed by other means such as vacuuming or blowing out with compressed air.

M2101.3 Protection of potable water. The potable water system shall be protected from backflow in accordance with the provisions listed in Section P2902.

- ❖ Hydronic systems require means of supplying initial fill water and makeup water to replace any water lost because of evaporation, leakage or intentional draining. Where direct connections are made to the potable water supply, the connections must be isolated from the potable water source in compliance with the plumbing provisions of the code. This provision protects the potable water system from contamination where a direct connection is made to a hydronic system. Because hydronic systems are usually pressurized and can contain nonpotable water and fluids, antifreeze and conditioning or cleaning chemicals, the potable water system must be protected so that backflow does not occur.

M2101.4 Pipe penetrations. Openings through concrete or masonry building elements shall be sleeved.

- ❖ Concrete and masonry penetrations must be sleeved to protect the pipe from abrasion.

M2101.5 Contact with building material. A hydronic piping system shall not be in direct contact with any building material that causes the piping material to degrade or corrode.

- ❖ Piping must be protected to avoid external degradation resulting from corrosion, abrasion and chemical reac-

HYDRONIC PIPING

tions. Allowing the pipe to come into contact with certain materials can cause corrosion or degradation. For example, some plastic pipe materials can interact with petroleum-based materials, and concrete can be corrosive to some metals. If hydronic piping is to be installed

in an environment or soils that are corrosive, the piping must be protected. Coating, wrappings and sleeves are forms of protection for piping installed in such an environment.

TABLE M2101.1
HYDRONIC PIPING MATERIALS

MATERIAL	USE CODE ^a	STANDARD ^b	JOINTS	NOTES
Acrylonitrile butadiene styrene (ABS) plastic pipe	1, 5	ASTM D1527; ASTM F2806; ASTM F2969	Solvent cement joints	
Brass pipe	1	ASTM B43	Brazed, welded, threaded, mechanical and flanged fittings	
Brass tubing	1	ASTM B135	Brazed, soldered and mechanical fittings	
Chlorinated poly (vinyl chloride) (CPVC) pipe and tubing	1, 2, 3	ASTM D2846	Solvent cement joints, compression joints and threaded adapters	
Copper pipe	1	ASTM B42, B302	Brazed, soldered and mechanical fittings threaded, welded and flanged	
Copper tubing (type K, L or M)	1, 2	ASTM B75, B88, B251, B306	Brazed, soldered and flared mechanical fittings	Joints embedded in concrete
Cross-linked polyethylene (PEX)	1, 2, 3	ASTM F876, F877	(See PEX fittings)	Install in accordance with manufacturer's instructions
Cross-linked polyethylene/aluminum/cross-linked polyethylene-(PEX-AL-PEX) pressure pipe	1, 2	ASTM F1281 or CAN/ CSA B137.10	Mechanical, crimp/insert	Install in accordance with manufacturer's instructions
PEX fittings		ASTM F877 ASTM F1807 ASTM F1960 ASTM F2098 ASTM F2159 ASTM F2735	Copper-crimp/insert fittings, cold expansion fittings, stainless steel clamp, insert fittings	Install in accordance with manufacturer's instructions
Polybutylene (PB) pipe and tubing	1, 2, 3	ASTM D3309	Heat-fusion, crimp/insert and compression	Joints in concrete shall be heat-fused
Polyethylene/aluminum/polyethylene (PE-AL-PE) pressure pipe	1, 2, 3	ASTM F1282 CSA B 137.9	Mechanical, crimp/insert	
Polypropylene (PP)	1, 2, 3	ISO 15874 ASTM F2389	Heat-fusion joints, mechanical fittings, threaded adapters, compression joints	
Raised temperature polyethylene (PE-RT)	1, 2, 3	ASTM F2623 ASTM F2769	Copper crimp/insert fitting stainless steel clamp, insert fittings	
Raised temperature polyethylene (PE-RT) fittings	1, 2,3	ASTM F1807 ASTM F2159 ASTM F2735 ASTM F2769 ASTM F2098	Copper crimp/insert fitting stainless steel clamp, insert fittings	
Steel pipe	1, 2	ASTM A53, A106	Brazed, welded, threaded, flanged and mechanical fittings	Joints in concrete shall be welded. Galvanized pipe shall not be welded or brazed.
Steel tubing	1	ASTM A254	Mechanical fittings, welded	

For SI: °C = [(°F)-32]/1.8.

a. Use code:

1. Above ground.
2. Embedded in radiant systems.
3. Temperatures below 180°F only.
4. Low temperature (below 130°F) applications only.
5. Temperatures below 160°F only.

b. Standards as listed in Chapter 44.

M2101.6 Drilling and notching. Wood-framed structural members shall be drilled, notched or altered in accordance with the provisions of Sections R502.8, R602.6, R602.6.1 and R802.7. Holes in load bearing members of cold-formed steel light-frame construction shall be permitted only in accordance with Sections R505.2.6, R603.2.6 and R804.2.6. In accordance with the provisions of Sections R505.3.5, R603.3.4 and R804.3.3, cutting and notching of flanges and lips of load-bearing members of cold-formed steel light-frame construction shall not be permitted. Structural insulated panels (SIPs) shall be drilled and notched or altered in accordance with the provisions of Section R610.7.

❖ The code recognizes that cutting or notching framing members may sometimes be necessary. Experience and testing has shown that proper drilling and notching techniques must be followed when mechanical equipment, ducts, piping and related electrical wiring and cables are installed through framing members. Notches that are too deep or holes that are too large or too close together will significantly weaken these members. The code refers to the building chapters (Chapters 5: Floors, 6: Wall Construction, and 8: Roof/Ceiling Construction) that elaborate on such requirements and limitations. Reference to these sections is imperative for these installations so that the structure will not be weakened beyond its design parameters. This section is limited in scope to those framing members cited in the code and does not cover engineered framing members, such as trusses, laminated veneer beams and premanufactured I-joists.

M2101.7 Prohibited tee applications. Fluid in the supply side of a hydronic system shall not enter a tee fitting through the branch opening.

❖ Commentary Figure M2101.7 depicts a prohibited “bullhead” tee arrangement. Installation of such a connection creates excessive pressure drop, poor system performance and possible cavitation (air bubbles) that cause erosion of metal pipes. Supply side flow must not enter a tee from the branch opening. This section does not apply to tees in return piping arrangements because the flow entering a tee branch opening merges with the unidirectional flow in the run of the tee.

M2101.8 Expansion, contraction and settlement. Piping shall be installed so that piping, connections and equipment

shall not be subjected to excessive strains or stresses. Provisions shall be made to compensate for expansion, contraction, shrinkage and structural settlement.

❖ Changes in temperatures cause dimensional changes in all materials to varying degrees. The greatest amount of expansion and contraction in piping occurs along its length. For systems operating at high temperatures, such as steam and hot water, the amount of expansion is substantial, and significant movements can occur even in short runs of piping. Larger movements can be expected in longer lengths of piping. Accordingly, larger forces can develop in restrained piping. Piping systems must be capable of accommodating the forces resulting from thermal expansion and contraction. Inadequate provisions to accommodate these forces can result in failure of pipe and supports, joint damage and leakage.

M2101.9 Piping support. Hangers and supports shall be of material of sufficient strength to support the piping, and shall be fabricated from materials compatible with the piping material. Piping shall be supported at intervals not exceeding the spacing specified in Table M2101.9.

❖ As with all piping systems, the support of the piping is as important as any other part of the overall design. Proper supports are necessary to maintain piping alignment and slope, to support the weight of the piping and fluid within, to control movement and to resist imposed loads. Table M2101.9 provides hanger spacing intervals required for different types of piping material.

**TABLE M2101.9
HANGER SPACING INTERVALS**

PIPING MATERIAL	MAXIMUM HORIZONTAL SPACING (feet)	MAXIMUM VERTICAL SPACING (feet)
ABS	4	10 ^a
CPVC ≤ 1-inch pipe or tubing	3	5 ^a
CPVC ≥ 1¼ inches	4	10 ^a
Copper or copper alloy pipe	12	10
Copper or copper alloy tubing	6	10
PB pipe or tubing	2.67	4
PE pipe or tubing	2.67	4
PE-RT ≤ 1 inch	2.67	10 ^a
PE-RT ≥ 1¼ inches	4	10 ^a
PEX tubing	2.67	4
PP < 1-inch pipe or tubing	2.67	4
PP > 1¼ inches	4	10 ^a
PVC	4	10 ^a
Steel pipe	12	15
Steel tubing	8	10

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. For sizes 2 inches and smaller, a guide shall be installed midway between required vertical supports. Such guides shall prevent pipe movement in a direction perpendicular to the axis of the pipe.

❖ See the commentary to Section M2101.9. Note a requires a guide to be installed to prevent lateral move-

ment of vertical plastic piping. The axis of the pipe is along its length and movement perpendicular to that axis is lateral movement in a horizontal plane. Where the piping is plastic and the distance between vertical supports is allowed to be up to 10 feet, it is expected that the pipe will need the guide to maintain alignment and help prevent stress, abrasion and noise.

M2101.10 Tests. Hydronic piping systems shall be tested hydrostatically at a pressure of one and one-half times the maximum system design pressure, but not less than 100 pounds per square inch (689 kPa). The duration of each test shall be not less than 15 minutes and not more than 20 minutes.

- ❖ Hydronic piping systems must be tested to determine that the system is leak free and capable of withstanding system operating pressures. The piping under test must be isolated from any component that cannot safely tolerate the test pressure. The prescribed test pressure of 100 psi (690 kPa) will typically exceed the maximum operating pressure of boilers and related components as well as the setting of the system's pressure relief devices. The code official will normally observe required tests. Maintaining the test pressure for at least 15 minutes allows time for any leaks to be detected.

SECTION M2102 BASEBOARD CONVECTORS

M2102.1 General. Baseboard convectors shall be installed in accordance with the manufacturer's instructions. Convectors shall be supported independently of the hydronic piping.

- ❖ Convectors must be installed in accordance with the manufacturer's installation instructions. This section requires that convectors be supported independently of the hydronic piping to prevent strain on the piping system and to allow for independent expansion and contraction.

SECTION M2103 FLOOR HEATING SYSTEMS

M2103.1 Piping materials. Piping for embedment in concrete or gypsum materials shall be standard-weight steel pipe, copper and copper alloy pipe and tubing, cross-linked polyethylene/aluminum/cross-linked polyethylene (PEX-AL-PEX) pressure pipe, chlorinated polyvinyl chloride (CPVC), polybutylene, cross-linked polyethylene (PEX) tubing, polyethylene of raised temperature (PE-RT) or polypropylene (PP) with a minimum rating of 100 psi at 180°F (690 kPa at 82°C).

- ❖ Piping embedded in concrete or covered by permanent construction materials or assemblies is not accessible. Therefore, this section is more restrictive than Section M2101.1, in that it allows only specific materials for embedded hydronic piping.

M2103.2 Thermal barrier required. Radiant floor heating systems shall have a thermal barrier in accordance with Sections M2103.2.1 through M2103.2.4.

Exception: Insulation shall not be required in engineered systems where it can be demonstrated that the insulation

will decrease the efficiency or have a negative effect on the installation.

- ❖ In order for the maximum amount of heat to be transferred to the space intended to be heated, the hydronic piping system must be insulated to limit the amount of heat transferred to spaces or materials that are not intended to be heated. Sections M2103.2.1 and M2103.2.2 describe two applications where this is a concern and provides the insulation requirements.

M2103.2.1 Slab-on-grade installation. Radiant piping used in slab-on-grade applications shall have insulating materials having a minimum *R*-value of 5 installed beneath the piping.

- ❖ Typically, rigid foam board insulation is used for insulating slabs on grade that will be heated by hydronic systems. For most manufacturers of this product, an *R*-value of 5 equates to 1-inch (25 mm) material thickness. Other types of insulation products that are suitable for under-slab installation are also available and can be used if marked in accordance with Section M2103.2.4.

M2103.2.2 Suspended floor installation. In suspended floor applications, insulation shall be installed in the joist bay cavity serving the heating space above and shall consist of materials having a minimum *R*-value of 11.

- ❖ Typically, fiberglass insulation is used for insulating hydronically heated floors that are above an unheated space, such as a crawl space or basement. Insulation is placed between the joists (or floor trusses) and should be held in place.

M2103.2.3 Thermal break required. A thermal break consisting of asphalt expansion joint materials or similar insulating materials shall be provided at a point where a heated slab meets a foundation wall or other conductive slab.

- ❖ The exterior edges of heated concrete slabs must be protected against heat loss. Placement of a thermal barrier at the edge of the slab where it would contact the foundation wall breaks the heat conduction path to the exterior.

M2103.2.4 Thermal barrier material marking. Insulating materials used in thermal barriers shall be installed so that the manufacturer's *R*-value mark is readily observable upon inspection.

- ❖ Insulation materials must be marked so that the inspector can verify that the correct *R*-value is being used for the application. "Readily observable" means that the inspector will not be required to remove insulation in order to see the marking. The *R*-value marking requirement might be a problem where unfaced fiberglass insulation is used or where the facing of the fiberglass insulation is required to be located such that the marking is not observable without removal of the insulation.

M2103.3 Piping joints. Copper and copper alloy systems shall be soldered in accordance with ASTM B828. Fluxes for soldering shall be in accordance with ASTM B813. Brazing fluxes shall be in accordance with AWS A5.31. Piping joints

that are embedded shall be installed in accordance with the following requirements:

1. Steel pipe joints shall be welded.
 2. Copper tubing shall be joined by brazing complying with Section P3003.6.1.
 3. Polybutylene pipe and tubing joints shall be installed with socket-type heat-fused polybutylene fittings.
 4. CPVC tubing shall be joined using solvent cement joints.
 5. Polypropylene pipe and tubing joints shall be installed with socket-type heat-fused polypropylene fittings.
 6. Cross-linked polyethylene (PEX) tubing shall be joined using cold expansion, insert or compression fittings.
 7. Raised temperature polyethylene (PE-RT) tubing shall be joined using insert or compression fittings.
- ❖ Joints for these types of installations must be of the type that is least susceptible to failures. For that reason, steel pipe joints must be welded, copper pipe joints brazed, polypropylene heat-fused, etc.

M2103.4 Testing. Piping or tubing to be embedded shall be tested by applying a hydrostatic pressure of not less than 100 psi (690 kPa). The pressure shall be maintained for 30 minutes, during which, the joints shall be visually inspected for leaks.

- ❖ Hydronic piping systems must be tested to determine that the system is leak free and capable of withstanding the pressures to which it will be subjected. It is customary for the code official to observe required tests. This testing is especially important where the piping is to be encased and inaccessible. See Section M2101.10.

SECTION M2104 LOW TEMPERATURE PIPING

M2104.1 Piping materials. Low temperature piping for embedment in concrete or gypsum materials shall be as indicated in Table M2101.1.

- ❖ Table M2101.1 lists piping materials that can be used in low temperature piping, along with their applicable standards. This section does not prohibit the use of other approved materials that provide equivalent performance.

M2104.2 Piping joints. Piping joints, other than those in Section M2103.3, that are embedded shall comply with the following requirements:

1. Cross-linked polyethylene (PEX) tubing shall be installed in accordance with the manufacturer's instructions.
 2. Polyethylene tubing shall be installed with heat fusion joints.
 3. Polypropylene (PP) tubing shall be installed in accordance with the manufacturer's instructions.
 4. Raised temperature polyethylene (PE-RT) shall be installed in accordance with the manufacturer's instructions.
- ❖ All joining methods for PEX tubing are considered to be mechanical joints that must be installed in accor-

dance with the manufacturer's installation instructions. Polyethylene pipe and fittings are joined by heat-fusion joining methods, which provide dependability for underground piping. Embedded polypropylene tubing must be installed in accordance with the manufacturer's instructions for underground installations. Heat-fusion joining methods are considered to be highly dependable.

M2104.3 Raised temperature polyethylene (PE-RT) plastic tubing. Joints between raised temperature polyethylene tubing and fittings shall conform to Sections M2104.3.1, M2104.3.2 and M2104.3.3. Mechanical joints shall be installed in accordance with the manufacturer's instructions.

- ❖ The fitting manufacturer's installation instructions must be followed when making connections of raised temperature polyethylene (PE-RT) tubing.

M2104.3.1 Compression-type fittings. Where compression-type fittings include inserts and ferrules or O-rings, the fittings shall be installed without omitting such inserts and ferrules or O-rings.

- ❖ All parts of a fitting assembly must be utilized as intended by the manufacturer.

M2104.3.2 PE-RT-to-metal connections. Solder joints in a metal pipe shall not occur within 18 inches (457 mm) of a transition from such metal pipe to PE-RT pipe.

- ❖ The required heat for soldering fittings to copper pipe could damage the PE-RT pipe if the soldering operation was performed too close to a PE-RT-to-copper transition. This section applies to solder joints that occur in the same section of pipe as a PE-RT-to-copper transition joint.

M2104.3.3 PE-RT insert fittings. PE-RT insert fittings shall be installed in accordance with the manufacturer's instructions.

- ❖ Insert fittings are mechanical joints that involve a metal insert and a crimp ring or that involve a compression nut assembly. The piping manufacturer will specify what fittings are to be used with their product.

M2104.4 Polyethylene/Aluminum/Polyethylene (PE-AL-PE) pressure pipe. Joints between polyethylene/aluminum/polyethylene pressure pipe and fittings shall conform to Sections M2104.4.1 and M2104.4.2. Mechanical joints shall be installed in accordance with the manufacturer's instructions.

- ❖ The fitting manufacturer's installation instructions must be followed when making connections of polyethylene/aluminum/polyethylene (PE-AL-PE) tubing.

M2104.4.1 Compression-type fittings. Where compression-type fittings include inserts and ferrules or O-rings, the fittings shall be installed without omitting such inserts and ferrules or O-rings.

- ❖ All parts of a fitting assembly must be utilized as intended by the manufacturer. It is hard to imagine that an installer would purposely omit parts of a fitting assembly, but, this code text is testament to the fact that this must have been an issue for some types of fittings.

M2104.4.2 PE-AL-PE to metal connections. Solder joints in a metal pipe shall not occur within 18 inches (457 mm) of a transition from such metal pipe to PE-AL-PE pipe.

- ❖ The required heat for soldering fittings to copper pipe could damage the PE-AL-PE pipe if the soldering operation was performed too close to a PE-AL-PE-to-copper transition. This section applies to solder joints that occur in the same section of pipe as a PE-AL-PE-to-copper transition joint.

**SECTION M2105
GROUND-SOURCE HEAT-PUMP
SYSTEM LOOP PIPING**

M2105.1 Plastic ground-source heat-pump loop piping. Plastic piping and tubing material used in water-based ground-source heat-pump ground-loop systems shall conform to the standards specified in this section.

- ❖ Section M2105 applies to ground-source heat-pump loop systems, specifically, the piping for the loops. These systems are mistakenly referred to as Geo-thermal systems, but Geo-thermal systems involve underground sources of heat associated with hot springs, lava domes and other areas in the earth's crust where inner earth heat energy rises close the earth's surface. Ground-source heat-pump systems simply use the soil, water wells and surface bodies of water as a heat source and as a heat sink. See Sections M2105.4 and M2105.5.

M2105.2 Used materials. Reused pipe, fittings, valves, and other materials shall not be used in ground-source heat-pump loop systems.

- ❖ For the greatest reliability, the piping system must be constructed of new (unused) materials.

M2105.3 Material rating. Pipe and tubing shall be rated for the operating temperature and pressure of the ground-source heat-pump loop system. Fittings shall be suitable for the pressure applications and recommended by the manufacturer for installation with the pipe and tubing material installed. Where used underground, materials shall be suitable for burial.

- ❖ All materials must be rated for the pressures and temperatures to which they will be exposed. Fittings have

to be a type that is specifically recommended by the fitting manufacturer for use with the piping being installed. Components that are to be buried must be intended for burial.

M2105.4 Piping and tubing materials standards. Ground-source heat-pump ground-loop pipe and tubing shall conform to the standards listed in Table M2105.4.

- ❖ See Table M2105.4.

M2105.5 Fittings. Ground-source heat-pump pipe fittings shall be approved for installation with the piping materials to be installed, shall conform to the standards listed in Table M2105.5 and, where installed underground, shall be suitable for burial.

- ❖ See Table M2105.5.

M2105.6 Joints and connections. Joints and connections shall be of an approved type. Joints and connections shall be tight for the pressure of the ground-source loop system. Joints used underground shall be approved for such applications.

- ❖ This section requires code official approval of the types of joints and connections. Such approval would be based on the compliance with Table M2105.5, fitting manufacturer's instructions and recommendations, product literature and consideration for the conditions to which the joints and connections will be exposed.

M2105.6.1 Joints between different piping materials. Joints between different piping materials shall be made with approved transition fittings.

- ❖ See Section M2105.6.

M2105.7 Preparation of pipe ends. Pipe shall be cut square, reamed, and shall be free of burrs and obstructions. CPVC, PE and PVC pipe shall be chamfered. Pipe ends shall have full-bore openings and shall not be undercut.

- ❖ This section requires proper workmanship for preparing pipe to be joined. These requirements are very often disregarded. Cutting pipe ends squarely, deburring and chamfering are necessary to achieve a reliable joint for many reasons related to structural strength and leak-tightness. With some types of joints, it is possible to inspect for compliance, but with others, inspection is not possible without disassembling the

**TABLE M2105.4
GROUND-SOURCE LOOP PIPE**

MATERIAL	STANDARD
Chlorinated polyvinyl chloride (CPVC)	ASTM D2846; ASTM F437; ASTM F438; ASTM F439; ASTM F441; ASTM F442; CSA B137.6
Cross-linked polyethylene (PEX)	ASTM F876; ASTM F877 CSA B137.5
Polyethylene/aluminum/polyethylene (PE-AL-PE) pressure pipe	ASTM F1282; CSA B137.9; AWWA C 903
High-density polyethylene (HDPE)	ASTM D2737; ASTM D3035; ASTM F714; AWWA C901; CSA B137.1; CSA C448; NSF 358-1
Polypropylene (PP-R)	ASTM F2389; CSA B137.11
Polyvinyl chloride (PVC)	ASTM D1785; ASTM D2241; CSA 137.3
Raised temperature polyethylene (PE-RT)	ASTM F2623; ASTM F2769

joint or connection. The inspector may determine compliance by requiring a sample joint to be opened, by observing discarded parts of joints that have been removed or by interviewing the installers about their procedures. There are requirements for installation that are very difficult to inspect and this sort of difficulty has led to code requirements such as purple primer for PVC pipe joints. The purple color is used because the use of a primer cannot be visually verified without the distinguishing color.

M2105.8 Joint preparation and installation. Where required by Sections M2105.9 through M2105.11, the preparation and installation of mechanical and thermoplastic-welded joints shall comply with Sections M2105.8.1 and M2105.8.2.

❖ Some of the material specific subsections could refer back to Sections M2105.8.1 and M2105.8.2 relative to mechanical and thermoplastic welded joints where necessary. Thermoplastic welding is similar to metal welding and involves a heat source and welding rod (spline). The plastic pipe and fittings and the welding rod (spline) are heated typically by hot air and the materials fuse together.

M2105.8.1 Mechanical joints. Mechanical joints shall be installed in accordance with the manufacturer's instructions.

❖ Mechanical joints can be of many different types. See the definition of "Mechanical joint."

M2105.8.2 Thermoplastic-welded joints. Joint surfaces for thermoplastic-welded joints shall be cleaned by an approved procedure. Joints shall be welded in accordance with the manufacturer's instructions.

❖ See section M2105.8.

M2105.9 CPVC plastic pipe. Joints between CPVC plastic pipe or fittings shall be solvent-cemented in accordance with Section P2906.9.1.2. Threaded joints between fittings and CPVC plastic pipe shall be in accordance with Section M2105.9.1.

❖ See Sections M2105.9.1 and P2906.9.1.2.

M2105.9.1 Threaded joints. Threads shall conform to ASME B1.20.1. The pipe shall be Schedule 80 or heavier plastic pipe and shall be threaded with dies specifically designed for plastic pipe. Thread lubricant, pipe-joint compound or tape shall be applied on the male threads only and shall be approved for application on the piping material.

❖ Schedule 40 pipe cannot be threaded because the pipe wall is too thin to provide the necessary strength. It is very important to make sure that pipe thread compounds (pipe dope) are compatible with the pipe material. Some compounds can degrade plastic piping.

M2105.10 Cross-linked polyethylene (PEX) plastic tubing. Joints between cross-linked polyethylene plastic tubing and fittings shall comply with Sections M2105.10.1 and M2105.10.2. Mechanical joints shall comply with Section M2105.8.1.

❖ See Sections M2105.8.1, M2105.10.1 and M2105.10.2.

M2105.10.1 Compression-type fittings. Where compression-type fittings include inserts and ferrules or O-rings, the fittings shall be installed without omitting the inserts and ferrules or O-rings.

❖ See Section M2104.3.1.

M2105.10.2 Plastic-to-metal connections. Solder joints in a metal pipe shall not occur within 18 inches (457 mm) of a transition from such metal pipe to plastic pipe or tubing.

❖ Solder joints involve temperatures of 400°F and higher. Copper pipe is an excellent conductor of heat and the heat of soldering could be conducted to nearby plastic piping, possibly damaging the plastic pipe and fittings. Where plastic pipe connects to metal pipe, soldering must occur at a safe distance from the plastic components.

M2105.11 Polyethylene plastic pipe and tubing. Joints between polyethylene plastic pipe and tubing or fittings for ground-source heat-pump loop systems shall be heat-fusion joints complying with Section M2105.11.1, electrofusion

**TABLE M2105.5
GROUND-SOURCE LOOP PIPE FITTINGS**

PIPE MATERIAL	STANDARD
Chlorinated polyvinyl chloride (CPVC)	ASTM D2846; ASTM F437; ASTM F438; ASTM F439; ASTM F1970; CSA B137.6
Cross-linked polyethylene (PEX)	ASTM F877; ASTM F1807; ASTM F1960; ASTM F2080; ASTM F2159; ASTM F2434; CSA B137.5
Polyethylene/aluminum/polyethylene (PE-AL-PE)	ASTM F2434; ASTM F1282; CSA B137.9
High-density polyethylene (HDPE)	ASTM D2683; ASTM D3261; ASTM F1055; CSA B137.1; CSA C448; NSF 358-1
Polypropylene (PP-R)	ASTM F2389; CSA B137.11; NSF 358-2
Polyvinyl chloride (PVC)	ASTM D2464; ASTM D2466; ASTM D2467; ASTM F1970; CSA B137.2; CSA B137.3
Raised temperature polyethylene (PE-RT)	ASTM D3261; ASTM F1807; ASTM F2159; F2769; B137.1

HYDRONIC PIPING

joints complying with Section M2105.11.2, or stab-type insertion joints complying with Section M2105.11.3.

- ❖ See Sections M2105.11.1, M2105.11.2 and M2105.11.3.

M2105.11.1 Heat-fusion joints. Joints shall be of the socket-fusion, saddle-fusion or butt-fusion type, and joined in accordance with ASTM D2657. Joint surfaces shall be clean and free of moisture. Joint surfaces shall be heated to melt temperatures and joined. The joint shall be undisturbed until cool. Fittings shall be manufactured in accordance with ASTM D2683 or ASTM D3261.

- ❖ Heat fusion joints are very reliable if created using the proper procedures and using the proper tools.

M2105.11.2 Electrofusion joints. Joints shall be of the electrofusion type. Joint surfaces shall be clean and free of moisture, and scoured to expose virgin resin. Joint surfaces shall be heated to melt temperatures for the period of time specified by the manufacturer. The joint shall be undisturbed until cool. Fittings shall be manufactured in accordance with ASTM F1055.

- ❖ Electrofusion joining utilizes special fittings that have integral heating elements. The fittings are connected to a power supply that provides the necessary current for the correct amount of time to heat the mating parts to the fusion temperature.

M2105.11.3 Stab-type insert fittings. Joint surfaces shall be clean and free of moisture. Pipe ends shall be chamfered and inserted into the fittings to full depth. Fittings shall be manufactured in accordance with ASTM F1924.

- ❖ Stab-type fittings are referred to as such because of the action that inserts (roughly analogous to stabbing) the tubing into the fitting. Such fittings utilize O-rings and gripping devices that retain the tubing in the fitting. Chamfering is necessary to remove the sharp angular outside edge that could damage the O-ring seals when the tubing is inserted.

M2105.12 Polypropylene (PP) plastic. Joints between PP plastic pipe and fittings shall comply with Sections M2105.12.1 and M2105.12.2.

- ❖ See Sections M2105.12.1 and M2105.12.2.

M2105.12.1 Heat-fusion joints. Heat-fusion joints for polypropylene (PP) pipe and tubing joints shall be installed with socket-type heat-fused polypropylene fittings, electrofusion polypropylene fittings or by butt fusion. Joint surfaces shall be clean and free from moisture. The joint shall be undisturbed until cool. Joints shall be made in accordance with ASTM F2389.

- ❖ Heat fusion and mechanical joints are used with polypropylene (PP) because it cannot be solvent welded. Specialized tools must be used to heat the pipe/tubing and the fittings to the point where the mating parts fuse together.

M2105.12.2 Mechanical and compression sleeve joints. Mechanical and compression sleeve joints shall be installed in accordance with the manufacturer's instructions.

- ❖ Mechanical joints come in many varieties and they all rely on sealing elements and mechanical compression. Strict compliance with the manufacturer's instructions is imperative to create dependable joints.

M2105.13 Raised temperature polyethylene (PE-RT) plastic tubing. Joints between raised temperature polyethylene tubing and fittings shall comply with Sections M2105.13.1 and M2105.13.2. Mechanical joints shall comply with Section M2105.8.1.

- ❖ See Sections M2105.8.1, M2105.13.1 and M2105.13.2.

M2105.13.1 Compression-type fittings. Where compression-type fittings include inserts and ferrules or O-rings, the fittings shall be installed without omitting the inserts and ferrules or O-rings.

- ❖ See Section M2104.3.1.

M2105.13.2 PE-RT-to-metal connections. Solder joints in a metal pipe shall not occur within 18 inches (457 mm) of a transition from such metal pipe to PE-RT pipe or tubing.

- ❖ See Section M2105.10.2.

M2105.14 PVC plastic pipe. Joints between PVC plastic pipe or fittings shall be solvent-cemented in accordance with Section P2906.9.1.4. Threaded joints between fittings and PVC plastic pipe shall be in accordance with Section M2105.9.1.

- ❖ See Section M2105.9.1. Solvent welding is performed as dictated in Chapter 29 for water service piping.

M2105.15 Shutoff valves. Shutoff valves shall be installed in ground-source loop piping systems in the locations indicated in Sections M2105.15.1 through M2105.15.6.

- ❖ Shutoff valves are required to allow the system to be serviced and repaired and to allow components and buildings to be isolated from the system.

M2105.15.1 Heat exchangers. Shutoff valves shall be installed on the supply and return side of a heat exchanger.

Exception: Shutoff valves shall not be required where heat exchangers are integral with a boiler or are a component of a manufacturer's boiler and heat exchanger packaged unit and are capable of being isolated from the hydronic system by the supply and return valves required by Section M2001.3.

- ❖ Heat exchangers include water-to-air, refrigerant-to-water and water-to-water coils. Heat exchangers are sometimes integral to storage tanks and heat pump units.

M2105.15.2 Central systems. Shutoff valves shall be installed on the building supply and return of a central utility system.

- ❖ Multiple buildings could be served by a single heat pump system and each building must be capable of being isolated.

M2105.15.3 Pressure vessels. Shutoff valves shall be installed on the connection to any pressure vessel.

- ❖ Pressure vessels include expansion tanks and storage tanks.

M2105.15.4 Pressure-reducing valves. Shutoff valves shall be installed on both sides of a pressure-reducing valve.

- ❖ Pressure-reducing valves need to be isolated to allow replacement and repair.

M2105.15.5 Equipment and appliances. Shutoff valves shall be installed on connections to mechanical equipment and appliances. This requirement does not apply to components of ground-source loop systems such as pumps, air separators, metering devices, and similar equipment.

- ❖ This section exempts water pumps; however, replacing or servicing a water pump without pump isolation valves can be difficult. Heat pump equipment isolation valves facilitate servicing and replacement, and can also allow specific equipment to be taken in and out of service.

M2105.15.6 Expansion tanks. Shutoff valves shall be installed at connections to nondiaphragm-type expansion tanks.

- ❖ Diaphragm-type expansion tanks do not require maintenance or servicing, so isolation valves are required only for tanks that do not have a diaphragm membrane. Not having a shutoff valve makes it impossible to inadvertently isolate the piping system from the expansion tank.

M2105.16 Reduced pressure. A pressure relief valve shall be installed on the low-pressure side of a hydronic piping system that has been reduced in pressure. The relief valve shall be set at the maximum pressure of the system design. The valve shall be installed in accordance with Section M2002.

- ❖ A relief valve must be installed downstream of a pressure reducing valve (PRV) to protect the lower pressure system from pressure excursions or PRV failure.

M2105.17 Installation. Piping, valves, fittings, and connections shall be installed in accordance with the manufacturer's instructions.

- ❖ See Sections M1301.3, M1307.1 and M1401.1.

M2105.18 Protection of potable water. Where ground-source heat-pump ground-loop systems have a connection to a potable water supply, the potable water system shall be protected from backflow in accordance with Section P2902.

- ❖ The potable water system must be protected against backflow because the heat pump system contains nonpotable water and can contain antifreeze mixtures and other chemicals.

M2105.19 Pipe penetrations. Openings for pipe penetrations in walls, floors and ceilings shall be larger than the penetrating pipe. Openings through concrete or masonry building elements shall be sleeved. The annular space surrounding pipe penetrations shall be protected in accordance with Section P2606.1.

- ❖ See Section P2606.1. Larger openings and sleeves protect the piping against abrasion damage caused by expansion, contraction and vibration.

M2105.20 Clearance from combustibles. A pipe in a ground-source heat pump piping system having an exterior surface temperature exceeding 250°F (121°C) shall have a clearance of not less than 1 inch (25 mm) from combustible materials.

- ❖ Such temperature would be unlikely in a heat pump system, even where a supplemental source of heat such as a boiler might be involved.

M2105.21 Contact with building material. A ground-source heat-pump ground-loop piping system shall not be in direct contact with building materials that cause the piping or fitting material to degrade or corrode, or that interfere with the operation of the system.

- ❖ Piping must be separated or otherwise protected from contact with building materials that can cause detrimental chemical reactions with the piping.

M2105.22 Strains and stresses. Piping shall be installed so as to prevent detrimental strains and stresses in the pipe. Provisions shall be made to protect piping from damage resulting from expansion, contraction and structural settlement. Piping shall be installed so as to avoid structural stresses or strains within building components.

- ❖ Piping must be supported such that stresses are not created in the piping. Offsets, loops and expansion fitting must be provided as necessary to compensate for the expansion and contraction of the piping. Plastic piping, in general, has a high coefficient of expansion and the forces generated are substantial.

M2105.22.1 Flood hazard. Piping located in a flood hazard area shall be capable of resisting hydrostatic and hydrodynamic loads and stresses, including the effects of buoyancy, during the occurrence of flooding to the *design flood elevation*.

- ❖ Buried ground-source loop piping that is filled with liquid is likely to be immune from damage caused by area flooding, however, such immunity must be demonstrated.

M2105.23 Pipe support. Pipe shall be supported in accordance with Section M2101.9.

- ❖ See Section M2101.9.

M2105.24 Velocities. Ground-source heat-pump ground-loop systems shall be designed so that the flow velocities do not exceed the maximum flow velocity recommended by the pipe and fittings manufacturer. Flow velocities shall be controlled to reduce the possibility of water hammer.

- ❖ The flow velocity in piping of all materials (plastic and metal) must be kept within the recommendations of the

material manufacturer to protect the piping from erosion and cavitation damage. Water hammer results from the sudden deceleration of flow velocity and the forces generated can be destructive to piping and system components.

M2105.25 Labeling and marking. Ground-source heat-pump ground-loop system piping shall be marked with tape, metal tags or other methods where it enters a building. The marking shall state the following words: "GROUND-SOURCE HEAT-PUMP LOOP SYSTEM." The marking shall indicate if antifreeze is used in the system and shall indicate the chemicals by name and concentration.

- ❖ Proper labeling will help prevent mistaken identity of piping systems when any system in the building is to be worked on. The nature of the heat transfer medium must be identified to help prevent the introduction of the wrong chemicals and incompatible chemicals, and to maintain the required freeze protection. The label also serves as a warning about potentially toxic chemicals.

M2105.26 Chemical compatibility. Antifreeze and other materials used in the system shall be chemically compatible with the pipe, tubing, fittings and mechanical systems.

- ❖ Plastic pipe manufacturers publish chemical compatibility information for their products. Chemicals must not be introduced into a piping system without verifying that the chemicals and the piping system materials are compatible. Damage to underground piping would be quite expensive to repair and could result in hazardous operation of equipment in the building.

M2105.27 Makeup water. The transfer fluid shall be compatible with the makeup water supplied to the system.

- ❖ Makeup water is water added to the system to replace any fluid that is lost through leakage and intentional draining for repairs and maintenance. Makeup water is limited to the amount absolutely necessary to maintain a completely filled system because makeup water contains dissolved minerals and gasses that are undesirable in the system.

M2105.28 Testing. Before connection header trenches are backfilled, the assembled loop system shall be pressure tested with water at 100 psi (689 kPa) for 15 minutes without observed leaks. Flow and pressure loss testing shall be performed and the actual flow rates and pressure drops shall be compared to the calculated design values. If actual flow rate or pressure drop values differ from calculated design values by more than 10 percent, the cause shall be identified and corrective action taken.

- ❖ Groundwater heat pump systems are either closed loop or open loop. Closed-loop systems circulate water or an antifreeze solution through plastic pipes buried in the ground. Some loop systems, although not as common, use surface water bodies or underground water as the source of heat energy. The heat-transfer fluid absorbs heat from the ground (earth) and transfers it to the building in the heating season, then reverses to

absorb heat from the building and transfer it to the ground in the cooling season.

Ground source loop systems use significant lengths of piping installed in multiple circuits (loops) to provide the required area of heat-exchange surface. Also, multiple loops have the advantage over a single loop system because a single piping failure will not cause failure of the entire heat pump system.

The significant difference between testing ground source loop systems and other hydronic systems is that ground source loops are allowed to be buried prior to testing. The connection headers (manifolds) that connect the loops (circuits) of piping must remain exposed until completion of testing. Because loops (circuits) are typically installed without joints, all of the potential sources of leaks will likely be located at the point of connection between the ends of the loops and the header. For this reason, the loops can be covered during testing while the headers remain exposed. Also, it is difficult to dig trenches for large loop fields without backfilling each trench before digging the adjacent trenches.

Depending on the lot, it may be necessary to backfill "as you go" to allow room for the excavator machine.

Requiring that each loop be inspected prior to covering could require time-consuming multiple inspections at the same property if the excavator had to backfill each trench before digging the next.

M2105.29 Embedded piping. Ground-source heat-pump ground-loop piping to be embedded in concrete shall be pressure tested prior to pouring concrete. During pouring, the pipe shall be maintained at the proposed operating pressure.

- ❖ Embedding piping in concrete is generally avoided because the loop piping will be inaccessible and because the piping is easily damaged during the concrete placement process. If the piping is damaged during the concrete pour, the leak will be apparent if the system is kept under pressure.

Chapter 22: Special Piping and Storage Systems

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

This chapter regulates the design and installation of fuel oil storage and piping systems. The regulations include reference to construction standards for above-ground and underground storage tanks, material standards for piping systems (both above-ground and underground) and extensive requirements for the proper assembly of system piping and components.

The importance of adequate regulations for the storage, handling and use of combustible liquid fuel cannot be overstated. A fuel-oil piping system includes piping, valves and fittings. If installed, pumps, reservoirs, regulators, strainers, filters, relief valves, oil preheaters, controls and gauges are also included in the fuel-oil piping system. The piping materials and the method of joining sections of pipe must be approved, and all other components included in the piping system must be labeled and installed in accordance with the manufacturer's instructions. Over the past 10 years, public scrutiny of flammable and combustible liquid storage installations has increased with the public's awareness of the consequences of release of these liquids into the environment. Environmental studies have shown that improper installation of these storage systems is a major contributing factor in system failure. Improper use of such systems also accounts for many fire losses. Although the hazards are well known, accidents involving combustible liquids remain one of the most common fire scenarios in the United States.

Fuel oil is considered a Class II combustible liquid, having a flash point of 100°F (38°C) or higher. Though the classification boundaries are somewhat arbitrary, flammable and combustible liquids are distinguished by their flash points. The flash point is that temperature at which

the liquid produces sufficient vapor to form an ignitable vapor-air mixture above its surface. Because Class I flammable liquids all have a flash point below 100°F (38°C), it is prudent to assume that such liquids may be capable of igniting when unconfined under normal environmental conditions. On the other hand, combustible liquids, including fuel oil, are materials with flash points above 100°F (38°C) and must usually be heated above their flash points or, in the case of extremely high flash-point liquids, above their boiling points before they will ignite.

Combustible liquids possess significant characteristics other than their flash points. These include ignition temperature, autoignition temperature, flammable (explosive) range, viscosity, vapor density, vapor pressure, boiling point, evaporation rate, specific gravity and water solubility. Once the liquid is ignited, these variables have little influence over the material's heat release rate. Factors such as evaporation rate, viscosity and water solubility may profoundly affect how these fires are extinguished.

Generally, combustible liquids have low specific gravities, high vapor densities and narrow flammable ranges. These characteristics mean that liquids usually float on water, vapors most often hug the ground and ignitable vapor-air mixtures are generally confined to a range between 6 and 15 percent in air. Thus, smothering is difficult and ignition sources near the ground are more likely to pose a hazard.

Purpose

The requirements in this chapter are intended to prevent fires, leaks and spills involving fuel oil storage and piping systems, whether inside or outside structures and above or below ground.

SECTION M2201 OIL TANKS

M2201.1 Materials. Supply tanks shall be *listed* and *labeled* and shall conform to UL 58 for underground tanks and UL 80 for indoor tanks.

❖ Shop-fabricated tank(s) must be listed and labeled by an approved agency. The code specifies the national standards applicable to the manufacture of these tanks.

M2201.2 Above-ground tanks. The maximum amount of fuel oil stored above ground or inside of a building shall be

660 gallons (2498 L). The supply tank shall be supported on rigid noncombustible supports to prevent settling or shifting.

Exception: The storage of fuel oil, used for space or water heating, above ground or inside buildings in quantities exceeding 660 gallons (2498 L) shall comply with NFPA 31.

❖ The quantity of fuel oil is limited to lessen the hazard associated with leakage and storage system failures. Tanks must have good support bases to support large point loads and to prevent the tanks from moving and stressing piping connected to the tanks.

M2201.2.1 Tanks within buildings. Supply tanks for use inside of buildings shall be of such size and shape to permit installation and removal from *dwelling*s as whole units. Supply tanks larger than 10 gallons (38 L) shall be placed not less than 5 feet (1524 mm) from any fire or flame either within or external to any fuel-burning *appliance*.

- ❖ This section limits the size of a tank, in addition to the capacity limitation of Section M2201.2, by taking into consideration the maintenance aspect of replacing a tank. If a tank must be cut apart to be removed from a residence, it could create a hazardous condition.

In addition, this section limits the location of a tank with respect to an open flame to prevent ignition of spilled or leaking fuel.

M2201.2.2 Outside above-ground tanks. Tanks installed outdoors above ground shall be not less than 5 feet (1524 mm) from an adjoining property line. Such tanks shall be suitably protected from the weather and from physical damage.

- ❖ This section takes into account the location of tanks installed outside of a building and above ground. Protection of a tank from physical damage and deterioration caused by local weather conditions is the main concern. The location of the tank must be evaluated with respect to possible impact damage (vehicles, equipment, etc.) and protected in an approved manner. Such protection usually consists of high-quality exterior grade paint. In areas subject to extreme weather conditions, additional protection may be required.

M2201.3 Underground tanks. Excavations for underground tanks shall not undermine the foundations of existing structures. The clearance from the tank to the nearest wall of a *basement*, pit or property line shall be not less than 1 foot (305 mm). Tanks shall be set on and surrounded with noncorrosive inert materials such as clean earth, sand or gravel well tamped in place. Tanks shall be covered with not less than 1 foot (305 mm) of earth. Corrosion protection shall be provided in accordance with Section M2203.7.

- ❖ These requirements exist so that a tank will not shift or move because of settlement of the surrounding earth. Shifting stresses a tank and piping and can cause leakage of oil.

M2201.4 Multiple tanks. Cross connection of two supply tanks shall be permitted in accordance with Section M2203.6.

- ❖ A maximum of two interconnected tanks are allowed in place of one, as long as the total capacity does not exceed 660 gallons (2498 L). See the commentary to Section M2203.6.

M2201.5 Oil gauges. Inside tanks shall be provided with a device to indicate when the oil in the tank has reached a predetermined safe level. Glass gauges or a gauge subject to breakage that could result in the escape of oil from the tank shall not be used. Liquid-level indicating gauges shall comply with UL 180.

- ❖ This section applies to indoor tanks and prohibits the use of any gauging device, including sight glasses, that

would release tank contents in the event of the gauging device breaking. This helps prevent a hazardous material spill and possible fuel oil vapor ignition. Liquid-level gauges must be in compliance with UL 180, which contains construction and performance requirements for gauges used in fuel-oil storage systems. A predetermined safe level is related to the filling of tanks.

M2201.6 Flood-resistant installation. In flood hazard areas as established by Table R301.2(1), tanks shall be installed in accordance with Section R322.2.4 or R322.3.7.

- ❖ The local jurisdiction must fill in Table R301.2(1) upon adoption of the code, including the “Flood Hazards” information. Tanks that are located in flood hazard areas must be installed above the design flood elevation or must be designed and installed to resist the lateral and buoyant forces of the flood waters. See the commentary to Sections 322.1.6, R322.2.4 and R322.3.7.

M2201.7 Tanks abandoned or removed. Exterior above-grade fill piping shall be removed when tanks are abandoned or removed. Tank abandonment and removal shall be in accordance with the *International Fire Code*.

- ❖ The *International Fire Code*[®] (IFC[®]) contains the requirements for abandoning or removing fuel oil tanks. The IFC does not, however, require the removal of the above-grade fill piping associated with the tanks. Exterior fill and vent piping has to be removed because of the potential danger that hundreds of gallons of fuel oil could be accidentally delivered to the wrong address. There have been instances of accidental filling where tanks have been removed but the fill pipe has remained. The oil delivery service sees only the exterior connection and may not be aware that the tank has been removed or disconnected. Piping must be removed, not just capped off; accidental filling has occurred when piping systems have been “capped off.” When fuel oil contamination occurs, the cost of repairs and cleanup is extremely high and in some cases contamination has led to condemnation of such structures.

SECTION M2202

OIL PIPING, FITTING AND CONNECTIONS

M2202.1 Materials. Piping shall consist of steel pipe, copper and copper alloy pipe and tubing or steel tubing conforming to ASTM A539. Aluminum tubing shall not be used between the fuel-oil tank and the burner units.

- ❖ Aluminum is prohibited because it corrodes more readily when it is exposed to moisture or is adjacent to some types of construction material.

M2202.2 Joints and fittings. Piping shall be connected with standard fittings compatible with the piping material. Cast iron fittings shall not be used for oil piping. Unions requiring gaskets or packings, right or left couplings, and sweat fittings employing solder having a melting point less than 1,000°F (538°C) shall not be used for oil piping. Threaded joints and

connections shall be made tight with a lubricant or pipe thread compound.

- ❖ Joining and connecting methods and materials must be compatible with the pipe and the fuel oil used. Lubricants and tape are designed to lubricate the threads for proper mating and to fill in small imperfections within these threads. Lubricants must be compatible with the pipe and fuel oil used or they will deteriorate and allow fuel oil leaks. Gaskets and packing materials in unions can lose their resiliency and deteriorate over time, which can also lead to fuel oil leaks. Solder with a low melting point can quickly fail in a fire. Cast-iron fittings are very brittle and can be damaged by impact.

M2202.3 Flexible connectors. Flexible metallic hoses shall be *listed* and *labeled* in accordance with UL 536 and shall be installed in accordance with their *listing* and *labeling* and the manufacturer's installation instructions. Connectors made from combustible materials shall not be used inside of buildings or above ground outside of buildings.

- ❖ Flexible metal hoses are used to reduce the transfer of vibrations and to compensate for movements in the system. These connectors must be listed and labeled in accordance with UL 536 for their intended use so that they are compatible with the environment and the type of fuel used. Combustible connectors are prohibited for installations inside the building and are also prohibited anywhere above ground because of concern for fire damage and longevity of the material.

SECTION M2203 INSTALLATION

M2203.1 General. Piping shall be installed in a manner to avoid placing stresses on the piping, and to accommodate expansion and contraction of the piping system.

- ❖ Changes in temperatures can result in substantial longitudinal movement of piping, especially in long runs. Provisions must be made to allow expansion or contraction without creating stresses on the system. Otherwise, leakage or failure of pipe, pipe supports and pipe joints can occur.

M2203.2 Supply piping. Supply piping used in the installation of oil burners and *appliances* shall be not smaller than $\frac{3}{8}$ -inch (9 mm) pipe or $\frac{3}{8}$ -inch (9 mm) outside diameter tubing. Copper tubing and fittings shall be a minimum of Type L.

- ❖ This section requires that the fuel oil supply piping be of a size capable of delivering the maximum fuel demand of the appliance it supplies at the recommended working pressure of the appliance burner. For purposes of flow volume and pressure control, pumps may supply more fuel oil than an appliance consumes, in which case the excess oil must be routed back to the tank through a return line. Because the amount returning to the tank is less than what was supplied, the return line pipe diameter may be smaller than that of the supply pipe.

M2203.3 Fill piping. Fill piping shall terminate outside of buildings at a point not less than 2 feet (610 mm) from any building opening at the same or lower level. Fill openings shall be equipped with a tight metal cover.

- ❖ Requiring fill pipe terminations to be outside buildings and at least 2 feet (610 mm) from building openings that are at the same level or lower than the fill pipe reduces the possibility that liquid or vapor spillage during delivery will enter the building and come into contact with a source of ignition. Likewise, fill pipes must be arranged to reduce the possibility of liquid spilling onto the ground or pavement upon completion of the filling operation, which could result in vapors traveling to an ignition source. One method of managing such spills is to install a spill containment device at the end of the fill pipe. These devices are usually equipped with a water-tight cover and are essentially reservoirs designed to catch any spilled fuel oil and retain it for proper disposal. Some models of these devices have a manual drain valve that allows the captured liquid to drain through the fill pipe and into the tank. Other models have a liquid level alarm to warn responsible parties on the premises that the reservoir needs to be emptied.

M2203.4 Vent piping. Vent piping shall be not smaller than $\frac{1}{4}$ -inch (32 mm) pipe. Vent piping shall be laid to drain toward the tank without sags or traps in which the liquid can collect. Vent pipes shall not be cross connected with fill pipes, lines from burners or overflow lines from auxiliary tanks. The lower end of a vent pipe shall enter the tank through the top and shall extend into the tank not more than 1 inch (25 mm).

- ❖ Because vent piping can have oil in it under certain circumstances, this section requires that it be laid to drain back to the tank without sags or traps. If oil reaches the vent, it can drain back to the tank without leaving pockets of oil that could block the vent. The vent must enter the tank through the top and not extend more than 1 inch (25.4 mm) into the tank, again to protect against the vent being blocked by fuel oil.

M2203.5 Vent termination. Vent piping shall terminate outside of buildings at a point not less than 2 feet (610 mm), measured vertically or horizontally, from any building opening. Outer ends of vent piping shall terminate in a weather-proof cap or fitting having an unobstructed area at least equal to the cross-sectional area of the vent pipe, and shall be located sufficiently above the ground to avoid being obstructed by snow and ice.

- ❖ The 2-foot (610 mm) minimum clearance reduces the possibility of vapors entering the building. Protection of the open end of the vent pipe with an approved vent cap or fitting is necessary to prevent rainwater from entering the tank through the vent.

The vent pipe must terminate above ground at a level that will reduce the possibility of the opening being obstructed by snow accumulation.

M2203.6 Cross connection of tanks. Cross connection of two supply tanks, not exceeding 660 gallons (2498 L) aggregate capacity, with gravity flow from one tank to another, shall be acceptable providing that the two tanks are on the same horizontal plane.

- ❖ Cross connection of two supply tanks, with gravity flow from one tank to another, is acceptable if the two tanks are installed on the same horizontal plane. The capacity of both tanks combined must not exceed 660 gallons (2498 L). Two smaller supply tanks connected together, instead of a single larger tank, allow more flexibility of location, such as with indoor storage tanks.

M2203.7 Corrosion protection. Underground tanks and buried piping shall be protected by corrosion-resistant coatings or special alloys or fiberglass-reinforced plastic.

- ❖ To minimize the possibility of a hazardous fuel oil spill, underground tanks and buried piping must be protected by corrosion-resistant coating, use of special alloys or fiberglass-reinforced plastic. Materials installed underground and left unprotected are subject to moisture, soil chemistry and stresses that can cause rapid deterioration.

SECTION M2204 OIL PUMPS AND VALVES

M2204.1 Pumps. Oil pumps shall be positive displacement types that automatically shut off the oil supply when stopped. Automatic pumps shall be *listed* and *labeled* in accordance with UL 343 and shall be installed in accordance with their *listing*.

- ❖ Pumps must be of the positive-displacement type to prevent gravity or siphon delivery of oil when the pump is not operating. Otherwise, oil could drain through the pump and burner and into the combustion chamber, creating a hazard.

M2204.2 Shutoff valves. A *readily accessible* manual shutoff valve shall be installed between the oil supply tank and the burner. Where the shutoff valve is installed in the discharge line of an oil pump, a pressure-relief valve shall be incorporated to bypass or return surplus oil. Valves shall comply with UL 842.

- ❖ Valves can be used to stop the flow of oil if a leak occurs and can also be used during maintenance or repair of the burners. When the shutoff valve is installed downstream of a pump, the pump becomes capable of overpressurizing the piping system if it pumps against a closed valve. Therefore, if the pump has no built-in bypass, a pressure relief valve must be installed. The fuel oil discharged by the relief valve must be routed back to the tank through a return line to prevent a spill.

M2204.3 Maximum pressure. Pressure at the oil supply inlet to an *appliance* shall be not greater than 3 pounds per square inch (20.7 kPa).

- ❖ Higher pressures could cause malfunctioning of the appliance and/or leaks if the internal parts of the appliance are not designed to withstand higher pressures.

M2204.4 Relief valves. Fuel-oil lines incorporating heaters shall be provided with relief valves that will discharge to a return line when excess pressure exists.

- ❖ Fuel-oil systems are sometimes designed to incorporate a heater that decreases the viscosity of the oil and improves flow within the system. Because oil will expand when heated, it can reach pressures beyond those of the design operating pressure. Relief valves are necessary to prevent overpressures.

Chapter 23: Solar Thermal Energy Systems

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

General Comments

Chapter 14 contains requirements for the construction, alteration and repair of all systems and components of solar energy systems used for space heating or cooling and domestic hot water heating or processing. The provisions of this chapter are limited to those necessary to achieve safe installations that are relatively hazard free.

A solar energy system can be designed to handle 100 percent of the energy load of a building, although this is rarely accomplished. Because solar energy is a low-intensity energy source and dependent on the weather, it is usually necessary to supplement a solar energy system with traditional energy sources.

Solar heating and cooling systems are classified as either passive or active systems. A passive solar energy system uses solar collectors, a gas or liquid heat-transfer medium and distribution piping or ductwork. This system does not use circulators or fans but relies on natural (gravity) flow. The flow of energy (heat) is by natural convection, conduction, and radiation. Commentary Figures 23(1) and 23(2) show typical passive solar heating applications.

A complete active solar energy system includes solar collectors, a gas or liquid heat transfer medium, piping, ducts, circulators, fans and controls to move the medium to the load or to an energy storage system. Commentary Figure 23(3) shows a typical active solar system used for space and domestic water heating, supplemented by an auxiliary furnace and water heater.

Many design variations exist, such as hybrid systems with components of both active and passive systems. Solar systems can act in harmony with the architectural features of the building and can be very complex, or they can be as simple as glazing [see Commentary Figure 23(4)]. Solar designs can be used to work with, and

improve the performance of, conventional space heating systems. For example, a simple passive collection system can greatly improve the performance of an air-to-air or water-to-air heat pump system.

The energy collected by a solar system can be used as it is collected or transferred to some form of thermal storage system. Typical thermal storage systems consist of large quantities of a dense mass, such as stone, masonry or water. Storage mass can also consist of materials in which a phase change occurs, such as chemical compounds that store the latent heat required to liquefy the compounds that are solid at room temperature.

If the energy collected by a solar system is not used or stored for later use, and unless the collection system is designed to withstand the higher temperatures and pressures resulting from the static (no-flow) mode of operation, the collection system must either stop collecting or dump the energy to the building exterior.

The structural loading effect that the collectors and supports have on the building's roof system also must be considered. Collectors can add considerable weight, affect snow accumulation and increase wind loads and uplift forces. As with any roof-mounted equipment or appliances, the installation also must comply with the applicable provisions of the building portions of this code.

Purpose

This chapter establishes provisions for the safe installation, operation and repair of solar energy systems. Although these systems use components similar to those of conventional mechanical equipment, many of these provisions are unique to solar energy systems.

SECTION M2301 THERMAL SOLAR ENERGY SYSTEMS

M2301.1 General. This section provides for the design, construction, installation, *alteration* and repair of *equipment* and systems using thermal solar energy to provide space heating or cooling, hot water heating and swimming pool heating.

❖ The provisions within the this section cover the design, installation, construction, alteration and repair of equipment for thermal solar systems that heat water for domestic hot water use, space heating and, on rare

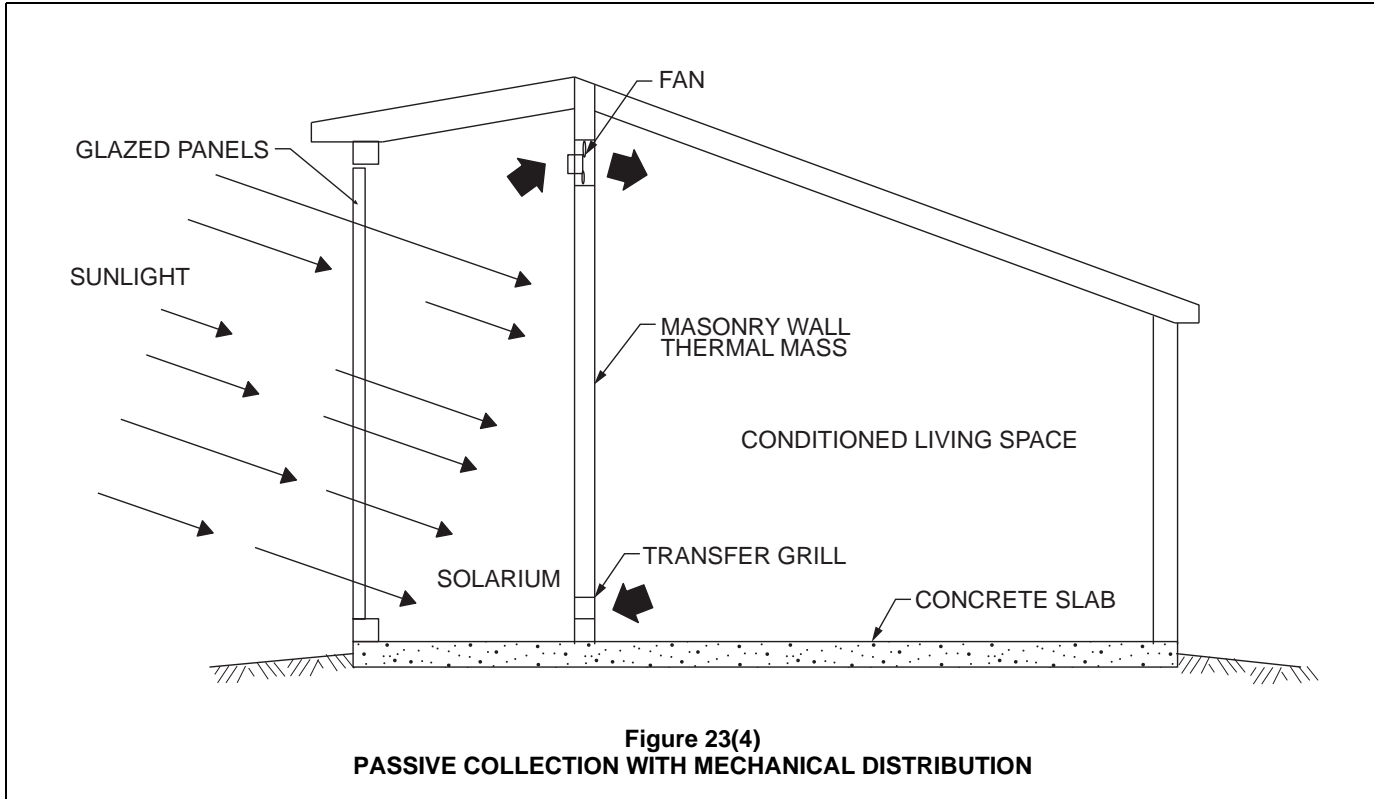

occasions, space cooling. The *International Residential Code*[®] (IRC[®]) also covers the installation of collector systems that provide hot water for swimming pools. There are five major components in active solar heating systems:

- Collector(s) to capture solar energy. Usually, systems used for space heating will have many more collectors than systems designed for domestic water heating only.
- Circulation system to move a fluid between the collectors to a storage tank. The circulation

system will either be a direct (open loop) system or an indirect (closed loop) system. A direct system pumps domestic water directly from the storage tank (usually a hot water heater) through the collectors and back to the storage tank. An indirect system circulates an antifreeze fluid, oil, refrigerant or other fluid with a high boiling temperature and low freezing temperature through the collectors and back through a heat exchanger. The heat exchanger keeps the collection fluid separate from the domestic water.

- Storage tank(s) to collect heated water. This may be a standard water heater or a separate un-fired hot water storage tank located next to the water heater.
- Backup heating system. For domestic water heating this will usually be a hot water heater. Backup space-heating systems may consist of electric baseboard heating or a gas or electric heater.
- Control system to regulate overall system operation. The control system will include valves and shutoff devices to protect from excessively high temperatures.

M2301.2 Design and installation. The design and installation of thermal solar energy systems shall comply with Sections M2301.2.1 through M2301.2.13.

- ❖ The requirements of this chapter address the potential hazards to life and property associated with solar installations. The systems must be installed in accordance with the manufacturer's installation instructions. Components of the solar system must also conform to other applicable sections of the code.

M2301.2.1 Access. Solar energy collectors, controls, dampers, fans, blowers and pumps shall be accessible for inspection, maintenance, repair and replacement.

- ❖ This section requires that solar collectors, controls, dampers, fans, blowers and pumps associated with the solar system be accessible for inspection, maintenance, repair and replacement. The collection system pumps and controls are often located in the garage or pool equipment building, allowing easy access for the inspector, and are mounted in close proximity to each other. While not a code requirement, it is beneficial to have operation and maintenance manuals available to the owner once the system is installed.

M2301.2.2 Collectors and panels. Solar collectors and panels shall comply with Sections M2301.2.2.1 and M2301.2.2.2.

- ❖ See Sections M2301.2.2.1 and M2301.2.2.2.

M2301.2.2.1 Roof-mounted collectors. The roof shall be constructed to support the loads imposed by roof-mounted solar collectors. Roof-mounted solar collectors that serve as a roof covering shall conform to the requirements for roof coverings in Chapter 9 of this code. Where mounted on or above the roof coverings, the collectors and supporting structure shall be constructed of noncombustible materials or fire-retardant-treated wood equivalent to that required for the roof construction.

- ❖ Roof mounted solar collectors can be designed to be installed integral with the roof, thereby serving as the roof covering. They can also be mounted on or above the roof covering. Systems that are installed as a roof covering must be watertight and properly flashed, in addition to meeting the other requirements applicable to the installation in Chapter 9 of this code. Systems installed on or above the roof covering must be securely fastened to the roof/rafter system. Often, solar collector systems are installed with manufactured metal mounting brackets that can be attached to the roofing system or wood blocking, or with sleepers using lag bolts or other secure mounting systems. The manufacturer's mounting specifications must be followed so that the panels are properly mounted. This is especially important in areas with high wind loads. Also, the weight of the collector system must be checked (when operational and filled with fluid) to confirm that the roof structure is designed to meet the increased load.

Most manufactured panel systems used for domestic hot water are constructed using a metal housing to hold the collection system. This housing must meet the requirements for noncombustible materials. Panel sys-

tems constructed on site by the owner/builder that use a housing made of wood may or may not meet the requirements for noncombustible materials.

M2301.2.2.2 Collector sensors. Collector sensor installation, sensor location and the protection of exposed sensor wires from ultraviolet light shall be in accordance with SRCC 300.

- ❖ The referenced standard contains installation instructions for sensor devices used in collectors and collector arrays. Sunlight will degrade many materials, especially certain plastics.

M2301.2.3 Pressure and temperature relief valves and system components. System components containing fluids shall be protected with temperature and pressure relief valves or pressure relief valves. Relief devices shall be installed in sections of the system so that a section cannot be valved off or isolated from a relief device. Direct systems and the potable water portion of indirect systems shall be equipped with a relief valve in accordance with Section P2804. For indirect systems, pressure relief valves in solar loops shall comply with SRCC 300. System components shall have a working pressure rating of not less than the setting of the pressure relief device.

- ❖ Pressure and temperature relief valves are required to prevent collector, piping and equipment failures caused by excessive temperatures and pressures. Such failures could involve violent explosions, similar to those associated with boilers and water heaters. The collection surface, or absorber plate, can easily heat up to 200°F (93°C) on a freezing winter day and up to 400°F (204°C) on a summer day when the water is stagnant and not circulated through the collector. These relief valves are often installed as part of the collector system. Multiple relief valves could be necessary where there are separate piping system circuits.

M2301.2.4 Vacuum relief. System components that might be subjected to pressure drops below atmospheric pressure during operation or shutdown shall be protected by a vacuum-relief valve.

- ❖ System components that are subjected to pressure drops below atmospheric pressure during operation or shutdown can be damaged by the force of atmospheric pressure acting on the external side. Partial vacuums can also interfere with system drain-down. Vacuum relief valves can be used in conjunction with freeze protection valves that drain the collector panels when the temperature reaches close to 32°F (0°C) or a drain-down system that automatically drains the collector fluid when the system is shut off.

M2301.2.5 Piping insulation. Piping shall be insulated in accordance with the requirements of Chapter 11. Exterior insulation shall be protected from ultraviolet degradation. The entire solar loop shall be insulated. Where split-style insulation is used, the seam shall be sealed. Fittings shall be fully insulated.

Exceptions:

1. Those portions of the piping that are used to help prevent the system from overheating shall not be required to be insulated.

2. Those portions of piping that are exposed to solar radiation, made of the same material as the solar collector absorber plate and are covered in the same manner as the solar collector absorber, or that are used to collect additional solar energy, shall not be required to be insulated.
3. Piping in thermal solar systems using unglazed solar collectors to heat a swimming pool shall not be required to be insulated.

❖ Piping insulation will improve the efficiency of the system. Sunlight will degrade many types of pipe insulation, such as closed cell plastic insulation. Split-type insulation refers to insulation tubes that are split down their length to allow them to be fitted over installed piping. The split seam must be permanently sealed. The exceptions recognize portions of the piping that are meant to absorb solar energy or dissipate heat energy.

M2301.2.6 Protection from freezing. System components shall be protected from damage resulting from freezing of heat-transfer liquids at the winter design temperature provided in Table R301.2(1). Freeze protection shall be provided by heating, insulation, thermal mass and heat transfer fluids with freeze points lower than the winter design temperature, heat tape or other *approved* methods, or combinations thereof.

Exception: Where the winter design temperature is greater than 32°F (0°C).

❖ In climates where the design winter temperature is 32°F (0°C) or less, the system must be protected from freezing. The greatest damage that can occur to the collector system is for water to freeze in the collection system, causing the collectors, components and piping to rupture. To meet the intent of the code, an indirect system can be protected with antifreeze heat transfer fluids or the system can be a type that drains the outdoor system components when the temperature drops to a specific temperature.

M2301.2.7 Storage tank sensors. Storage tank sensors shall comply with SRCC 300.

❖ Storage tanks store the energy collected from the sun for eventual use external to the storage tank. The storage might be domestic potable water or it might be nonpotable heat transfer fluid. Tank sensors communicate the storage temperatures to the system's pumps and controllers.

M2301.2.8 Expansion tanks. Expansion tanks in solar energy systems shall be installed in accordance with Section M2003 in solar collector loops that contain pressurized heat transfer fluid. Where expansion tanks are used, the system shall be designed in accordance with SRCC 300 to provide an expansion tank that is sized to withstand the maximum operating pressure of the system.

Exception: Expansion tanks shall not be required in *drain-back* systems.

❖ This section requires the installation of pressure expansion tanks in closed loop systems. The text is

stating two different requirements; one being that an expansion tank must be installed and the other being that the installation must comply with Section M2003. Closed loop systems cannot accommodate the increased volume of expanded liquid that results from a rise in temperature. Without an expansion tank, the expanding fluid would rupture a system component or a pressure relief device would have to routinely open and discharge heat transfer fluid. Manufactured systems that are preengineered based on the number of panels in the system, storage tank size and circulation pump size often come with a specified expansion tank engineered for the system. The expansion tank is usually installed next to the pumps, storage tank and controls. Expansion tanks are installed in closed loop hydronic heating systems for the same reasons.

M2301.2.9 Roof and wall penetrations. Roof and wall penetrations shall be flashed and sealed in accordance with Chapter 9 of this code to prevent entry of water, rodents and insects.

❖ Roof and wall penetrations must be sealed during and after installation of the solar systems. At a minimum, there will be roof penetrations for the supply and return piping going to and from the collector panels. Systems mounted above the roof covering will require penetrations into the rafter system or blocking to attach the collectors to the roof, and care must be taken to seal the holes with a waterproof sealant. Chapter 9 states flashing and waterproofing requirements for several roof types. Wall penetrations must also be sealed to prevent the entry of water, rodents and insects.

M2301.2.10 Description and warning labels. Solar thermal systems shall comply with description label and warning label requirements of Section M2301.2.11.2 and SRCC 300.

❖ Labeling of system components provides valuable guidance to homeowners, occupants and service personnel and also provides necessary warnings relative to high temperatures and pressures and required actions to prevent hazards.

M2301.2.11 Solar loop. Solar loops shall be in accordance with Sections M2301.2.11.1 and M2301.2.11.2.

❖ See Sections M2301.2.11.1 and M2301.2.11.2.

M2301.2.11.1 Solar loop isolation. Valves shall be installed to allow the solar collectors to be isolated from the remainder of the system.

❖ Isolation of the collectors could be necessary for servicing, repair or replacement. A loop is a circuit of piping and components that circulates a fluid in a closed circuit (loop). In an indirect system, the collector loop circulates between the collectors and a heat exchanger or storage tank. This section requires isolation of the collector loop, not necessarily isolation of the collectors from their collector loop. If the collectors themselves were isolated from loop piping, they might be isolated from the required expansion tanks and pressure and temperature relief devices, thereby creating a serious hazard.

M2301.2.11.2 Drain and fill valve labels and caps. Drain and fill valves shall be labeled with a description and warning that identifies the fluid in the solar loop and a warning that the fluid might be discharged at high temperature and pressure. Drain caps shall be installed at drain and fill valves.

- ❖ Access points into a collector loop, such as fill valve ports and drain valve ports, must be labeled to warn of the potential hazards relative to chemical content of the loop and the pressures and temperatures in the loop. Personnel and occupants could be injured by opening valves if they are unaware of the dangers and fail to take the necessary precautions. All access valves, such as hose bibb drain valves, must be capped to prevent accidental discharge. Discharge of system fluid would require two actions; removing a cap and opening one or more valves.

M2301.2.12 Maximum temperature limitation. Systems shall be equipped with means to limit the maximum water temperature of the system fluid entering or exchanging heat with any pressurized vessel inside the *dwelling* to 180°F (82°C). This protection is in addition to the required temperature- and pressure-relief valves required by Section M2301.2.3.

- ❖ To prevent potential problems with clearances to combustibles, to prevent burn injuries resulting from human contact with piping or pressure vessels and to prevent overheating of the loads served by the solar system, the system fluid temperature is limited to 180°F (82°C) where the fluid enters or conveys heat energy to any pressurized vessel inside of a dwelling. The method of limiting the temperature is to be determined by the designer or system installer. Possible methods include a system to bypass the solar collectors and/or a rejection heat exchanger outside of the dwelling.

M2301.2.13 Thermal storage unit seismic bracing. In Seismic Design Categories D₀, D₁ and D₂ and in townhouses in Seismic Design Category C, thermal storage units shall be anchored in accordance with Section M1307.2.

- ❖ See the commentary to Section M1307.2.

M2301.3 Labeling. *Labeling* shall comply with Sections M2301.3.1 and M2301.3.2.

- ❖ The designer, installer, owner and building official must know the quality, design and application limitations of the collectors and thermal storage units. This section requires that they be labeled. The label is a form of quality assurance and lists specifications that apply to the equipment, as well as any necessary information for its installation and application.

M2301.3.1 Collectors and panels. Solar thermal collectors and panels shall be listed and labeled in accordance with SRCC 100 or SRCC 600. Collectors and panels shall be *listed* and *labeled* to show the manufacturer's name, model number, serial number, collector weight, collector maximum allowable temperatures and pressures, and the type of heat transfer fluids that are compatible with the collector or panel. The

label shall clarify that these specifications apply only to the collector or panel.

- ❖ Solar collectors must be listed and labeled to the specified standards and must be labeled to indicate the manufacturer's name, model number, serial number, collector weight, collector maximum allowable temperatures and pressures and the type of heat transfer fluids that are compatible with the collector. The label must state that the specifications on the label do not apply to components external to the collectors, otherwise, dangerous assumptions could be implied about the other portions of the solar system. The Solar Rating and Certification Corporation (SRCC) is one entity that provides a third party certification that will meet the requirements of this provision. The *Directory of SRCC Certified Solar Collector System Ratings*, *Directory of SRCC Certified Water Heating System Ratings*, and *Summary of SRCC Certified Solar Collector and Water Heating System Ratings* are published by the SRCC annually and list all the information required for this provision except for the serial number, which can be found on the collector.

M2301.3.2 Thermal storage units. Pressurized thermal storage units shall be *listed* and *labeled* to show the manufacturer's name, model number, serial number, storage unit maximum and minimum allowable operating temperatures and pressures, and the type of heat transfer fluids that are compatible with the storage unit. The *label* shall clarify that these specifications apply only to the thermal storage unit.

- ❖ Pressurized thermal storage units must bear a listing and label that discloses the manufacturer's name, model, serial number and important operating characteristics such as operating temperatures and pressures, and the type of heat transfer fluid. The information is important for installation, application, servicing, repairs and inspection. The label must state that the specifications on the label do not apply to components external to the thermal storage unit, otherwise dangerous assumptions could be implied about the other portions of the solar system.

M2301.4 Heat transfer gasses or liquids and heat exchangers. *Essentially toxic transfer fluids*, ethylene glycol, flammable gases and flammable liquids shall not be used as heat transfer fluids. Heat transfer gasses and liquids shall be rated to withstand the system's maximum design temperature under operating conditions without degradation. Heat exchangers used in solar thermal systems shall comply with Section P2902.5.2 and SRCC 300.

Heat transfer fluids shall be in accordance with SRCC 300. The flash point of the heat transfer fluids utilized in solar thermal systems shall be not less than 50°F (28°C) above the design maximum nonoperating or no-flow temperature attained by the fluid in the collector.

- ❖ Flammable gases, flammable liquids, toxic chemicals and ethylene glycol must not be used as heat transfer fluids because they each pose significant risks. Ethylene glycol is automotive antifreeze, is very toxic and

is an unacceptable risk as a heat transfer fluid. Chemicals introduced into a solar system must be compatible with the piping and system components and must also be capable of tolerating, without degradation, the temperatures to which they will be exposed.

M2301.5 Backflow protection. Connections from the potable water supply to solar systems shall comply with Section P2902.5.5.

- ❖ The potable water supply connected to a solar system must be protected from backflow because this is a direct connection between a potable and a nonpotable piping system, which poses significant health risks. See Section P2902.5.5.

M2301.6 Filtering. Air provided to occupied spaces that passes through thermal mass storage systems by mechanical means shall be filtered for particulates at the outlet of the thermal mass storage system.

- ❖ Some thermal storage systems utilize mass, such as stone aggregate, to store heat energy and force air through the stone bed to condition the air. Before such conditioned air is delivered to an occupied space, it must filtered to remove any particulate matter picked up from the mass, whatever the mass may be.

M2301.7 Solar thermal systems for heating potable water. Where a solar thermal system heats potable water to supply a potable hot water distribution system, the solar thermal system shall be in accordance with Sections M2301.7.1, M2301.7.2 and P2902.5.5.

- ❖ See Sections M2301.7.1, M2301.7.2 and P2902.5.5.

M2301.7.1 Indirect systems. Heat exchangers that are components of indirect solar thermal heating systems shall comply with Section P2902.5.2.

- ❖ See Section P2902.5.2. Indirect systems consist of a collector loop that conveys the energy from the collectors to a heat exchanger that transfers that energy to the potable water. It is considered as indirect because there is a heat exchange coil or plate type exchanger that isolates the potable water system from the solar collector system. A direct system would pass the potable water through the collectors without a heat exchanger. See Section M2301.7.2.

M2301.7.2 Direct systems. Where potable water is directly heated by a solar thermal system, the pipe, fittings, valves and other components that are in contact with the potable water in the solar heating system shall comply with the requirements of Chapter 29.

- ❖ Because a direct solar system heats the potable water without an isolating heat exchanger, the potable water is in contact with the collectors, the collector loop piping, the pumps, expansion tanks, etc. Anything in contact with the potable water must not contaminate the water, therefore, the components of a direct system have to meet the same requirements as potable water piping and potable water system components. See Chapter 29.

Part VI—Fuel Gas

Chapter 24: Fuel Gas

User note: Code change proposals to this chapter will be considered by the IRC – Plumbing and Mechanical Code Development Committee during the 2015 (Group A) Code Development Cycle.

The text of this chapter is extracted from the 2015 edition of the *International Fuel Gas Code* and has been modified where necessary to conform to the scope of application of the *International Residential Code for One- and Two-Family Dwellings*. The section numbers appearing in parentheses after each section number are the section numbers of the corresponding text in the *International Fuel Gas Code*.

General Comments

This chapter covers all installations of gas piping, gas appliance installation and gas appliance venting systems. It is extracted from the *International Fuel Gas Code*® (IFGC®) and is identical in intent. This chapter contains its own gas-specific coverage of combustion air, clearance reduction methods, chimneys and vents, and appliance installation. The dual section numbering system allows this text to be cross-referenced with the IFGC. Chapters 12, 13, 14 and 20 also contain requirements applicable to gas appliance installations.

The IFGC itself is segregated by section number into

two categories: code and standard. In that document, code sections are identified as IFGC; standards sections are identified as IFGS. The IFGS is a copyrighted work of the American Gas Association.

The commentary text of this chapter is produced and copyrighted by the International Code Council® (ICC®).

Purpose

Chapter 24 intends to protect occupants and their property from fire, explosion and health hazards that could result from the improper installation of gas piping systems, gas appliances and appliance venting systems.

SECTION G2401 (101) GENERAL

G2401.1 (101.2) Application. This chapter covers those fuel gas *piping systems*, fuel-gas *appliances* and related accessories, *venting systems* and *combustion air* configurations most commonly encountered in the construction of one- and two-family dwellings and structures regulated by this *code*.

Coverage of *piping systems* shall extend from the *point of delivery* to the outlet of the *appliance shutoff valves* (see definition of “*Point of delivery*”). *Piping systems* requirements shall include design, materials, components, fabrication, assembly, installation, testing, inspection, operation and maintenance. Requirements for *gas appliances* and related accessories shall include installation, combustion and ventilation air and venting and connections to *piping systems*.

The omission from this chapter of any material or method of installation provided for in the *International Fuel Gas Code* shall not be construed as prohibiting the use of such material or method of installation. Fuel-gas *piping systems*, fuel-gas *appliances* and related accessories, *venting systems* and *combustion air* configurations not specifically covered in these chapters shall comply with the applicable provisions of the *International Fuel Gas Code*.

Gaseous hydrogen systems shall be regulated by Chapter 7 of the *International Fuel Gas Code*.

This chapter shall not apply to the following:

1. Liquefied natural gas (LNG) installations.
 2. Temporary LP-gas *piping* for buildings under construction or renovation that is not to become part of the permanent *piping system*.
 3. Except as provided in Section G2412.1.1, gas *piping*, meters, gas pressure regulators, and other appurtenances used by the serving gas supplier in the distribution of gas, other than undiluted LP-gas.
 4. Portable LP-gas *appliances* and *equipment* of all types that is not connected to a fixed fuel *piping system*.
 5. Portable fuel cell *appliances* that are neither connected to a fixed *piping system* nor interconnected to a power grid.
 6. Installation of hydrogen gas, LP-gas and compressed natural gas (CNG) systems on vehicles.
- ❖ This section describes the types of fuel gas systems to which the code is intended to apply and specifically lists those systems to which the code does not apply. The applicability of the code spans from the initial

design of fuel gas systems, through the installation and construction phases, and into the maintenance of operating systems. Chapter 24 of the *International Residential Code*® (IRC®) covers fuel gas systems and is a duplication of the applicable IFGC text. The provisions of Chapter 24 of the IRC are identical to those in the IFGC. Chapter 24 contains only the IFGC text that is applicable to one- and two-family dwellings and townhouses. If something is encountered on plans or in the field that is not covered by Chapter 24, the provisions of the IFGC take over. Note that each Chapter 24 section number is followed by the corresponding IFGC section number. This makes it easy to cross-reference Chapter 24 to its source, the IFGC.

SECTION G2402 (201) GENERAL

G2402.1 (201.1) Scope. Unless otherwise expressly stated, the following words and terms shall, for the purposes of this chapter, have the meanings indicated in this chapter.

❖ In the application of the code, the terms used have the meanings given in Section G2403.

G2402.2 (201.2) Interchangeability. Words used in the present tense include the future; words in the masculine gender include the feminine and neuter; the singular number includes the plural and the plural, the singular.

❖ Although the definitions contained in Section G2403 are to be taken literally, gender and tense are considered to be interchangeable; thus, any grammatical inconsistencies within the code text will not hinder the understanding or enforcement of the requirements.

G2402.3 (201.3) Terms defined in other codes. Where terms are not defined in this code and are defined in the *International Building Code*, *International Fire Code*, *International Mechanical Code*, *International Fuel Gas Code* or *International Plumbing Code*, such terms shall have meanings ascribed to them as in those codes.

❖ When a word or term appears in the code that is not defined in this chapter, other references may be used to find its definition. These include the *International Building Code*® (IBC®), the *International Fire Code*® (IFC®), the *International Mechanical Code*® (IMC®) and the *International Plumbing Code*® (IPC®). These codes contain additional definitions (some parallel and duplicative) that may be used in the enforcement of this code or in the enforcement of the other codes by reference.

SECTION G2403 (202) GENERAL DEFINITIONS

❖ Definitions of terms can help in the understanding and application of the code requirements. The purpose for including here those definitions that are most closely associated with the subject matter of this chapter is to provide more convenient access to them without having to refer back to Chapter 2. For convenience, these

terms are also listed in Chapter 2 with a cross reference to this section. The use and application of all defined terms, including those defined in this section, are set forth in Section 201.

ACCESS (TO). That which enables a device, *appliance* or *equipment* to be reached by ready *access* or by a means that first requires the removal or movement of a panel, door or similar obstruction (see also “Ready *access*”).

AIR CONDITIONER, GAS-FIRED. A gas-burning, automatically operated *appliance* for supplying cooled and/or dehumidified air or chilled liquid.

❖ Gas-fired air conditioners are not specifically referred to in the code, but would include systems fueled with natural or propane gas including absorption type units and reciprocating units powered by internal combustion engines.

AIR CONDITIONING. The treatment of air so as to control simultaneously the temperature, humidity, cleanness and distribution of the air to meet the requirements of a conditioned space.

AIR, EXHAUST. Air being removed from any space or piece of *equipment* or *appliance* and conveyed directly to the atmosphere by means of openings or ducts.

❖ Exhaust air may be from a space, an appliance or a piece of equipment. Exhaust air systems are terminated outside of the building, in some cases after the exhaust air has been treated to remove any harmful emissions. Exhaust air is not recirculated.

AIR-HANDLING UNIT. A blower or fan used for the purpose of distributing supply air to a room, space or area.

❖ In addition to blowers, air-handling units may contain heat exchangers, filters and means to control air volume.

AIR, MAKEUP. Any combination of outdoor and transfer air intended to replace exhaust air and exfiltration.

❖ Makeup air is not to be confused with combustion air. Makeup air replaces the air being exhausted through such systems as bathroom and toilet exhausts, kitchen exhaust hoods, and clothes dryer exhaust systems. Refer to Section G2439.5 for specific requirements for makeup air. Exhaust systems cannot function at design capacity without adequate volumes of makeup air to replace the air being exhausted.

ALTERATION. A change in a system that involves an extension, addition or change to the arrangement, type or purpose of the original installation.

❖ An alteration is any modification or change made to an existing installation. For example, increasing the size of piping for a portion of the system to accommodate different appliances would be an alteration.

ANODELESS RISER. A transition assembly in which plastic *piping* is installed and terminated above ground outside of a building.

❖ As the name implies, these riser assemblies protect the steel riser from corrosion by means other than

Photo courtesy of Perfection Corporation

Figure G2403(1)
ANODELESS RISERS

cathodic protection that involves a sacrificial anode. Some anodeless risers allow the termination of plastic piping above ground by encasing the piping in a steel conduit equipped with a plastic-to-steel transition fitting [see Commentary Figure 2403(1)].

APPLIANCE. Any apparatus or device that utilizes a fuel or raw material to produce light, heat, power, refrigeration or air conditioning.

❖ An appliance is a manufactured component or assembly of components that converts one source of energy into a different form of energy to serve a specific purpose. The term “appliance” generally refers to residential- and commercial-type utilization equipment that is manufactured in standardized sizes or types. The term “appliance” is generally not associated with industrial-type equipment. For the application of the code provisions, the terms “appliance” and “equipment” are not interchangeable.

Examples of appliances regulated by the code include furnaces; boilers; water heaters; room heaters; decorative gas log sets; cooking equipment; clothes dryers; pool, spa and hot tub heaters; unit heaters; ovens and similar gas-fired appliances (see the definition of “Equipment”). Note that the definition intends to state that a fuel can be used as a raw material to produce energy rather than the apparent statement that an appliance utilizes raw materials that are not fuels. For example, a fuel-cell system could use natural gas as a raw material for the production of hydrogen for use in the fuel cell. The definition was revised to recognize that in a few instances in the code, the term “appliance” is used to describe appliances that are fueled by other

than gaseous fuels, whereas generally, the term describes gas-fired appliances.

APPLIANCE, AUTOMATICALLY CONTROLLED.

Appliances equipped with an automatic *burner* ignition and safety shut-off device and other automatic devices, which accomplish complete turn-on and shut-off of the gas to the *main burner* or *burners*, and graduate the gas supply to the *burner* or *burners*, but do not affect complete shut-off of the gas.

❖ With respect to the code, an automatically controlled appliance is an appliance that is cycled through its operation by controls, such as thermostats, pressure switches and timers, without manual intervention. A residential water heater is automatically controlled: a four-burner cooktop is not.

APPLIANCE, FAN-ASSISTED COMBUSTION. An *appliance* equipped with an integral mechanical means to either draw or force products of combustion through the combustion chamber or heat exchanger.

❖ Fan-assisted appliances are a specific type of Category I appliance, typically furnaces and boilers. They are not to be confused with Category II, III or IV appliances; power-vented appliances; or appliances served by exhausters. As the name implies, these appliances use a fan (blower) to “assist” the combustion process by helping the flue gases to overcome the internal flow resistance of the appliance heat exchanger. Some fan-assisted appliances are field-convertible to Category III appliances.

APPLIANCE, UNVENTED. An *appliance* designed or installed in such a manner that the products of combustion are

FUEL GAS

not conveyed by a vent or *chimney* directly to the outside atmosphere.

❖ Direct-fired makeup air heaters, gas-fired infrared radiant unit heaters, gas-fired cooking equipment and small gas-fired room heaters are examples of appliances that are sometimes unvented. With the exception of direct-fired equipment, the appliances listed herein can also be of the vented type, depending on the design and type of appliance and the particular application. Unvented appliances must be designed, installed and operated to avoid both the depletion of the oxygen supply and the accumulation of toxic combustion by products (see Sections G2425.8, G2445 and G2451).

APPLIANCE, VENTED. An *appliance* designed and installed in such a manner that all of the products of combustion are conveyed directly from the *appliance* to the outside atmosphere through an *approved chimney* or vent system.

❖ Most fuel-fired appliances are designed to vent the products of combustion to the outdoors through one or more specific types of vent or chimney (see Section G2425.2).

APPROVED. Acceptable to the *code official*.

❖ As related to the process of acceptance of fuel gas related installations, including materials, equipment and construction systems, this definition identifies where ultimate authority rests. Whenever this term is used, it means that only the enforcing authority can accept a specific installation or component as complying with the code. Research reports prepared and published by the ICC may be used by code officials to aid in their review and approval of the material or method described in the report. Publishing a report does not indicate automatic “approval” for the material or method described in the report. When the code states that an item or method “shall be approved,” it does not mean that the code official is obligated to allow or accept it. Rather, it means that the code official must determine whether the item or method is acceptable; that is, the code official must make the decision to allow or disallow; accept or reject.

APPROVED AGENCY. An established and recognized agency that is regularly engaged in conducting tests or furnishing inspection services, where such agency has been approved by the *code official*.

ATMOSPHERIC PRESSURE. The pressure of the weight of air and water vapor on the surface of the earth, approximately 14.7 pounds per square inch (psia) (101 kPa absolute) at sea level.

❖ This is the “standard” atmospheric pressure at sea level. The actual atmospheric pressure varies with climate conditions. Barometric pressure is a measure of the actual atmospheric pressure, usually given as inches of mercury. One standard atmosphere (14.7 psi) is equal to 29.9 inches of mercury (101.4 kPa) at 32°F (0°C). Absolute pressure includes atmospheric pressure. Gauge pressure is the pressure above atmo-

spheric pressure. If not otherwise defined, stated pressure is the pressure above atmospheric pressure (gauge pressure). A vacuum (partial or complete) is a pressure below atmospheric pressure.

AUTOMATIC IGNITION. Ignition of gas at the *burner(s)* when the gas controlling device is turned on, including reignition if the flames on the *burner(s)* have been extinguished by means other than by the closing of the gas controlling device.

❖ As opposed to manual ignition, automatic ignition is accomplished by pilot burners, spark ignitors, hot surface ignitors and similar means.

BAROMETRIC DRAFT REGULATOR. A balanced *damper* device attached to a *chimney*, vent *connector*, breeching or flue gas manifold to protect combustion *appliances* by controlling *chimney draft*. A double-acting *barometric draft regulator* is one whose balancing *damper* is free to move in either direction to protect combustion *appliances* from both excessive *draft* and backdraft.

❖ These units automatically open or close depending on the difference between the internal vent pressure and the atmospheric pressure. See the commentary to the definition of “Atmospheric pressure.” Excessive negative pressure in the vent will cause excessive draft; therefore, the draft regulator will open as a result of the higher atmospheric pressure on the exterior of the damper, allowing air to enter the vent and thereby increase the internal vent pressure. With excessive positive internal vent pressure, a double-acting regulator will open to relieve the pressure, lowering the vent internal pressure [see Commentary Figure G2403(2)].

FIGURE G2403(2)
BAROMETRIC DRAFT REGULATOR

BOILER, LOW-PRESSURE. A self-contained *appliance* for supplying steam or hot water.

- ❖ Low-pressure boilers operate at pressures less than or equal to 15 pounds per square inch (psi) (103 kPa) for steam and 160 psi (1103 kPa) for water. High-pressure boilers operate at pressures exceeding those pressures.

Boilers are usually manufactured of steel, cast iron or copper and are used to transfer heat from the combustion of a fuel or from an electric-resistance element to water to make steam or pressurized hot water for heating or other process or power purposes.

Boilers are usually installed in closed systems where the heat transfer medium is recirculated and retained within the system.

Boilers must be labeled and installed in accordance with the manufacturer's installation instructions and

the applicable sections of the code. Boilers are rated in accordance with standards published by the American Society of Mechanical Engineers (ASME), the Hydronics Institute, the Steel Boiler Institute (SBI), the Canadian Standards Association (CSA) and the American Boiler Manufacturers Association (ABMA). Boilers can be classified by working temperature, working pressure, type of fuel used (or electric boilers), materials of construction and whether or not the heat transfer medium changes phase from a liquid to a vapor [see Commentary Figure G2403(3)].

Hot water heating boiler. A boiler in which no steam is generated, from which hot water is circulated for heating purposes and then returned to the boiler, and that operates at water pressures not exceeding 160 pounds per square inch gauge (psig) (1100 kPa gauge) and at water tempera-

MAWP, WATER 50 PSI
MAWP, STEAM 15 PSI
MAX. WATER TEMP. 250°F

Electrical Input Less Than
12 Amperes, 120 Volts, & 60 Hertz.
Canadian Registration No. H7268.51234679T
MEA Number: 333-85-E
Design Certified Under ANSI Z21.13a 2005 • CSA 4.9a 2005
Low Pressure Boiler

IMPORTANT

Installation not complete unless gas information label attached here.
Labels are attached to gas train in gas control carton.

- For installation on noncombustible flooring.
- Provide service clearances and minimum 24" between jacket and any combustible wall(s) and ceiling. Install in space large in comparison to size of boiler.
- Vent Category I.

550-223-880 (0606)

Figure G2403(3)
LABEL FOR LOW-PRESSURE BOILER

FUEL GAS

tures not exceeding 250°F (121°C) at or near the boiler outlet.

- ❖ Hot water heating boilers are normally part of a closed system in which the heated water is circulated through fan coils or radiators of various types, including convectors, finned tube units, radiant floor tubing systems and baseboard units.

Hot water supply boiler. A boiler, completely filled with water, which furnishes hot water to be used externally to itself, and that operates at water pressures not exceeding 160 psig (1100 kPa gauge) and at water temperatures not exceeding 250°F (121°C) at or near the boiler outlet.

- ❖ Hot water supply boilers are normally part of open systems in which the heated water is supplied and used externally to the boiler. Large domestic (potable) water heating systems often use hot water supply boilers. Such boilers will not likely be found in dwellings.

Steam heating boiler. A boiler in which steam is generated and that operates at a steam pressure not exceeding 15 psig (100 kPa gauge).

- ❖ Steam heating boilers are normally part of a closed system in which low-pressure steam can be circulated through a variety of terminal units, including natural convection units, forced-convection units and radiant panel systems.

BONDING JUMPER. A conductor installed to electrically connect metallic gas *piping* to the grounding electrode system.

- ❖ This term is used in subsections of G2411.1.1 relative to the bonding of gas piping systems. It is a number 6 AWG or larger copper conductor or equivalent that is used to electrically bond gas piping to the grounding electrodes that are a part of the electrical service for the structure.

BRAZING. A metal-joining process wherein coalescence is produced by the use of a nonferrous filler metal having a melting point above 1,000°F (538°C), but lower than that of the base metal being joined. The filler material is distributed between the closely fitted surfaces of the joint by capillary action.

- ❖ Brazing is the act of producing a brazed joint and is often referred to as silver soldering. Silver soldering is more accurately described as silver brazing and uses high-silver-bearing alloys primarily composed of silver, copper and zinc. Silver soldering (brazing) typically requires temperatures in excess of 1,000°F (538°C), and these solders are classified as “hard” solders.

Confusion has always existed concerning the distinction between “silver solder” and “silver-bearing solder.” Silver solders are unique and can be further subdivided into soft and hard categories that are determined by the percentages of silver and the other component elements of the particular alloy. The distinction is that silver-bearing solders [melting point below 600°F (316°C)] are used in soft-soldered joints, and silver solders [melting point above 1,000°F (538°C)] are used in silver-brazed joints.

Brazed joints are considered to have superior strength and stress resistance and, because of the high melting point, are less likely to fail when exposed to fire.

Brazing with a filler metal conforming to AWS A5.8 produces a strong joint that will perform under extreme service conditions. The surfaces to be brazed must be cleaned to be free from oxides and impurities. Flux should be applied as soon as possible after the surfaces have been cleaned. Flux helps to remove residual traces of oxides, to promote wetting and to protect the surfaces from oxidation during heating. Care should be taken to prevent flux from entering the piping system during the brazing operation because flux that remains may corrode the pipe or contaminate the system.

Air and any other residual products should be removed from the pipe being brazed by purging the piping with a nonflammable gas such as carbon dioxide or nitrogen. Purging the system has several benefits, such as preventing oxidation from occurring on the inside of the pipe and preventing the creation of toxic gases that can result from the chemical breakdown of other products. Additionally, purging will eliminate the possibility of an explosion from any other flammable gas in the pipe that could ignite when mixed with air.

BTU. Abbreviation for British thermal unit, which is the quantity of heat required to raise the temperature of 1 pound (454 g) of water 1°F (0.56°C) (1 *Btu* = 1055 J).

BURNER. A device for the final conveyance of the gas, or a mixture of gas and air, to the combustion zone.

- ❖ There are several types of burners that vary in the method of providing combustion air and the pressures of fuel/air mixtures. Burner types include atmospheric ribbon, ported, porous ceramic, slotted and cone types and atmospheric or powered inshot and upshot gun burners.

Induced-draft. A *burner* that depends on *draft* induced by a fan that is an integral part of the *appliance* and is located downstream from the *burner*.

- ❖ See the commentary to the definition of “Draft/mechanical or induced draft.”

Power. A *burner* in which gas, air or both are supplied at pressures exceeding, for gas, the line pressure, and for air, atmospheric pressure, with this added pressure being applied at the *burner*.

- ❖ Power burners are typically used on very large non-residential-type appliances and use a blower to introduce combustion air under pressure and mix it with the fuel.

CHIMNEY. A primarily vertical structure containing one or more flues, for the purpose of carrying gaseous products of *combustion* and air from an *appliance* to the outside atmosphere.

- ❖ Chimneys differ from vents in their materials of construction and the type of appliance they are designed to serve. Chimneys are capable of venting much

higher temperature flue gases than vents [see Commentary Figure G2403(4)].

Factory-built chimney. A *listed* and *labeled* chimney composed of factory-made components, assembled in the field in accordance with manufacturer’s instructions and the conditions of the listing.

- ❖ A factory-built chimney is a manufactured listed and labeled chimney that has been tested by an approved agency to determine its performance characteristics. Factory-built chimneys are manufactured in two basic designs: a double-wall mineral fiber insulated design and a triple-wall air-cooled design. Some chimneys use both convection cooling and mineral-fiber insulation. Both designs use stainless steel inner liners to resist the corrosive effects of combustion products [see Commentary Figure G2403(5)].

Masonry chimney. A field-constructed chimney composed of solid masonry units, bricks, stones or concrete.

- ❖ Masonry chimneys can have one or more flues within them and are field constructed of brick, stone, concrete or fire-clay materials. Masonry chimneys can stand alone or be part of a masonry fireplace.

CLEARANCE. The minimum distance through air measured between the heat-producing surface of the mechanical *appliance*, device or *equipment* and the surface of the *combustible material* or *assembly*.

- ❖ Clearances between sources of heat and combustibles are always airspace clearances.

CLOTHES DRYER. An *appliance* used to dry wet laundry by means of heated air.

- ❖ Type 1 clothes dryers are used in dwelling units and in residential settings.

Type 1. Factory-built package, multiple production. Primarily used in the family living environment. Usually the smallest unit physically and in function output.

- ❖ Type 1 clothes dryers are used in dwelling units and in residential settings.

CODE. These regulations, subsequent amendments thereto, or any emergency rule or regulation that the administrative authority having jurisdiction has lawfully adopted.

- ❖ The adopted regulations are generally referred to as “the code” and include not only this code, but also any adopted modifications to the code and all other related rules and regulations promulgated and enacted by the jurisdiction.

CODE OFFICIAL. The officer or other designated authority charged with the administration and enforcement of this code, or a duly authorized representative.

- ❖ The statutory power to enforce the code is normally vested in a building department (or the like) of a state, county or municipality whose designated enforcement officer is termed the “code official.”

COMBUSTIBLE ASSEMBLY. Wall, floor, ceiling or other assembly constructed of one or more component materials that are not defined as noncombustible.

- ❖ A combustible assembly is made up of one or more combustible components. For example, a wall assem-

**Figure G2403(5)
AIR-COOLED FACTORY-BUILT CHIMNEY SECTION**

bly with wood studs is combustible regardless of the nature of the sheathing attached to the studs. Likewise, a metal stud wall with gypsum board sheathing is a combustible assembly because the gypsum board is not noncombustible. A noncombustible assembly has no combustible elements (see the definition of “Noncombustible materials”).

COMBUSTIBLE MATERIAL. Any material not defined as noncombustible.

❖ See the definition of “Noncombustible materials.”

COMBUSTION. In the context of this code, refers to the rapid oxidation of fuel accompanied by the production of heat or heat and light.

❖ The primary components of combustion are fuel, oxygen and heat. The code regulates many aspects of combustion technology, including the process of combustion and providing sufficient air; the use of energy produced from combustion; the safe venting of the products of combustion; combustion efficiency; the containment and control of combustion; and the fuel supplies for combustion equipment and appliances.

COMBUSTION AIR. Air necessary for complete combustion of a fuel, including theoretical air and excess air.

❖ The process of combustion requires a specific amount of oxygen to initiate and sustain the combustion reaction. Combustion air includes primary air, secondary air, draft hood dilution air and excess air. Combustion air includes the amount of atmospheric air required for complete combustion of a fuel and is related to the molecular composition of the fuel being burned, the design of the fuel-burning equipment and the percentage of oxygen in the combustion air. Too little combustion air will result in incomplete combustion of a fuel and the possible formation of carbon deposits (soot), carbon monoxide, toxic alcohols, ketones, aldehydes, nitrous oxides and other by-products. The required amount of combustion air is usually stated in terms of cubic feet per minute (m³/s) or pounds per hour (kg/h).

COMBUSTION CHAMBER. The portion of an *appliance* within which combustion occurs.

❖ Combustion chambers are either open to the atmosphere or are isolated (sealed) from the atmosphere in which the appliance is installed. Combustion chambers are often referred to as “fireboxes.”

COMBUSTION PRODUCTS. Constituents resulting from the combustion of a fuel with the oxygen of the air, including the inert gases, but excluding excess air.

❖ Such products include water, carbon dioxide, carbon monoxide, nitrous oxides and various trace compounds.

CONCEALED LOCATION. A location that cannot be accessed without damaging permanent parts of the building structure or finish surface. Spaces above, below or behind

readily removable panels or doors shall not be considered as concealed.

❖ The space above a “drop-in” tile suspended ceiling system, for example, would not be considered as a concealed location.

CONCEALED PIPING. *Piping* that is located in a *concealed location* (see “*Concealed location*”).

❖ This refers to gas piping in locations meeting the definition of “Concealed location.”

CONDENSATE. The liquid that condenses from a gas (including flue gas) caused by a reduction in temperature or increase in pressure.

❖ Condensate forms when the temperature of a vapor is lowered to its dew point temperature. Air conditioning systems produce condensate when an airstream contacts cooling coils. The moisture in the air condenses on the cold surface of the coils and the air is “dehumidified.” High-efficiency (84 percent and up) fuel burning appliances produce condensate from the combustion gases. Condensate also forms within improperly designed chimneys and vents when the products of combustion (which contain water vapor) contact the colder inner walls of the vent or chimney. If the temperature of the products of combustion is lowered to the dew point temperature of the water vapor, condensate will form on the inside walls of the vent or chimney. Condensed steam in hydronic systems is also referred to as “condensate.”

CONNECTOR, APPLIANCE (Fuel). Rigid metallic *pipe* and fittings, semirigid metallic *tubing* and fittings or a *listed* and *labeled* device that connects an *appliance* to the *gas piping system*.

❖ An appliance fuel connector is the piping, tubing or factory-built device that is installed downstream of the equipment shutoff to connect the appliance to the gas piping system. See the definition of “Piping system.” Section G2422.1 lists the types of appliance connectors which include both factory-built assemblies and field-constructed assemblies of pipe, tube and fittings. Note that rigid metallic piping, such as Schedule 40 black steel, used to connect an appliance to the gas piping system is considered to be an appliance connector because it is placed between the appliance and the piping system, downstream of the appliance shutoff valve. As defined, the gas piping ends at the appliance/equipment shutoff valve, therefore, everything downstream of that point is defined, sized and installed as a connector except as required by Sections G2420.5.2, G2420.5.3 and the exception to Section G2422.1.2.1.

CONNECTOR, CHIMNEY OR VENT. The *pipe* that connects an *appliance* to a chimney or vent.

❖ In most cases, appliances are not located directly in line with the vertically rising chimney or vent; therefore,

a vent or chimney connector is necessary to connect the appliance flue outlet to the vent or chimney. Vent and chimney connectors can be single- or double-wall pipes and are usually made from steel, galvanized steel, stainless steel or aluminum sheet metal, depending on the application. Vent connectors are also made of corrugated aluminum. In many installations, the vent connectors must be constructed of the same material as the vent, as is typically done with Type B vent systems. There are many requirements in the code (Sections G2427 and G2428) regulating the location, length, size and type of connector.

CONTROL. A manual or automatic device designed to regulate the gas, air, water or electrical supply to, or operation of, a mechanical system.

- ❖ A control is a device designed to respond to changes in temperature, pressure, liquid or gas flow rates, current, voltage, resistance, humidity or liquid levels.

CONVERSION BURNER. A unit consisting of a *burner* and its *controls* for installation in an *appliance* originally utilizing another fuel.

- ❖ Typical conversion burners are designed to convert an appliance, such as a boiler, from solid-fuel fired to oil fired or from oil fired to gas fired.

CUBIC FOOT. The amount of gas that occupies 1 cubic foot (0.02832 m³) when at a temperature of 60°F (16°C), saturated with water vapor and under a pressure equivalent to that of 30 inches of mercury (101 kPa).

- ❖ This definition applies specifically to a measurement of fuel gas.

DAMPER. A manually or automatically controlled device to regulate *draft* or the rate of flow of air or combustion gases.

- ❖ Dampers act as restrictors or valves in a gaseous flow stream (see Section G2427).

DECORATIVE APPLIANCE, VENTED. A *vented appliance* wherein the primary function lies in the aesthetic effect of the flames.

- ❖ Such appliances include so-called “gas fireplaces” that are designed to simulate a wood-burning fireplace. The title of the standard for vented decorative gas-fired appliances (ANSI Z21.50) has been changed to “Vented Gas Fireplaces.”

DECORATIVE APPLIANCES FOR INSTALLATION IN VENTED FIREPLACES. A *vented appliance* designed for installation within the fire chamber of a vented *fireplace*, wherein the primary function lies in the aesthetic effect of the flames.

- ❖ These appliances include gas log sets for installation in solid-fuel-burning fireplaces.

DEMAND. The maximum amount of gas input required per unit of time, usually expressed in cubic feet per hour, or *Btu/h* (1 *Btu/h* = 0.2931 W).

- ❖ Demand refers to the load that appliances place on the fuel-gas distribution system.

DESIGN FLOOD ELEVATION. The elevation of the “design flood,” including wave height, relative to the datum specified on the community’s legally designated flood hazard map. In areas designated as Zone AO, the *design flood elevation* shall be the elevation of the highest existing grade of the *building’s* perimeter plus the depth number, in feet, specified on the flood hazard map. In areas designated as Zone AO where a depth number is not specified on the map, the depth number shall be taken as being equal to 2 feet (610 mm).

- ❖ This term is used in Section G2404.7. See the commentary to Sections R322.1.4 and R322.1.4.1.

DILUTION AIR. Air that is introduced into a *draft hood* and is mixed with the *flue gases*.

- ❖ Dilution air is associated only with draft-hood equipped Category I appliances. Fan-assisted Category I appliances do not involve dilution air because all of the air brought in by the fan passes directly through the combustion chamber of the appliance. Dilution air lowers the dew point of vent gases, reducing the possibility that condensation will occur inside the vent or chimney.

DIRECT-VENT APPLIANCES. *Appliances* that are constructed and installed so that all air for combustion is derived directly from the outside atmosphere and all *flue gases* are discharged directly to the outside atmosphere.

- ❖ These appliances have independent exhaust and intake pipes or have concentric pipes that vent combustion gases through the inner pipe and convey combustion air in the annular space between the inner and outer pipe walls [see Commentary Figures G2403(6) and G2403(7)].

DRAFT. The pressure difference existing between the *appliance* or any component part and the atmosphere, that causes a continuous flow of air and products of combustion through the gas passages of the *appliance* to the atmosphere.

- ❖ Draft is the negative static pressure measured relative to atmospheric pressure that is developed in chimneys and vents and in the flue-ways of fuel-burning appliances. Draft can be produced by hot flue-gas buoyancy (“stack effect”), mechanically by fans and exhausters or by a combination of both natural and mechanical means.

Mechanical or induced draft. The pressure difference created by the action of a fan, blower or ejector that is located between the *appliance* and the chimney or vent termination.

- ❖ Induced draft systems use a fan or blower to boost or “induce” draft in a venting system that produces insufficient natural draft. Draft induction implies that the combustion gases are “pulled” through a passageway or conduit. Draft inducers produce negative pressures on the inlet (upstream) side of the fan or blower. They are separate field-installed units located between an appliance and its venting system. Draft inducers are used with natural draft venting systems to overcome the resistance of vent or chimney connectors and to

compensate for the inability of the chimney or vent to produce sufficient and reliable draft.

Draft induction is also a design principle used in many fan-assisted appliances. Draft-inducer fans or blowers that are integral with fuel-fired appliances are necessary to overcome the internal resistance of the heat exchanger flue passageways. To attain higher thermal transfer efficiencies, some heat exchanger designs use flue passageways that retain the combustion gases longer over a greater surface area, thus extracting more heat. Such heat exchanger designs cannot rely on natural (gravity) venting to overcome the higher resistance to flow and, therefore, must rely on mechanical means to pull the combustion gases through the heat exchanger.

Induced draft systems are not to be confused with systems using power exhausters or other self-venting equipment.

Mechanical draft systems produce positive pressures on the discharge side of the fan or blower and can be said to “push” combustion gases through a passageway or conduit.

Natural draft. The pressure difference created by a vent or chimney because of its height, and the temperature difference between the *flue gases* and the atmosphere.

- ❖ Natural draft systems do not use mechanical devices such as fans or blowers, but instead rely on the princi-

ple of buoyancy to carry the products of combustion to the atmosphere. Because of the difference in temperature and the resultant difference in density between the hot products of combustion and the ambient atmosphere, the gases within the chimney or flue will rise, creating a buoyant “draft.” The phenomenon of natural draft is sometimes referred to as “stack effect” and is measured in inches of water column (kPa). The amount of draft is affected by the height of the chimney or vent and also by the ability of the chimney or vent to maintain the temperature differential between the combustion gases and the ambient air.

DRAFT HOOD. A nonadjustable device built into an *appliance*, or made as part of the *vent connector* from an *appliance*, that is designed to (1) provide for ready escape of the *flue gases* from the *appliance* in the event of no *draft*, back-draft, or stoppage beyond the *draft hood*, (2) prevent a back-draft from entering the *appliance*, and (3) neutralize the effect of stack action of the chimney or gas vent upon operation of the *appliance*.

- ❖ Draft hoods are integral to or supplied with natural draft atmospheric-burner gas-fired appliances other than fan-assisted appliances. When classified, appliances equipped with draft hoods are classified by the manufacturer as Category I appliances. Because of minimum efficiency standards and the popularity of mechanical and other special proprietary venting systems, draft-hood-equipped appliances are becoming increasingly rare in the marketplace [see Commentary Figure G2403(8)].

Photo courtesy of A. O. Smith Water Products

Figure G2403(8)
DRAFT-HOOD-EQUIPPED APPLIANCE

DRAFT REGULATOR. A device that functions to maintain a desired *draft* in the *appliance* by automatically reducing the *draft* to the desired value.

- ❖ Excessive draft reduces the combustion and thermal efficiency of an appliance. Draft regulators automatically adjust the draft by admitting air into the vent, thereby reducing the draft [see Commentary Figure G2403(2)].

DRIP. The container placed at a low point in a system of *pip-ing* to collect *condensate* and from which the *condensate* is removable.

- ❖ These reservoirs, also referred to as “drip legs,” are made up of pipe and fittings and are intended to collect liquid in piping systems where condensables are possible. A “drip leg” is distinct from a “sediment trap” even though they may be constructed identically.

DUCT FURNACE. A warm-air *furnace* normally installed in an air-distribution duct to supply warm air for heating. This definition shall apply only to a warm-air heating *appliance*

that depends for air circulation on a blower not furnished as part of the *furnace*.

- ❖ Duct furnaces are vented appliances and consist of burners, heat exchangers and related controls. Duct furnaces depend on an external air handler or blower.

DWELLING UNIT. A single unit providing complete, independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

- ❖ Contrast this definition with the definition of “Sleeping unit.” All of the listed provisions must be present for the occupancy to be considered as a dwelling unit.

EQUIPMENT. Apparatus and devices other than *appliances*.

- ❖ The term “equipment” does not refer to or describe anything that is defined as an “Appliance,” despite the fact that some appliances are commonly referred to in the field as “pieces of equipment.” The term “equipment” includes control devices, pressure regulators, valves, appliance appurtenances, gas connectors, power exhausters, fans, air handlers and a multitude of other devices that do not fit the description of “appliance.”

EXCESS FLOW VALVE (EFV). A valve designed to activate when the fuel gas passing through it exceeds a prescribed flow rate.

- ❖ Some utility companies install excess flow valves (EFVs) in gas service lines to provide protection against high-pressure leaks resulting from damage to the piping caused by excavation, hole boring or hand digging. The device is a type of shutoff valve that abruptly closes when the gas flow through it reaches an abnormal flow rate corresponding to its design setting. The excess flow pushes a spring-loaded element against a seat in the EFV body. The upstream gas pressure holds the valve in the closed position. After the gas line is repaired and closed off on the load end, the EFV will reset itself by allowing a small flow of gas to pass through an orifice in the valve into the downstream piping, thereby equalizing the pressure on both sides of the valve and allowing the valve to reopen by the force of the spring. Service line EFVs do not fall within the scope of the code because the service line is upstream of the point of delivery. Appliance-type EFVs are addressed by the code, are designed to protect individual appliances and are installed in the supply piping to the appliance. Some types are installed on the supply end of a gas appliance connector. The basic operating principle is the same for all types, although some do not allow bypass gas flow and are, therefore, not self-resetting. The moving component of EFVs, depending on the type, is held open by gravity, a spring or a magnet. The gravity type must be installed in a vertical position.

EFVs can be compared to electrical circuit breakers in that they stop gas flow when a predetermined flow rate is exceeded, just as circuit breakers interrupt electrical current flow when the amperage setting is exceeded. Imagine a scenario where an appliance gas connector is severed or a gas line breaks loose at a fitting and gas would be flowing into the space at a high rate. An EFV device installed upstream of the point of leakage would recognize the abnormal flow and either shut off the gas flow completely or reduce the flow to a small bypass flow (see Section G2421.4 and Figure G2421.4).

EXTERIOR MASONRY CHIMNEYS. Masonry chimneys exposed to the outdoors on one or more sides below the roof line.

- ❖ The part of a chimney that extends above the roof will obviously be exposed to the outdoors, but the sizing methods in Section G2428 are based on the chimney being indoors below the roof. If any one wall or multiple walls of a chimney are exposed to the outdoors, the chimney will lose heat more rapidly, will likely produce condensation internally and may fail to produce the required draft.

Exterior masonry chimneys are not addressed in Chapter 24 because such chimneys are rarely used to vent gas appliances today and the code attempts to limit its coverage to those installations that are common and relevant. These chimneys are addressed in the IFGC and if one is encountered on a job site, the provisions of the IFGC would apply (see Section G2401.1).

FIREPLACE. A fire chamber and hearth constructed of *non-combustible material* for use with solid fuels and provided with a chimney.

- ❖ Fireplaces burn solid fuels (wood, coal, etc.) and are not referred to as appliances in the code. The IBC and the code cover construction of masonry fireplaces.

Factory-built fireplace. A *fireplace* composed of *listed* factory-built components assembled in accordance with the terms of listing to form the completed *fireplace*.

- ❖ Factory-built fireplaces are solid-fuel-burning units having a fire chamber that is intended to be either open to the room or, if equipped with doors, operated with the doors either open or closed. Fireplaces are not referred to as appliances. The term “fireplace” describes a complete assembly that includes the hearth, the fire chamber and a chimney. A factory-built fireplace is composed of factory-built components representative of the prototypes tested and is installed in accordance with the manufacturer’s installation instructions to form the completed fireplace.

Masonry fireplace. A hearth and fire chamber of solid masonry units such as bricks, stones, *listed* masonry units or reinforced concrete, provided with a suitable chimney.

- ❖ Masonry fireplaces must be constructed in accordance with the requirements found in Chapter 10. These specific requirements are based on tradition and field

experience and describe the conventional fireplace that has proven to be reliable where properly constructed, used and maintained.

FLAME SAFEGUARD. A device that will automatically shut off the fuel supply to a *main burner* or group of *burners* when the means of ignition of such *burners* becomes inoperative, and when flame failure occurs on the *burner* or group of *burners*.

- ❖ These devices are primary safety controls and are provided on all automatically operated fuel-fired appliances.

FLASHBACK ARRESTOR CHECK VALVE. A device that will prevent the backflow of one gas into the supply system of another gas and prevent the passage of flame into the gas supply system.

- ❖ See the commentary to Section G2421.5.

FLOOD HAZARD AREA. The greater of the following two areas:

1. The area within a floodplain subject to a 1 percent or greater chance of flooding in any given year.
2. This area designated as a *flood hazard area* on a community’s flood hazard map, or otherwise legally designated.

- ❖ See the commentary to Sections R322.1.4 and R322.1.4.1.

FLOOR FURNACE. A completely self-contained *furnace* suspended from the floor of the space being heated, taking air for combustion from outside such space and with means for observing flames and lighting the *appliance* from such space.

- ❖ These units supply heat through a floor grille placed directly over the unit’s heat exchanger.

FLUE, APPLIANCE. The passage(s) within an *appliance* through which *combustion products* pass from the *combustion chamber* of the *appliance* to the *draft hood* inlet opening on an *appliance* equipped with a *draft hood* or to the outlet of the *appliance* on an *appliance* not equipped with a *draft hood*.

- ❖ Appliance flues are the passages through an appliance from the combustion chamber, through the heat exchanger and through the vent outlet.

FLUE COLLAR. That portion of an *appliance* designed for the attachment of a *draft hood*, *vent connector* or venting system.

- ❖ The flue collar size will be a determining factor in vent connector sizing.

FLUE GASES. Products of combustion plus excess air in *appliance flues* or heat exchangers.

- ❖ The exact composition of flue gases will depend on the fuel being burned. The primary components of flue gases are nitrogen, carbon dioxide, water vapor, particulates and a myriad of compounds and trace elements that vary with the nature of the fuel and purity of the combustion air. Carbon monoxide is also a component of flue gas.

FLUE LINER (LINING). A system or material used to form the inside surface of a flue in a *chimney* or vent, for the purpose of protecting the surrounding structure from the effects of *combustion products* and for conveying *combustion products* without leakage to the atmosphere.

❖ Flue liners must be resistant to heat and the corrosive action of the products of combustion. They provide insulation value to retard the transfer of heat to the chimney structure and limit exposure of the chimney structure to the harmful effects of combustion products. Flue liners are generally made of fire-clay tile, refractory brick, poured-in-place refractory materials, stainless steel alloys and aluminum. Flue liners used with gas-fired appliances are typically made of stainless steel or aluminum [see Commentary Figure G2403(9)].

FUEL GAS. A natural gas, manufactured gas, *liquefied petroleum gas* or mixtures of these gases.

❖ The nature of fuel gases makes proper design, installation and selection of materials and devices necessary to minimize the possibility of fire or explosion. Bringing fuel gases into a building is in itself a risk. The provisions of the code are intended to reduce that risk to a level comparable to that associated with other energy sources such as electricity.

The two most commonly used fuel gases are natural gas and liquefied petroleum gas (LP-gas or LPG). These fuel gases have the following characteristics or properties.

Natural gas: The principal constituent of natural gas is methane (CH₄). It can also contain small quantities of nitrogen, carbon dioxide, hydrogen sulfide, water vapor, other hydrocarbons (such as ethane and propane) and various trace elements. Natural gas is colorless, tasteless and odorless; however, an odorant (methyl mercaptan) is added to the gas so that it can be readily detected. Natural gas is lighter than air (specific gravity of 0.60 typical) and has the tendency to rise when escaping to the atmosphere.

Natural gas has a rather narrow flammability range (approximately 3 to 15 percent volume in air) above and below which the gas-to-air mixture ratio will be too rich or too lean to support combustion. The heating value of natural gas is approximately 1,050 Btu per cubic foot (39 MJ/m³).

LP-gas: Liquefied petroleum gases include commercial propane and commercial butane. LP-gas vapors are heavier than air (specific gravity of 1.52 typical) and tend to accumulate in low areas and near the floor; however, a gas-air mixture that is within the flammability range will have a specific gravity very close to that of air. The ranges of flammability for LP-gases are narrower than those of natural gas (approximately 2 to 10 percent volume in air). Like natural gas, LP-gases are odorized to make them detectable. The heating value of propane is approximately 2,500 Btu per cubic foot (93 MJ/m³) of gas. The heating value of butane is approximately 3,300 Btu per cubic foot (123 MJ/m³) of gas.

Basic Kits contain 25' or 35' of flexible liner, cap assembly, flashing, flex coupling, mortar sleeve, female adapter, and universal adapter.

Gas Fireplace kits contain 25' of flexible liner, cap assembly, flashing, flex coupling, and universal adapter.

For SI: 1 foot = 304.8 mm.

Figure G2403(9)
CHIMNEY FLUE LINER SYSTEM FOR GAS APPLIANCE

FUEL GAS

FURNACE. A completely self-contained heating unit that is designed to supply heated air to spaces remote from or adjacent to the *appliance* location.

❖ The single most distinguishing characteristic of furnaces is that they use air as the heat transfer medium. Furnaces can be fueled by gas, oil, solid fuel or electricity and use fans, blowers or gravity (convection) to circulate air to and from the unit. In the context of the code, the primary usage of the term “furnace” refers to heating appliances that combine a combustion chamber with related burner and control components, one or more heat exchangers, a flue gas conveying system and air-handling fans/blowers.

FURNACE, CENTRAL. A self-contained *appliance* for heating air by transfer of heat of *combustion* through metal to the air, and designed to supply heated air through ducts to spaces remote from or adjacent to the *appliance* location.

❖ The term “central furnace” has been adopted to identify a furnace that supplies conditioned air to remote locations from a central location. There are many types of furnaces. Most of these variations are a result of architectural design related to available space, desired location of the unit and size of the area to be conditioned.

FURNACE PLENUM. An air compartment or chamber to which one or more ducts are connected and which forms part of an air distribution system.

❖ The term “plenum” is no longer defined or used in this chapter. A furnace plenum is a box made of sheet metal or other duct material. Such a box is attached directly to a furnace to facilitate connection of supply and return ducts to the furnace air inlet and outlet. This

term does not refer to cavities within a building, such as stud and joist spaces and spaces above dropped ceilings.

GAS CONVENIENCE OUTLET. A permanently mounted, manually operated device that provides the means for connecting an *appliance* to, and disconnecting an *appliance* from, the supply *pipng*. The device includes an integral, manually operated valve with a nondisplaceable valve member and is designed so that disconnection of an *appliance* only occurs when the manually operated valve is in the closed position.

❖ These devices are listed and labeled and designed to mate with specialized appliance connectors. A gas outlet is the point at which the gas distribution system connects to a gas appliance. The outlets are intended for use with portable appliances such as space heaters and outdoor cooking appliances [see Commentary Figures G2403(10) and G2403(11)].

GAS PIPING. An installation of pipe, valves or fittings installed on a premises or in a building and utilized to convey fuel gas.

❖ Gas piping includes all the components, fittings and piping needed to deliver the fuel gas from the point of delivery to the appliance or equipment connection. The point of delivery may be a regulator or meter that is typically installed by the gas utility. The point of delivery may be located at the user’s property line, immediately outside the structure or in some instances in the structure.

**Figure G2403(11)
GAS CONVENIENCE OUTLET**

HAZARDOUS LOCATION. Any location considered to be a fire hazard for flammable vapors, dust, combustible fibers or other highly combustible substances. The location is not necessarily categorized in the *International Building Code* as a high-hazard use group classification.

- ❖ The environment in which mechanical equipment and appliances operate plays a significant role in the safe performance of the equipment installation. Locations that may contain ignitable or explosive atmospheres are classified as hazardous locations for the installation of mechanical equipment and appliances. For example, repair garages can be classified as hazardous locations because they can contain gasoline vapors from vehicles stored within them as well as other volatile chemicals. Public and private garages are not considered hazardous locations even though the presence of motor vehicles and the storage of fuel, paint, varnish, thinner, lawn- and home-maintenance products and other chemicals are a concern, as evidenced by Sections G2408.2 and G2408.3.

HOUSE PIPING. See “*Piping system.*”

- ❖ House piping is the distribution piping downstream of the point of delivery. House piping is an antiquated term.

IGNITION PILOT. A *pilot* that operates during the lighting cycle and discontinues during *main burner* operation.

- ❖ Commonly referred to as “interrupted pilots,” such pilots are ignited by a spark or hot surface device. Generally an electronic circuit controls the ignition system. When main burner ignition has been proven, the ignition pilot is shut off, and the main burner flame is supervised for the entire burn cycle.

IGNITION SOURCE. A flame spark or hot surface capable of igniting flammable vapors or fumes. Such sources include *appliance burners*, *burner* ignitors and electrical switching devices.

- ❖ This definition is important in the application of Section G2408.2 regarding the elevation of ignition sources. By means of this definition, Section G2408.2 applies to unintentional ignition sources, such as electrical switching devices, as well as intentional ignition sources, such as pilot lights, spark ignitors and hot surface ignitors.

In the context of Section G2408.2, an “ignition source” is something capable of igniting flammable vapors that are present in the atmosphere in the locations listed in Section G2408.2.

INFRARED RADIANT HEATER. A heater which directs a substantial amount of its energy output in the form of infrared radiant energy into the area to be heated. Such heaters are of either the vented or unvented type.

- ❖ These heaters include low-intensity tubular types and high-intensity ceramic burner element types. They heat objects (such as people) by direct radiation and do not heat the ambient air.

JOINT, FLARED. A metal-to-metal compression joint in which a conical spread is made on the end of a tube that is compressed by a flare nut against a mating flare.

- ❖ Because the pipe end is expanded in a flared joint, only annealed and bending-tempered soft-drawn copper tubing may be flared. Commonly used flaring tools use a screw yoke and block assembly or an expander tool that is driven into the tube with a hammer. The flared tubing end is compressed between a fitting seat and a threaded nut to form a metal-to-metal seal.

JOINT, MECHANICAL. A general form of gas-tight joints obtained by the joining of metal parts through a positive-holding mechanical construction, such as press joint, flanged joint, threaded joint, flared joint or compression joint.

- ❖ Mechanical joints can take many forms, but most share a common characteristic, which is applying a radial pressure to the pipes or fittings they join. Mechanical joining means can be proprietary, meaning that they are specific to one manufacturer of the fittings and devices and such manufacturer must provide adequate instructions for assembling the joint. Press-joint fittings must be assembled with a special tool that is unique to the fitting. Press joints are irreversible because the fitting and pipe are permanently deformed by the pressing operation. Some press-joint systems are manufactured for use with copper piping and some are manufactured for use with steel piping.

JOINT, PLASTIC ADHESIVE. A joint made in thermoset plastic *piping* by the use of an adhesive substance which forms a continuous bond between the mating surfaces without dissolving either one of them.

- ❖ Unlike solvent welded joints, adhesive (glue) joints are surface bonded. Often, people refer to solvent welded joints, such as used for PVC, CPVC and ABS piping, as “glued” joints, when actually they are chemically welded, not glued.

LABELED. Equipment, materials or products to which have been affixed a label, seal, symbol or other identifying mark of a nationally recognized testing laboratory, inspection agency or other organization concerned with product evaluation that maintains periodic inspection of the production of the above-labeled items and whose labeling indicates either that the *equipment*, material or product meets identified standards or has been tested and found suitable for a specified purpose.

- ❖ When a product is labeled, the label indicates that the material has been tested for conformance to an applicable standard and that the component is subject to third-party inspection to verify that the minimum level of quality required by the standard is maintained. Labeling provides a readily available source of information that is useful for field inspection of installed products. The label identifies the product or material and provides other information that can be further investigated if there is question concerning the suitability of the product or material for the specific installation.

The labeling agency performing the third-party inspection must be approved by the code official. The basis for this approval may include, but is not necessarily limited to, the capacity and capability of the agency to perform the specific testing and inspection.

The referenced standard often states the minimum identifying information that must be on a label. The data contained on a label typically includes, but is not necessarily limited to, name of the manufacturer; product name or serial number; installation specifications; applicable tests and standards; and the approved testing and labeling agency.

LEAK CHECK. An operation performed on a *gas piping system* to verify that the system does not leak.

- ❖ A leak check is not the same as the pressure test required by Sections G2417.1 through G2417.5.2 (see Section G2417.6).

LIQUEFIED PETROLEUM GAS or LPG (LP-GAS).

Liquefied petroleum gas composed predominately of propane, propylene, butanes or butylenes, or mixtures thereof that is gaseous under normal atmospheric conditions, but is capable of being liquefied under moderate pressure at normal temperatures.

- ❖ LP-gases are usually obtained as a by product of oil refinery operations or by stripping natural gas and are commercially available as butane, propane or a mixture of the two. Propane has a boiling point of -40°F (-40°C) at atmospheric pressure and a heating value of approximately 2,500 Btu per cubic foot (93 MJ/m³). Butane has a boiling point of 32°F (0°C) at atmospheric pressure and a heating value of approximately 3,300 Btu per cubic foot (123 MJ/m³). LP-gas is odorized so that gas leakage can be detected.

LISTED. Equipment, materials, products or services included in a list published by an organization acceptable to the code official and concerned with evaluation of products or services that maintains periodic inspection of production of *listed equipment* or materials or periodic evaluation of services and whose listing states either that the *equipment*, material, product or service meets identified standards or has been tested and found suitable for a specified purpose.

- ❖ When a product is listed, it indicates that it has been tested for conformance to an applicable standard and is subject to a third-party inspection quality assurance (QA) program. The QA verifies that the minimum level of quality required by the appropriate standard is maintained. The agency performing the third-party inspection must be approved by the code official, and the basis for this approval may include, but is not limited to, the capacity and capability of the agency to perform the specified testing and inspection.

LIVING SPACE. Space within a *dwelling unit* utilized for living, sleeping, eating, cooking, bathing, washing and sanitation purposes.

- ❖ The code uses this term to define locations that are not to be considered as part of a private garage for the purpose of requiring the elevation of ignition sources (see Section G2408.2).

LOG LIGHTER. A manually operated solid-fuel ignition *appliance* for installation in a vented solid-fuel-burning *fireplace*.

- ❖ Log lighters are simple, manually operated burners used to start wood fires. Log lighters are not considered as decorative but rather as functional appliances. The heat produced by the log lighter flame raises the temperature of the wood fuel to its ignition temperature. A log lighter is designed to be turned off manually after the wood fire is capable of sustaining combustion.

MAIN BURNER. A device or group of devices essentially forming an integral unit for the final conveyance of gas or a mixture of gas and air to the combustion zone, and on which combustion takes place to accomplish the function for which the *appliance* is designed.

- ❖ With the exception of small amounts of fuel for the pilot or ignition burners, the main burner consumes the entire fuel input into an appliance. Common types of atmospheric burners are the drilled port, slotted port, ribbon and single port.

METER. The instrument installed to measure the volume of gas delivered through it.

- ❖ The meter is the actual point of commerce and is usually associated with the point of delivery. This code does not require or regulate meters. The gas-supplying utility generally installs meters for natural gas. Occasionally in locations where there are several tenants (large office buildings, mobile home parks and apartment complexes, for example), the gas utility installs one meter for the property owner and the owner installs individual tenant meters. Liquefied petroleum may be metered to individual tenants from a storage tank in the same manner [see Commentary Figure G2403(12)].

MODULATING. Modulating or throttling is the action of a *control* from its maximum to minimum position in either predetermined steps or increments of movement as caused by its actuating medium.

- ❖ In the context of this code, modulating is associated with burner control valves. One type of automatic control is a modulating control that can infinitely vary the controlled variable over the range being controlled. Another common type of control is a two-position action control, which simply turns the variable being controlled, such as fuel gas, on and off. Another type of control is the floating action control. It regulates the controlled device by adjusting the controlled variable between the open or closed position using a sensing element, which must react faster than the actuating drive time or the system would be essentially the same as a two-position control.

Figure G2403(12)
TYPICAL RESIDENTIAL GAS METER SETTING

NONCOMBUSTIBLE MATERIALS. Materials that, when tested in accordance with ASTM E136, have at least three of four specimens tested meeting all of the following criteria:

1. The recorded temperature of the surface and interior thermocouples shall not at any time during the test rise more than 54°F (30°C) above the furnace temperature at the beginning of the test.
 2. There shall not be flaming from the specimen after the first 30 seconds.
 3. If the weight loss of the specimen during testing exceeds 50 percent, the recorded temperature of the surface and interior thermocouples shall not at any time during the test rise above the furnace air temperature at the beginning of the test, and there shall not be flaming of the specimen.
- ❖ If the material is not determined to be noncombustible, it is, by default, a combustible material. ASTM E136 is a test standard used to determine the combustion characteristics of building materials. This test method in the standard is intended to indicate whether a material will assist in combustion or add appreciable heat to an ambient fire. The three listed criteria are taken from ASTM E136. Items 1 and 2 are applicable if the weight loss of the specimen during the test is 50 percent or less and Item 3 applies if such weight loss is greater

than 50 percent. The standard intends for three out of four samples to comply with either Items 1 and 2 or Item 3.

OFFSET (VENT). A combination of *approved* bends that make two changes in direction bringing one section of the vent out of line, but into a line parallel with the other section.

- ❖ An offset results in the lateral displacement of a vertical vent. Vent offsets are measured in degrees of angle from vertical and are limited in venting systems because they restrict the flow of flue gas. An offset angle is measured between a line that is an extension of the original vertical vent and the new line of direction of the vent [see Commentary Figure G2403(13)]. Note that an offset is more than just a single change in direction and always involves two or more fittings and two changes of direction.

Photo courtesy of Selkirk L.L.C.

Figure G2403(13)
VENT OFFSET

OUTLET. The point at which a gas-fired *appliance* connects to the gas *pipng* system.

- ❖ A gas outlet is analogous to an electrical receptacle outlet. See Section G2415.13 for requirements covering the location of gas piping outlets.

OXYGEN DEPLETION SAFETY SHUTOFF SYSTEM (ODS). A system designed to act to shut off the gas supply to the main and *pilot burners* if the oxygen in the surrounding atmosphere is reduced below a predetermined level.

- ❖ An oxygen depletion safety shutoff system (ODS) is intended to protect the occupants from carbon monox-

ide build-up. The ODS measures the oxygen level in the air and shuts off the appliance if the level falls below a preset level, typically 18 percent. Monitoring oxygen levels will inversely monitor carbon monoxide levels because of the natural relationship between a decreasing oxygen level and an increasing carbon monoxide level [see Commentary Figure G2403(14)].

courtesy of DESA International

Figure G2403(14)
OXYGEN DEPLETION SAFETY SHUTOFF

PILOT. A small flame that is utilized to ignite the gas at the *main burner or burners*.

❖ Pilot burners (pilot lights) can be continuously burning or can be intermittent or interrupted depending upon the type of appliance. Continuously burning (standing) pilots are becoming more rare and are typically found only in certain hearth appliances, water heaters and commercial ranges. Intermittent pilots burn only while the main burner(s) are firing and interrupted pilots burn only until the main burner(s) are ignited and proven.

PIPING. Where used in this code, “*pipng*” refers to either *pipe* or *tubing*, or both.

Pipe. A rigid conduit of iron, steel, copper, brass or plastic.

Tubing. Semirigid conduit of copper, aluminum, plastic or steel.

❖ Piping includes tubing and pipe used to convey fuel gases (see definition of “Piping system”).

PIPING SYSTEM. All fuel *pipng*, valves and fittings from the outlet of the *point of delivery* to the outlets of the *appliance* shutoff valves.

❖ A piping system includes tubing, pipe, fittings, valves and line pressure regulators used to convey fuel gas from the point of delivery to the appliance. This definition was revised to state that the piping system ends at the outlets of the appliance shutoff valves. This revision allows the last 6 feet (1829 mm) or less of gas conduit between the shutoff valve and the appliance inlet connection to be sized as a connector (see Section 409.5 and the definition for “Point of delivery”).

PLASTIC, THERMOPLASTIC. A plastic that is capable of being repeatedly softened by increase of temperature and hardened by decrease of temperature.

❖ Polyvinyl chloride (PVC) is a type of thermoplastic.

POINT OF DELIVERY. For natural gas systems, the *point of delivery* is the outlet of the service meter assembly or the outlet of the service regulator or service shutoff valve where a meter is not provided. Where a valve is provided at the outlet of the service meter assembly, such valve shall be considered to be downstream of the *point of delivery*. For undiluted liquefied petroleum gas systems, the point of delivery shall be considered to be the outlet of the service pressure regulator, exclusive of line gas regulators, in the system.

❖ It is necessary to understand where the point of delivery begins with respect to fuel gas systems because that is the location where the enforcement of Chapter 24 begins. The point of delivery is a point of demarcation that determines what is or is not covered by this chapter. For natural gas systems, the utility-owned service piping, service shutoff valve, service pressure regulator and meter are all upstream of the point of delivery and thus are not covered by the code. Any valve located on the outlet of the service meter assembly is considered to be part of the piping system and under the scope of the code.

For LP-gas applications, the point of delivery is the outlet of the service pressure regulator (see definition). NFPA 58 regulates the piping and components upstream of the outlet of the service pressure regulator, including the regulator itself. In typical two-stage LP-gas systems, the service pressure regulator is the second-stage regulator. Two-stage systems use a first-stage regulator located at the tank to reduce tank pressure down to 10 psig, and a second-stage regulator to reduce the 10 psig pressure down to 11 inches water column (w.c.). Some two-stage systems use separate first- and second-stage regulators and some use integral two-stage regulators, located at the tank, in which both the first- and second-stage regulators are contained within a single unit. Two-psig systems are becoming more popular in LP-gas applications and these systems use three stages of regulation, which include a first-stage regulator to reduce tank pressure to 10 psig, a 2-psi regulator (the service pressure regulator) to reduce the 10 psig pressure to 2 psig and line gas pressure regulators (see definition) used to reduce the 2-psig pressure to 11 inches w.c. for delivery to the appliances. In these systems, the point of delivery is the outlet of the 2-psi regulator.

PRESSURE DROP. The loss in pressure due to friction or obstruction in pipes, valves, fittings, *regulators* and *burners*.

❖ The pressure in a fuel gas system is reduced as the gas flows in the system. This is caused by a loss of energy resulting from friction and turbulence. Fuel gas systems are designed so that the pressure drop does not result in the system pressure falling below the minimum pressure required for proper equipment operation.

PRESSURE TEST. An operation performed to verify the gas-tight integrity of *gas piping* following its installation or modification.

- ❖ Installed piping systems are tested on the job site to verify that the system is free of leaks.

PURGE. To free a gas conduit of air or gas, or a mixture of gas and air.

- ❖ See Section G2417.7.

READY ACCESS (TO). That which enables a device, *appliance* or *equipment* to be directly reached, without requiring the removal or movement of any panel, door or similar obstruction. (See “Access.”)

- ❖ Ready access can be described as the capability of being quickly reached or approached for the purpose of operation, inspection, observation or emergency action. Ready access does not require the removal or movement of any access door, panel or similar obstruction, nor does it require surmounting physical obstructions or obstacles, including differences in elevation. Note that this definition does not refer to the egress/ingress door through which a person enters a room or building.

REGULATOR. A device for controlling and maintaining a uniform gas supply pressure, either pounds-to-inches water column (MP regulator) or inches-to-inches water column (*appliance regulator*).

- ❖ In the context of the code, these devices are fuel-gas pressure regulating devices that reduce a higher pressure to a lower pressure.

REGULATOR, GAS APPLIANCE. A *pressure regulator* for controlling pressure to the manifold of the *gas appliance*.

- ❖ These regulators are integral to the appliance and serve to stabilize the appliance input pressure and supply fuel gas to the appliance at the desired pressure. Most appliances come equipped with appliance regulators because the appliances are designed to operate at a pressure lower than the delivery pressure, even when low pressure gas [0.5 psig or lower (3.4 kPa)] is supplied. Commonly, appliance regulators reduce a pressure of 5 to 8 inches w.c. down to a manifold pressure of 3.5 inches w.c.

REGULATOR, LINE GAS PRESSURE. A device placed in a gas line between the *service pressure regulator* and the *appliance* for controlling, maintaining or reducing the pressure in that portion of the *piping system* downstream of the device.

- ❖ Line gas pressure regulators are used to reduce the gas pressure supplied by the service (point of delivery) regulator. They are typically located at the connection to each gas appliance and are commonly used as “pounds to inches” regulators in systems having elevated [14 inches w.c. (3.5 kPa) to 5 psi typical (34.5 kPa)] supply pressures.

REGULATOR, MEDIUM-PRESSURE (MP Regulator). A *line pressure regulator* that reduces gas pressure from the

range of greater than 0.5 psig (3.4 kPa) and less than or equal to 5 psig (34.5 kPa) to a lower pressure.

- ❖ With the increased use of high-pressure gas distribution systems, systems are designed with one or more regulators in addition to the service regulators. Medium-pressure regulators (MP regulators) are most commonly associated with 2 psi manifold distribution systems used with copper tubing or corrugated stainless steel tubing (CSST) systems. Appliances are also equipped with factory-installed regulators that control burner input (manifold) pressure. MP regulators are used to reduce the service pressure to a pressure suitable for delivery to the gas appliances where the appliance regulator may further reduce the pressure (see Section G2421.2). MP regulators are used where the distribution line pressure is in the range of 5 psig (34.5 kPa) down to 0.5 psig (3.4 kPa) and such pressure needs to be reduced to be compatible with the input pressure needs of the load.

REGULATOR, PRESSURE. A device placed in a gas line for reducing, controlling and maintaining the pressure in that portion of the *piping system* downstream of the device.

- ❖ See the definition and commentary to “Regulator.”

REGULATOR, SERVICE PRESSURE. For natural gas systems, a device installed by the serving gas supplier to reduce and limit the service line pressure to delivery pressure. For undiluted liquefied petroleum gas systems, the regulator located upstream from all line gas pressure regulators, where installed, and downstream from any first stage or a high pressure regulator in the system.

- ❖ The utility company (gas supplier) installs this regulator to reduce the gas pressure from the utility distribution mains to that required for delivery to the meter and customer. For the typical house service, the pressure is reduced from 60 psig to 2 psig or less. The devices are usually located near the meter and outdoors [see Commentary Figure G2403(15)]. For LP-gas systems, the service regulator is the regulator between the first-stage regulator and the line-pressure regulators or between the first-stage regulator and the appliances served where there are no line-pressure regulators. The service regulator is upstream of the point of delivery for natural and LP-gases (see the definition of “Point of delivery”).

RELIEF OPENING. The opening provided in a *draft hood* to permit the ready escape to the atmosphere of the flue products from the *draft hood* in the event of no *draft*, backdraft or stoppage beyond the *draft hood*, and to permit air into the *draft hood* in the event of a strong chimney updraft.

- ❖ Dilution air, a component of combustion air, enters the venting system through the draft hood opening. Combustion gases spilling from (exiting) a draft hood relief opening create an abnormal and potentially hazardous condition except for brief periods of spillage that might occur at the start of an appliance firing cycle. Typical periods of spillage at start-up last only a few seconds.

Photo courtesy of Washington Gas

**Figure G2403(15)
SERVICE REGULATOR**

RELIEF VALVE (DEVICE). A safety valve designed to forestall the development of a dangerous condition by relieving either pressure, temperature or vacuum in the hot water supply system.

❖ A relief valve is a safety device designed to prevent the development of a potentially damaging or dangerous condition in a closed system. This is usually associated with a closed system that has a heat source as part of the system. Requirements for the installation of relief valves in water distribution systems and water heaters are given in Section 504 of the IPC.

RELIEF VALVE, PRESSURE. An *automatic valve* that opens and closes a relief vent, depending on whether the pressure is above or below a predetermined value.

❖ Pressure relief valves are intended to prevent harm to life and property. These valves are safety devices used to relieve abnormal pressures and to prevent the over-pressurization of the vessel or system to which the valves are connected. Pressure relief valves are designed to operate (discharge) only when an abnormal pressure exists in a system. They are not to be used as regulating valves, nor are they intended to control or regulate flow or pressure. Pressure relief valves are set at the factory to begin opening at a predetermined pressure and are rated according to the maximum energy discharge per unit of time, usually in units of British thermal units per hour (Btu/h) (W).

Pressure relief valves must be properly sized and rated for the boiler, pressure vessel or system served; otherwise, a system malfunction could cause the pressure within the system to continue to rise, thereby creating a hazardous condition. Pressure relief valves do not open fully when they reach the factory-preset pressure; rather, the valves open an amount proportional to the forces produced by the pressure in the system. The valves open fully at a certain percentage above the

preset pressure, then close when the pressure drops below the preset pressure. Pressure relief valves are sometimes combined in the same body with temperature relief valves, creating combination temperature and pressure relief valves.

RELIEF VALVE, TEMPERATURE.

Manual reset type. A valve that automatically opens a *relief vent* at a predetermined temperature and that must be manually returned to the closed position.

Reseating or self-closing type. An *automatic valve* that opens and closes a relief vent, depending on whether the temperature is above or below a predetermined value.

❖ Temperature relief valves are designed to open in response to excessive temperatures and to discharge heated water to limit the temperature of the water in the vessel, tank or system. Water heater control failure or improper adjustments could allow excessive temperature rises, which can heat water above the temperature at which it would vaporize at atmospheric pressure. Water heated to above 212°F (100°C) is referred to as superheated water and will flash to steam when the pressure is reduced below its vapor pressure. Very hot water and the presence of steam are hazardous; however, more importantly, higher temperatures produce higher pressures and superheated water increases the potential for and the magnitude of an explosion.

RELIEF VALVE, VACUUM. A valve that automatically opens and closes a vent for relieving a vacuum within the hot water supply system, depending on whether the vacuum is above or below a predetermined value.

❖ The vacuum relief valve is intended to prevent the possible reduction in pressure within the system (water heater tanks being of main concern) to below atmospheric pressure (that is, a partial vacuum). Many tanks are not designed to resist external pressures exceeding internal pressures; therefore, a vacuum relief valve is necessary to prevent atmospheric pressure from possibly collapsing or otherwise damaging the tank. A partial vacuum could also cause water to be siphoned from the tank, thereby creating an overheating hazard in a water heater.

The vacuum relief valve operates by automatically opening the system to the atmosphere when a partial vacuum is created, thereby permitting air to enter and maintaining the internal pressure at atmospheric pressure.

RISER, GAS. A vertical *pipe* supplying fuel gas.

❖ A vertical gas pipe that distributes gas from a building main to upper floor levels is commonly referred to as a "riser."

ROOM HEATER, UNVENTED. See "Unvented room heater."

❖ See the commentary to "Unvented room heater" and Commentary Figure G2403(16).

Photo courtesy of Empire Comfort Systems, Inc.

Figure G2403(16)
UNVENTED ROOM HEATER

ROOM HEATER, VENTED. A free-standing heating unit used for direct heating of the space in and adjacent to that in which the unit is located. (See also “Vented room heater.”)

❖ These heaters are typically small space-heating appliances designed to heat a single room.

SAFETY SHUTOFF DEVICE. See “Flame safeguard.”

❖ See the commentary to “Flame safeguard.”

SHAFT. An enclosed space extending through one or more stories of a building, connecting vertical openings in successive floors, or floors and the roof.

❖ A shaft is an enclosed, vertical passage that passes through stories and floor levels within a building. Shafts are sometimes referred to as “chases” and are usually constructed of fire-resistance-rated assemblies.

SPECIFIC GRAVITY. As applied to gas, *specific gravity* is the ratio of the weight of a given volume to that of the same volume of air, both measured under the same condition.

❖ Analogous to density, specific gravity values are used to describe how a gaseous substance will behave in, for example, air or piping systems. “Specific gravity” indicates the density of a gas with respect to air, with air being assigned a value of 1. For example, natural gas has a specific gravity of less than 1; therefore, it is less dense and lighter than air. LP-gas has a specific gravity of 1.5; therefore, it is one and one-half times the density of air.

THERMOSTAT.

Electric switch type. A device that senses changes in temperature and controls electrically, by means of separate components, the flow of gas to the *burner(s)* to maintain selected temperatures.

Integral gas valve type. An automatic device, actuated by temperature changes, designed to control the gas supply to the *burner(s)* in order to maintain temperatures between predetermined limits, and in which the thermal actuating element is an integral part of the device.

1. Graduating thermostat. A thermostat in which the motion of the *valve* is approximately in direct proportion to the effective motion of the thermal element induced by temperature change.
2. Snap-acting thermostat. A thermostat in which the thermostatic valve travels instantly from the closed to the open position, and vice versa.

❖ Thermostats most often consist of one or more thermally actuated on/off switches, but also include types that transmit varying voltage and signals. A thermostat is also referred to as a controller. The set point or desired unit of temperature is adjusted or set at the thermostat. The thermostat transmits a signal to the controlled device or appliance.

THIRD-PARTY CERTIFICATION AGENCY. An approved agency operating a product or material certification system that incorporates initial product testing, assessment and surveillance of a manufacturer’s quality control system.

❖ These agencies evaluate products, verify compliance with specific standards or criteria and conduct periodic inspections of the manufacturer’s production facilities to verify ongoing compliance with such standards or criteria (see Section 401.10).

THIRD-PARTY CERTIFIED. Certification obtained by the manufacturer indicating that the function and performance characteristics of a product or material have been determined by testing and ongoing surveillance by an approved third-party certification agency. Assertion of certification is in the form of identification in accordance with the requirements of the third-party certification agency.

❖ A third-party certification agency certifies that a product meets specific standards or criteria and identifies the product with a certification mark. This mark is an indication to the installer and inspector that the product has been evaluated and tested and the manufacturing process has been monitored so as to verify compliance with the relative product standards or criteria. Additionally, the agency typically provides a list of the products that it certifies, which provides information relative to the certification (see Section 401.10).

THIRD-PARTY TESTED. Procedure by which an approved testing laboratory provides documentation that a product, material or system conforms to specified requirements.

❖ A third-party testing laboratory or agency tests a product to verify that it meets specific standards or criteria

and provides documentation to that fact. Having a product tested is not the same as having it listed, as listing entails additional requirements such as ongoing monitoring of the manufacturing process. Third-party tested products can be marked to indicate the testing agency.

TRANSITION FITTINGS, PLASTIC TO STEEL. An adapter for joining plastic *pipe* to steel *pipe*. The purpose of this fitting is to provide a permanent, pressure-tight connection between two materials that cannot be joined directly one to another.

- ❖ Joining of piping of dissimilar materials such as plastic and steel requires specialized transition fittings. For example, such fittings are used with underground plastic fuel-gas piping and steel meter setting risers [see Commentary Figure G2403(17)].

Photo courtesy of Perfection Corporation

Figure G2403(17)
TRANSITION FITTINGS

UNIT HEATER.

High-static pressure type. A self-contained, automatically controlled, vented *appliance* having integral means for circulation of air against 0.2 inch w.c. (50 Pa) or greater static pressure. Such *appliance* is equipped with provisions for attaching an outlet air duct and, where the *appliance* is for indoor installation remote from the space to be heated, is also equipped with provisions for attaching an inlet air duct.

Low-static pressure type. A self-contained, automatically controlled, vented *appliance*, intended for installation in the space to be heated without the use of ducts, having integral means for circulation of air. Such units are allowed to be equipped with louvers or face extensions made in accordance with the manufacturer’s specifications.

- ❖ Unit heaters are similar to warm-air furnaces, except that ducts are not usually associated with unit heaters.

These heaters are typically suspended from ceilings or roof structures.

UNVENTED ROOM HEATER. An unvented heating *appliance* designed for stationary installation and utilized to provide comfort heating. Such *appliances* provide radiant heat or convection heat by gravity or fan circulation directly from the heater and do not utilize ducts.

- ❖ As opposed to vented heaters, unvented heaters discharge all products of combustion into the space being heated [see Commentary Figure G2403(16)].

VALVE. A device used in *piping* to control the gas supply to any section of a system of *piping* or to an *appliance*.

- ❖ The code requires valves to perform various functions in a fuel-gas system as described in the definitions below. These valves are designed for the specific use intended and many are factory installed on equipment and are part of the listed equipment. However, there are valves that are not listed or manufactured in accordance with the standards listed in the code and if allowed must be evaluated in accordance with Section R104.11.

Appliance shutoff. A *valve* located in the *piping system*, used to isolate individual *appliances* for purposes such as service or replacement.

- ❖ The definition makes it clear that the primary purpose of an appliance shutoff valve is not related to the emergency shutoff of the appliance.

Automatic. An automatic or semiautomatic device consisting essentially of a *valve* and an operator that control the gas supply to the *burner(s)* during operation of an *appliance*. The operator shall be actuated by application of gas pressure on a flexible diaphragm, by electrical means, by mechanical means or by other *approved* means.

Automatic gas shutoff. A *valve* used in conjunction with an automatic gas shutoff device to shut off the gas supply to a water-heating system. It shall be constructed integrally with the gas shutoff device or shall be a separate assembly.

Individual main burner. A *valve* that controls the gas supply to an individual *main burner*.

Main burner control. A *valve* that controls the gas supply to the *main burner* manifold.

Manual main gas-control. A manually operated *valve* in the gas line for the purpose of completely turning on or shutting off the gas supply to the *appliance*, except to *pilot* or pilots that are provided with independent shutoff.

Manual reset. An automatic shutoff valve installed in the gas supply *piping* and set to shut off when unsafe conditions occur. The device remains closed until manually reopened.

Service shutoff. A valve, installed by the serving gas supplier between the service meter or source of supply and the customer *piping system*, to shut off the entire *piping system*.

VENT. A pipe or other conduit composed of factory-made components, containing a passageway for conveying *combustion products* and air to the atmosphere, *listed* and *labeled* for use with a specific type or class of *appliance*.

- ❖ In code terminology, vents are distinguished from chimneys and usually are constructed of factory-made listed and labeled components intended to function as a system. Type B and BW vents are constructed of galvanized steel and aluminum sheet metal and are double wall and air insulated. Such vents are designed to vent gas-fired appliances and equipment that are equipped with draft hoods or are specifically listed (labeled) for use with Type B or BW vents. Type L vents are typically constructed of sheet steel and stainless steel. They are double wall and air insulated and are designed to vent gas- and oil-fired appliances and equipment. Some appliances are designed for use with corrosion-resistant special vents, such as those made of plastic pipe and special alloys of stainless steel [see Commentary Figure G2403(18)].

Photo courtesy of Selkirk, L.L.C.

Figure G2403(18)
TYPE B VENT

Special gas vent. A vent *listed* and *labeled* for use with *listed* Category II, III and IV gas *appliances*.

- ❖ These vents include high-temperature plastic pipe, stainless steel pipe and low-temperature (PVC and CPVC) plastic pipes.
- Type B vent.** A vent *listed* and *labeled* for use with *appliances* with *draft hoods* and other Category I *appliances* that are *listed* for use with Type B vents.
- ❖ See the commentary to “Vent.”

Type BW vent. A vent *listed* and *labeled* for use with wall *furnaces*.

- ❖ See the commentary to “Vent.”

Type L vent. A vent *listed* and *labeled* for use with *appliances* that are *listed* for use with Type L or Type B vents.

- ❖ See the commentary to “Vent.”

VENT CONNECTOR. See “Connector.”

- ❖ See the commentary to “Connector.”

VENT PIPING.

Breather. *Piping* run from a pressure-regulating device to the outdoors, designed to provide a reference to *atmospheric pressure*. If the device incorporates an integral pressure *relief* mechanism, a breather vent can also serve as a *relief* vent.

- ❖ A breather vent is distinct from a relief vent and allows the cavity on the air side of the regulator diaphragm to “breathe” by letting air in and out as the diaphragm moves within the regulator housing (see commentary, Section G2421.3). Although not addressed in the definition, breather vents are also part of diaphragm-operated gas controls such as high- and low-pressure gas cutoffs.

Relief. *Piping* run from a pressure-regulating or pressure-limiting device to the outdoors, designed to provide for the safe venting of gas in the event of excessive pressure in the *gas piping system*.

- ❖ Relief-vent piping discharges fuel gas from a pressure relief valve or pressure regulator with an integral relief valve. Unlike breather vents that would discharge fuel gas only in the event of diaphragm failure, relief vents will always discharge fuel gas, if they discharge at all. Relief devices release fuel gas under emergency conditions to prevent overpressurizing the piping system being monitored and protected.

VENTED APPLIANCE CATEGORIES. *Appliances* that are categorized for the purpose of vent selection are classified into the following four categories:

- ❖ Gas appliances are categorized for the purpose of matching the appliance to the required type of venting. Not all gas appliances are assigned a category.

Category I. An *appliance* that operates with a nonpositive vent static pressure and with a vent gas temperature that avoids excessive *condensate* production in the vent.

- ❖ These appliances include draft-hood-equipped and fan-assisted types.

Category II. An *appliance* that operates with a nonpositive vent static pressure and with a vent gas temperature that is capable of causing excessive *condensate* production in the vent.

- ❖ The condition of nonpositive pressure (draft dependent) combined with low flue-gas temperatures makes it difficult to design such an appliance. At the time of this publication, no such appliances are known to exist in the marketplace.

Category III. An *appliance* that operates with a positive vent static pressure and with a vent gas temperature that avoids excessive *condensate* production in the vent.

- ❖ These appliances include mid-efficiency (approximately 78 to 83 percent) appliances that are typically side-wall-vented with stainless steel special vents.

Category IV. An *appliance* that operates with a positive vent static pressure and with a vent gas temperature that is capable of causing excessive *condensate* production in the vent.

- ❖ These appliances include high-efficiency (84 percent and higher) condensing-type furnaces, boilers and water heaters.

VENTED ROOM HEATER. A vented self-contained, free-standing, nonrecessed *appliance* for furnishing warm air to the space in which it is installed, directly from the heater without duct connections.

- ❖ These appliances are typically small space heaters that discharge all products of combustion to the outdoors.

VENTED WALL FURNACE. A self-contained vented *appliance* complete with grilles or equivalent, designed for incorporation in or permanent attachment to the structure of a building, mobile home or travel trailer, and furnishing heated air circulated by gravity or by a fan directly into the space to be heated through openings in the casing. This definition shall exclude *floor furnaces*, *unit heaters* and *central furnaces* as herein defined.

- ❖ Wall furnaces are designed to occupy very little area of the room and provide space heating for one or more rooms in small occupancies such as dwelling units, cottages and the like.

VENTING SYSTEM. A continuous open passageway from the *flue collar* or *draft hood* of an *appliance* to the outdoor atmosphere for the purpose of removing flue or vent gases. A venting system is usually composed of a vent or a chimney and *vent connector*, if used, assembled to form the open passageway.

- ❖ Venting systems fall into one of two categories: natural draft or mechanical draft systems. Natural draft chimneys and vents do not rely on any mechanical means to convey combustion products to the outdoors. Draft is produced by the temperature difference between the vent gases (combustion gases) and the ambient atmosphere. Hot gases are less dense and more buoyant; therefore, they are displaced by cooler (more dense) ambient gases, causing the hotter gases to rise and produce a draft.

Mechanical draft systems use fans or other mechanical means to cause the removal of flue or vent gases and also fall into one of two categories, based on positive or nonpositive static vent pressure. The positive vent pressure systems are referred to as forced-draft or power venting systems, and the nonpositive vent pressure systems are referred to as induced-draft venting systems.

WALL HEATER, UNVENTED TYPE. A room heater of the type designed for insertion in or attachment to a wall or partition. Such heater does not incorporate concealed venting arrangements in its construction and discharges all products of *combustion* through the front into the room being heated.

- ❖ See the definition and commentary to “Unvented room heater.”

WATER HEATER. Any heating *appliance* or *equipment* that heats potable water and supplies such water to the potable hot water distribution system.

- ❖ A water heater is a closed pressure vessel or heat exchanger that has a heat source and that supplies potable (drinkable) water to the building’s hot water distribution system. Large commercial water heaters are sometimes referred to as “hot water supply boilers.” Water heaters can be of the storage type with an integral storage vessel, circulating type for use with an external storage vessel, tankless instantaneous type without storage capacity and point-of-use type with or without storage capacity. This chapter and the plumbing chapters regulate water heaters because these appliances have elements and installation requirements related to both mechanical and plumbing systems (see Chapter 28).

SECTION G2404 (301) GENERAL

G2404.1 (301.1) Scope. This section shall govern the approval and installation of all *equipment* and *appliances* that comprise parts of the installations regulated by this *code* in accordance with Section G2401.

- ❖ This section states that this chapter governs the approval and installation of all gas-fired equipment and appliances that are regulated by the code. Section G2401.1 establishes the scope of application of the code (see commentary, Section G2401.1).

G2404.2 (301.1.1) Other fuels. The requirements for *combustion* and *dilution air* for gas-fired *appliances* shall be governed by Section G2407. The requirements for *combustion* and *dilution air* for *appliances* operating with fuels other than fuel gas shall be regulated by Chapter 17.

- ❖ Chapters 17 and 24 each have combustion air provisions that are specific to the fuels addressed in the respective chapters.

G2404.3 (301.3) Listed and labeled. *Appliances* regulated by this *code* shall be *listed* and *labeled* for the application in which they are used unless otherwise *approved* in accordance with Section R104.11. The approval of unlisted *appliances* in accordance with Section R104.11 shall be based upon *approved* engineering evaluation.

- ❖ Gas-fired appliances must be listed and labeled by an approved agency to show that they comply with the applicable national standards. The code requires listing and labeling for appliances such as boilers, furnaces, space heaters, direct-fired heaters, cooking appliances, clothes dryers, rooftop heating, ventilating

and air-conditioning (HVAC) units, etc. The code also requires listing for system components as specifically stated in the text addressing those components. The label is the primary, if not the only, assurance to the installer, the inspector and the end user that a representative sample of an appliance model has been tested and evaluated by an approved agency and has been determined to perform safely and efficiently when installed and operated in accordance with its listing.

Appliances must be listed and labeled for the application in which they are used, otherwise the installation would be a misapplication of the appliance. For example, if an appliance is listed for indoor use only and is installed outdoors, this installation is a misapplication of the appliance and serious malfunctions and/or conditions could result. An appliance might be marketed and installed for a particular purpose for which it was not tested and listed and this is what this section intends to prohibit. Verifying that an appliance has a testing agency label is only part of the code official's responsibility. He or she must also verify that the listing from the testing agency includes the application at hand. The bottom line is, the use of an appliance must match the use for which the appliance was tested.

The presence of a label is part of the information that the code official is to consider in the approval of appliances. The only exception to the labeling requirement occurs when the code official approves a specific appliance in accordance with the authority granted in Section R104.11.

Approval of unlabeled appliances must be based on documentation that demonstrates compliance with applicable standards or, where no product standards exist, that the appliance is appropriate for the intended use and will provide the same level of performance as would be provided by listed and labeled appliances. A fundamental principle of the code is the reliance on the listing and labeling process to ensure appliance performance; approvals granted in accordance with Section 105 must be well justified with supporting documentation. To the code official, the installer and the end-user, very little is known about the performance of an appliance that is not tested and built to an appliance standard.

G2404.4 (301.8) Vibration isolation. Where means for isolation of vibration of an *appliance* is installed, an *approved* means for support and restraint of that *appliance* shall be provided.

- ❖ Where vibration isolation connections are used in ducts and piping and where equipment is mounted with vibration dampers, support is required for the ducts, piping and equipment to maintain positioning and alignment and to prevent stress and strain on the vibration connectors and dampers.

G2404.5 (301.9) Repair. Defective material or parts shall be replaced or repaired in such a manner so as to preserve the original approval or listing.

- ❖ Repair work must not alter the nature of appliances and equipment in a way that would invalidate the listing

or conditions of approval. For example, replacement of safety control devices with different devices could alter the design and operation of an appliance from that intended by the manufacturer and the listing agency.

G2404.6 (301.10) Wind resistance. *Appliances* and supports that are exposed to wind shall be designed and installed to resist the wind pressures determined in accordance with this *code*.

- ❖ Installations of equipment and appliances that are subject to wind forces must be designed to resist those forces. The wind pressures must be based on the wind provisions in this code. The wind pressure requirements are based on the exposure of the building and wind speeds for that region.

G2404.7 (301.11) Flood hazard. For structures located in flood hazard areas, the appliance, equipment and system installations regulated by this code shall be located at or above the elevation required by Section R322 for utilities and attendant equipment.

Exception: The appliance, equipment and system installations regulated by this code are permitted to be located below the elevation required by Section R322 for utilities and attendant equipment provided that they are designed and installed to prevent water from entering or accumulating within the components and to resist hydrostatic and hydrodynamic loads and stresses, including the effects of buoyancy, during the occurrence of flooding to such elevation.

- ❖ Fuel gas appliances, equipment and installations in flood hazard areas must be installed at or above the elevation specified in the code or must be designed and installed to prevent the entry of water into components and to resist flood loads on the components (see commentary, Section R322.1.6). Exposure to water can cause deterioration of system components and serious appliance and equipment malfunctions. For example, most appliance manufacturers require the replacement of appliances that have been submerged in floodwaters. Components such as pressure regulators, gas controls, motors and electronic circuitry can be ruined by exposure to water. The exception allows appliances and system components to be located below the design flood elevation if they are designed for submersion in floodwaters. Appliances and system components designed for submersion might be difficult or impossible to obtain and it might be extremely difficult to install effective barriers to keep out floodwaters.

G2404.8 (301.12) Seismic resistance. When earthquake loads are applicable in accordance with this code, the supports shall be designed and installed for the seismic forces in accordance with this code.

- ❖ This code requires building systems to be designed for specified seismic forces. This section references the detailed equipment and component seismic support requirements contained in this code to bring these requirements to the attention of the design professional and the permit applicant.

Equipment piping must be braced for earthquake loads as stated in this code. The failure of the supports for these components has been shown to be a threat to health and safety in geographical areas where moderate- to high-magnitude earthquakes occur. The code specifies the geographical locations where earthquake design is required for certain piping and equipment and the size of the components that must be braced.

G2404.9 (301.14) Rodentproofing. Buildings or structures and the walls enclosing habitable or occupiable rooms and spaces in which persons live, sleep or work, or in which feed, food or foodstuffs are stored, prepared, processed, served or sold, shall be constructed to protect against the entry of rodents.

❖ This section states the requirements to prevent rodent infestation of a building. Efforts must be made to protect the annular spaces around openings in exterior walls. The annular spaces can be sealed by any effective method, but the primary methods used are to fill the annular space with a sealant material or to place a metal collar around the penetrating pipe, duct, etc. The collar material must be durable for the weather exposure and strong enough to prevent the rodents from chewing through and entering the building.

Effort must also be made to cover ventilation and combustion air openings with wire cloth to prevent the entry of rodents through the opening.

G2404.10 (307.5) Auxiliary drain pan. Category IV condensing *appliances* shall be provided with an auxiliary drain pan where damage to any building component will occur as a result of stoppage in the *condensate* drainage system. Such pan shall be installed in accordance with the applicable provisions of Section M1411.

Exception: An auxiliary drain pan shall not be required for *appliances* that automatically shut down operation in the event of a stoppage in the *condensate* drainage system.

❖ This section treats condensing (Category IV) appliances the same as the mechanical chapters treat appliances and equipment having evaporators and cooling coils. Category IV appliances produce condensate and, like cooling equipment and evaporators, can cause structural damage to a building if the condensate drainage system fails. This section parallels Section M1411.3. Section M1411.3.1 is applicable; however, only Items 1 and 3 apply because this section requires an auxiliary pan in all cases. In many cases, this provision will require nothing more than what is already being provided for the cooling coil or evaporator that is part of the gas appliance installation (e.g., the typical gas-fired furnace with cooling coil/evaporator). For example, an up-flow Category IV furnace with an “A” coil on its outlet is installed in an attic and it is sitting in an auxiliary drain pan. This pan can also serve as protection for the furnace, therefore, no additional installation is required because the furnace happened to be a condensing type (see Commentary Figure G2404.10).

The exception recognizes that some condensing appliances are designed to shut down automatically upon failure of the condensate drainage system. For example, the design/test standards for some appliances allow a choice of appliance reaction to a failed condensate drain. The appliance may either continue to function safely with a failed condensate drain or the appliance must shut down upon failure of the condensate drain.

G2404.11 (307.6) Condensate pumps. Condensate pumps located in uninhabitable spaces, such as attics and crawl spaces, shall be connected to the *appliance* or *equipment* served such that when the pump fails, the *appliance* or *equipment* will be prevented from operating. Pumps shall be installed in accordance with the manufacturer’s instructions.

❖ Condensate pumps are often located in attics and crawl spaces and above ceilings, where they are not readily observable. If they fail, the condensate overflow can cause structural damage to the building, especially where the overflow will not be immediately noticed. The majority of such pumps are equipped with simple float controls that can be wired in series with the appliance/equipment control circuit. When the pump system fails, the float will rise in the reservoir and open a switch before the condensate starts to overflow the reservoir. These float controls are commonly not connected, and in other cases the pump might not be equipped with an overflow switch. This new code section requires the installation of condensate pumps that have this overflow shutoff capability and requires that the appliance/equipment served be connected to take advantage of that feature (see Commentary Figure G2404.11).

SECTION G2405 (302) STRUCTURAL SAFETY

G2405.1 (302.1) Structural safety. The building shall not be weakened by the installation of any *gas piping*. In the process of installing or repairing any *gas piping*, the finished floors, walls, ceilings, tile work or any other part of the building or premises which is required to be changed or replaced shall be left in a safe structural condition in accordance with the requirements of this code.

❖ The installation of fuel-gas systems must not adversely affect the structural integrity of the building components. This code dictates the structural safety requirements that must be applied to any structural portion of the building that is penetrated, altered or removed during the installation, replacement or repair of fuel-gas systems.

G2405.2 (302.4) Alterations to trusses. Truss members and components shall not be cut, drilled, notched, spliced or otherwise altered in any way without the written concurrence and approval of a registered design professional. *Alterations* resulting in the addition of loads to any member, such as HVAC equipment and water heaters, shall not be permitted

without verification that the truss is capable of supporting such additional loading.

- ❖ A truss is an engineered system of components that function as a structural unit. Trusses are susceptible to weakening by almost any type of alteration, such as boring, notching and cutting. Unlike dimensional solid lumber members, such as studs, rafters and joists, trusses cannot be altered in a code-prescribed way. The only exception is obtaining written approval of a specific alteration from a registered design professional.

The placement of a water heater in an attic, for example, can result in abnormal loads on roof trusses that must be accounted for structurally. A simple 40-gallon water heater weighs well over 400 pounds and is a point load. Subjecting trusses to loads that they were not designed to carry is considered to be an alter-

ation and is prohibited without a structural analysis to verify that the truss can bear the additional weight.

G2405.3 (302.3.1) Engineered wood products. Cuts, notches and holes bored in trusses, structural composite lumber, structural glued-laminated members and I-joists are prohibited except where permitted by the manufacturer's recommendations or where the effects of such *alterations* are specifically considered in the design of the member by a registered design professional.

- ❖ This section applies to engineered lumber products which are manufactured structural members. These products often have installation instructions that specifically state if, where and how the member can be altered, drilled, notched, etc. What appears to be a harmless cut, notch or boring might actually be structurally damaging to the member (see Section G2405.2).

Figure G2404.10
AUXILIARY DRAIN PAN REQUIRED (WITH OR WITHOUT COILING COIL)

**SECTION G2406 (303)
APPLIANCE LOCATION**

G2406.1 (303.1) General. *Appliances* shall be located as required by this section, specific requirements elsewhere in this code and the conditions of the *equipment* and *appliance* listing.

❖ Section G2406 is a consolidation of the code’s generally applicable location requirements and limitations. The listing for an appliance or equipment will often contain location requirements parallel with or in addition to these sections.

G2406.2 (303.3) Prohibited locations. *Appliances* shall not be located in sleeping rooms, bathrooms, toilet rooms, storage closets or surgical rooms, or in a space that opens only into such rooms or spaces, except where the installation complies with one of the following:

1. The *appliance* is a direct-vent *appliance* installed in accordance with the conditions of the listing and the manufacturer’s instructions.
2. *Vented room heaters*, wall *furnaces*, vented decorative *appliances*, vented gas *fireplaces*, vented gas *fireplace heaters* and decorative *appliances* for installation in vented solid fuel-burning *fireplaces* are installed in rooms that meet the required volume criteria of Section G2407.5.
3. A single wall-mounted *unvented room heater* is installed in a bathroom and such *unvented room heater* is equipped as specified in Section G2445.6 and has an input rating not greater than 6,000 *Btu/h* (1.76 kW). The bathroom shall meet the required volume criteria of Section G2407.5.

4. A single wall-mounted *unvented room heater* is installed in a bedroom and such *unvented room heater* is equipped as specified in Section G2445.6 and has an input rating not greater than 10,000 *Btu/h* (2.93 kW). The bedroom shall meet the required volume criteria of Section G2407.5.
5. The *appliance* is installed in a room or space that opens only into a bedroom or bathroom, and such room or space is used for no other purpose and is provided with a solid weather-stripped door equipped with an *approved self-closing device*. All *combustion air* shall be taken directly from the outdoors in accordance with Section G2407.6.

❖ The intent of this section is to prevent fuel-fired appliances from being installed in rooms and spaces where the combustion process could pose a threat to the occupants. Potential threats include depleted oxygen levels; elevated levels of carbon dioxide, nitrous oxides, carbon monoxide, and other combustion gases; ignition of combustibles and elevated levels of flammable gases.

In small rooms such as bedrooms and bathrooms, the doors are typically closed when the room is occupied, which could allow combustion gases to build up to life-threatening levels. In bedrooms, sleeping occupants would not be alert to or aware of impending danger.

If an appliance obtains combustion air from a room or space, it communicates with the atmosphere in that room or space whether or not it is installed in that room or space. An appliance might be in a room, closet or alcove and obtain combustion air from an adjacent room, so Section G2406.2 is worded to address the

location of an appliance in the rooms listed and in spaces that open only into such rooms. In other words, an appliance in a closet accessed from a bedroom is no different from an appliance located within the bedroom. It is not the intent of this section to prevent combustion air from being taken from a bedroom, bathroom, etc., as evidenced in Items 2, 3 and 4. For example, the volume of a bedroom could be added to the volume of other rooms for the purpose of providing indoor combustion air for an appliance not installed in a location prohibited by this section if openings are installed to conjoin the space volumes in accordance with Section G2407.5.3. If an appliance obtains combustion air from a room, the appliance combustion chamber would be open to the room and the appliance must be considered to be in that room.

Item 1 recognizes that direct-vent appliances have sealed combustion chambers and obtain all combustion air directly from the outdoors. The appliance combustion chambers do not communicate with the room atmosphere.

Item 2 requires that the room be able to supply the necessary combustion air by infiltration as specified in Section G2407.5. Note that Item 2 includes both vented decorative appliances and vented gas fireplaces which are both addressed by ANSI Z21.50 and are essentially the same appliance, known by different names. Vented gas fireplace heaters (ANSI Z21.88) were also added to Item 2.

Items 3 and 4 allow the installation of a single wall-mounted unvented room heater in bathrooms and bedrooms if the heaters are equipped with oxygen depletion safety shutoff systems, are limited in Btu input rating and the space is capable of supplying indoor combustion air in accordance with Section G2407.5. These exceptions specify "wall-mounted" heaters, which are fully enclosed and less susceptible to tampering and other conditions that might affect the combustion process. Items 3 and 4 would not apply to room heaters that stand on the floor or fasten to a fireplace hearth or ventless firebox hearth [see Commentary Figure G2406.2(1)].

Item 5 would allow installation of fuel-fired appliances within a separate dedicated space that is accessed from the rooms and spaces listed in this section. A separated space containing the appliance must be open to the outdoors in accordance with Section G2407.6, and the access door to the space must be solid and weather-stripped to prevent communication between atmospheres in the separated spaces. The door must also be self-closing and not rely on occupants to keep it closed. The enclosure must not be used for storage or any other purpose. The intent is to isolate the appliance(s) from the rooms listed in this section and to obtain all combustion air directly from the outdoors [see Commentary Figure G2406.2(2)]. This item can be used to avoid relocating an appliance when an existing appliance installed in a prohibited location needs to be replaced [see Commentary Figure G2406.2(2)].

G2406.3 (303.6) Outdoor locations. *Appliances* installed in outdoor locations shall be either listed for outdoor installation or provided with protection from outdoor environmental factors that influence the operability, durability and safety of the *appliance*.

- ❖ Appliances installed outdoors must be specifically listed for outdoor installation or be protected from outdoor conditions that will affect the "operability, durability and safety of the equipment."

The concern is for weather and ambient temperatures. The manufacturer's instructions and listing must be consulted to determine whether a particular appliance is designed for or can be made suitable for outdoor installation. For example, furnaces cannot be installed outdoors in cold climates regardless of any weather-proof enclosure, unless the heat exchanger, burner assemblies and venting system are designed for exposure to temperatures below normal indoor temperatures. Cold ambient temperatures can cause harmful condensation to occur on heat exchanger surfaces of fuel-fired appliances.

Additionally, there may be local ordinances that govern the outdoor installation of appliances. Before installing an appliance outdoors, consult local zoning regulations, ordinances and subdivision covenants. Many of these regulations strictly limit the location of outdoor mechanical equipment and appliances. Also, for roof installations, the roof structure must be able to support all imposed static and dynamic structural loads. Substantiating data on the structural adequacy of the entire installation must be submitted and approved.

UNVENTED WALL-MOUNTED ROOM HEATER

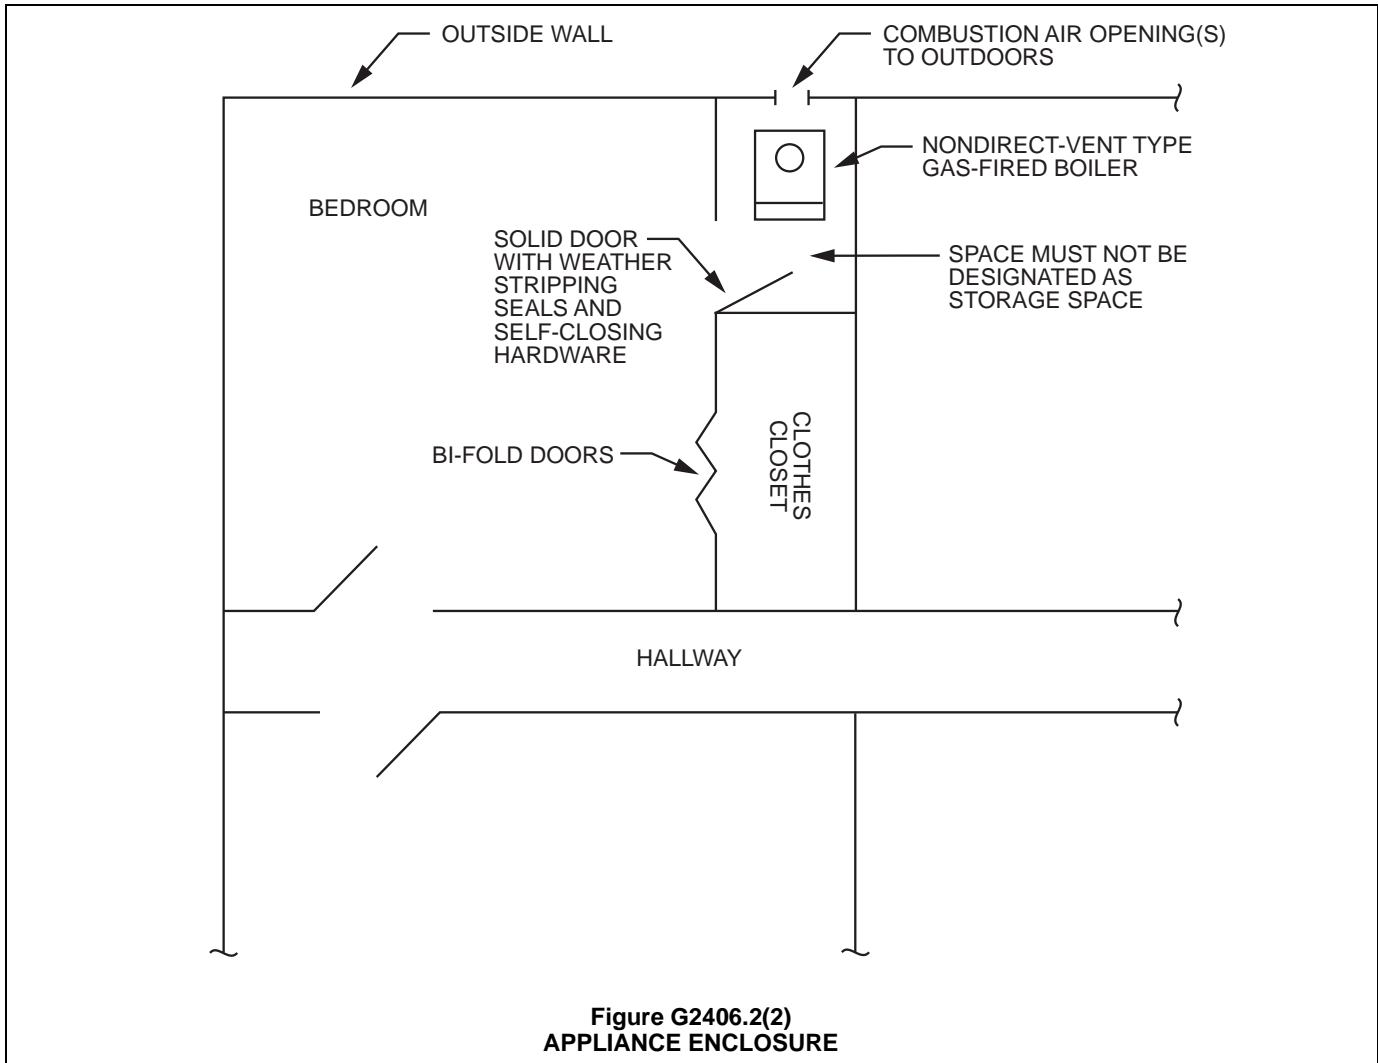

Figure G2406.2(2)
APPLIANCE ENCLOSURE

**SECTION G2407 (304)
COMBUSTION, VENTILATION AND DILUTION AIR**

G2407.1 (304.1) General. Air for *combustion*, ventilation and dilution of *flue gases* for *appliances* installed in buildings shall be provided by application of one of the methods prescribed in Sections G2407.5 through G2407.9. Where the requirements of Section G2407.5 are not met, outdoor air shall be introduced in accordance with one of the methods prescribed in Sections G2407.6 through G2407.9. *Direct-vent appliances*, *gas appliances* of other than *natural draft* design, *vented gas appliances* not designated as Category I and *appliances* equipped with power burners, shall be provided with *combustion*, ventilation and *dilution air* in accordance with the *appliance* manufacturer’s instructions.

Exception: *Type 1 clothes dryers* that are provided with *makeup air* in accordance with Section G2439.5.

- ❖ The provisions of Section G2407 describe requirements for the combustion air necessary for the complete combustion of fuel gas, dilution of flue gases, and ventilation of gas-fired appliances and the space in which they are installed. An inadequate combustion air

supply to gas-fired appliances can compromise safety by causing in-complete combustion, resulting in appliance malfunction and production of excess carbon monoxide.

Complete combustion of fuel gas is essential for the proper operation of gas-fired appliances. If insufficient quantities of oxygen are supplied, the combustion process will be incomplete, creating hazardous by-products [see Commentary Figures G2407.1(1) and G2407.1(2)].

Although not implied in the term, combustion air also serves other purposes in addition to supplying oxygen. Combustion air ventilates and cools appliances and the rooms or spaces that enclose them. Combustion air also plays an important role in producing and controlling draft in vents and chimneys.

Despite the fact that an adequate combustion air supply is extremely important, it is one aspect of gas-fired equipment installations that is often overlooked, ignored or compromised. Depending on the appliance type, location and building construction, supplying combustion air can either be easy or can involve com-

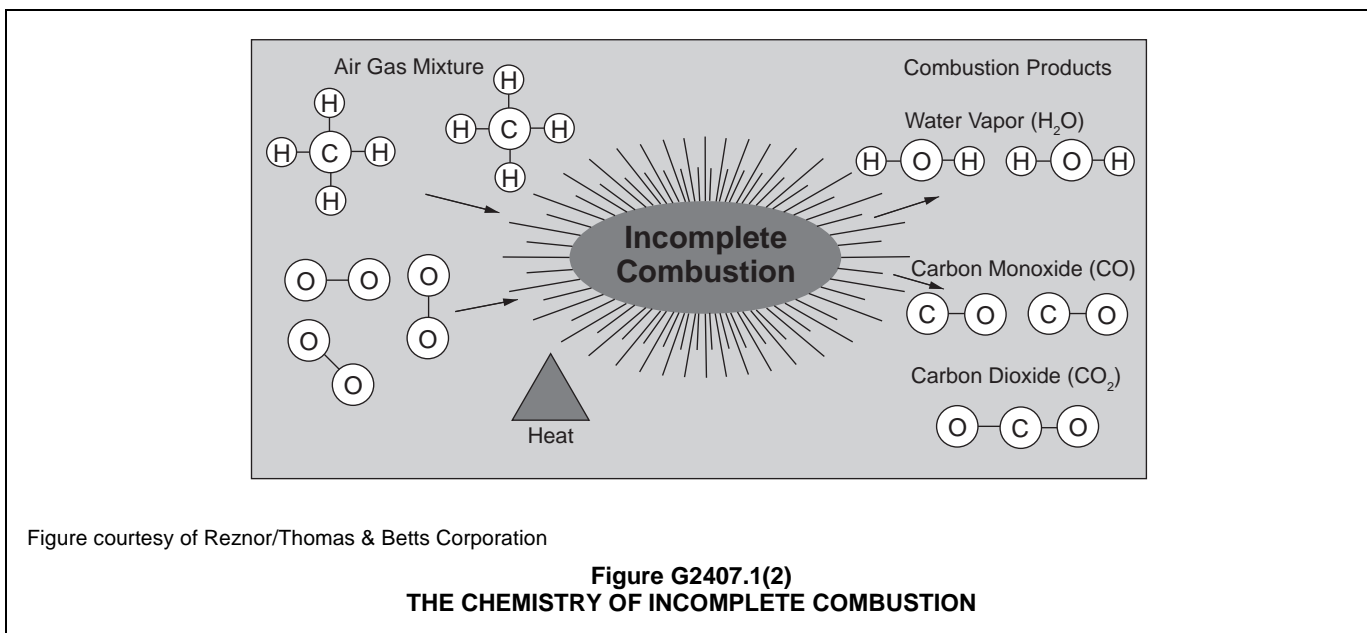

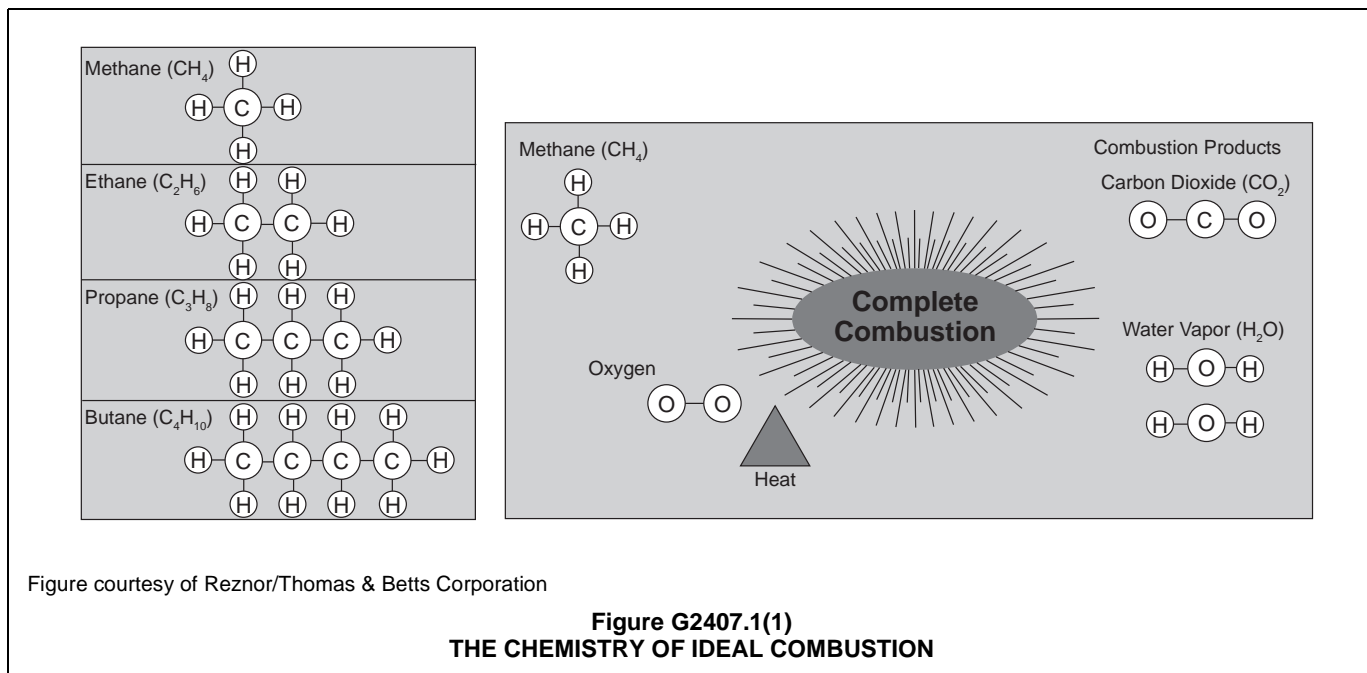

plex designs and extraordinary methods. In any case, the importance of a proper combustion air supply cannot be overemphasized.

The methods of supplying combustion air range from simple (inherently more dependable) methods to more complex methods. This section offers five methods for providing combustion air [see Commentary Figure G2407.1(3)]:

1. All indoor air.
2. All outdoor air.
3. Combination indoor and outdoor air.
4. Mechanical combustion air supply.

5. Engineered design.

The last sentence of this section clarifies that the section is intended to apply only to natural-draft atmospheric-burner-design appliances, Category I appliances, nondirect-vent appliances and appliances not equipped with power burners (see commentary, Section G2407.8). For example, the application of Section G2407.6 with large power-burner-equipped (nonnatural draft, nonatmospheric-burner designs) boilers could result in excessively large openings in an outside wall, causing environmental problems within the boiler room.

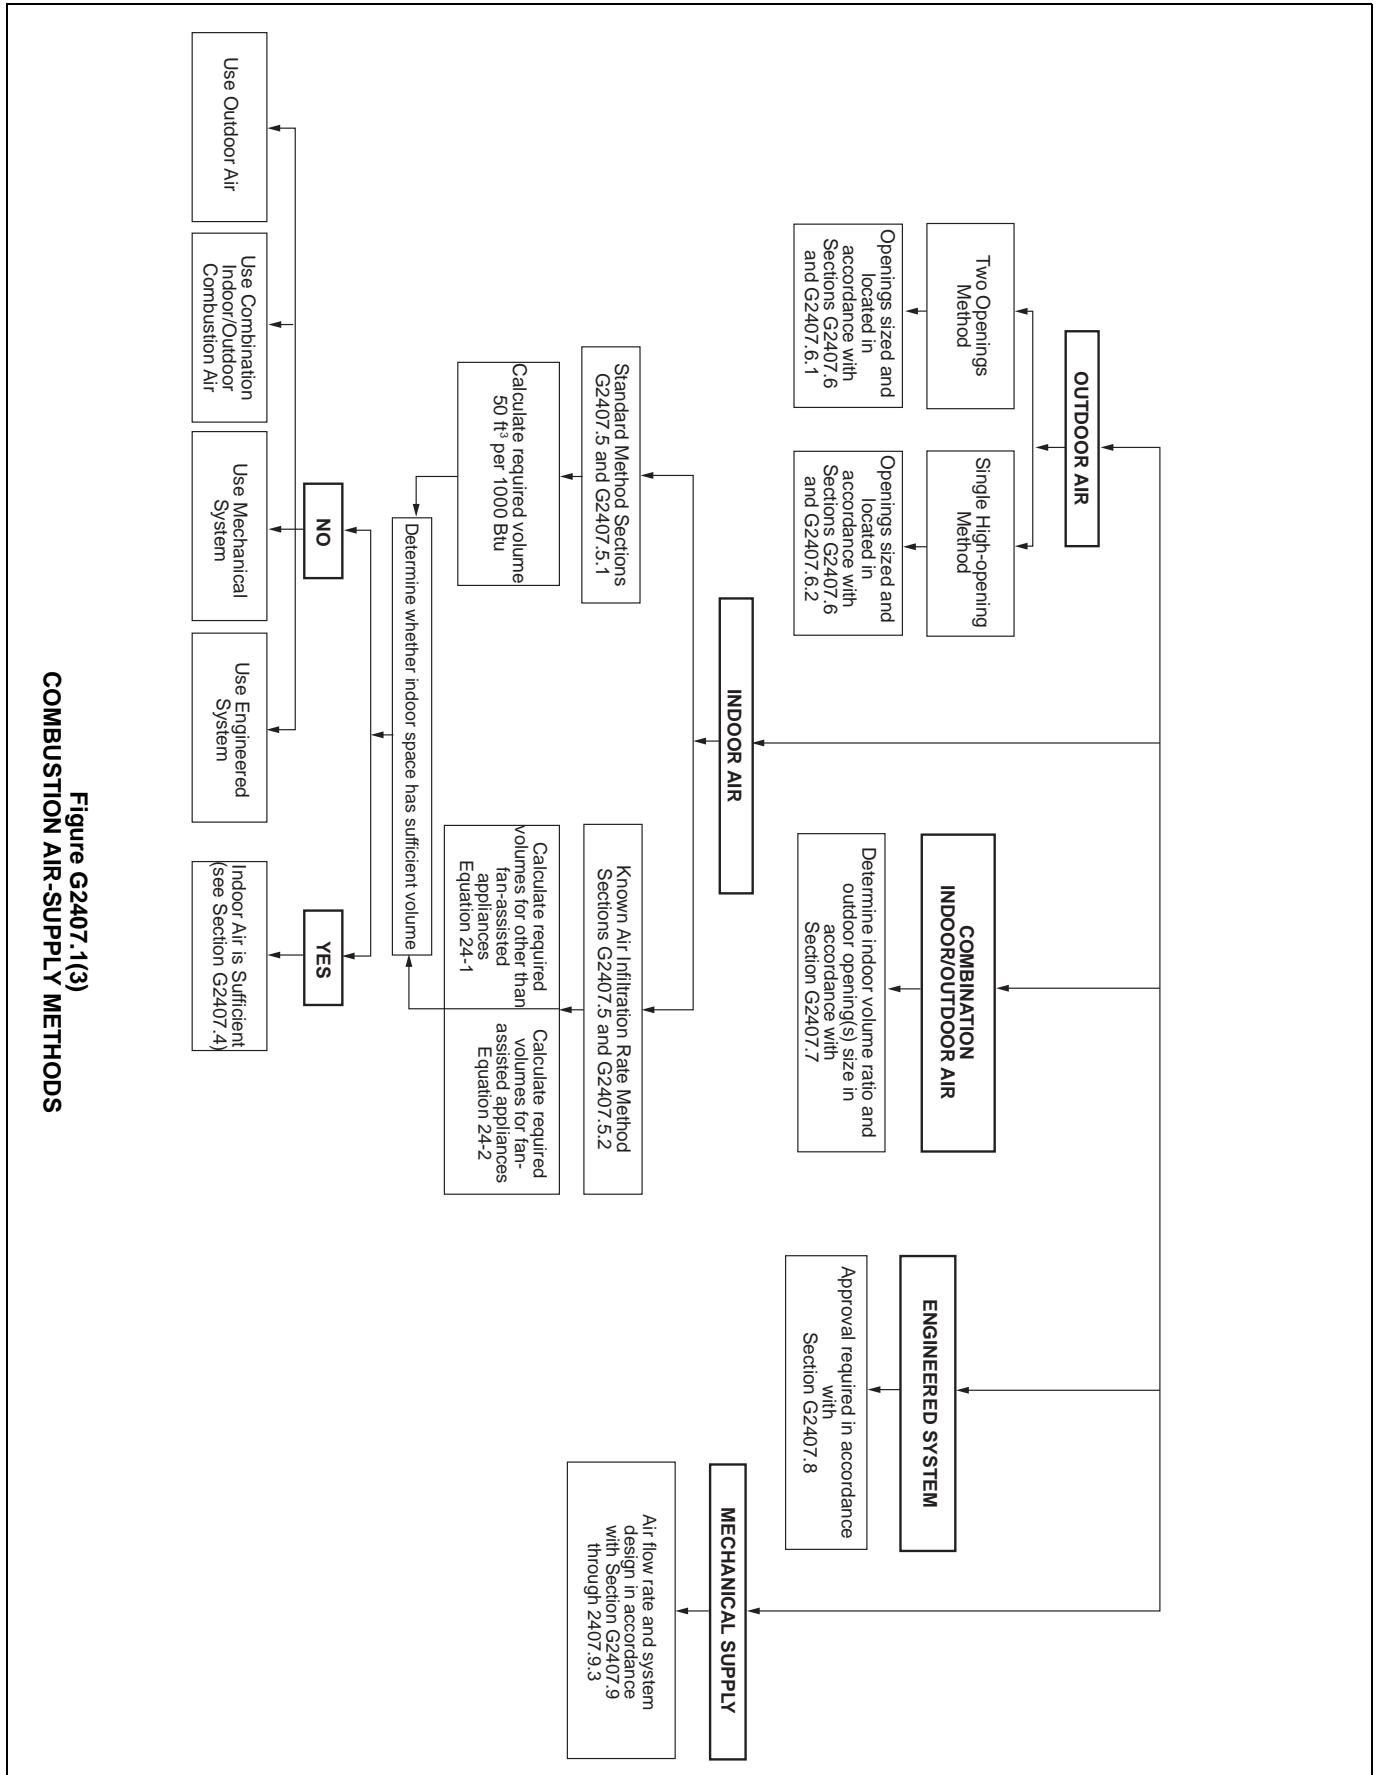

Figure G2407.1(3)
COMBUSTION AIR-SUPPLY METHODS

Section G2407.1 states that the methods of providing combustion air as prescribed in Sections G2407.5 through G2407.9 are applicable only to certain types of appliances, namely natural-draft appliances with draft hoods and fan-assisted appliances. The other types of appliances, including direct-vent appliances (direct-vent appliances can be natural-draft type but have no draft hoods), power-vented appliances and Categories II, III and IV appliances, must be provided with combustion air as dictated in the appliance manufacturer's instructions. Another type of appliance has been added to the types that are subject only to the requirements in the manufacturer's instructions—appliances equipped with power burners. Power burners pull in combustion air under fan power and mix it with the fuel gas before conveying it to the burner.

Natural-draft appliances take in combustion air by means of the weak force produced by the natural draft in the venting system only. Clearly there is a significant difference between the mechanical force of power burners with combustion air fans and natural-draft appliances that must rely on the venting system draft to cause combustion air to enter the appliance. The methods in Sections G2407.5 through G2407.9 were based on the physics of natural-draft, fan-assisted and Category I appliances and therefore failed to account for the nature of powered systems like power burners. This fact has perplexed designers for many years as they tried to design combustion air openings for large input boilers and similar appliances that are commonly equipped with power burners. When they used the sizing rules in the code for combustion air openings in the exterior wall of a boiler room, for example, the opening size would be so large that it would be impossible to prevent the freezing of pipes and equipment in colder climates. The openings to the outdoors were prohibitively large for such large input power-burner appliances and out of proportion with the need when considering that power burners mechanically draw in combustion air. When natural draft is depended on, larger openings are necessary to reduce the pressure drop across the openings, but power burners can tolerate much larger pressure drops, thus allowing smaller openings. The manufacturer's instructions for large input power-burner appliances specify the size of combustion air openings by their own methods. Typically those methods result in much smaller openings than prescribed in the code; however, some manufacturers simply refer back to the code instead of offering their own method. A research study demonstrated that the code-prescribed opening sizing methods were overkill for power-burner appliances [see Commentary Figure G2407.1(6)]. Direct-vent appliances supply their own combustion air through an outdoor air intake pipe or duct [see Commentary Figures G2407.1(4) and G2407.1(5)].

The exception recognizes that clothes dryers receive the required combustion air from the makeup air that compensates for the exhaust air flow from the appliance.

Figure G2407.1(4)
DIRECT-VENT APPLIANCE

G2407.2 (304.2) Appliance location. *Appliances shall be located so as not to interfere with proper circulation of combustion, ventilation and dilution air.*

- ❖ The provisions of Section G2407 rely on the natural (gravity) movement of air; therefore, installations must allow unimpeded flow of combustion air from the source to the appliances being supplied. Other mechanical systems, appliances or equipment in the same room or building can adversely affect the combustion air supply. For example, when placed too close to the combustion air openings, gas-fired appliances or equipment will restrict the free circulation of air.

G2407.3 (304.3) Draft hood/regulator location. *Where used, a draft hood or a barometric draft regulator shall be installed in the same room or enclosure as the appliance served to prevent any difference in pressure between the hood or regulator and the combustion air supply.*

- ❖ It is important that draft hoods and barometric draft regulators be located in the same pressure zone as the appliance combustion chamber.

Draft hoods and barometric regulators both serve to stabilize draft through an appliance and in some cases act to relieve backpressure/downdraft in the venting system. It is the draft in a Category I appliance that moves combustion air into the appliance and conveys the combustion gases to the venting system. Pressure differences between the atmospheres in which the draft hood/regulator and the combustion chamber are located could interfere with the function of the draft hood/regulator, resulting in poor combustion, excess draft, insufficient draft, combustion gas spillage and/or hazardous appliance operation. A draft hood/regulator is installed under the assumption that the combustion

chamber it serves sees the same atmospheric pressure.

G2407.4 (304.4) Makeup air provisions. Where exhaust fans, clothes dryers and kitchen ventilation systems interfere with the operation of appliances, makeup air shall be provided.

❖ The introduction of makeup air is critical to the proper operation of all fuel-burning appliances located in areas subject to the effects of exhaust systems. Too little makeup air will cause excessive negative pressures to develop, not only reducing the exhaust airflow but also interfering with appliance venting. Too little makeup air can cause loss of draft in appliance vents and chimneys

or cause combustion byproducts to discharge into the building. It is the draft produced in an appliance that causes combustion air to enter the combustion chamber of natural-draft atmospheric-burner appliances. It is the draft in the venting system that causes the combustion gases and dilution air to move through the venting system toward the vent terminal. A lack of combustion air can result in incomplete fuel combustion, appliance malfunction and flue gas spillage.

A significant reduction in building pressure could be created by fireplaces, exhaust fans, ventilation systems, clothes dryers and similar appliances and equipment. Gas-fired appliances are often in competition

**Figure G2407.1(5)
DIRECT COMBUSTION AIR CONNECTION TO THE OUTDOORS**

**Figure G2407.1(6)
POWER BURNER**

(Combustion air is provided to power burners in accordance with the appliance manufacturer's instructions.)

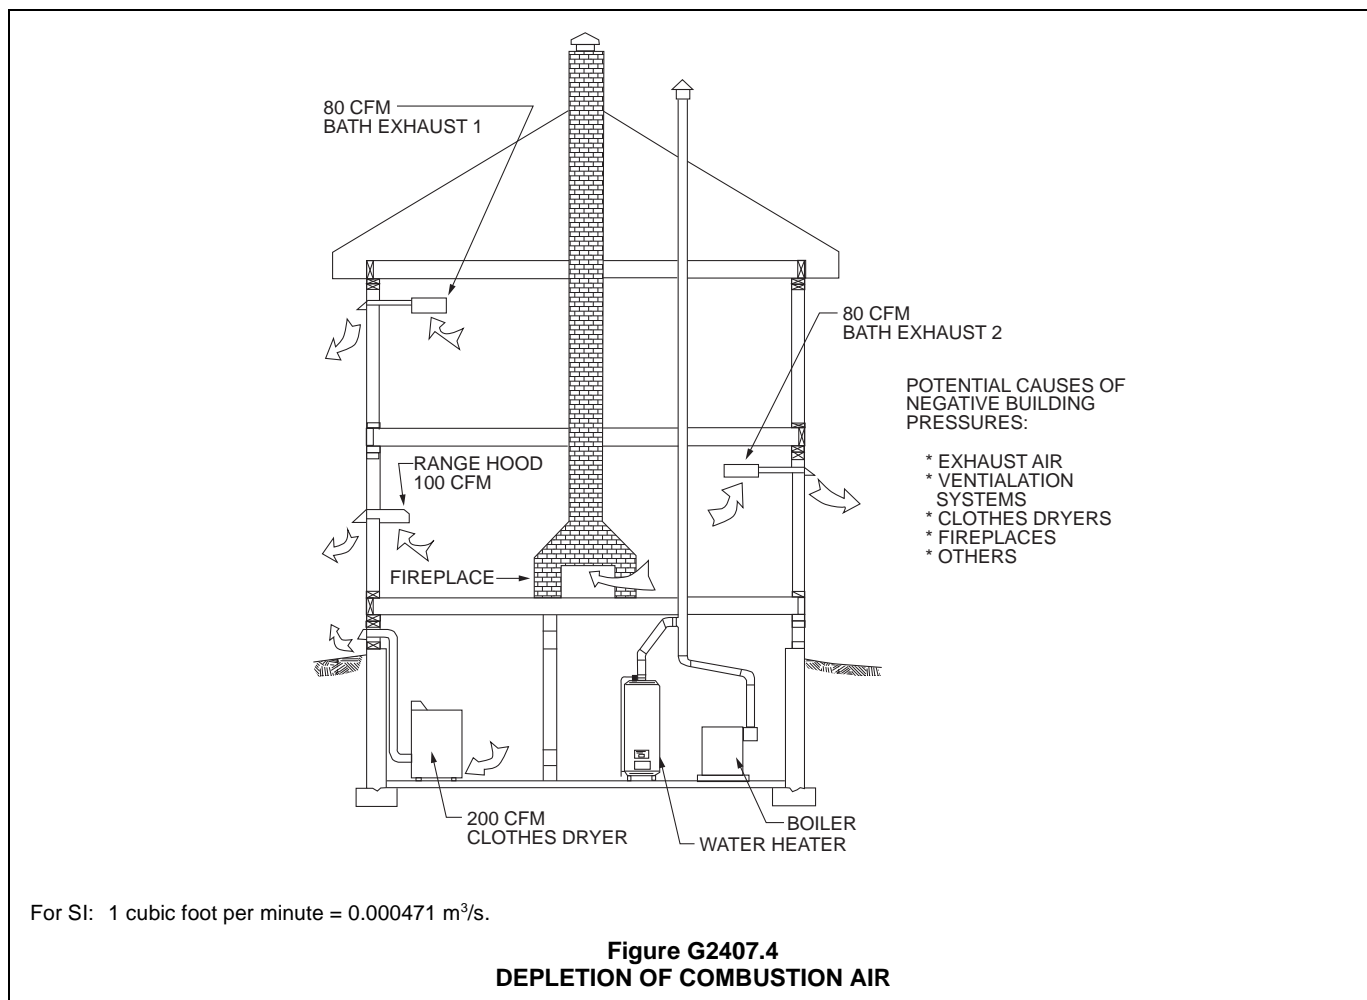

with other equipment or systems for the available combustion air and makeup air that flows through (infiltrates) the building envelope or is otherwise introduced into a building, room or space. The competition between powered exhaust equipment and natural-draft gas-fired appliance venting systems is an unfair contest at best. Eventually, the powered equipment will starve the natural-draft appliances unless provisions are made to compensate for the effect of the powered exhaust equipment/appliances. Supplying makeup air will prevent negative pressures within a space, thus negating the effect of exhaust fans and clothes dryers. In many cases, makeup air will be required because this is the only way to prevent exhaust systems from negatively affecting the appliance venting systems that draw combustion air from the same space from which the exhaust systems remove air.

Natural draft appliances also compete among themselves for combustion air. The appliance venting system that produces the strongest draft, such as a solid-fuel appliance or fireplace, can cause combustion air shortages for the appliance venting systems that produce a weaker draft.

Exhaust fans and similar equipment and appliances can produce significant negative building pressures that can interfere with the operation of vents and chim-

neys. This interference can cause reverse flow as outdoor air enters the building through the vents and chimneys because of the pressure difference. Any such interference with vents or chimneys could cause products of combustion to be discharged into the building and, therefore, must be avoided. The provisions of Section G2407 could be woefully inadequate or nullified where compensating features are not installed to mitigate the effect of appliances or equipment removing air from any room or space.

When any system depends on infiltration as the source of combustion air, it will probably be necessary to supply makeup air to offset the deficiency in many buildings. It is obvious that natural draft appliance installations cannot compete with exhaust fans and clothes dryers for the available infiltration air. Without makeup air, the gas-fired appliance venting systems and the mechanical exhaust systems will indeed compete for the same infiltration air, which could be insufficient to satisfy either need (see Commentary Figure G2407.4). Note that exhaust fans, clothes dryers and similar equipment that remove air from a space will have no negative impact on unvented appliances because unvented appliances have no venting system. Direct-vent appliances are also immune in most cases.

G2407.5 (304.5) Indoor combustion air. The required volume of indoor air shall be determined in accordance with Section G2407.5.1 or G2407.5.2, except that where the air infiltration rate is known to be less than 0.40 air changes per hour (ACH), Section G2407.5.2 shall be used. The total required volume shall be the sum of the required volume calculated for all *appliances* located within the space. Rooms communicating directly with the space in which the *appliances* are installed through openings not furnished with doors, and through *combustion air* openings sized and located in accordance with Section G2407.5.3, are considered to be part of the required volume.

❖ The terms “confined space,” “unconfined space” and “unusually tight construction” are no longer used in the code. The required room volume is determined by two methods: one method based on the actual air infiltration rate of the building and the other based on the familiar fixed ratio of 50 ft³ per 1000 Btu/h (4.8 m³/kW). Air taken directly from inside the building is an acceptable source of combustion air if a sufficient volume of air is available for the appliances served and the building construction allows sufficient infiltration. The provisions of this section rely on building envelope infiltration as the only source of combustion air.

The method given in Section G2407.5.1 is based on a conservative assumed air infiltration rate of at least 0.40 air change per hour (ACH); therefore, if the ACH is known to be less than 0.40, this method cannot be used. The air infiltration rate for most buildings is not known, and it is possible for the ACH rate of a building to be actually less than 0.40; however, research suggests that buildings having less than 0.40 ACH are rare. It is believed that 80 to 95 percent of U.S. homes have infiltration rates of 0.35 ACH or greater; however, those numbers are changing because of more stringent energy codes and sustainable “green” building practices. A rate of 0.40 ACH or less is the quantitative expression of “tight construction.” Testing also indicates that the 50 ft³/1 000 Btu/h (4.8 m³/kW) convention is somewhat liberal; thus, a built-in safety factor exists. If the designer suspects that the building in question is extraordinarily tight (less than 0.40 ACH), calculations and/or testing should be done to verify the ACH rate. A conservative approach could be to use the method in Section G2407.5.2 with a conservative ACH rate such as 0.25, 0.30 or 0.35. Commentary Figure G2407.5.2 shows calculated required volumes for appliances up to 300,000 Btu/h (87.9 kW) input rating based on the standard method and known ACH method for multiple ACH rates.

The standard method can be calculated for each appliance and then all the volumes are added or can be calculated by adding all of the appliance inputs first and then calculating the total volume. The known ACH-rate method must be performed in at least two distinct calculations where both fan-assisted and draft-hood-equipped appliances are present.

To increase the available volume, the code allows rooms and spaces to be coupled together by doorways

without doors and by openings installed in accordance with Section G2407.5.3.

G2407.5.1 (304.5.1) Standard method. The minimum required volume shall be 50 cubic feet per 1,000 Btu/h (4.8 m³/kW) of the appliance input rating.

❖ This is the optional default method intended for use when the ACH rate is unknown. If the actual ACH rate is known to be greater than 0.40, the method of Section G2407.5.2 will yield smaller required volumes.

If the ACH rate is known to be less than 0.40, this method must not be used because it is based on an assumed ACH rate of at least 0.40. The rate of 50 ft³/1,000 Btu/h (4.8 m³/kW) is a carryover from the previous editions of the code and was used for buildings that were not of unusually tight construction.

G2407.5.2 (304.5.2) Known air-infiltration-rate method. Where the air infiltration rate of a structure is known, the minimum required volume shall be determined as follows:

For *appliances* other than fan-assisted, calculate volume using Equation 24-1.

$$Required\ Volume_{other} \geq \frac{21\text{ft}^3}{ACH} \left(\frac{I_{other}}{1,000\text{ Btu/h}} \right) \quad \text{(Equation 24-1)}$$

For fan-assisted *appliances*, calculate volume using Equation 24-2.

$$Required\ Volume_{fan} \geq \frac{15\text{ft}^3}{ACH} \left(\frac{I_{fan}}{1,000\text{ Btu/hr}} \right) \quad \text{(Equation 24-2)}$$

where:

I_{other} = All *appliances* other than fan assisted (input in Btu/h).

I_{fan} = Fan-assisted *appliance* (input in Btu/h).

ACH = Air change per hour (percent of volume of space exchanged per hour, expressed as a decimal).

For purposes of this calculation, an infiltration rate greater than 0.60 ACH shall not be used in Equations 24-1 and 24-2.

❖ This method considers the actual or calculated ACH rate and requires space volumes to be commensurate with that rate. This method can also be used when the ACH rate is unknown by simply picking a conservative ACH rate (0.40 ACH or less) representing the lowest anticipated ACH rate for the given building. Equation 24-1 is for draft-hood-equipped appliances and reflects recent research and test results that show that such appliances need less air flow than previously assumed. The standard ratio of 50 ft³/1,000 Btu/h (4.8 m³/kW) that has been in codes for many years was based on an assumed combustion air flow need of 25 ft³/1,000 Btu/h (2.4 m³/kW) with an assumed ACH rate of 0.50. The 25 ft³/1,000 Btu/h air flow consisted of the air required for stoichiometric combustion [10 ft³/ft³ of natural gas] plus excess air to assure complete combustion, draft hood dilution air and a safety factor

allowance. The volume of 25 cubic feet (0.7 m³) divided by an ACH rate of 0.50 yields the familiar 50 ft³/1,000 Btu/h ratio. Equation 24-1 is based on a total airflow need of 21 cubic feet (0.6 m³) instead of 25(0.7 m³) because research supports a less conservative revised volume.

Equation 24-2 is for fan-assisted appliances only and accounts for the fact that fan-assisted appliances have no draft hood and, therefore, do not need dilution air. Fan-assisted appliances need only air for stoichiometric combustion [(10 ft³/ft³) of natural gas] and excess air [5 ft³/ft³ of natural gas]. Dividing by the ACH rate adjusts the required volume to correspond to the available infiltration rate.

For example, if the ACH rate is 0.35, 42.8 cubic feet (1.2 m³) would be required for each 1,000 Btu/h (ft³ natural gas), and if the ACH rate is 0.50, 30 cubic feet (0.8 m³) would be required for each 1,000 Btu/h. The greater the ACH rate, the lower the room volume needed.

Research and testing results indicate that the absolute minimum volume for draft-hood-equipped appliances must be 35 ft³/1,000 Btu/h (3.4 m³/kW) and for fan-assisted appliances it must be 25 ft³/1,000 Btu/h (2.4 m³/kW). This is why this section limits the infiltration rate to a maximum of 0.60 ACH. Limiting the ACH rate to 0.60 results in a lower limit safety factor for the required volume, thereby preventing appliances from being installed in exceedingly small spaces. Commentary Figure G2407.5.2 is based on the methodology of Sections G2407.5.1 and G2407.5.2 and is provided for convenience.

G2407.5.3 (304.5.3) Indoor opening size and location.

Openings used to connect indoor spaces shall be sized and located in accordance with Sections G2407.5.3.1 and G2407.5.3.2 (see Figure G2407.5.3).

❖ Sections G2407.5.3.1 and G2407.5.3.2 prescribe the size and location of openings used to conjoin (couple) spaces for the purpose of increasing the available volume. The last sentence of Section G2407.5 speaks of this. These openings must be permanently open, except where interlocked motorized dampers are used in accordance with Section G2407.10.

G2407.5.3.1 (304.5.3.1) Combining spaces on the same story. Each opening shall have a minimum free area of 1 square inch per 1,000 Btu/h (2,200 mm²/kW) of the total input rating of all *appliances* in the space, but not less than 100 square inches (0.06 m²). One opening shall commence within 12 inches (305 mm) of the top and one opening shall commence within 12 inches (305 mm) of the bottom of the enclosure. The minimum dimension of air openings shall be not less than 3 inches (76 mm).

❖ This section is applicable to adjacent spaces on the same floor level and provides for the familiar high and

low openings. The opening configuration creates a thermosiphon air flow with the bottom opening acting as an inlet and the top opening acting as an outlet. This provision originated as a means to conjoin a small appliance enclosure (such as a furnace or boiler room) with other spaces, thereby effectively increasing the volume of the enclosures.

G2407.5.3.2 (304.5.3.2) Combining spaces in different stories. The volumes of spaces in different stories shall be considered as communicating spaces where such spaces are connected by one or more openings in doors or floors having a total minimum free area of 2 square inches per 1,000 Btu/h (4402 mm²/kW) of total input rating of all *appliances*.

❖ This section is a new concept that allows spaces on different floor levels to be conjoined, thereby effectively increasing the available volume for supplying combustion air. Installing a high and low opening configuration in accordance with the previous section would serve no purpose when vertically connecting adjacent stories; thus, a single opening is permitted. The opening or openings can be in a floor or in a door opening to an unenclosed stairway that connects the two stories. This method of conjoining spaces is particularly useful for dwelling units where the volume of a basement in which the appliances are located can be conjoined with the open spaces on upper stories by means of a louvered door at the basement stairs. The opening size requirement is simply the addition of the areas of the two openings required by Section G2407.5.3.1. A combustion air opening in a floor would be considered as a transfer opening in a horizontal assembly.

**Figure G2407.5.2
CALCULATED VOLUMES**

G2407.6 (304.6) Outdoor combustion air. Outdoor *combustion* air shall be provided through opening(s) to the outdoors in accordance with Section G2407.6.1 or G2407.6.2. The minimum dimension of air openings shall be not less than 3 inches (76 mm).

❖ This section describes two methods for supplying combustion air from the outdoors: the traditional method of two direct openings or ducts to the outdoors and a newer method using one opening or duct to the outdoors.

Openings to spaces that are naturally ventilated with outdoor air, such as attic or crawl spaces, are considered as an acceptable alternative to a direct connection to the outdoors. Attic and crawl spaces can be acceptable sources of combustion air only where such spaces have adequate natural ventilation openings directly to the outdoors. Attic and crawl spaces ventilated by mechanical means are not an acceptable source of combustion air.

Combustion air ducts and openings that penetrate components of wall, floor, ceiling and roof assemblies must be installed as required by this code.

When designing combustion air installations, the effect that openings to the outdoors can have on appliances, plumbing systems and building occupants must be considered. For example, depending on the location, openings to the outdoors can:

- Cause drafts that can blow out pilot lights or otherwise interfere with appliance ignition and operation.
- Cause freezing of plumbing piping or other water-containing components.
- Cause objectionable cold drafts that encourage the occupants to block or cover the openings.

In all cases, combustion air openings should be located to reduce the likelihood they will be accidentally or intentionally blocked or covered. A ceiling transfer opening that connects a furnace room with an attic is an example of a combustion air opening that is likely to be intentionally blocked by an occupant because of the drafts that can occur in cold climates.

Building occupants typically do not understand the need for or the importance of combustion air openings.

No side dimension of a square or rectangular opening and no diameter of a round opening can be less than 3 inches (76 mm). The smallest allowed square opening area would be 9 square inches (5806 mm²) and the smallest allowed round opening area would be 7 square inches (4516 mm²) (see commentary, Section G2407.10).

G2407.6.1 (304.6.1) Two-permanent-openings method. Two permanent openings, one commencing within 12 inches (305 mm) of the top and one commencing within 12 inches (305 mm) of the bottom of the enclosure, shall be provided. The openings shall communicate directly or by ducts with the

outdoors or spaces that freely communicate with the outdoors.

Where directly communicating with the outdoors, or where communicating with the outdoors through vertical ducts, each opening shall have a minimum free area of 1 square inch per 4,000 *Btu/h* (550 mm²/kW) of total input rating of all *appliances* in the enclosure [see Figures G2407.6.1(1) and G2407.6.1(2)].

Where communicating with the outdoors through horizontal ducts, each opening shall have a minimum free area of not less than 1 square inch per 2,000 *Btu/h* (1,100 mm²/kW) of total input rating of all *appliances* in the enclosure [see Figure G2407.6.1(3)].

❖ Two openings located as prescribed in this section are intended to induce a convective air current in the room or space by admitting cooler, denser air in the lower opening and allowing the escape of warmer, less dense air through the upper opening. The farther apart the openings, the greater the temperature differential and the greater the convective force behind the current. A component of combustion air is cooling (ventilation) air for the appliance enclosure. The two-opening method was created to ventilate the appliance enclosure in addition to supplying combustion air. This ventilation cools the appliances and would help remove any combustion gases that spilled from the appliances.

G2407.6.2 (304.6.2) One-permanent-opening method. One permanent opening, commencing within 12 inches (305 mm) of the top of the enclosure, shall be provided. The *appliance* shall have *clearances* of at least 1 inch (25 mm) from the sides and back and 6 inches (152 mm) from the front of the *appliance*. The opening shall directly communicate with the outdoors or through a vertical or horizontal duct to the outdoors, or spaces that freely communicate with the outdoors (see Figure G2407.6.2) and shall have a minimum free area of 1 square inch per 3,000 *Btu/h* (734 mm²/kW) of the total input rating of all *appliances* located in the enclosure and not less than the sum of the areas of all *vent connectors* in the space.

❖ Research has shown that for modern appliances, a single opening to the outdoors will perform as well as the traditional two-opening method. The one-opening method described in this section depends on a reduced pressure being created in the enclosure by the draft created by the venting system. This reduced pressure causes combustion air to enter the enclosure through the single opening. The opening must be properly sized considering both sizing criteria: the square-inch-area-per-*Btu/h* ratio and the area minimum based on the sum of the areas of all vent connectors in the enclosure. This method allows for fewer openings, fewer ducts and fewer objections by the owners/occupants.

G2407.7 (304.7) Combination indoor and outdoor combustion air. The use of a combination of indoor and outdoor combustion air shall be in accordance with Sections G2407.7.1 through G2407.7.3.

- ❖ This method of supplying combustion air is a combined application of Section G2407.5 and Section G2407.6. This method allows credit for the amount of infiltration that exists and makes up for the shortage with supplemental outdoor air. In other words, in addition to obtaining combustion air directly from the outdoors, this method relies on building infiltration for a portion of the total combustion air. In spaces where the volume is insufficient to satisfy the method of Section G2407.5 or where smaller outdoor air openings than required by Section G2407.6 are desired, this method allows infiltration and outdoor openings to supplement each other. If the appliances are enclosed in a small room such as a closet, openings to adjacent spaces as prescribed by Section G2407.5.3 must be provided to couple the appliance room volume with any other space volume counted on to provide combustion air. Frequently, sufficient volume cannot be obtained in the appliance enclosure or by opening the appliance enclosure to adjacent spaces. This method of combining indoor and outdoor air is an alternative solution. Simply stated, this section uses ratios of what is required to what is actually supplied so that when com-

bined, the indoor air component and the outdoor air component add up to the whole required.

G2407.7.1 (304.7.1) Indoor openings. Where used, openings connecting the interior spaces shall comply with Section G2407.5.3.

❖ See the commentary to Section G2407.5.3.

G2407.7.2 (304.7.2) Outdoor opening location. Outdoor opening(s) shall be located in accordance with Section G2407.6.

❖ See the commentary to Section G2407.6.

G2407.7.3 (304.7.3) Outdoor opening(s) size. The outdoor opening(s) size shall be calculated in accordance with the following:

1. The ratio of interior spaces shall be the available volume of all communicating spaces divided by the required volume.
2. The outdoor size reduction factor shall be one minus the ratio of interior spaces.
3. The minimum size of outdoor opening(s) shall be the full size of outdoor opening(s) calculated in accordance with Section G2407.6, multiplied by the reduction factor. The minimum dimension of air openings shall be not less than 3 inches (76 mm).

❖ Although the principle has not changed, this method has been simplified compared to the same provision in previous editions of the code. The intent is still the same; that is, the fraction of the required indoor volume plus the fraction of outdoor openings must be equal to or greater than 1. The indoor volume method and the outdoor air method can both be stand-alone methods; therefore, half of one and half of the other will work, as will three fourths of one and a quarter of the other, etc.

This section is expressed in the following equation:

$$\left[1 - \left(\frac{\text{available indoor volume}}{\text{volume required by Section G2407.5}} \right) \right] \times \frac{\text{full size opening required by Section G2407.6}}{\text{reduced size outdoor air openings}} = \text{outdoor air openings}$$

Example:

Given:

7,500 ft³ of indoor volume is required if all indoor air is to be used.

4,950 ft³ of indoor volume is available.

One opening to the outdoors is desired and must be 50 in.² if all outdoor air is to be used.

$$\left[1 - \left(\frac{4,950 \text{ ft}^3}{7,500 \text{ ft}^3} \right) \right] \times 50 \text{ in.}^2 = \text{reduced outdoor opening size}$$

$$0.34 \times 50 \text{ in.}^2 = 17 \text{ in.}^2 \text{ outdoor opening size}$$

Either of the provisions of Section G2407.6 when combined with the provision of this section can be used to satisfy the equation.

Example 1:

Room A is within a dwelling unit and contains a fuel-fired furnace and a fuel-fired water heater with input ratings of 150,000 and 50,000 Btu/h, respectively.

The size of Room A is 20 feet by 30 feet, and adjacent Room B is also 20 feet by 30 feet. Both rooms have 8-foot-high ceilings. Rooms A and B communicate through two openings located in accordance with Section G2407.5.3, each having dimensions of 10 inches by 20 inches. Two 3-inch-diameter (round) direct openings to the outdoors are installed in Room A and are located in accordance with Section G2407.6.1.

Question: Do the openings to the outdoors, when combined with the volumes of Rooms A and B, meet the combustion air demand of the appliances?

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 Btu/h = 0.2931 W, 1 cubic foot = 0.0283 m³, 1 square inch = 645 mm².

Given:

The air infiltration rate of the building is unknown.

Volume of Room A = 4,800 ft³

Volume of Room B = 4,800 ft³

Area of 3-inch-diameter direct openings = 7.07 in²

Area of each opening between Rooms A and B = 200 in²

Total input rating of appliances = 200,000 Btu/h

Step 1: Determine whether Rooms A and B meet the volume requirements of Section G2407.5.

Available volume of Rooms A and B = 4,800 ft³ + 4,800 ft³ = 9,600 ft³

The required volume is:

$$\frac{200,000 \text{ Btu/h}}{1,000 \text{ Btu/h}} \times 50 \text{ ft}^3 = 10,000 \text{ ft}^3$$

Rooms A and B combined do not meet the volume requirements of Section G2407.5.

Step 2: Determine whether the openings between Rooms A and B meet the requirements of Section G2407.5.3.

The minimum required area is:

$$\frac{200,000 \text{ Btu/h}}{1,000 \text{ Btu/h}} \times 1 \text{ in.}^2 = 200 \text{ in.}^2$$

Actual area of each opening = 200 in²

The area of each opening meets the size requirement of Section G2407.5.3.

Step 3: Determine the required area of each direct outdoor opening in accordance with Section G2407.6.1.

Required area of each opening:

$$\frac{200,000 \text{ Btu/h}}{4,000 \text{ Btu/h}} \times 1 \text{ in}^2 = 50 \text{ in}^2$$

Step 4: Determine whether the 3-inch-diameter direct openings combined with the volumes of Rooms A and B comply with:

$$\left[1 - \left(\frac{9,600 \text{ ft}^3}{10,000 \text{ ft}^3} \right) \right] \times 50 = (1 - 0.96) \times 50 = 0.04 \times 50 = 2 \text{ in}^2$$

The actual area of each direct opening (7.07 in²) exceeds the required area of 2 in².

Therefore, the combination of the 3-inch-diameter direct openings and the volumes of Rooms A and B satisfies the combustion air demand of the appliances.

Example 2:

A combination of indoor and outdoor combustion air is to be supplied for two natural draft boilers in a room as shown in Commentary Figure G2407.7.3 (the air infiltration rate is not known).

1. In accordance with Section G2407.5.1, the required volume of the room containing the boilers would be:

$$\frac{90,000 \text{ Btu/h} + 90,000 \text{ Btu/h}}{1,000} \times 50 \text{ ft}^2 = \frac{180,000}{1,000} \times 50 \text{ ft}^2 = 180 \times 50 \text{ ft}^2 = 9,000 \text{ ft}^3$$

2. The actual room volume is 20ft x 50ft x 8ft = 8,000 ft³.
3. In accordance with Section G2407.7.3, Item 1, determine the ratio of available (actual) volume to the required volume.

$$\frac{\text{Actual Volume } 8,000 \text{ ft}^3}{\text{Required Volume } 9,000 \text{ ft}^3} = 0.89$$

4. In accordance with Section G2407.7.3, Item 2, determine outdoor opening size reduction factor.

$$1 - 0.89 = 0.11$$

5. In accordance with Section G2407.7.3, Item 3, determine the size of the outdoor opening required as if all combustion air is to be supplied through the outdoor opening. Because a single high opening is built into an exterior wall, Section G2407.6.2 applies and would require an area of 1 in²/3000 Btu/h of total appliance input rating (Assuming 6-in. vent connectors, the total area of the boiler vent connectors is 56.6 in²).

$$\frac{90,000 \text{ Btu/h} + 90,000 \text{ Btu/h}}{3,000} = 60 \text{ in}^2$$

6. The required size of the outdoor air opening is 60 in² x 0.11 = 6.6 in². Because the minimum dimensions must be not less than 3 inches, the minimum area of a square opening must be 9 in². This combination satisfies the combustion air demand of the appliances; however, note that Section G2407.6.2 requires an area not less than the sum of the vent connector areas, which is 56.6 in² in this example.

G2407.8 (304.8) Engineered installations. Engineered *combustion air* installations shall provide an adequate supply of *combustion*, ventilation and *dilution air* and shall be *approved*.

❖ Potential sources of combustion air are the indoor atmosphere in which the appliance is located, outdoor openings and ducts that communicate with the outdoor atmosphere, a combination of these or any other

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 British thermal unit per hour = 0.293 W.

Figure G2407.7.3
ROOM CONFIGURATION USED IN EXAMPLE 2

approved arrangement for the dependable introduction of outdoor air into the building or directly to the fuel-burning appliance.

The provisions of Section G2407 are intended for application only to appliances and equipment using natural draft atmospheric burners. Gas-fired appliances, especially those that are not of the atmospheric-burner type, are commonly supplied with combustion air by engineered systems. For example, special engineered systems are usually designed for appliances equipped with power burners. Power burners force combustion air into the burner under pressure and are, therefore, not dependent on gravity airflow. In some applications, engineered combustion air supplies have advantages and can be preferable to large gravity (natural) openings to the outdoors. Engineered designs must be evaluated for code compliance, approved and installed in accordance with the appliance manufacturer's instructions [see Commentary Figures G2407.8(1) through G2407.8(3)].

G2407.9 (304.9) Mechanical combustion air supply. Where all *combustion air* is provided by a mechanical air supply system, the *combustion air* shall be supplied from the outdoors at a rate not less than 0.35 cubic feet per minute per 1,000 Btu/h (0.034 m³/min per kW) of total input rating of all *appliances* located within the space.

❖ This method supplies combustion air by means of a fan/blower that runs when any of the served appliances are in a firing cycle. The fan/blower must be sized to supply the required airflow based on the simultaneous operation of all appliances that are served by the fans/blowers. The total Btu/h input rating of all fuel-burning appliances located in the room or space must

be used because the potential exists for all of the appliances to be operating at the same time. This method is used where gravity openings to the outdoors are impractical or undesirable. A small fan-powered intake opening can substitute for comparatively large gravity openings, especially where freezing temperatures are a problem or there is no room for the required size gravity openings. Commentary Figures G2407.8(1), (2) and (3) illustrate factory-engineered mechanical combustion air supply units (see Commentary Figure G2407.9).

The prescribed air flow rate of 0.35 cfm per 1,000 Btu/h is equivalent to 1 cfm per 2,867 Btu/h and is based on a combustion air need of 21 cubic feet of volume for each cubic foot of natural gas (1,000 Btu/h). The rate is derived as follows:

$$\frac{2857 \text{ Btu/h}}{1000 \text{ Btu/ft}^3} = 2.857 \text{ ft}^3 \text{ of gas per hour}$$

Thus, 1 cfm is required for each 2,857 Btu/h or 0.35 cfm per 1,000 Btu/h.

G2407.9.1 (304.9.1) Makeup air. Where exhaust fans are installed, *makeup air* shall be provided to replace the exhausted air.

❖ This section expresses the exact same concern as Section G2407.4 (see commentary, Section G2407.4). If the air that is supplied by the combustion air fan becomes makeup air for an exhaust fan, the combustion air will not be available to the appliance(s) for which the air was intended.

Figure G2407.8(3)
MECHANICAL COMBUSTION AIR/MAKEUP AIR-SUPPLY SYSTEM

FUEL GAS

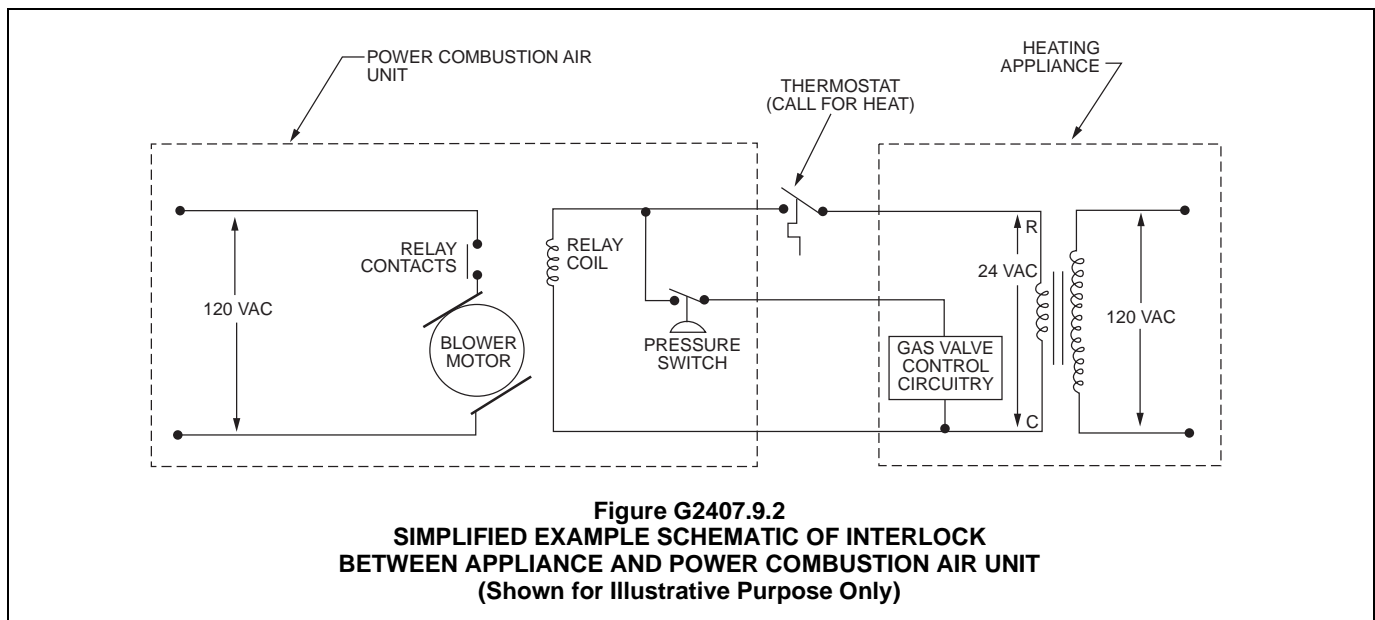

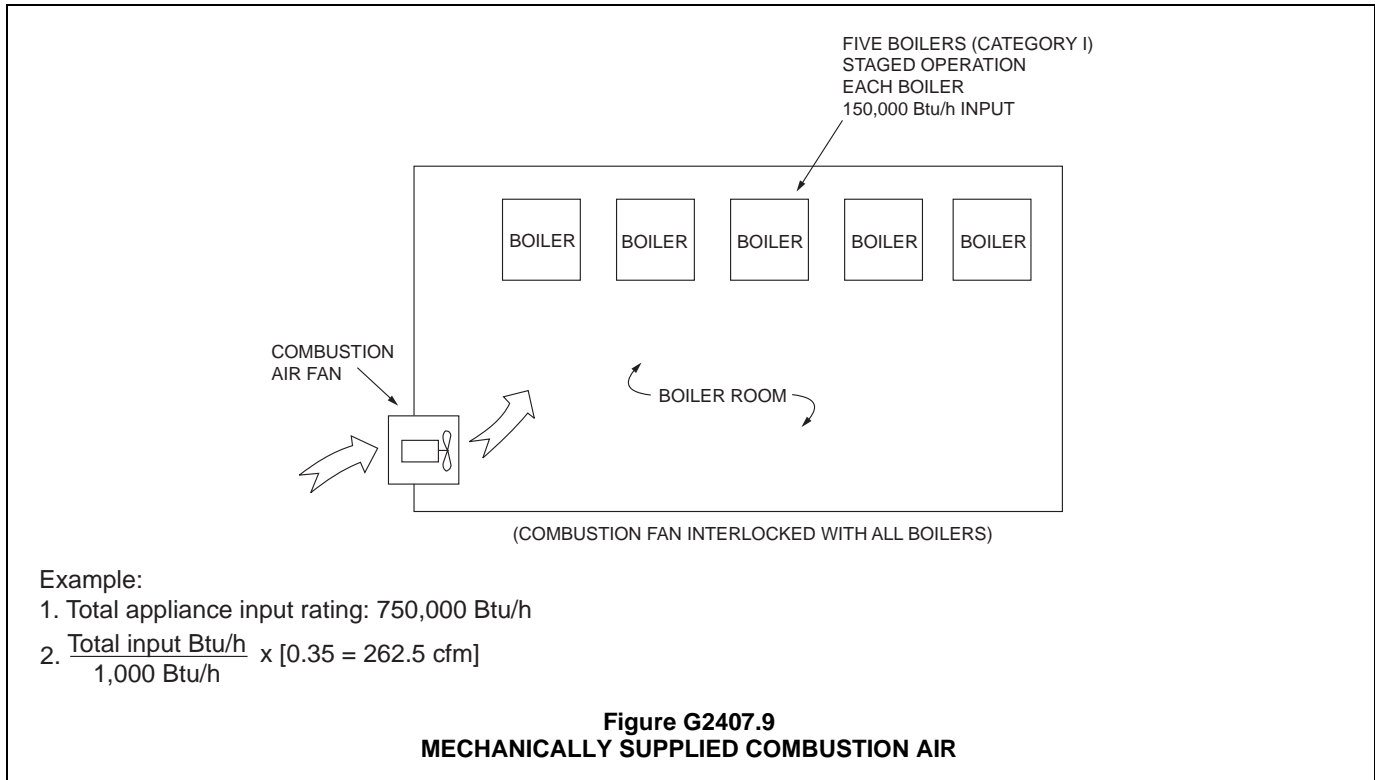

G2407.9.2 (304.9.2) Appliance interlock. Each of the *appliances* served shall be interlocked with the mechanical air supply system to prevent *main burner* operation when the mechanical air supply system is not in operation.

❖ This section requires an interlock circuit as opposed to simple parallel operation wiring. In other words, the combustion air fan/blower must start when initiated by the means that controls the appliance operation cycles (e.g., thermostat), and only after the combustion air fan/blower is proven to be operating will the appliance be allowed to start a firing cycle. If the combustion air

fan/blower fails during a firing cycle of an appliance, the appliance firing cycle must be terminated (see Commentary Figure G2407.9.2).

The following steps must occur in this order:

1. Call for heat.
2. Combustion air fan/blower starts.
3. Combustion air fan/blower is proven to be operating.
4. Proving controls allow appliance to fire.

G2407.9.3 (304.9.3) Combined combustion air and ventilation air system. Where *combustion air* is provided by the building's mechanical ventilation system, the system shall provide the specified *combustion air* rate in addition to the required ventilation air.

- ❖ If combustion air is mechanically supplied through an HVAC system, the system must deliver the required combustion air rate above and beyond any outdoor air rate supplied for ventilation of the occupied spaces. The HVAC system must also be interlocked with the appliance(s) as required by Section G2407.9.2. Neither continuous operation nor parallel operation of the HVAC system satisfies the requirement for a true interlock as required by Section G2407.9.2.

G2407.10 (304.10) Louvers and grilles. The required size of openings for *combustion*, ventilation and *dilution air* shall be based on the net free area of each opening. Where the free area through a design of louver, grille or screen is known, it shall be used in calculating the size opening required to provide the free area specified. Where the design and free area of louvers and grilles are not known, it shall be assumed that wood louvers will have 25-percent free area and metal louvers and grilles will have 75-percent free area. Screens shall have a mesh size not smaller than $\frac{1}{4}$ inch (6.4 mm). Nonmotorized louvers and grilles shall be fixed in the open position. Motorized louvers shall be interlocked with the *appliance* so that they are proven to be in the full open position prior to *main burner* ignition and during *main burner* operation. Means shall be provided to prevent the *main burner* from igniting if the louvers fail to open during *burner* start-up and to shut down the *main burner* if the louvers close during operation.

- ❖ This section recognizes that louvers and grilles are usually installed over air inlets and outlets to prevent rain, snow and animals from entering the building. When louvers or grilles are used, the solid portion of the louver or grille must be considered when determining the unobstructed (net clear) area of the opening.

Combustion air openings are sized based on there being a free, unobstructed area for the passage of air into the space where the fuel-burning appliances are located. Louvers or grilles placed over these openings reduce the area of the openings because of the area occupied by the solid portions of the grille or louver. The reduction in area must be considered because only the unobstructed area can be credited toward the required opening size.

The reduction in opening area caused by the presence of grilles or louvers will always require openings to be larger than determined from the sizing ratios of this chapter and larger than any duct of the minimum required size that might connect to these openings. Once the required size of a combustion air duct or opening is determined, any increase in opening size that must be made as a result of the effect of louvers or grilles must be determined. If a metal louver is used and based on the default opening area of 75 percent, the designer must calculate what size opening times

75 percent will yield the previously determined combustion air opening or duct area.

For example, assume that a combustion air duct needs to have a cross-sectional area of 200 square inches and this duct connects to an exterior wall opening with a metal louver protecting it.

x = The required opening area adjusted to account for the louver.

$$0.75x = 200 \text{ in}^2$$

$$x = \frac{200}{0.75}$$

$$x = 266.7 \text{ in}^2$$

This can be simplified to multiplying by the reciprocal of the percentage as follows:

For metal louvers and grilles, the required combustion air duct or opening size multiplied by 1.33 equals the adjusted opening size.

For wooden louvers and grilles, the required combustion air duct or opening size multiplied by 4 equals the adjusted opening size.

The actual free opening of a louver or grille should be obtained from the manufacturer rather than relying on default assumptions.

This section does not apply to grilles, louvers or screens that are an integral component of a labeled appliance that is installed in accordance with the manufacturer's instructions. Where the manufacturer states the free, unobstructed area of a grille or louver, it is acceptable to consider that area as actual without requiring further calculation.

The code also requires the free area of screens to be considered in the opening sizing calculations. If it is unknown, it will have to be calculated because there is no stated default area for screens as there is for louvers and grilles. The code prohibits screens having mesh sizes smaller than $\frac{1}{4}$ inch (6 mm). Screens with a mesh size of $\frac{1}{4}$ inch (6 mm) and larger are not insect screens and would be suitable only for keeping out large debris, rodents and other small animals. Smaller size mesh is likely to become obstructed by lint, plant fibers, cottonwood seeds, etc. At best, placing screens in combustion air openings is risky, and grilles and louvers are preferred to keep out the unwanted.

Metal louvers are constructed so that the solid portion of the louver occupies approximately 25 percent of the opening area, leaving 75 percent of this area unobstructed. Wood louvers occupy approximately 75 percent of the opening area, leaving 25 percent of the area unobstructed. When the required amount of unobstructed area is determined, the effect that a louver has on that area must be taken into account to make certain the minimum amount of unobstructed opening is achieved. The material type, thickness and spacing all have a significant effect on the actual net free area of any louver or grille.

Note that the 75-percent and 25-percent default numbers might be too liberal for some louvers or grilles and every effort should be made to consult the louver or grille manufacturer's specifications.

To prevent freezing of pipes, to save energy and maintain comfortable temperatures in appliance rooms, outdoor openings often have motorized dampers that close during the appliance(s) off cycle. The damper motors and/or damper blades must be supervised so that an interlock can be established between the dampers and the appliances, thereby preventing appliance operation when the dampers are closed.

Combustion air openings must not be closable unless they open and close automatically using a mechanism that is interlocked with the appliances (see Commentary Figure G2407.10). Damper supervision is easily accomplished by damper motor end switches or blade position travel switches that monitor the position of the drive motor shaft, the damper/motor linkage hardware or the damper blades. These switches provide feedback to the appliance control circuitry to allow firing only when the dampers are proven to be fully open.

G2407.11 (304.11) Combustion air ducts. *Combustion air ducts shall comply with all of the following:*

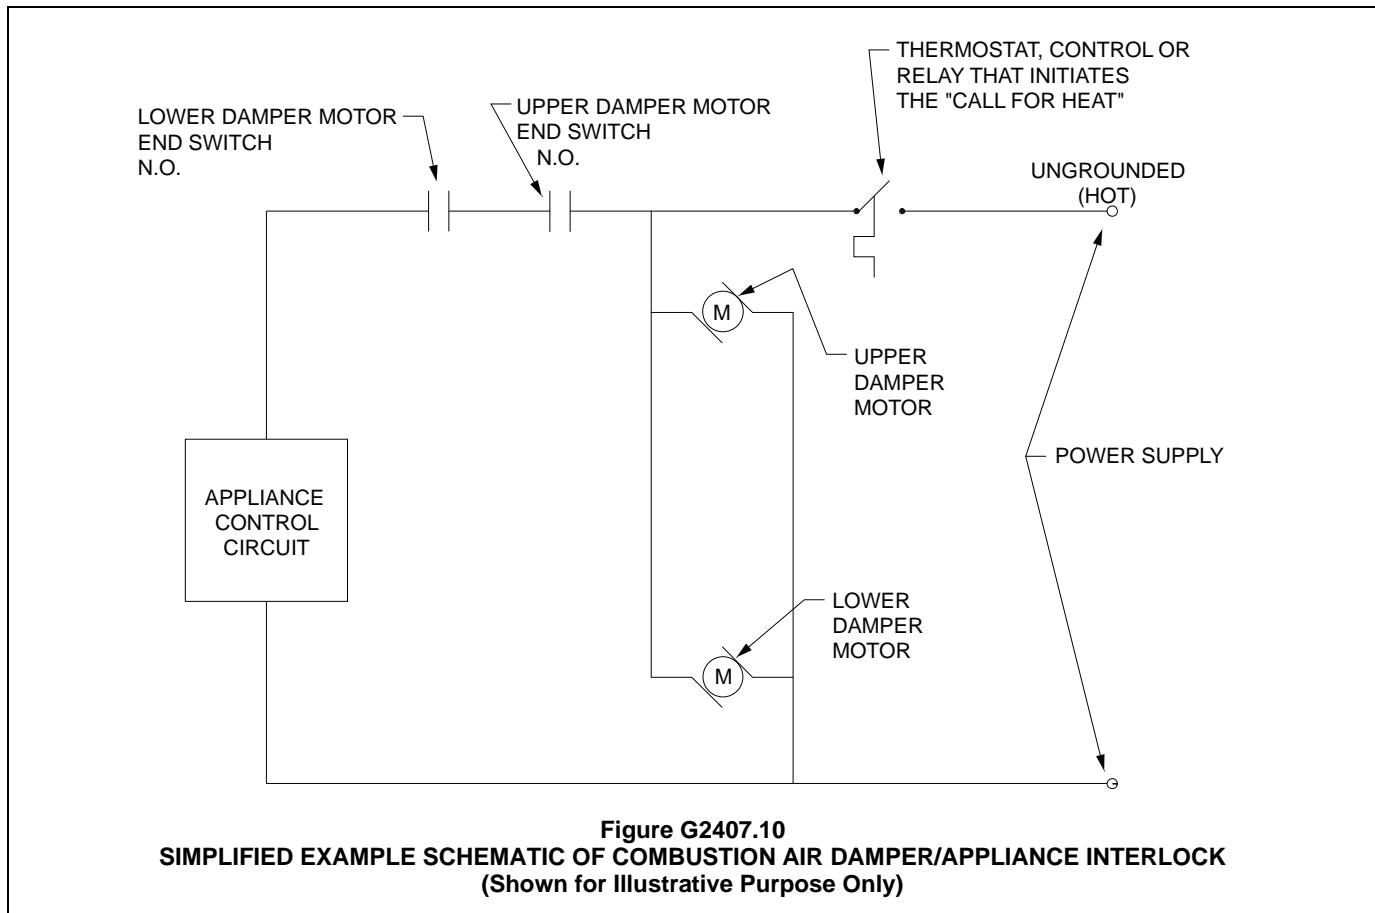

1. Ducts shall be constructed of galvanized steel complying with Chapter 16 or of a material having equivalent corrosion resistance, strength and rigidity.

Exception: Within dwellings units, unobstructed stud and joist spaces shall not be prohibited from conveying *combustion air*, provided that not more than one required fireblock is removed.

2. Ducts shall terminate in an unobstructed space allowing free movement of *combustion air* to the *appliances*.
3. Ducts shall serve a single enclosure.
4. Ducts shall not serve both upper and lower *combustion air* openings where both such openings are used. The separation between ducts serving upper and lower *combustion air* openings shall be maintained to the source of *combustion air*.
5. Ducts shall not be screened where terminating in an attic space.
6. Horizontal upper *combustion air* ducts shall not slope downward toward the source of *combustion air*.
7. The remaining space surrounding a *chimney* liner, gas vent, special gas vent or plastic *pipng* installed within a masonry, metal or factory-built *chimney* shall not be used to supply *combustion air*.

Exception: Direct-vent gas-fired *appliances* designed for installation in a solid fuel-burning *fireplace* where installed in accordance with the manufacturer's instructions.

8. *Combustion air* intake openings located on the exterior of a building shall have the lowest side of such open-

ings located not less than 12 inches (305 mm) vertically from the adjoining finished ground level.

- ❖ This section addresses the construction and installation of combustion air ducts.

Item 1 requires that combustion air ducts be constructed of galvanized sheet steel or an approved equivalent material. The intent is to cause ducts to be constructed of a material that is resistant to corrosion and physical damage, which would allow the ducts to remain in place undamaged for the life of the installation. It is doubtful that the authors of Item 1 ever anticipated the use of flexible ducts and the higher friction losses associated with such rough-wall ducts. It is also reasonable to assume that all of the sizing criteria in Section G2407 are based on smooth-wall ducts. The strength and rigidity of typical flexible ducts would not be equivalent to rigid steel ducts. The exception expresses a concern for fire safety where stud cavities are used as a duct.

Item 2 is intended to prevent blockages and minimize resistance (friction loss) to airflow.

Item 3 prohibits a duct from serving more than one appliance enclosure because the duct and opening sizing criteria are based on a single duct serving a single opening in an appliance location. Multiple openings supplied by a single duct could result in unpredictable airflow and might not create the convective movements of air intended by the combustion air methods.

Item 4 recognizes that where both upper and lower combustion air openings are required, air circulation cannot occur if a single duct serves both combustion air openings. The lower opening functions as an air inlet and the upper opening as an air outlet, thus independent ducts are required (see Commentary Figure G2407.11).

Item 5 is intended to prevent obstruction or blockage by insulation materials.

Item 6 is intended to prevent trapping or sloping of the upper combustion air opening in a way that would impede the convective movement of air. The horizontal duct for the upper openings must slope upward as it

travels away from the appliance(s) and toward the outdoors.

When a vent or chimney liner is installed within a chimney, an annular space will exist between the vent or liner and the interior chimney walls. According to Item 7, this space cannot be used as a conduit for conveying combustion air because of poor flow characteristics, the tendency for reverse flow to occur as the combustion air is warmed by the liner or vent and the adverse cooling effect on the vent or liner. The exception recognizes that there could be appliances that are designed and listed for the type of installation that this item intends to prohibit.

Item 8 intends to prevent combustion air openings from being obstructed by snow, leaves and vegetation. No part of a combustion air opening is allowed to be less than 12 inches (305 mm) above the finished ground level under such opening.

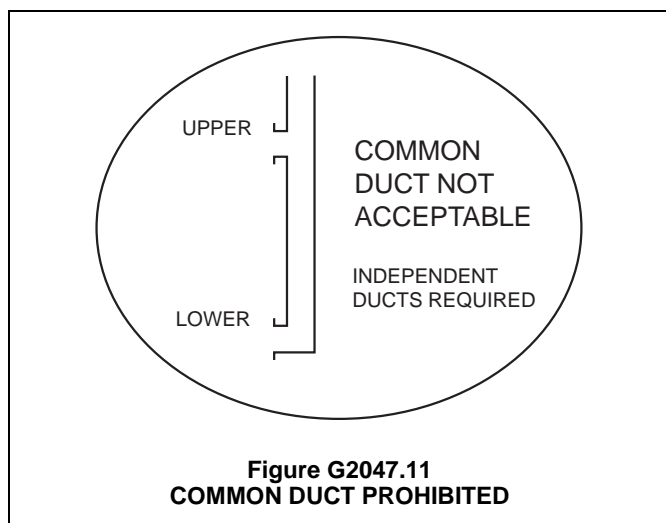

G2407.12 (304.12) Protection from fumes and gases.

Where corrosive or flammable process fumes or gases, other than products of *combustion*, are present, means for the disposal of such fumes or gases shall be provided. Such fumes or gases include carbon monoxide, hydrogen sulfide, ammonia, chlorine and halogenated hydrocarbons.

In barbershops, beauty shops and other facilities where chemicals that generate corrosive or flammable products, such as aerosol sprays, are routinely used, nondirect vent-type *appliances* shall be located in a mechanical room separated or partitioned off from other areas with provisions for *combustion air* and *dilution air* from the outdoors. *Direct-vent appliances* shall be installed in accordance with the *appliance* manufacturer's instructions.

- ❖ In many occupancies, the routine use of chemicals contaminates the indoor combustion air. These contaminants can combine with water vapor in the combustion gases to produce acids and other corrosive compounds that can destroy appliance components, vents, chimneys and connectors. For example, it is common to see vents and vent connectors for draft-hood-equipped water heaters in beauty shops that have deteriorated to the point of structural failure. Other examples are swimming pool heaters exposed to chlorine, boilers exposed to laundry and dry cleaning chemicals and boilers exposed to refrigerant leakage. Some contaminants are more toxic to life after they have passed through an appliance combustion chamber. The highly poisonous chemical "phosgene" (carbonyl chloride) can be produced when common refrigerants contaminate combustion air.

Obviously, choosing direct-vent appliances will eliminate this problem in most cases and will not require isolation enclosures for the appliances. It is possible that some atmospheres are unsuitable for any appliance, direct-vent or otherwise. The code provides an alternative to direct-vent appliances that requires the appliances to be isolated from the contaminated atmosphere by reasonably air-tight enclosures and requires that all combustion air be supplied for the appliance(s) from the outdoors.

**Figure G2407.11
COMMON DUCT PROHIBITED**

SECTION G2408 (305) INSTALLATION

G2408.1 (305.1) General. *Equipment and appliances* shall be installed as required by the terms of their approval, in accordance with the conditions of listing, the manufacturer's instructions and this code. Manufacturer's installation instructions shall be available on the job site at the time of inspection. Where a code provision is less restrictive than the conditions of the listing of the *equipment or appliance* or the manufacturer's installation instructions, the conditions of the listing and the manufacturer's installation instructions shall apply.

Unlisted *appliances approved* in accordance with Section G2404.3 shall be limited to uses recommended by the manufacturer and shall be installed in accordance with the manufacturer's instructions, the provisions of this code and the requirements determined by the *code official*.

❖ Manufacturers' installation instructions are evaluated by the listing agency verifying compliance with the applicable standard. The listing agency can require that the manufacturer alter, delete or add information to the instructions as necessary to achieve compliance with applicable standards and code requirements. Manufacturers' installation instructions are an enforceable extension of the code and must be in the hands of the code official when an inspection takes place.

When an appliance is tested to obtain a listing and label, the approved agency installs the appliance in accordance with the manufacturer's installation instructions. The appliance is tested under these conditions; thus, the installation instructions become an integral part of the labeling process.

The listing and labeling process assures that the appliance and its installation instructions are in compliance with applicable standards. Therefore, an installation in accordance with the manufacturer's instructions is required, except where the code requirements are more stringent. An inspector must carefully and completely read and comprehend the manufacturer's instructions to properly perform an installation inspection.

In some cases, the code will specifically address an installation requirement that is also addressed in the manufacturer's installation instructions. The code requirements may be the same or may exceed the requirements in the manufacturer's installation instructions, or the manufacturer's installation instructions could contain requirements that exceed those in the code. In all such cases, the more restrictive requirements would apply.

In addition to the installation requirements for the appliance or equipment itself, this section also regulates the connections to appliances and equipment by requiring compliance with all other applicable sections of this code and other *International Codes*®. These connections include but are not limited to fuel and electrical supplies, control wiring, hydronic piping, chimneys, vents and ductwork. Some overlap or coincidence of connection requirements may occur in the code and

the manufacturer's installation instructions. In the unlikely event that the code was less restrictive (more lenient) than the manufacturer's instructions regarding an installation issue, the manufacturer's instructions must prevail. Where differences or conflicts occur, the requirements that provide the greatest level of safety always apply.

Even if an installation appears to be in compliance with the manufacturer's instructions, the installation cannot be complete or approved until all associated components, connections, and systems that serve the appliance or equipment are also in compliance with the applicable provisions of the code. For example, a gas-fired boiler installation must not be approved if the boiler is connected to a deteriorated, undersized, improper or otherwise unsafe chimney or vent. Likewise, the same installation must not be approved if the existing gas piping is in poor condition or if the electrical supply circuit is inadequate or unsafe.

In the case of replacement installations, the intent of this section is to require all new work associated with the installation to comply with the code without necessarily requiring full compliance for the existing, unchanged portions of the related ductwork, piping, electrical, venting and similar mechanical systems. In the case of an appliance replacement, such as a furnace, it is the expectation of both the manufacturer's instructions and the code that the new furnace be connected to a code-complying venting system, fuel supply system and electrical circuit, all of which are part of the furnace installation. If the ductwork system was such that the furnace temperature rise across the heat exchanger exceeded the maximum allowable temperature rise, the ductwork system might have to be altered as part of the furnace installation. Existing mechanical systems are accepted on the basis that they are free from hazard although not necessarily compliant with current codes. The code is not retroactive except where specifically stated that it applies to existing systems.

Manufacturer's installation instructions are often updated and changed for various reasons, such as changes in the appliance or equipment design, revisions to the product standards and as a result of field experience related to existing installations. The code official should stay abreast of any changes by reviewing the manufacturer's instructions for every installation.

Equipment and appliances must be installed in accordance with the manufacturer's installation instructions. The manufacturer's label and installation instructions must be consulted in determining whether or not an appliance or piece of equipment can be installed and operated in a particular hazardous location. Without the manufacturer's installation instructions, an inspector cannot fully perform his or her job, which is why the manufacturer's installation instructions must be available on the job site when the equipment is being inspected.

G2408.2 (305.3) Elevation of ignition source. *Equipment and appliances having an ignition source shall be elevated such that the source of ignition is not less than 18 inches (457 mm) above the floor in hazardous locations and public garages, private garages, repair garages, motor fuel-dispensing facilities and parking garages. For the purpose of this section, rooms or spaces that are not part of the living space of a dwelling unit and that communicate directly with a private garage through openings shall be considered to be part of the private garage.*

Exception: Elevation of the *ignition source* is not required for *appliances* that are *listed* as flammable-vapor-ignition resistant.

- ❖ To reduce the possibility of ignition of flammable vapors in hazardous areas, the potential sources of ignition must be elevated above the surface supporting the equipment or appliance. It is not the intent of this section for the installer to measure the elevation from the surface of a dedicated appliance stand or other structure built to support the appliance where that stand or structure does not afford room for the storage of flammable liquids. Some flammable and combustible liquids typically associated with hazardous locations give off vapors that are denser than air and tend to collect near the floor. The 18-inch (457 mm) height requirement is intended to reduce the possibility of flammable vapor ignition by keeping the ignition sources elevated above the anticipated level of accumulated vapors. The 18-inch (457 mm) value is a minimum requirement and must be increased when required by the manufacturer's installation instructions.

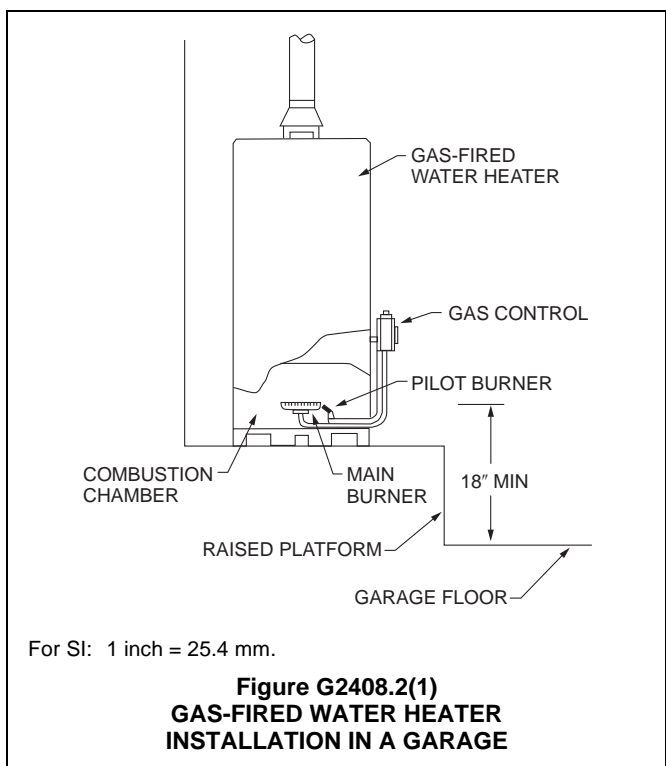

This section will effectively prohibit the installation of most furnaces, boilers, space heaters, clothes dryers

and water heaters directly on the floor of residential garages.

The accumulation of flammable vapors more than 18 inches (457 mm) deep is unlikely in most ventilated locations; therefore, maintaining all possible sources of ignition at least 18 inches (457 mm) above the floor will substantially reduce the risk of explosion and fire [see Commentary Figures G2408.2(1) and G2408.2(2)].

In the context of this section, a source of ignition could be a pilot flame, burner, burner igniter or electrical component capable of producing a spark. The term "ignition source" is defined and can be interpreted as meaning an intentional source of ignition, such as for a burner, or an unintentional source of ignition for any flammable vapors that may be present (see definition of "Ignition source").

An appliance installed in a closet or room that is accessible only from the garage must be considered as part of the garage for application of this section. Even though the room may be separated from the garage by walls and a door, there is no practical means of making the door vapor tight, nor is there any assurance that the door will remain closed during normal use. An appliance room that is accessed only from the outdoors or only from the living space would not be considered as part of the garage (see Section G2408.2.1). Rooms

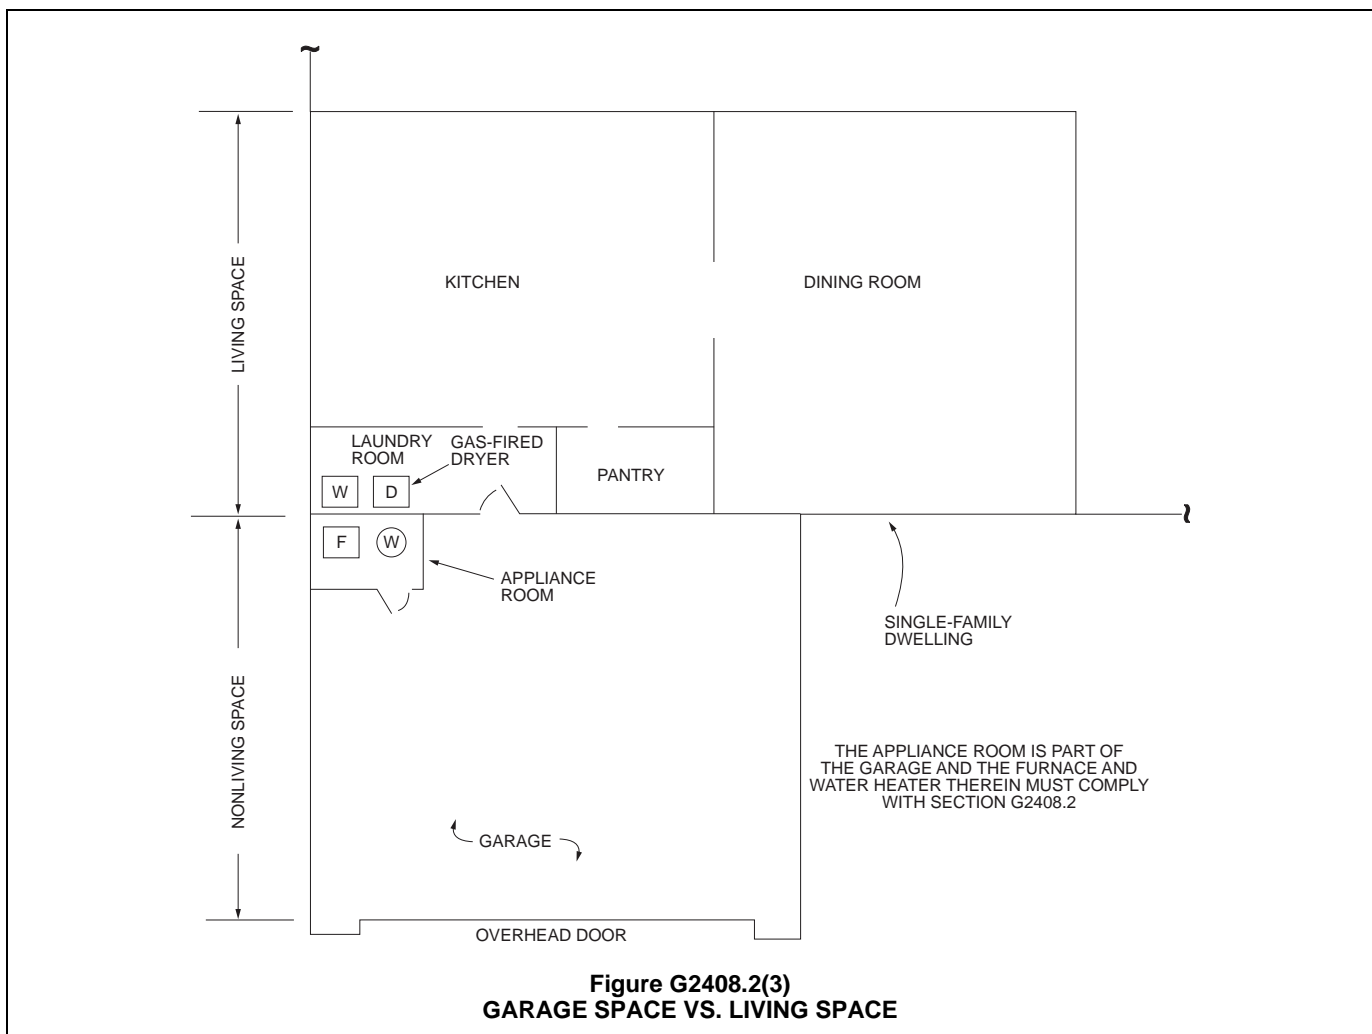

FUEL GAS

such as utility rooms or laundry rooms that communicate with both the garage and the living space and that are considered as part of the living space are not part of the garage (see definition of “Living space”). If a room opens to the garage and that room is not living space, it is part of the garage for the purpose of this section [see Commentary Figure G2408.2(3)].

The exception recognizes that new technology exists that allows appliances, such as water heaters, to be tested and listed as being flammable-vapor-ignition resistant and suitable for installation without the 18-inch (457 mm) elevation requirement. This new technology was developed for conventional draft-hood-equipped water heaters, and now the standard for these appliances, ANSI Z21.10.1, mandates that by specified effective dates, all water heaters must comply with the flammable-vapor-ignition criteria in the standard. The technology involves variously configured flame arrestor screens having precisely engineered openings (slots). All combustion air for the appliance is passed through the flame arrestor screen. To pass through the small slots in the screen, the combustion air velocity is increased (Venturi principle) such that it exceeds the velocity at which flames travel through a

flammable vapor. If the combustion air contains flammable vapors, the vapors will enter the appliance and be ignited within the combustion chamber. The flames will be contained (trapped) within the combustion chamber because the arrestor screen will not allow flames to exit the combustion chamber. The result is that vapor ignition is limited to the appliance interior and is not allowed to spread to the atmosphere surrounding the appliance. During such an event, a thermal sensing device shuts down and locks out the appliance. Some appliance manufacturers might require that the appliance be replaced after a flammable-vapor-ignition event. Others require that a sensor be replaced or reset. The appliance standard includes testing requirements to determine whether the arrestor screen is subject to blockage by debris, including lint, plant fibers, dust particles, etc. If the arrestor screen openings become restricted by debris, the appliance will be deprived of combustion air and incomplete combustion and serious appliance malfunction can result. If an appliance shuts down as a result of the arrestor screen being blocked by debris, thus restricting the combustion air supply, typically a thermal device can be reset or replaced to restore operation of the appliance.

If the installation instructions or the label of a water heater equipped with flammable-vapor-ignition-resistant technology state that the appliance must be elevated so that the source of ignition is at least 18 inches (457 mm) above the floor, it must be installed as directed [see Commentary Figures G2408.2(1) through G2408.2(6)].

G2408.2.1 (305.3.1) Installation in residential garages. In residential garages where *appliances* are installed in a separate, enclosed space having access only from outside of the garage, such *appliances* shall be permitted to be installed at floor level, provided that the required *combustion air* is taken from the exterior of the garage.

❖ See Commentary Figure G2408.2.1 and Section G2408.2.

G2408.3 (305.5) Private garages. *Appliances* located in private garages shall be installed with a minimum *clearance* of 6 feet (1829 mm) above the floor.

Exception: The requirements of this section shall not apply where the *appliances* are protected from motor vehicle impact and installed in accordance with Section G2408.2.

❖ Appliances located in a private garage or carport must be protected from vehicle impact (also see Section M1307.3.1). This section is applicable to appliances located in an area where motor vehicles can be operated and includes appliances under which a vehicle can pass and those located anywhere in a vehicle's path where impact is possible. The 6-foot (1829 mm) minimum height requirement is intended to provide adequate clearance above the typical automobile.

**Figure G2408.2(5)
EXAMPLE OF FLAMMABLE-VAPOR-IGNITION-
RESISTANT WATER HEATER TECHNOLOGY**

**Figure G2408.2.1
ELEVATION OF APPLIANCES NOT REQUIRED**

With the popularity of conversion vans and recreational vehicles, which can be much higher than other automobiles, the 6-foot (1829 mm) minimum installation height above the floor may not provide adequate clearance; additional height might be necessary. The garage door height can be used as a guide in determining the maximum vehicle height [see Commentary Figures G2408.3(1) through G2408.3(5)].

G2408.4 (305.7) Clearances from grade. *Equipment and appliances* installed at grade level shall be supported on a level concrete slab or other *approved* material extending out

less than 3 inches (76 mm) above adjoining grade or shall be suspended not less than 6 inches (152 mm) above adjoining grade. Such supports shall be installed in accordance with the manufacturer's instructions.

❖ This section is consistent with Section M1305.1.4.1 and addresses outdoor and crawl space installations where an appliance is resting on the earth and not supported by a building. The intent is to maintain level support and protect the appliance from corrosion and deterioration. The slab should be concrete or a material having comparable strength and longevity. Outdoor appliance installations must be designed to tolerate movement where frost heave will cause a slab to rise and fall.

G2408.5 (305.8) Clearances to combustibles construction. Heat-producing *equipment and appliances* shall be installed to maintain the required clearances to combustibles construction as specified in the listing and manufacturer's instructions. Such *clearances* shall be reduced only in accordance with Section G2409. *Clearances* to combustibles shall include such considerations as door swing, drawer pull, overhead projections or shelving and window swing. Devices, such as door stops or limits and closers, shall not be used to provide the required *clearances*.

❖ Section G2409 allows clearances to be reduced where protective assemblies are installed to decrease the transfer of heat from the source to the combustible material/assembly. Clearances must be measured from shelving, overhead projections and the possible positions of doors, windows and drawers. Doorstops and closers are easily defeated and subject to failure.

G2408.6 (305.12) Avoid strain on gas piping. Appliances shall be supported and connected to the piping so as not to exert undue strain on the connections.

❖ Connections under strain can transmit forces to gas controls that can distort valve/control bodies and put strain on burner manifolds and other components. Gas piping must not exert forces on the appliance connection and vice versa. To accomplish this intent, the appliance and the gas piping must be supported independently. “Undue” strain is not specific, but is to be taken to mean any strain that is reasonably capable of threatening the integrity of the appliance connection over any period of time. That being very hard to determine, it would be wise to make the point of connection a neutral point where no forces are transmitted to or from the appliance. For example, where steel gas piping connects to an appliance’s gas control, it can be determined if the piping is exerting strain on the gas control by simply observing if the piping moves when the union is opened. If the piping moves in some direction, it is exerting a force on the appliance gas control in that same direction.

SECTION G2409 (308)
CLEARANCE REDUCTION

G2409.1 (308.1) Scope. This section shall govern the reduction in required clearances to *combustible materials*, includ-

ing gypsum board, and *combustible assemblies* for chimneys, vents, appliances, devices and equipment. Clearance requirements for air-conditioning equipment and central heating boilers and furnaces shall comply with Sections G2409.3 and G2409.4.

❖ Heat-producing appliances and mechanical equipment must be installed with the required minimum clearances to combustible materials indicated by their listing label. It is not uncommon to encounter practical or structural difficulties in maintaining clearances. Therefore, clearance reduction methods have been developed to allow, in some cases, reduction of the minimum prescribed clearance distance while achieving equivalent protection. An important understanding is that all prescribed clearances to combustibles are air-space clearances measured from the heat source to the face of the nearest combustible surface (see Commentary Figure G2409.1). When using the assemblies described in Table G2409.2, the clearance is measured as described in Note b. In the case of listed equipment, the required clearances are intended to be clear airspace, and therefore the space is not to be filled with insulation or any other material other than an assembly intended to allow clearance reduction. This is especially important where clearances are required from appliances and equipment that rely on the airspace for convection cooling to maintain their proper operating temperature.

The provisions contained in this section are based on the principles of heat transfer. Mechanical equipment or appliances producing heat can become hot, and many appliances have hot exterior surfaces by design. The heat energy is then radiated to objects surrounding the appliances or equipment. When mechanical equipment and appliances are tested, the minimum clearances are established so that radiant and, to a lesser extent, convective heat transfer do not represent an ignition hazard to adjacent surfaces and objects. This distance is called the “required clearance” to combustible materials. Appliance and equipment labels must specify minimum clearances in all directions.

This section permits the use of materials and systems as radiation shields, decreasing the amount of heat energy transferred to surrounding objects and reducing the required clearances between gas-fired appliances and equipment to combustibles.

Plaster and gypsum by themselves are classified as noncombustible materials. Under continued exposure to heat, however, these materials will gradually decompose as water molecules are driven out of the material. Plaster on wood lath, plasterboard, sheetrock and drywall are all considered to be combustible materials when the code provisions are applied.

Additionally, gypsum wallboard is faced with paper that has a flame spread index that is measurable in the ASTM E84 test. This alone identifies the need to classify gypsum wallboard as a combustible material for the purpose of requiring a separation from heat-producing equipment and appliances.

The code specifically prohibits the reduction of clearances in certain applications. For examples, see Sections G2409.2 through G2409.4.

G2409.2 (308.2) Reduction table. The allowable *clearance* reduction shall be based on one of the methods specified in Table G2409.2 or shall utilize a reduced *clearance* protective assembly *listed* and *labeled* in accordance with UL 1618. Where required *clearances* are not listed in Table G2409.2, the reduced clearances shall be determined by linear interpolation between the distances listed in the table. Reduced *clearances* shall not be derived by extrapolation below the range of the table. The reduction of the required *clearances* to combustibles for *listed* and *labeled appliances* and *equipment* shall be in accordance with the requirements of this section, except that such *clearances* shall not be reduced where reduction is specifically prohibited by the terms of the *appliance* or *equipment listing* [see Figures G2409.2(1) through 2409.2(3)].

❖ Another option for reducing the required clearances to combustible materials is to use one of the on-site field-constructed methods specified in Table G2409.2.

FIGURES G2409.2(1) and G2409.2(2). See page 24-58.

❖ See the commentary to Section G2409.2

TABLE G2409.2. See page 24-60.

❖ The column headings of Table G2409.2 list required clearances without protection. The numbers to the right of each method indicate the permissible reduced

**Figure G2409.1
CLEARANCE TO COMBUSTIBLES—
EXAMPLES OF HOW TO MEASURE**

FUEL GAS

clearance measured from the heat-producing appliances/equipment to the face of the combustible material.

The rationale behind the methods of protection listed in Table G2409.2 is based on the ability of the protection to reduce radiant heat transmission from the appliance and equipment to the combustible material so that the temperature rise of the combustible material will remain below the maximum allowed.

Although the materials referred to in Table G2409.2 are common construction materials, confusion often arises over what satisfies the requirement for “insula-

tion board” (Item 6 in the table), sometimes referred to as an inorganic insulating board, noncombustible mineral board or noncombustible insulating board. These products are not made of carbon-based compounds.

Carbon-based compounds are those found in cellulose (wood), plastics and other materials manufactured from raw materials that once existed in living organisms. Cement board materials must have a specified maximum “C” (conductance) value in addition to being noncombustible.

Note h specifies a maximum thermal conductivity of $Btu/in^2 \cdot h \cdot ^\circ F$. Conductivity is the amount of heat in

NOTES:

“A” equals the *clearance* without protection.

“B” equals the reduced *clearance* permitted in accordance with Table G2409.2. The protection applied to the construction using *combustible material* shall extend far enough in each direction to make “C” equal to “A.”

FIGURE G2409.2(1) [308.2(1)]
EXTENT OF PROTECTION NECESSARY TO REDUCE CLEARANCES FROM GAS EQUIPMENT OR VENT CONNECTORS

For SI: 1 inch = 25.4 mm.

FIGURE G2409.2(2) [308.2(2)]
WALL PROTECTOR CLEARANCE REDUCTION SYSTEM

Btus that will flow each hour through a 1-foot-square (0.0929 m²) slab of material, 1-inch (25.4 mm) thick with a 1°F temperature difference between both sides and is usually identified by the symbol “k.” Tables of k values usually do not include the area term in the dimensions for conductivity, and it must be understood that the value must be multiplied by the area to obtain the total Btu value.

Thermal conductance (overall) is the time rate of heat flow through a body not taking thickness into account and is usually identified by the symbol “C” (Btu/h · ft² · °F).

Thermal resistance (overall) is the reciprocal of overall thermal conductance and is usually identified by the symbol “R” (hr · ft² · °F/Btu).

This translates into a minimum required insulation R-value of 1.0 (ft² · hr · °F)/Btu per inch of insulating material. The methods in Table G2409.2 control heat transmission by reflecting heat radiation, retarding thermal conductance and providing convective cooling. Where sheet metal materials or metal plates are specified, the effectiveness of the protection can be enhanced by the reflective surface of the metal. Painting or otherwise covering the surface would reduce the metal’s ability to reflect radiant heat and, depending on

the color, could increase heat absorption. The air-space between the protected surface and the clearance-reduction assembly allows convection air currents to cool the protection assembly by carrying away heat that has been conducted through the assembly. Where a clearance-reduction assembly must be spaced 1 inch off the wall, the top, bottom and sides of the assembly must remain open as required by Notes d and f to permit unrestricted airflow (convection currents). If the openings were not provided, the air-cooling effect would not take place, and the protection assembly would not be as effective in limiting the temperature rise on the protected surfaces. Ideally, the protection assembly should be open on all sides to provide maximum ventilation. Figure G2409.2(2) and Commentary Figure G2409.2 show assemblies incorporating airspace.

Spacers must be noncombustible. Spacers should not be placed directly behind the heat source because the location would increase the amount of heat conduction through the spacer, thus creating a “hot spot.” Figure G2409.2(2) specifically shows a noncombustible spacer arrangement.

The performance of a protective assembly when applied to a horizontal surface, such as a ceiling, will

For SI: 1 inch = 25.4 mm.

**FIGURE G2409.2(3) [308.2(3)]
MASONRY CLEARANCE REDUCTION SYSTEM**

differ substantially from the same assembly placed in a vertical plane. Obviously, temperatures at a ceiling surface will be higher because of natural convection and because the air circulation between the method of protection and the protected ceiling surface will be substantially reduced or nonexistent. It is for these reasons that Table G2409.2 is divided into two application groups.

The manufacturer’s instructions or label for many appliances will state an absolute minimum clearance, regardless of any clearance reduction method used.

Those clearance requirements take precedence over Table G2409.2.

The methods in Table G2409.2 are intended to be permanent installations properly supported to prevent displacement or deformation. Movement could adversely affect the performance of the protection method, thus posing a potential fire hazard.

The assemblies in Table G2409.2 are the product of experience and testing. To achieve predictable and dependable performance, the components of the various assemblies cannot be mixed, matched, combined

TABLE G2409.2 (308.2)^a through k
REDUCTION OF CLEARANCES WITH SPECIFIED FORMS OF PROTECTION

TYPE OF PROTECTION APPLIED TO AND COVERING ALL SURFACES OF COMBUSTIBLE MATERIAL WITHIN THE DISTANCE SPECIFIED AS THE REQUIRED CLEARANCE WITH NO PROTECTION [see Figures G2409.2(1), G2409.2(2), and G2409.2(3)]	WHERE THE REQUIRED CLEARANCE WITH NO PROTECTION FROM APPLIANCE, VENT CONNECTOR, OR SINGLE-WALL METAL PIPE IS: (inches)

8. 1-inch glass fiber or mineral wool batts sandwiched between two sheets 0.024-inch (nominal 24 gage) sheet metal with ventilated airspace	18	12	9	6	6	4	5	3	3	3

For SI: 1 inch = 25.4 mm, °C = [(°F - 32)/1.8], 1 pound per cubic foot = 16.02 kg/m³, 1 Btu per inch per square foot per hour per °F = 0.144 W/m² · K.

- a. Reduction of clearances from combustible materials shall not interfere with combustion air, draft hood clearance and relief, and accessibility of servicing.
- b. All clearances shall be measured from the outer surface of the combustible material to the nearest point on the surface of the appliance, disregarding any intervening protection applied to the combustible material.
- c. Spacers and ties shall be of noncombustible material. A spacer or tie shall not be used directly opposite an appliance or connector.
- d. For all clearance reduction systems using a ventilated airspace, adequate provision for air circulation shall be provided as described [see Figures G2409.2(2) and G2409.2(3)].
- e. There shall be at least 1 inch between clearance reduction systems and combustible walls and ceilings for reduction systems using ventilated airspace.
- f. Where a wall protector is mounted on a single flat wall away from corners, it shall have an air gap of not less than 1 inch. To provide air circulation, the bottom and top edges, or only the side and top edges, or all edges shall be left open.
- g. Mineral wool batts (blanket or board) shall have a density of not less than 8 pounds per cubic foot and a melting point of not less than 1500°F.
- h. Insulation material used as part of a clearance reduction system shall have a thermal conductivity of 1.0 Btu per inch per square foot per hour per °F or less.
- i. There shall be not less than 1 inch between the appliance and the protector. The clearance between the appliance and the combustible surface shall not be reduced below that allowed in this table.
- j. All clearances and thicknesses are minimum; larger clearances and thicknesses are acceptable.
- k. Listed single-wall connectors shall be installed in accordance with the manufacturer’s instructions.

or otherwise rearranged to comprise new assemblies, and materials cannot be substituted for those prescribed in the table. Any alterations or substitutions could have an effect on the assembly, and its performance must be tested and approved.

The reduced clearance is measured from the heat source to the combustible material, disregarding any intervening protection assembly.

Factory-built clearance reduction assemblies are available that are listed to UL1618. Such assemblies may or may not require field assembly of components.

G2409.3 (308.3) Clearances for indoor air-conditioning appliances. Clearance requirements for indoor air-conditioning appliances shall comply with Sections G2409.3.1 through G2409.3.4.

- ❖ Requirements for clearances to combustibles are emphasized because of the potential fire hazard posed when those clearances are not observed. Maintaining an appropriate distance from the outer surfaces of an appliance or piece of equipment to combustible materials reduces the possibility of ignition of combustible materials.

The minimum clearances to combustibles are specified in the manufacturer's installation instructions for a labeled appliance. Because an approved agency tests appliances in accordance with these instructions, the clearances required are necessary for correct installation and operation of the appliance.

Reduction of the required clearances to combustibles is allowed only when the combustibles are protected by one of the methods outlined in Section

G2409 and clearance reduction is not prohibited by Section G2409 or the appliance and equipment listing (see commentary, Section G2409). The manufacturer's specified minimum clearances and the clearances specified in Section G2409 are all airspace clearances, and such spaces cannot be filled with insulation or any other material, even if the material is non-combustible. In some cases, the manufacturer's installation instructions will specify absolute minimum clearances that must not be reduced by any clearance reduction method.

The most common wall covering material-gypsum wallboard-is a combustible finish material for the purpose of the code. As a result, gypsum wallboard as well as all other combustible wall finishes must be separated from an appliance or equipment in accordance with the prescribed clearance to combustibles. Clearances to combustibles also apply to furnishings, window treatments and moveable items that can be placed within the required clearance range of appliances and equipment.

G2409.3.1 (308.3.1) Appliances clearances. Air-conditioning appliances shall be installed with clearances in accordance with the manufacturer's instructions.

- ❖ The concept of "rooms large or not large in comparison with the appliance" is no longer part of the code. The code has been simplified by no longer tying rules for clearances to whether or not an appliance is installed in a room having a specific volume. The dated concept of room volume in comparison to appliance volume was meant to determine when the room was consid-

ered to be a closet or alcove. If the room was determined to be a closet or alcove, the code would then prohibit the use of clearance reduction methods and require the appliances to be listed for installation in closets and alcoves because the small room volume would not allow adequate dissipation of heat. This concept has outlived its intent because modern appliances are more efficient, have less jacket heat losses and are listed to current appliance standards. Now, the code simply defers to the appliance manufacturer's instructions and the appliance listing to establish the clearance requirements. In some cases, the installation instructions for an appliance might specifically prohibit the application of a clearance reduction method (see Section G2409.2).

G2409.3.2 (308.3.2) Clearance reduction. Air-conditioning appliances shall be permitted to be installed with reduced clearances to *combustible material*, provided that the *combustible material* or *appliance* is protected as described in Table G2409.2 and such reduction is allowed by the manufacturer's instructions.

❖ The clearance reduction methods in the code are always allowed unless the manufacturer's instructions specifically prohibit the reduction of clearances or specify different clearance reduction methods (see commentary, Section G2409.3.1). Note that some appliances specify clearances that are absolute minimums that cannot be reduced by any means.

G2409.3.3 (308.3.3) Plenum clearances. Where the *furnace plenum* is adjacent to plaster on metal lath or *noncombustible material* attached to *combustible material*, the *clearance* shall be measured to the surface of the plaster or other noncombustible finish where the *clearance* specified is 2 inches (51 mm) or less.

❖ Where the air-conditioning equipment plenum is adjacent to surfaces covered by noncombustible material as described in this section and the required clearance from combustibles is 2 inches (51 mm) or less, the required clearance must be measured to the surface of the adjacent material. Measuring to the combustible material would reduce the clearance between the equipment plenum and adjacent surface. Reducing this clearance would affect the cooling of the equipment and could cause overheating.

G2409.3.4 (308.3.4) Clearance from supply ducts. Supply air ducts connecting to listed central heating furnaces shall have the same minimum clearance to combustibles as required for the furnace supply plenum for a distance of not less than 3 feet (914 mm) from the supply plenum. Clearance is not required beyond the 3-foot (914 mm) distance.

❖ Portions of ducts that are within 3 feet (914 mm) of the supply plenum to which they connect will reach nearly the same temperature as the plenum.

G2409.4 (308.4) Central heating boilers and furnaces. *Clearance* requirements for central-heating boilers and fur-

naces shall comply with Sections G2409.4.1 through G2409.4.5. The *clearance* to these *appliances* shall not interfere with *combustion air*; *draft hood clearance* and relief; and accessibility for servicing.

❖ See the commentary to Section G2409.3.

G2409.4.1 (308.4.1) Appliances clearances. Central-heating furnaces and low-pressure boilers shall be installed with clearances in accordance with the manufacturer's instructions.

❖ See the commentary to Section G2409.3.1.

G2409.4.2 (308.4.2) Clearance reduction. Central-heating furnaces and low-pressure boilers shall be permitted to be installed with reduced clearances to *combustible material* provided that the *combustible material* or *appliance* is protected as described in Table G2409.2 and such reduction is allowed by the manufacturer's instructions.

❖ See the commentary to Section G2409.3.2.

G2409.4.3 (308.4.4) Plenum clearances. Where the *furnace plenum* is adjacent to plaster on metal lath or *noncombustible material* attached to *combustible material*, the *clearance* shall be measured to the surface of the plaster or other noncombustible finish where the *clearance* specified is 2 inches (51 mm) or less.

❖ See the commentary to Section G2409.3.3.

G2409.4.4 (308.4.5) Clearance from supply ducts. Supply air ducts connecting to listed central heating furnaces shall have the same minimum clearance to combustibles as required for the furnace supply plenum for a distance of not less than 3 feet (914 mm) from the supply plenum. Clearance is not required beyond the 3-foot (914 mm) distance.

❖ See the commentary to Section G2409.3.4.

G2409.4.5 (308.4.3) Clearance for servicing appliances. Front *clearance* shall be sufficient for servicing the *burner* and the *furnace* or boiler.

❖ Because mechanical equipment and appliances require routine maintenance, repairs and possible replacement, access is required. Additionally, access recommendations or requirements are usually stated in the manufacturer's installation instructions.

The intent of this section is to secure access to components that require observation, inspection, adjustment, servicing, repair or replacement such as controls, gauges, burners, filters, blowers, and motors. Access is also necessary to conduct operating procedures such as startup or shut down.

The code defines access as being able to be reached, but first may require the removal of a panel, door or similar obstruction. An appliance or piece of equipment is not accessible if any portion of the structure's permanent finish materials, such as drywall, plaster, paneling, built-in furniture, cabinets or any other similar permanently affixed building component must be removed.

SECTION G2410 (309) ELECTRICAL

G2410.1 (309.1) Grounding. *Gas piping* shall not be used as a grounding electrode.

- ❖ Section E3508.6 prohibits metal underground gas piping from being used as a grounding electrode. Metal gas piping must be bonded to the electrical service grounding electrode system, but it cannot serve as a grounding electrode. This is somewhat contradictory and this section has been the center of much confusion relative to the “equal-potential” bonding of gas piping. Underground gas piping cannot be used as an earth electrode because it is not recognized as such in the *National Electric Code*[®] (NEC[®]), also known as NFPA 70, and because of the perceived risk of potential current flow on piping that conveys flammable gas. There is also the obvious fact that underground piping is typically plastic or metal, with a dielectric fitting isolating the metal piping from above-ground piping. However, bonding underground metal gas piping to the grounding electrode system will cause the piping to act as an additional electrode whether or not this is intended or desired. This is unavoidable, unless dielectric fittings are used to electrically isolate the underground portion of the metal piping from the above-ground portion. Any fault current will take all possible paths to earth with the intensity dictated by the impedance of the path. The key to remember is that this section does not negate the requirement to bond all metal above-ground gas piping, as required by the NEC and Section G2411. See Sections G2411.1 and G2415.10 for clarification of gas piping bonding means.

G2410.2 (309.2) Connections. Electrical connections between *appliances* and the building wiring, including the grounding of the *appliances*, shall conform to Chapters 34 through 43.

- ❖ Field-installed power wiring and control wiring for appliances and equipment must be installed in accordance with Chapters 34 through 43.

The power wiring includes all the wiring, disconnects, overcurrent protection devices, starters and related hardware used to supply electrical power to the appliance or equipment. The control wiring includes all the wiring, devices and related hardware that connect the main unit to all external controls and accessories, such as temperature and pressure sensors, thermostats, exhausters, equipment contractors, interlock controls and remote damper motors. The internal factory wiring of appliances and equipment is not covered by this section unless it is specifically addressed in Chapters 34 through 43; however, the wiring is covered by the testing and review performed by an approved agency as part of the listing and labeling process.

The mechanical or electrical code official responsible for the inspection of appliances and equipment must be familiar with the applicable sections of Chapters 34 through 43.

SECTION G2411 (310) ELECTRICAL BONDING

G2411.1 (310.1) Pipe and tubing other than CSST. Each above-ground portion of a *gas piping system* other than corrugated stainless steel tubing (CSST) that is likely to become energized shall be electrically continuous and bonded to an effective ground-fault current path. *Gas piping* other than CSST shall be considered to be bonded where it is connected to *appliances* that are connected to the *equipment* grounding conductor of the circuit supplying that *appliance*.

- ❖ This section is consistent with Section 250.104(B) of the 2014 edition of the NEC (NFPA 70). Although difficult to define, gas piping that is likely to become energized is typically considered to be any gas piping that connects to one or more appliances that are electrically powered. The metal components of the appliances are required to be grounded; therefore, the metal gas piping that connects to the appliances should be as well because the piping has the same likelihood of being energized as the appliance components. The term “bonding” simply means to electrically tie metal parts together by means of conductors to create a low impedance path for electricity to flow between them. Metallic objects that are bonded together will have no voltage difference between them and they will all have the same potential with respect to ground.

In the majority of cases, the gas piping system will be connected to at least one, if not several, appliances that use electrical power. The gas connections involve metal-to-metal joints that ensure electrical continuity with the appliance. Those appliances will be connected to an equipment grounding conductor that will serve to bond the gas piping to the grounding electrode system for the building. Where the appliance branch circuits include grounding conductors properly connected to the appliances and one or more such appliances are connected to the gas piping system, the gas-piping system is automatically bonded as required by this section (see Commentary Figure G2411.1). This method of bonding is not allowed as the sole means of bonding for CSST gas piping systems. Note that the manufacturer’s installation instructions for some gas tubing systems will require additional bonding beyond what is required by this section. This is true for CSST systems and is also mandated by Section G2411.1.1 (see Section G2411.1.1).

The purpose of the bonding required by this section is to make sure that there is no electrical potential (voltage difference) between gas piping and appliances, between gas piping and any other piping and between any piping and the earth so as to eliminate electrical shock hazards. If all of the metal piping, systems and appliances are bonded together, there cannot be a voltage difference between them; therefore, human contact across any such piping systems and appliances will not result in electrical shock. This is referred to as “equal-potential” bonding, the primary purpose of which is to prevent shock. Section G2411.1.1 addresses bonding that has an additional purpose.

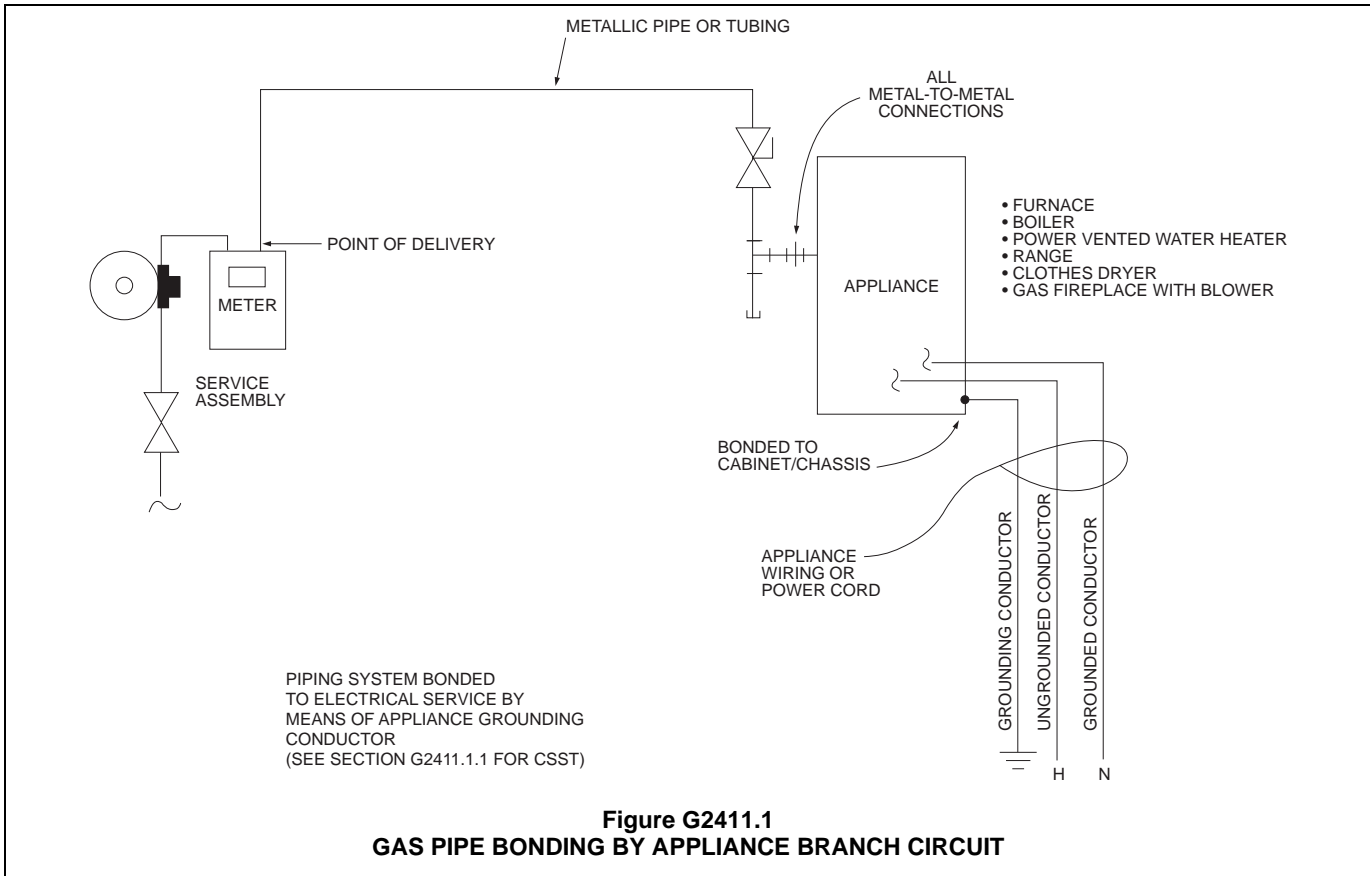

Figure G2411.1
GAS PIPE BONDING BY APPLIANCE BRANCH CIRCUIT

G2411.1.1 (310.1.1) CSST. Corrugated stainless steel tubing (CSST) gas *pip*ing systems and piping systems containing one or more segments of CSST shall be bonded to the electrical service grounding electrode system or, where provided, the lightning protection electrode system.

❖ This section addresses gas pipe bonding specific to CSST and does so for the purpose of lessening the possibility of damage to the CSST caused by the electrical energy created by indirect lightning strikes.

It is assumed that nothing is capable of fully protecting anything subjected to a direct strike by lightning because of the extremely high energy levels involved and unpredictability of the paths of flow. It is more common for building components to be energized by nearby lightning strikes to the earth, trees, poles, towers, etc. This intense electrical energy can travel through the earth or other objects and energize gas piping systems, among other metal systems and components. This can happen by simple conduction to the piping or by induction through forms of magnetic field coupling. The electrical energy can travel along a pipe or tube and unpredictably jump off and onto another metal pipe, wire, duct or other metal object. This “jumping off” point will experience an arc that has enough energy to burn through a pipe, tube or connector wall. The resulting exit wound caused by the arcing is a perforation that will result in gas leakage and possibly a fire or explosion. This damage can happen to any piping material, including steel pipe, CSST and copper

tube, and also gas connectors. Relatively recent experience has shown that CSST is susceptible to this type of lightning damage and this section intends to mitigate the possibility of such damage.

Recall that the CSST piping will already be bonded to some degree by the appliance grounding conductor(s), as explained in the commentary to Section G2411.1, assuming that it is connected to appliances that are electrically powered. This bonding, however, is not considered to be adequate to protect CSST, therefore, Section G2411.1.1 mandates a more effective bonding means. Directly bonding the CSST piping to the electrical service grounding electrode system or the lightning protection electrode system has been shown, by laboratory experiments, to substantially reduce the risk of lightning damage. The minimum size bonding jumper was chosen based on the maximum size grounding electrode conductor that is required to connect to “made” electrodes, such as ground rods and plates as addressed in the NEC (NFPA 70) (see Section E3608.3). A number 6 AWG copper bonding jumper provides an electrical path with considerably less impedance than the typical equipment grounding conductor found in an appliance branch circuit. The gas service and electrical service are often in close proximity, thus allowing for a short bonding jumper between the point of delivery and the electrical service. The shorter the bonding jumper, the better it will perform. In cases where the electrical service and gas ser-

vice are not in close proximity, the bonding jumper should be routed to take the shortest path, noting the length limit of Section G2411.1.1.3.

The requirement of this section is also a requirement in the manufacturer's installation instructions for CSST.

As stated in the manufacturer's instructions, the bonding clamp must connect only to rigid steel pipe or a brass CSST fitting and it must never connect directly to the tubing itself. Clamping directly to the corrugated tubing would result in a poor electrical connection and could promote failure from current flow at that location. Bonding clamps must be listed for the application, for example, clamps used outdoors must be a type identified for outdoor use. The typical installation will have Schedule 40 steel pipe extending from the point of delivery (typically the meter outlet) and passing through the outside wall into the building for some distance. The bonding clamp will be attached to this steel

pipe either indoors or outdoors or attached to any other section of steel pipe or any downstream CSST fitting. Note that this section applies to gas-piping systems that have any CSST in them. For example, if a piping system is constructed mostly of steel pipe, but contains one or more sections of CSST, such a system is treated as if it was constructed entirely of CSST and this code section applies [see Commentary Figures G2411.1.1(1) and G2411.1.1(2)].

Some CSST manufacturers have designed and are marketing a type of CSST that has an electrically conductive outer jacket or jacket assembly intended to conduct stray currents and dissipate them in such a manner that arcing is prevented. The code allows these conductive jacketed types, but the bonding provisions of this section still apply unless the code official approves otherwise in accordance with Section R104.11. See Sections G2411.1.1.1 through G2411.1.1.5.

Figure G2411.1.1(1)
CSST BONDING

**Figure G2411.1.1(2)
ALTERNATIVE LOCATION FOR BONDING CLAMP**

G2411.1.1.1 (310.1.1.1) Point of connection. The bonding jumper shall connect to a metallic pipe, pipe fitting or CSST fitting.

- ❖ The bonding jumper must connect to metal pipe or a CSST fitting, but such connection point can be anywhere in the distribution system. The bonding connection does not have to be between the point of delivery and the first downstream CSST fitting [see Commentary Figure G2411.1.1.3(1)].

G2411.1.1.2 (310.1.1.2) Size and material of jumper. The bonding jumper shall be not smaller than 6 AWG copper wire of equivalent.

- ❖ See the commentary to Section G2411.1.1.

G2411.1.1.3 (310.1.1.3) Bonding jumper length. The length of the bonding jumper between the connection to a gas piping system and the connection to a grounding electrode system shall not exceed 75 feet (22 860 mm). Any additional grounding electrodes used shall be bonded to the electrical service grounding electrode system or, where provided, the lightning protection grounding electrode system.

- ❖ It is a well-known fact that the longer a bonding jumper is the less effective it is because of the increasing impedance to electrical flow on the wire. Therefore, the shorter the better for jumper effectiveness. Extensive

testing was performed by the CSST industry to determine how well the bonding protects the CSST from indirect lightning strikes and lightning-induced currents. The testing concluded that the bonding was effective in preventing perforations in the CSST under the conditions of the predicted lightning events. The testing also determined that the bonding jumper was functionally adequate up to approximately 100 feet in preventing arcing, thus suggesting the need for a length limit. A length limit of 75 feet was chosen to provide a safety factor and also because it was believed that 75 feet would accommodate the majority of building designs and utility service entrances [see Commentary Figure G2411.1.1.3(1)].

Bonding the CCST to an independent grounding electrode is prohibited; however, the code does not prevent a designer or installer from installing a supplemental grounding electrode (“additional,” as stated in the code text) for perceived additional protection. Where such supplemental electrodes are installed, the code requires that they be bonded back to the electrical service grounding electrode system, as this is consistent with NFPA 70 requirements for a common grounding electrode system. The author believes that the code is not intended to allow the length limit to be circumvented by the installation of supplemental elec-

trodes. Where supplemental electrodes are installed by choice, the code implies that the bonding jumpers that connect to the electrical service grounding electrode system are still limited to 75 feet in combined length. An opposing interpretation is that the length of the bonding jumper between the CSST and the supplemental grounding electrode is limited to 75 feet, and the length of the jumper that connects the supplemental grounding electrode back to the electrical service grounding electrode system is limited only by the NEC, NFPA 70. The new code text implies that the more conservative interpretation is intended.

The points of connection to the electrical service grounding electrode system, the methods of connections and the protection of the bonding conductors must be in accordance with NFPA 70 (NEC). The devices, such as clamps, that are used to connect the bonding jumper on both ends must be listed for the application and environment in which they are installed. For example, clamps used outdoors must be listed for exposure to the elements. Some commonly used bonding clamps are suitable only for indoor use, and some are suitable for both indoor and outdoor use [see Commentary Figure G2411.1.1.3(2)].

G2411.1.1.4 (310.1.1.4) Bonding connections. Bonding connections shall be in accordance with NFPA 70.

❖ See the commentary to Section G2411.1.1.3.

G2411.1.1.5 (310.1.1.5) Connection devices. Devices used for making the bonding connections shall be *listed* for the application in accordance with UL 467.

❖ See the commentary to Section G2411.1.1.3.

SECTION G2412 (401) GENERAL

G2412.1 (401.1) Scope. This section shall govern the design, installation, modification and maintenance of *pipng systems*. The applicability of this *code* to *pipng systems* extends from the *point of delivery* to the connections with the *appliances* and includes the design, materials, components, fabrication, assembly, installation, testing, inspection, operation and maintenance of such *pipng systems*.

❖ This section regulates aspects of fuel-gas distribution systems, including design, installation, testing, repair and maintenance. The applicability of this chapter is limited to the consumer side of the public utility company's gas distribution system.

The code governs all piping and system components from the end point of the gas purveyor's (utility company) service line to the supplied appliances and equipment. Typically, the gas utility company service line terminates at the service pressure regulator and meter setting. In other words, the code does not apply to piping and components that are owned by the gas utility company. The construction of utility-owned gas piping is governed by the federal Department of Transportation (DOT) regulations wherever the piping is located. However, in cases where the utility-owned piping runs through, in or on a building, it must do so in a way that does not jeopardize the structural integrity or fire safety of the building. Therefore, the relationship of the utility-owned piping to the building (prohibited locations, penetrations, etc.) is governed by the building portion of this code (see Section G2412.1.1). No

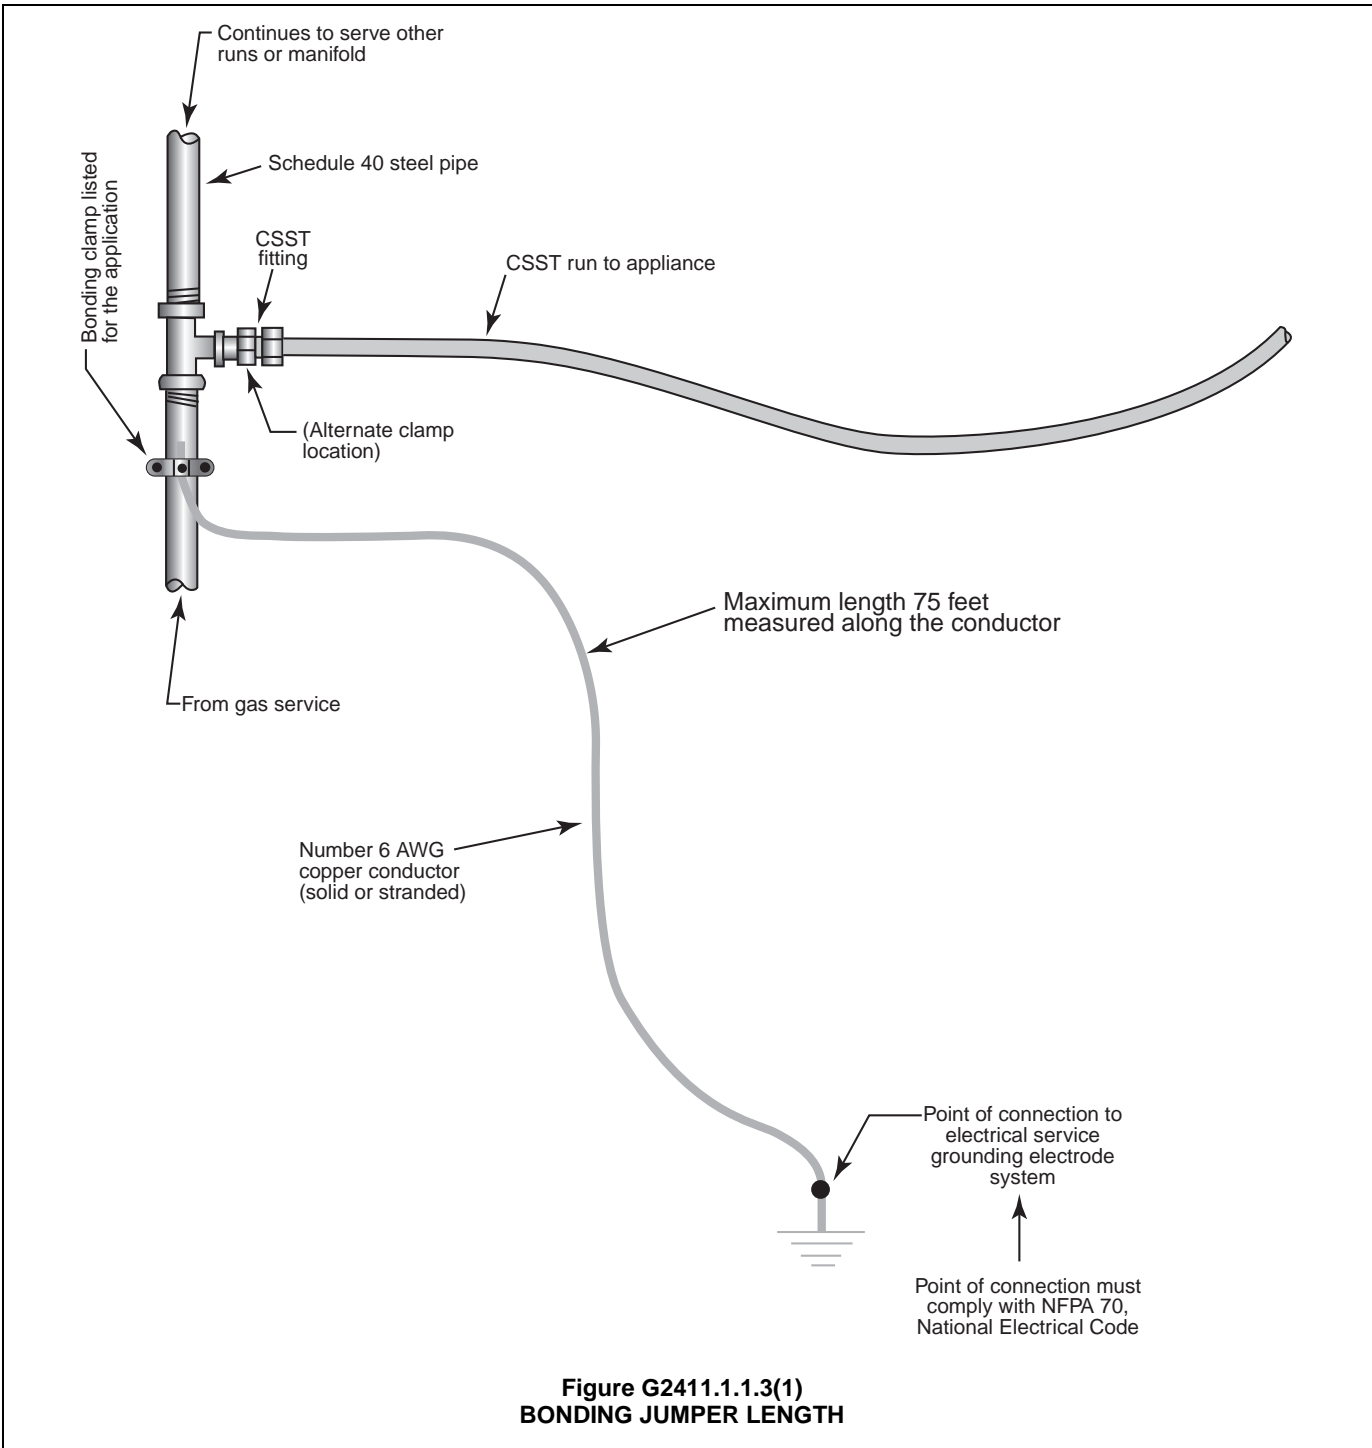

Figure G2411.1.1.3(2)
BONDING CLAMP

other provision within this chapter applies to utility-owned gas piping.

Although LP-gas storage systems generally remain under the ownership of the gas supplier, these systems are governed by the code through the reference to NFPA 58 (see commentary, Section G2412.2). An LP-gas piping system begins at the outlet side of the first-stage pressure regulator. The piping between the first- and second-stage (final) regulator is governed by NFPA 58, and the piping downstream of the second-

stage regulator is governed by this code. The first-stage pressure regulator reduces the storage container pressure to 10 pounds per square inch gauge (psig) (69 kPa) or less.

The termination point of gas utility services varies depending on the particular company's policies, but typically the service terminates at the property line or outdoors, immediately adjacent to the building or structure served by the service [see Commentary Figures G2412.1(1) and G2412.1(2)].

For SI: 1 pound per square inch gauge = 6.895 kPa.

Figure G2412.1(1)
SCOPE OF CODES

Figure courtesy of NORMAC

Figure G2412.1(2)
TYPICAL POINT OF DELIVERY FOR NATURAL GAS SERVICE

G2412.1.1 (401.1.1) Utility piping systems located within buildings. Utility service *piping* located within buildings shall be installed in accordance with the structural safety and fire protection provisions of this code.

❖ Piping and components upstream of the point of delivery are designed, installed, tested, owned and maintained by the gas utility company and are regulated by federal DOT regulations, not this code. This code does, however, regulate two aspects of the installation related to protection of the structure from a structural and fire safety standpoint. By reference, the building portion of this code would regulate the piping penetrations through structural components and through fire-resistance-rated assemblies. The building portion of this code would also regulate piping support to handle structural loads and seismic forces.

G2412.2 (401.2) Liquefied petroleum gas storage. The storage system for *liquefied petroleum gas* shall be designed and installed in accordance with the *International Fire Code* and NFPA 58.

❖ LP-gas tanks, containers, cylinders, storage vessels and related components must comply with NFPA 58. The storage system includes storage vessels of any type and the vessel appurtenances such as shutoff valves, pressure gauges, liquid level indicators, pressure regulators, pressure relief valves and filling connections. The first- and second-stage pressure regulators and interconnecting piping are also addressed by the standard and could, therefore, be considered part of the LP-gas storage system. If the piping between the first-stage regulator and the point of delivery [second-stage or 2-psi (13.7 kPa) regulator] is not placed under the control of NFPA 58, it would be unregulated because Section G2412.1 states that the code coverage begins at the point of delivery (see definition of "Point of delivery"). Second-stage 2-psi regulators reduce the outlet pressure of the first-stage regulator to 2-psi (13.7 kPa) and a line pressure regulator downstream of the 2-psi regulator reduces the pressure from 2-psi to a maximum of 14 inches w.c. (3.5 kPa). Second-stage regulators reduce the outlet pressure of the first-stage regulator to a maximum of 14 inches w.c. NFPA 58 addresses all aspects of LP-gas storage systems such as container design and construction, container appurtenances, safety devices, container location and installation. A referenced standard is enforceable only in the context in which it is referenced. Any portions of NFPA 58 that extend beyond the scope of the storage system are not applicable because of the context of the reference in this section.

G2412.3 (401.3) Modifications to existing systems. In modifying or adding to existing *piping systems*, sizes shall be maintained in accordance with this chapter.

❖ The gas volume demand on any portion of a distribution system cannot be increased beyond the capacity

of the piping serving that portion. Modifications and additions to existing piping systems can have a detrimental effect on the existing piping system's ability to serve the connected loads. Commonly, new gas-fired equipment or appliances will be added to existing distribution piping without any regard for the effect of the extra load. To prevent dangerously low gas pressures, existing piping must be able to adequately supply additional loads, or the piping size must be increased. For example, a substantial load increase would occur where a storage-type (tank) water heater is replaced by an instantaneous tankless water heater.

G2412.4 (401.4) Additional appliances. Where an additional *appliance* is to be served, the existing *piping* shall be checked to determine if it has adequate capacity for all *appliances* served. If inadequate, the existing system shall be enlarged as required or separate *piping* of adequate capacity shall be provided.

❖ This section parallels Section G2412.8 and makes it clear that when any appliances are added to an existing gas piping system, the system must be carefully evaluated to verify that adding an appliance will not create a dangerous low-gas-pressure condition within the gas piping system. The evaluation must be conducted on the completed system as it will be configured after the appliance is added, and if the results indicate that the existing piping system cannot adequately serve the gas demand of the new appliance, the system must be revised accordingly. Undersized (overloaded) piping will cause pressure losses that can result in serious appliance malfunction.

G2412.5 (401.5) Identification. For other than steel *pipe*, exposed *piping* shall be identified by a yellow label marked "Gas" in black letters. The marking shall be spaced at intervals not exceeding 5 feet (1524 mm). The marking shall not be required on *pipe* located in the same room as the *appliance* served.

❖ The intent of this section is to prevent gas piping from being mistaken for other piping. A case of mistaken identity could lead to a dangerous condition if gas piping were to be cut or opened unintentionally. It is not uncommon for fuel-gas piping systems and various other gas or liquid piping systems in a building to be constructed of the same materials and thus have the same appearance. The method of identifying fuel gas piping must be permanent, legible and conspicuous. Steel pipe (typically what is referred to as "black iron") is exempt from the identification requirements because it is the traditional gas pipe material and is generally recognized as such. CSST is manufactured in compliance with the marking requirements of this section, and some copper tubing is manufactured with a similar yellow plastic jacket [see Commentary Figures G2414.5 and G2414.5.3(1)]. Steel pipe does not have to be identified, regardless of its color and regardless of any applied paint. Note that steel pipe that has been painted another color is still steel pipe.

G2412.6 (401.6) Interconnections. Where two or more *meters* are installed on the same premises but supply separate consumers, the *piping systems* shall not be interconnected on the outlet side of the *meters*.

- ❖ If gas distribution systems with independent meters were connected downstream of the meters, it would be impossible to determine the actual consumption of each of the interconnected systems. As the result of building renovations, remodeling and additions, or as the result of intentionally valved cross-connections between separately metered systems, it is possible for a consumer to be paying for fuel gas consumed by another consumer. Accurate consumption metering can occur only if each metered distribution system is independent of all other metered distribution systems on the premises. Also, a system thought to be shut off could be backfed from an interconnected system, thereby maintaining pressure in a system that was intended to be shut off.

G2412.7 (401.7) Piping meter identification. *Piping* from multiple *meter* installations shall be marked with an *approved* permanent identification by the installer so that the *piping system* supplied by each *meter* is readily identifiable.

- ❖ This provision allows service and emergency personnel to readily locate the shutoff valve that serves each piping system. The identification also helps to prevent interconnections between systems and between spaces when additions and/or alterations are made in the piping systems.

G2412.8 (401.8) Minimum sizes. All *pipe* utilized for the installation, extension and *alteration* of any *piping system* shall be sized to supply the full number of outlets for the intended purpose and shall be sized in accordance with Section G2413.

- ❖ Undersized gas piping systems are not capable of delivering the required volume of fuel at the required pressure. Inadequate gas pressure can cause hazardous operation of appliances. Appliances depend on proper gas pressure to maintain the design Btu (J) input rate, to maintain the required minimum manifold pressure and to produce the required gas velocity in the burners. If the gas pressure to an appliance is too low, the result can be incomplete combustion, burner malfunction and flashback, soot production and appliance malfunction and damage. Gas piping must be sized to maintain the required minimum gas pressures at the appliance inlet.

When designing a gas piping distribution system, all connected appliances and equipment are assumed to operate simultaneously, except as provided for in Section G2413.2. In other words, the system is designed for maximum demand. The code contains provisions for sizing gas piping systems using an exact equation or design tables. The tabular method is most often used because it is simpler and less likely to produce errors. Factors that affect the sizing of gas piping systems include the specific gravity of the gas, the length of the pipe and the number of fittings installed, the

maximum gas demand, the allowable pressure loss through the system and any diversity factor that is applicable.

The design of gas piping installations should also take into account the possibility of future increases in gas demand (load). The farther the gas meter or point of delivery is from the building, the more extensive will be the disruption of the property in the event that a larger yard line between the meter and the building becomes necessary in the future as a result of increased gas demand within the building, a change in fuel gas type or a change in service pressure.

G2412.9 (401.9) Identification. Each length of pipe and tubing and each pipe fitting, utilized in a fuel gas system, shall bear the identification of the manufacturer.

- ❖ All pipe, tubing and fittings for the pipe and tubing must be able to be traced back to their source in case there is an issue with the material or its listing. Fittings of all sizes are easily marked with the symbol or logo of the manufacturer, but this requirement is more difficult for close and shoulder pipe nipples because there is little or no surface area suitable for such marking. Pipe nipples constructed in the field must be cut and threaded using pipe that meets the code. The pipe is marked, but the field-cut nipples might not be.

G2412.10 (401.10) Third-party testing and certification. Piping, tubing and fittings shall comply with the applicable referenced standards, specifications and performance criteria of this code and shall be identified in accordance with Section G2412.9. Piping, tubing and fittings shall either be tested by an approved third-party testing agency or certified by an approved *third-party certification agency*.

- ❖ These materials have always been required to comply with the standards prescribed by the code and this section requires verification by a third-party entity. The materials, or in some cases their packaging, must bear proof that a third-party entity has verified that the materials comply. This requirement will make it easier for builders, designers and code officials to determine that materials comply with the appropriate product standards.

SECTION G2413 (402) PIPE SIZING

G2413.1 (402.1) General considerations. *Piping systems* shall be of such size and so installed as to provide a supply of gas sufficient to meet the maximum *demand* and supply gas to each *appliance* inlet at not less than the minimum supply pressure required by the *appliance*.

- ❖ This section is a summation of the provisions of Sections G2412.8 and G2413.5, and is intended to give guidance to the designer (see commentary, Sections G2412.8 and G2413.5). The pressure loss (drop) in a gas piping system must not exceed the allowable loss described in Section G2413.5. Pressure loss must be controlled to make sure that the supply pressure at each appliance inlet is not less than the minimum

required by the appliance. Inadequate supply pressure can result in hazardous appliance operation or malfunction.

G2413.2 (402.2) Maximum gas demand. The volumetric flow rate of gas to be provided shall be the sum of the maximum input of the *appliances* served.

The total connected hourly load shall be used as the basis for pipe sizing, assuming that all appliances could be operating at full capacity simultaneously. Where a diversity of load can be established, pipe sizing shall be permitted to be based on such loads.

The volumetric flow rate of gas to be provided shall be adjusted for altitude where the installation is above 2,000 feet (610 m) in elevation.

❖ To determine the demand volume required by an appliance in cubic feet (m³) of gas per hour, the input rating of the appliance in British thermal units per hour (Btu/h) (W) as specified by the appliance manufacturer must be known. This information will be on the appliance nameplate. Note that, depending on the elevation above sea level at which the appliance is installed, the manufacturer of the appliance might also require that the input be derated to compensate for the effect of altitude. If a derating adjustment of input is required, this adjusted input rate would be used in the calculation. If the average heating value of the gas is known [typically about 1,000 Btu/ft³ (37.3 MJ/m³) for natural gas], the volume of gas required per hour can be calculated. The heating value can be obtained for the gas supplier. The input rating of all appliances must be shown on the appliance label. When the input rating of the appliances is unknown at the time of piping system design, the gas demand will have to be estimated based on input from appliance manufacturers, gas utilities or another source. However, when the actual appliance demands are determined upon appliance selection, any approximate calculations must be checked to verify that the piping system is, in fact, adequate to supply the known demand for all appliances. The designer must be aware of the fact that a system designed in accordance with an estimated load might be undersized relative to the actual connected load.

In all cases, the piping must have the capacity to supply the actual connected load of appliances. As also stated in this section and Section G2412.8, the load on the piping system must be based on the simultaneous operation of all appliances at full output. The only exception to this would be the demonstration of actual load diversity. For example, the designer could have access to data that demonstrates that the total load for cooking ranges or water heaters in a multiple-family dwelling (apartment building) is less than the sum of all of the appliance demands at full output. The code official would have to be convinced that any such diversity factor had been established. Any known diversity factors would likely come from the serving gas supplier.

The following is an example of how gas demand is calculated for a representative appliance: an appliance

installed at sea level has a nameplate (label) input rating of 120,000 Btu/h (35.2 kW). Using natural gas with an average heating value of 1,000 Btu/ft³ (37.3 MJ/m³), the volume of gas required for the appliance is: 120,000/1,000 = 120 cubic feet per hour (3.4 m³/h).

G2413.3 (402.3) Sizing. *Gas piping* shall be sized in accordance with one of the following:

1. *Pipe* sizing tables or sizing equations in accordance with Section G2413.4.
2. The sizing tables included in a *listed piping* system's manufacturer's installation instructions.
3. Other *approved* engineering methods.

❖ Using the sizing tables is generally simpler and less time consuming than using the equations found in Section G2413.4. The gas system pressure, allowable pressure drop, maximum gas demand and the specific gravity of the fuel gas must be known in order to use tables. The allowable pressure drop is the designer's choice because the intent of the code is to provide the appliance or equipment with the required rate of gas flow at the required minimum pressure. The tables are based on a given pressure drop and cannot be used if the designer wishes to use any other pressure drop. The sizing tables are based on using smooth-bore pipe or tube and can be used with the piping materials listed in Section G2414. Pipe materials with higher resistance to flow cannot be sized using these tables. CSST is sized using CSST-specific tables. The pipe sizes in the pipe sizing tables are based on the traditional steel pipe size designation as used in the material standards. More information may be obtained from a variety of pipe design publications, including the *Piping Handbook* by Sabin Crocker and the *ASHRAE Handbook of HVAC Systems and Equipment*. Each of the tables presents different piping material and design parameters and represents the most common system design applications. The tables assume that the system being sized is constructed of a single type pipe or tubing material throughout; thus, a single table cannot be used for systems constructed of multiple materials. For example, it is common to find hybrid systems composed of both steel pipe and CSST. Such systems would have to be sized from two different tables based on the longest run of the entire system.

The code does not limit sizing methodology to the tables or equations. Manufacturers of gas piping/tubing may provide sizing charts, tables or slide calculators that, in effect, become part of the installation instructions. This is the case for CSST, which is a listed piping system.

Section G2413.4 describes a sizing method that uses an exact thermodynamic flow equation to determine the required pipe sizes. Although this is an exact method, the degree of accuracy it affords may not always prove valuable, because pipe sizes are standardized and the pipe diameter calculated may not correspond to an available pipe size. For example, a calculated pipe diameter of 0.80 inch (20.3 mm) will

require the selection of the next larger standard pipe size [1-inch (25.4 mm) pipe].

There are two equations in Section G2413.4 to be used, depending on the gas pressure within the piping system.

As stated in Appendix A, Sections A.2.2 and A.2.3, an equivalent length of pipe should be added to the length of any piping run having four or more fittings (see Appendix A, Table A.2.2). Some designers simply add 50 percent of the actual length of piping as an all-inclusive fitting allowance (i.e., actual pipe length x 1.5). This is a conservative estimate and is used because the necessary number and type of fittings is usually not known when the system is being designed.

Steel pipe sizes 1/4 inch and 3/8 inch have been deleted from the tables because the use of such sizes is very rare. The pressure of "0.50 or less" that appeared in some table titles has been replaced by "less than 2 psi" because such tables can be used with any pressure less than 2 psi (13.8 kPa), including 0.50 psi (3.5 kPa) and less.

G2413.4 (402.4) Sizing tables and equations. Where Tables G2413.4(1) through G2413.4(21) are used to size piping or tubing, the pipe length shall be determined in accordance with Section G2413.4.1, G2413.4.2 or G2413.4.3.

Where Equations 24-3 and 24-4 are used to size piping or tubing, the pipe or tubing shall have smooth inside walls and the pipe length shall be determined in accordance with Section G2413.4.1, G2413.4.2 or G2413.4.3.

1. Low-pressure gas equation [Less than 1 1/2 pounds per square inch (psi) (10.3 kPa)]:

$$D = \frac{Q^{0.381}}{19.17 \left(\frac{\Delta H}{C_r \times L} \right)^{0.206}} \quad \text{(Equation 24-3)}$$

2. High-pressure gas equation [1.5 psi (10.3 kPa) and above]:

$$D = \frac{Q^{0.381}}{18.93 \left[\frac{(P_1^2 - P_2^2) \times Y}{C_r \times L} \right]^{0.206}} \quad \text{(Equation 24-4)}$$

where:

- D = Inside diameter of pipe, inches (mm).
- Q = Input rate appliance(s), cubic feet per hour at 60°F (16°C) and 30-inch mercury column.
- P₁ = Upstream pressure, psia (P₁ + 14.7).
- P₂ = Downstream pressure, psia (P₂ + 14.7).
- L = Equivalent length of pipe, feet.
- ΔH = Pressure drop, inch water column (27.7 inch water column = 1 psi).

- ❖ The length of pipe or tube to be used with the tables and equations is determined by the sizing method being used. Section G2413.4.1 involves only one length whereas Sections G2413.4.2 and G2413.4.3 involve multiple lengths.

**TABLE G2413.4 (402.4)
C_r AND Y VALUES FOR NATURAL GAS AND UNDILUTED PROPANE AT STANDARD CONDITIONS**

GAS	EQUATION FACTORS	
	C _r	Y
Natural gas	0.6094	0.9992
Undiluted propane	1.2462	0.9910

For SI: 1 cubic foot = 0.028 m³, 1 foot = 305 mm,
1-inch water column = 0.249 kPa,
1 pound per square inch = 6.895 kPa,
1 British thermal unit per hour = 0.293 W.

❖ **Example 1:**

Determine the required pipe sizes for the gas distribution system in Commentary Figure G2413.4 using the equation method outlined in this section. The system is designed to operate at less than 0.5 pound per square inch (psig) (3.5 kPa), using steel pipe. Assume the following:

- Fuel gas Natural
- Specific gravity 0.60
- Heating value 1,000 Btu per cubic foot
- Maximum allowable pressure drop 1/2 inch of water column
- Negligible number of fittings

For SI: 1 inch = 25.4mm, 1 foot = 304.8mm, 1 Btu/h = 0.2931 W, 1 Btu/ft³ = 0.0373 MJ/m³, 1 inch water column = 0.2488 kPa, 1 cubic foot = 0.02832 m³, 1 pound per square inch gauge = 6.895 kPa.

To use equations in this section, the gas volume of each appliance must be known.

For SI: 1 foot = 304.8 mm, 1 Btu/h = 0.294 W.

**Figure G2413.4
GAS PIPING LAYOUT**

Gas volume of an appliance = input rating of an appliance (Btu/h)/Heating value of the fuel gas (Btu/ft³).

Using the equation, we can solve for the minimum pipe diameter (D) as follows:

$$D = Q^{0.381} / 19.17 [(\Delta H) / (C_r \times L)]^{0.206}$$

APPLIANCE	INPUT RATING (Btu/h)	GAS VOLUME (ft ³ /h)
Range	70,000	70
Furnace	140,000	140
Water heater	45,000	45

Starting at the most remote appliance from the point of delivery (Point G - water heater), determine the minimum pipe size for pipe segment D.

$$D = (45)^{0.381} / 19.17 [(1/2) / (0.609 \times 80)]^{0.206} = 0.574$$

Repeat the calculation for each pipe segment. The gas piping system is sized as follows:

PIPE SEGMENT	FLOW RATE (Q)	CALCULATED PIPE DIAMETER (D) (in.)	NOMINAL PIPE SIZE (in.)
A-B	255	1.11	1 1/4
B-C	70	0.679	3/4
B-D	185	0.983	1
D-E	140	0.884	1
D-G	45	0.574	1/2

Most gas pipe sizing will be determined by using the sizing tables. In the event that circumstances warrant it, however, pipe sizing may be done by calculation using the provisions of Appendix A or other approved methods. If in a particular design, the piping length, desired pressure loss, system supply pressure, specific gravity or pipe size does not fall within the parameters of a table, an approved alternate sizing procedure must be used.

Instead of using the methods specified in this section, piping sizes may be determined by the use of accurate gas flow, computer or pressure drop charts. Such sizing tools must be acceptable to the code official. Note that calculators, charts and computer programs can be designed to size gas piping for any pressure drop because the intent of the code is to make sure that the supply pressure at the appliance is greater than or equal to the minimum pressure required for proper operation of the appliance (see Section G2413.5).

TABLES G2413.4(1) through G2413.4(21). See pages 24-76 through 24-96.

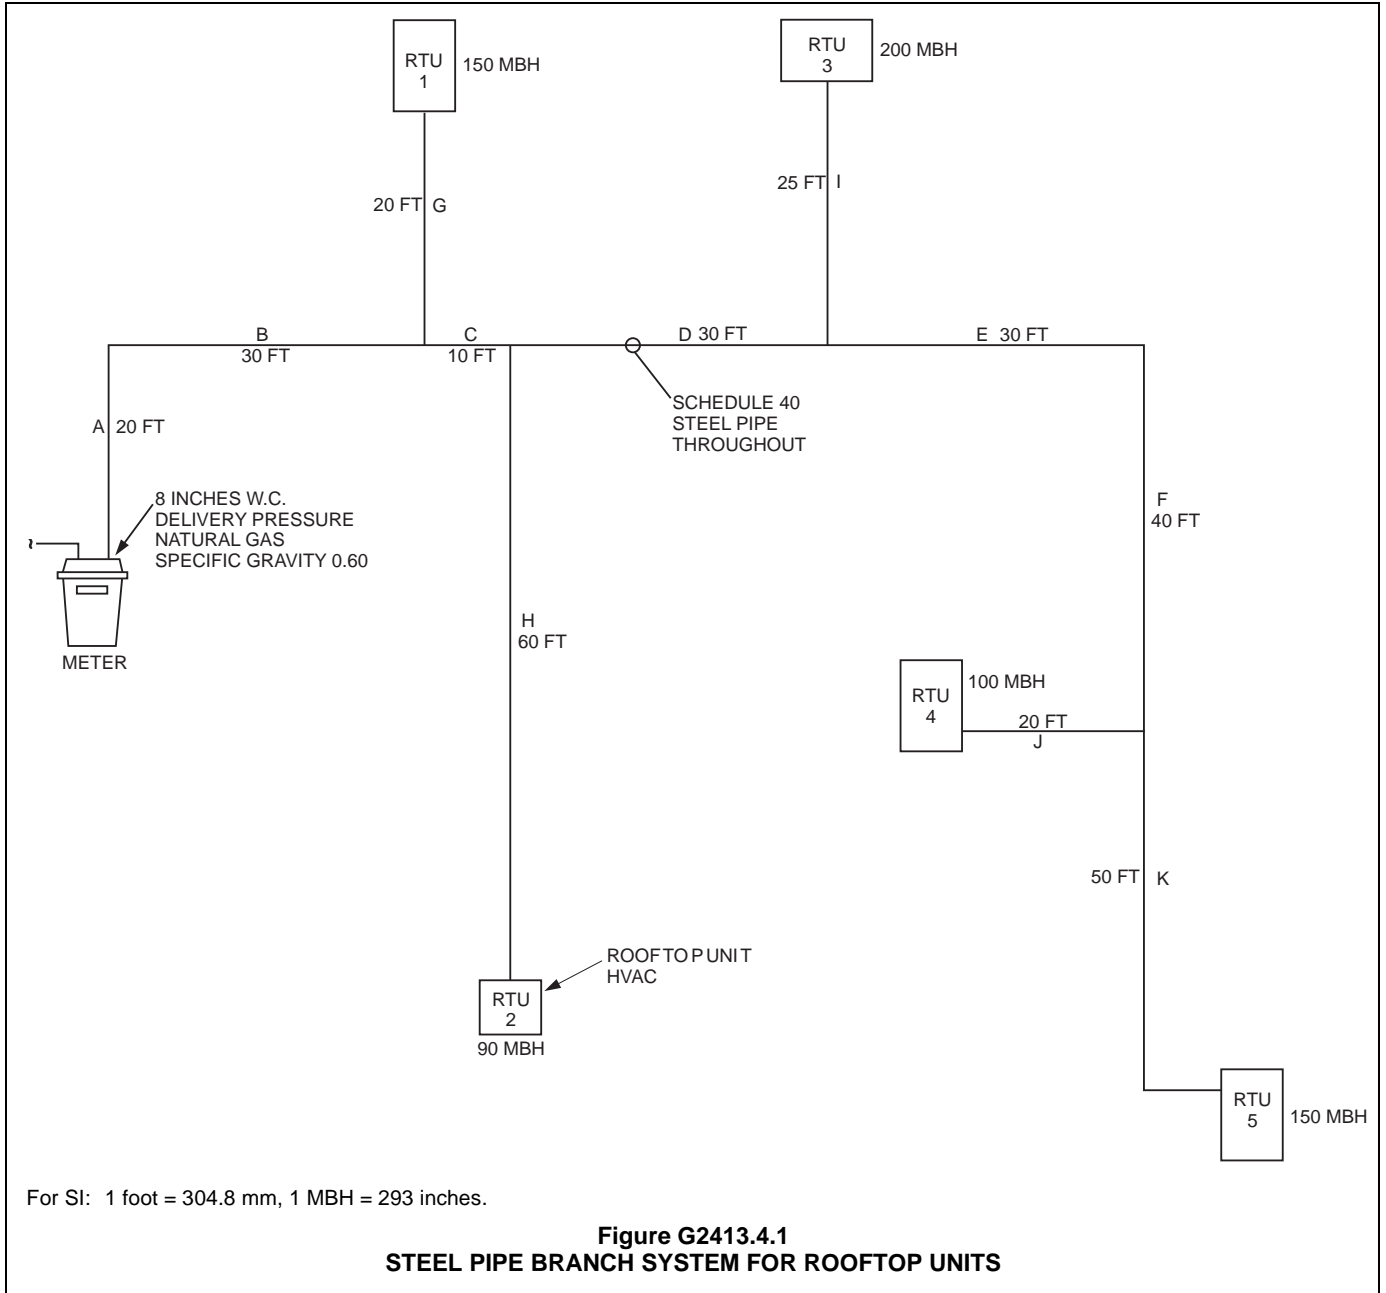

❖ See the commentary to Section G2413.4.

G2413.4.1 (402.4.1) Longest length method. The pipe size of each section of gas piping shall be determined using the longest length of piping from the point of delivery to the most remote outlet and the load of the section.

❖ This section provides a step-by-step approach to proper application of the tables using the traditional longest-length method. When using the tables, the maximum pipe length from the point of delivery to the farthest outlet must be determined, including any allowance for the equivalent length of fittings. The designer will use the row in the table that equals the determined length or the next higher row if the determined length is between table values. The system will be designed using only values taken from this row. This is known as the longest-run method. Basing the sizing on the most demanding circuit (longest run) compensates for pressure losses throughout the entire system. Even though the appliances are not typical for dwellings, Commentary Figure G2413.4.1 and the example serve to illustrate the longest length method.

Longest length method example: Basing the sizing on the most demanding circuit (longest run using Table G2413.4(1), size the piping system in Commentary Figure G2413.4.1. The longest run is from the meter (point of delivery) to Roof Top Unit (RTU) 5 and is 210 feet (64 008 mm), therefore, all pipe sizes will be chosen from the 250 foot (76 200 mm) row of the table.

PIPE SECTION	LOAD (MBH)	SIZE (in.)
A	690	2
B	690	2
C	540	2
D	450	2
E	250	1 1/2
F	250	1 1/2
G	150	1 1/4
H	90	1
I	200	1 1/4
J	100	1

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 kPa, 1-inch water column = 0.2488 kPa,
1 British thermal unit per hour = 0.2931 W, 1 cubic foot per hour = 0.0283 m³/h, 1 degree = 0.01745 rad.

Notes:

1. Table includes losses for four 90-degree bends and two end fittings. Tubing runs with larger numbers of bends or fittings shall be increased by an equivalent length of tubing to the following equation: $L = 1.3n$, where L is additional length (feet) of tubing and n is the number of additional fittings or bends.
2. EHD—Equivalent Hydraulic Diameter, which is a measure of the relative hydraulic efficiency between different tubing sizes. The greater the value of EHD, the greater the gas capacity of the tubing.
3. All table entries have been rounded to three significant digits.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 kPa, 1-inch water column = 0.2488 kPa,
1 British thermal unit per hour = 0.2931 W, 1 cubic foot per hour = 0.0283 m³/h, 1 degree = 0.01745 rad.

Notes:

1. Table does not include effect of pressure drop across the line regulator. Where regulator loss exceeds ³/₄ psi, DO NOT USE THIS TABLE. Consult with the regulator manufacturer for pressure drops and capacity factors. Pressure drops across a regulator can vary with flow rate.
2. CAUTION: Capacities shown in the table might exceed maximum capacity for a selected regulator. Consult with the regulator or tubing manufacturer for guidance.
3. Table includes losses for four 90-degree bends and two end fittings. Tubing runs with larger numbers of bends or fittings shall be increased by an equivalent length of tubing to the following equation: $L = 1.3n$ where L is additional length (feet) of tubing and n is the number of additional fittings or bends.
4. EHD—Equivalent Hydraulic Diameter, which is a measure of the relative hydraulic efficiency between different tubing sizes. The greater the value of EHD, the greater the gas capacity of the tubing.
5. All table entries have been rounded to three significant digits.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 kPa, 1-inch water column = 0.2488 kPa,
1 British thermal unit per hour = 0.2931 W, 1 cubic foot per hour = 0.0283 m³/h, 1 degree = 0.01745 rad.

Notes:

1. Table includes losses for four 90-degree bends and two end fittings. Tubing runs with larger numbers of bends or fittings shall be increased by an equivalent length of tubing to the following equation: $L = 1.3n$ where L is additional length (feet) of tubing and n is the number of additional fittings or bends.
2. EHD—Equivalent Hydraulic Diameter, which is a measure of the relative hydraulic efficiency between different tubing sizes. The greater the value of EHD, the greater the gas capacity of the tubing.
3. All table entries have been rounded to three significant digits.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square inch = 6.895 kPa, 1-inch water column = 0.2488 kPa,
1 British thermal unit per hour = 0.2931 W, 1 cubic foot per hour = 0.0283 m³/h, 1 degree = 0.01745 rad.

Notes:

- Table does not include effect of pressure drop across the line regulator. Where regulator loss exceeds 1/2 psi (based on 13 in. w.c. outlet pressure), DO NOT USE THIS TABLE. Consult with the regulator manufacturer for pressure drops and capacity factors. Pressure drops across a regulator can vary with flow rate.
- CAUTION: Capacities shown in the table might exceed maximum capacity for a selected regulator. Consult with the regulator or tubing manufacturer for guidance.
- Table includes losses for four 90-degree bends and two end fittings. Tubing runs with larger numbers of bends or fittings shall be increased by an equivalent length of tubing to the following equation: $L = 1.3n$ where L is additional length (feet) of tubing and n is the number of additional fittings or bends.
- EHD—Equivalent Hydraulic Diameter, which is a measure of the relative hydraulic efficiency between different tubing sizes. The greater the value of EHD, the greater the gas capacity of the tubing.
- All table entries have been rounded to three significant digits.

Note: All table entries have been rounded to three significant digits.

G2413.4.2 (402.4.2) Branch length method. *Pipe* shall be sized as follows:

1. *Pipe* size of each section of the longest *pipe* run from the *point of delivery* to the most remote *outlet* shall be determined using the longest run of *piping* and the load of the section.
2. The *pipe* size of each section of branch *piping* not previously sized shall be determined using the length of *piping* from the *point of delivery* to the most remote *outlet* in each branch and the load of the section.

❖ This sizing method is a variation of the longest-length method, and the results can be less conservative. Because less headroom is built into this method, it is especially important to account for the equivalent length of fittings installed in the system [see Commentary Figures G2413.4.2(1) and (2) and examples]. This method involves multiple piping lengths within a system for application of the tables or equations, whereas the longest-length method involves only one piping length per system.

G2413.4.3 (402.4.3) Hybrid pressure. The *pipe* size for each section of higher pressure *gas piping* shall be determined using the longest length of *piping* from the *point of delivery* to the most remote line *pressure regulator*. The *pipe* size from the line *pressure regulator* to each *outlet* shall be determined using the length of *piping* from the *regulator* to the most remote outlet served by the *regulator*.

❖ Hybrid pressure piping systems convey gas at different pressures in different parts of the system. One or more pressure regulators are used to reduce the pressure in portions of the system. In some cases, a single gas piping system must deliver widely varying pressure to loads throughout a building. The most common hybrid pressure systems allow small economically sized piping to carry large loads over long distances by conveying gas at high pressures. Near the load being supplied, pressure regulators reduce the higher pressure to suit the load. For example, rooftop units on

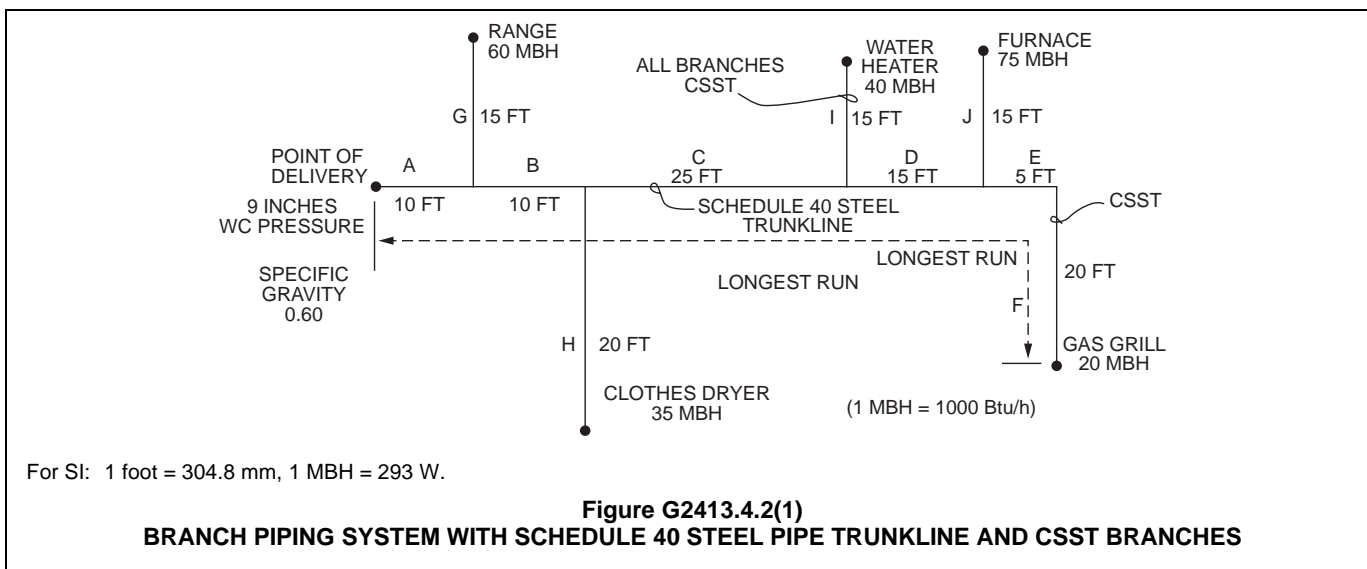

buildings are typically designed for a natural gas pressure of 14 inches w.c. (3.5 kPa) or less. Running hundreds of feet of pipe across expansive roofs would require large expensive pipe at such low pressure. At 5-psi (34.4 kPa) pressure, small, less expensive pipe can be run over long distances, and regulators at each rooftop unit reduce the 5-psi (34.4 kPa) pressure to less than 1/2 psi (3.4 kPa), which is typically 8 inches w.c. (2 kPa) [see Commentary Figures G2413.4.3(1) and (2) and examples].

Branch length method [Commentary Figure G2413.4.2(1)] Example 1:

1. In accordance with Section G2413.4.2 Item 1, determine the size of Sections A, B, C, D and E (constructed of Schedule 40 steel pipe) based on the load of each section and the longest run length of 85 feet (25 908 mm). Because the system pressure is less than 0.5 psi [(14 in. w.c.) (3.5 kPa), Table G2413.4(1) is chosen. Because the longest run length is between rows in the table, the 90-foot (27 432 mm) row must be chosen.

PIPE SECTION	LOAD (MBH)	SIZE (in.)
A	230	1 1/4
B	170	1
C	135	1
D	95	3/4
E	20	1/2

2. In accordance with Section G2413.4.2 Item 2, determine the size of Branch Sections F, G, H, I and J (constructed of CSST) based on the load of each section and the length of piping and tubing from the point of delivery to the outlet on that section. Table G2413.4(5) is chosen because the branch sections are constructed of CSST

FUEL GAS

and the pressure is less than 0.5 psi [(14 in. w.c) (3.5 kPa)]. Where a length falls between entries in the table, use the next longer length row.

CSST BRANCH	LOAD (MBH)	LENGTH PIPING AND TUBING (ft)	SIZE EHD
F	20	85	18
G	60	25	19
H	35	40	18
I	40	60	23
J	75	75	30

Branch length method [Commentary Figure G2413.4.2(2)] Example 2:

Determine the minimum required size of each piping section using branch length method.

Given:

- Piping arranged in parallel.
- Main section and individual appliance runs constructed of CSST.
- Supply pressure is 6 inches wc downstream of meter.
- Natural gas with specific gravity of 0.60.
- Chosen pressure drop 0.5 inch w.c. Minimum appliance supply pressure requirements are 5 inches wc.

- Heating value of gas is 1,000 Btu per cubic foot.

Sizing Section A:

- Size Section A based on appliance total load and length from meter to furthest appliance.
- Total load = 80 + 36 + 52 + 28 + 25 = 221 cfh.
- Section length = 45 + 20 + 5 = 70 feet.
- Use Table G2413.4(5).

Sizing Section B:

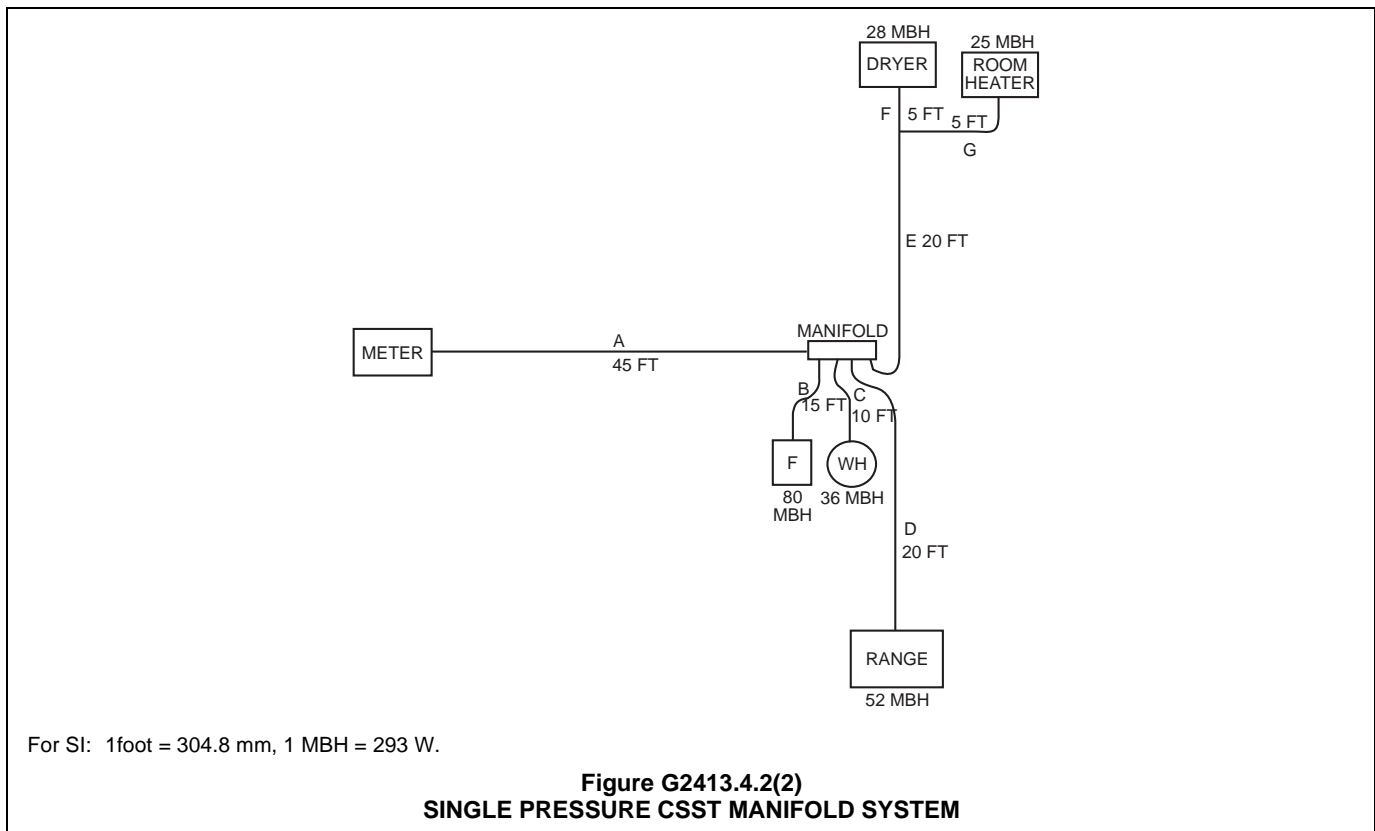

- Size Section B based on appliance total load and length from meter to appliance.
- Total load = 80 cfh.
- Section length (furnace) = 45 + 15 = 60 feet.
- Use Table G2413.4(5).

Sizing Section C:

- Size Section C based on appliance total load and length from meter to appliance.
- Total load = 36 cfh.
- Section length (water heater) = 45 + 10 = 55.
- Use Table G2413.4(5).

Sizing Section D:

- Size Section D based on appliance total load and length from meter to appliance.
- Total load = 52 cfh.
- Section Length (range) = 45 + 20 = 65 feet.
- Use Table G2413.4(5).

Sizing Section E:

- Size Section E base on appliance total load and length from meter to furthest appliance.
- Total load = 25 + 28 = 53 cfh.
- Section length (dryer/room heater) = 45 + 20 + 5 = 70 feet.
- Use Table G2413.4(5).

Sizing Section F:

- Size Section F based on appliance total load and length from meter to furthest appliance.
- Total load = 28 cfh.
- Section length (dryer) = 45 + 20 + 5 = 70 feet.
- Use Table G2413.4(5).

Sizing Section G:

- Size Section G based on appliance total load and length from meter to furthest appliance.
- Total load (room heater) = 25 cfh.
- Section length = 45 + 20 + 5 = 70 feet.
- Use Table G2413.4(5).

Branch length method [Commentary Figure G2413.4.3(1)] Example 1:

Note: This example illustrates hybrid system design, but is not typical for dwellings.

- Using Table 402.4(7) of the IFGC, determine the minimum required size of piping Sections A through D. The longest run of piping from the point of delivery to the most remote regulator is 175 feet.
 - Section A serves a load of 625 MBH and in the 175 foot row of the table, 1/2-inch pipe is shown to have a capacity of 728 ft³/hr or 728,000 Btu/h for gas with a heating value of 1,000 Btu/ft³.
 - Because Sections B, C and D all serve lesser loads than Section A, they too can be 1/2 inch in size.
 - Because Table 402.4(7) of the IFGC is based upon a pressure drop of 3.5 psi, the available pressure at the inlets of the

“pounds-to-inches” regulators under full load condition will be at least 1.5 psig.

- Determine size of piping Sections E, F and G, using Table 402.4(2) of the IFGC and the longest length of piping from the pounds-to-inches regulator to the most remote outlet. In this case, rooftop unit 1 is the most remote at 65 feet from the regulator.
- Determine size of piping sections H, I and J in the same manner described in Item 2.

NOTE: MBH = 1,000 Btu/h

Hybrid pressure [Commentary Figure G2413.4.3(2)] Example 2:

Given:

- All piping is CSST.
- Piping branches run in parallel.
- Individual CSST appliance branch runs supplied by manifold.
- Supply pressure is 2 psi downstream of meter.
- Chosen pressure drop is 1 psi for Section A.
- Natural gas with specific gravity of 0.60.
- Heating value of gas is 1,000 Btu/ft³.
- Supply pressure at manifold is 8 inches w.c.
- Chosen pressure drop is 3 inches w.c. for Sections B through G.
- Appliances need 5 inches w.c. minimum supply pressure.
- Pressure drop across regulator is less than 1/2 psi at full load of this system.

Sizing Section A:

- Size Section A based on total load and length from meter to regulator.
- Total load = 80 + 36 + 52 + 28 + 25 = 221 cfh.
- Section length = 45 feet.
- Use Table G2413.4(6).

Sizing Section B:

- Size Section B based on appliance load and length from regulator to appliance.

SUMMARY TABLE FOR BRANCH LENGTH METHOD EXAMPLE 2

SECTION	LOAD (cfh)	SECTION LENGTH (feet)	SECTION LENGTH (feet) USED WITH TABLE	REQUIRED SIZE (CSST)
A	221	45	70	
B	80	15	60	
C	36	10	55	
D	52	20	65	
E	53	20	70	
F	28	5	70	
G	25	5	70	

FUEL GAS

- Appliance load = 80 cfh.
- Section length (furnace) = 15 feet.
- Use Table 402.4(16) of the IFGC.

Sizing Section C:

- Size Section C based on appliance load and length from regulator to appliance.
- Total load = 36 cfh.
- Section length (water heater) = 10 feet.
- Use Table 402.4(16) of the IFGC.

Sizing Section D:

- Size Section D based on appliance load and length from regulator to appliance.
- Total load = 52 cfh.
- Section length (range) = 20 feet
- Use Table 402.4(16) of the IFGC

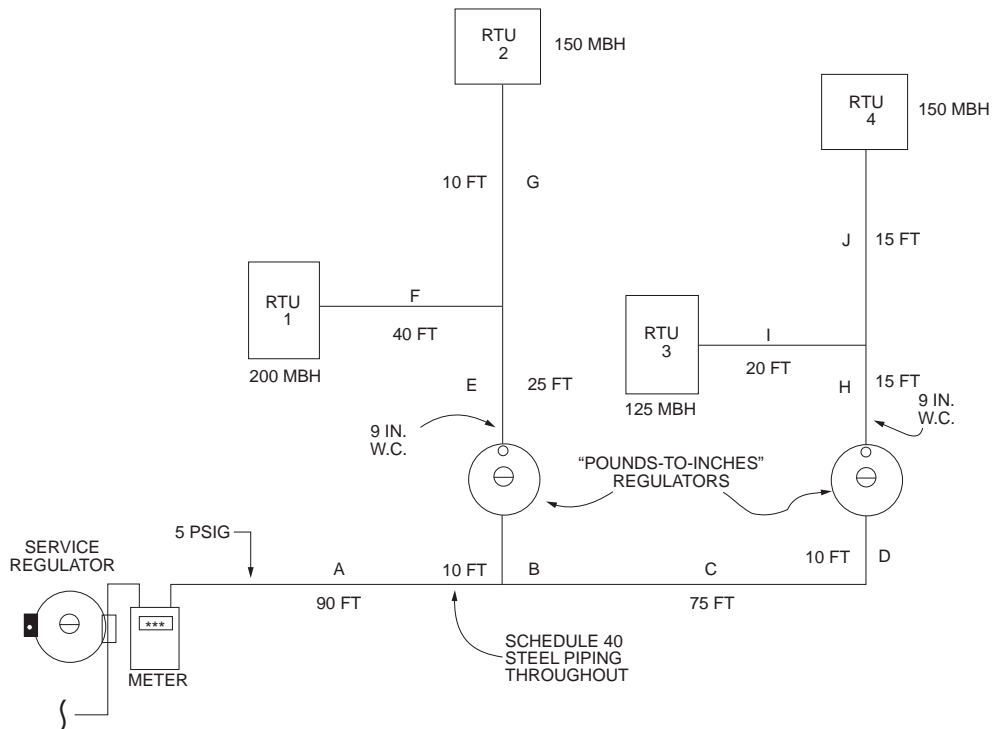

Sizing Section E:

- Size Section E based on appliance total load and length from regulator to furthest appliance.
- Total load = 25 + 28 = 53 cfh.

SUMMARY TABLE FOR HYBRID PRESSURE EXAMPLE 2

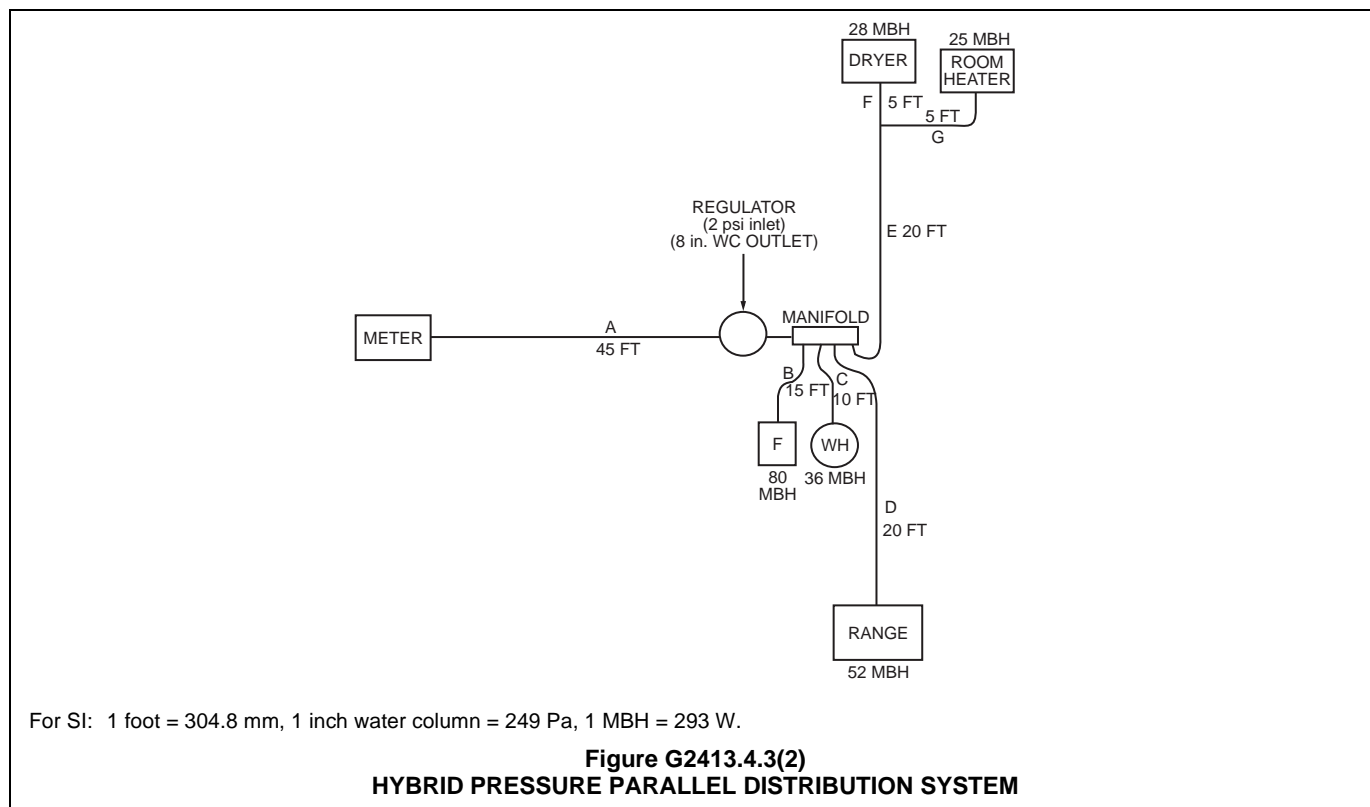

SECTION	LOAD (cfh)	ACTUAL SECTION LENGTH (feet) (including equivalent length of fittings and bends)	SECTION LENGTH (FT) USED WITH TABLE	REQUIRED SIZE (CSST)
A	221	45	45 ^a	
B	80	15	15 ^b	
C	36	10	10 ^b	
D	52	20	20 ^b	
E	53	20	25 ^b	
F	28	5	25 ^b	
G	25	5	25 ^b	

a. Distance from meter to regulator is the run length for the main section.
 b. Distance from regulator to each appliance is the run length for appliance branch run sections.

For SI: 1 foot 304.8 mm, 1 MBH = 293 W, 1 inch water column = 2.49 Pa.

**Figure G2413.4.3(1)
 HYBRID PRESSURE BRANCH SYSTEM FOR ROOF TOP UNITS**

- Section length (dryer/room heater) = 20 + 5 = 25 feet.
- Use Table 402.4(16) of the IFGC.

Sizing Section F:

- Size Section F based on appliance total load and length from regulator to furthest appliance.
- Total load (dryer) = 28 cfh (0.8 m³/h).
- Section length = 20 + 5 = 25 feet (7620 mm).
- Use Table 402.4(16) of the IFGC.

Sizing Section G:

- Size Section G based on appliance total load and length from regulator to furthest appliance.
- Total load (room heater) = 25 cfh.
- Section length = 20 + 5 = 25 feet.
- Use Table 402.4(16) of the IFGC.

G2413.5 (402.5) Allowable pressure drop. The design pressure loss in any *piping system* under maximum probable flow conditions, from the *point of delivery* to the inlet connection of the *appliance*, shall be such that the supply pressure at the *appliance* is greater than or equal to the minimum pressure required by the *appliance*.

- ❖ Between the point of delivery and the load, gas pressure losses will occur because of pipe friction. The design of the system must control these losses to ensure that the pressure at the load (appliance) connection point will be equal to or greater than the minimum required pressure as dictated by the appliance manufacturer. As stated in the commentary to Section

G2412.8, inadequate gas pressures can result in dangerous appliance operation. This section speaks of "maximum probable flow conditions," which must be taken to mean the total connected load of all appliances operating at full capacity except where a diversity-of-load factor is applied.

The designer can choose any pressure loss for a piping system if the goal of this section is met. The code does not specify any maximum pressure drop other than what is required by this section. For example, consider an appliance that has a minimum required inlet pressure of 5 inches w.c. (1.25 kPa), and the gas pressure at the point of delivery is 8 inches w.c. (2 kPa). The maximum allowable pressure drop through the piping system would be 3 inches w.c. (0.75 kPa) because the pressure at the appliance connection must be greater than or equal to 5 inches w.c. Some sizing tables such as Tables G2413.4(1) and G2413.4(3) are based on very small pressure drops [0.5 inch w.c. (125 Pa)] and, thus are quite conservative sizing methods that account for the friction losses through a limited number of fittings used in a piping system. The tables are optional sizing methods placed in the code for convenience. The code allows piping systems to be designed for the exact pressure losses allowed by this section. Some tables are based on much larger pressure losses and can be used where the designer wants to keep pipe sizes to their minimum. The code intends to allow the designer to have the option of choosing the system pressure losses, provided that such losses meet the requirement of this section.

G2413.6 (402.6) Maximum design operating pressure. The maximum design operating pressure for *pipng systems* located inside buildings shall not exceed 5 pounds per square inch gauge (psig) (34 kPa gauge) except where one or more of the following conditions are met:

1. The *pipng system* is welded.
 2. The *pipng* is located in a ventilated chase or otherwise enclosed for protection against accidental gas accumulation.
 3. The *pipng* is a temporary installation for buildings under construction.
- ❖ This section is specific to indoor piping systems. The pressure is limited to 5 psig (34 kPa) to minimize the consequences of a leak. Also, the higher the pressure, the more difficult it is to contain any gas and, thus leakage is more likely. Item 1 recognizes the superior strength and integrity of steel piping with welded joints. Item 2 allows the option of higher pressures where the piping is enclosed to prevent leakage from entering the building. Item 3 allows higher pressures for temporary piping for construction site applications, such as temporary space heating, because of low occupant density, the presence of trained personnel and the short duration of use. Item 3 recognizes the unique nature of temporary piping on construction sites where small piping is desirable, thus making higher pressures necessary.

This section applies to all fuel gases including LP-gas (see Section G2413.6.1).

G2413.6.1 (402.6.1) Liquefied petroleum gas systems. LP-gas systems designed to operate below -5°F (-21°C) or with butane or a propane-butane mix shall be designed to either accommodate liquid LP-gas or prevent LP-gas vapor from condensing into a liquid.

- ❖ In low-temperature environments, LP-gases might condense into the liquid state within the piping system. If the liquid fuel enters system components or appliances, dangerous malfunctions could result. The temperature and pressure of a gas both affect the point at which a gas will change states to a liquid phase. LP-gas can be made to condense to liquid by applying pressure, by cooling the gas and by a combination of both. At atmospheric pressure, 14.7 psia at sea level, propane will condense at -44°F (-42°C) and butane will condense at 15°F (-9°C) meaning that LP liquid would remain as a liquid in an open container at temperatures of minus 44 degrees F and lower. As the liquid warms to temperatures above the condensing temperature, the liquid will begin to boil producing gas vapor and the resultant vapor pressure will have to be held in a closed container to prevent vaporization of all of the liquid. This is what happens in an LP-gas storage tank. The tank holds both liquid and gaseous LP under pressure that will vary with the ambient temperature. Within a piping system, the pressure could be higher than one atmosphere and LP-gas would, therefore, condense at a higher temperature. For example, at 20 psig (138 kPa), propane will condense at -5°F (-21°C). The -5°F threshold requirement of this section was chosen

because 20 psi system piping was commonly installed outdoors.

SECTION G2414 (403) PIPING MATERIALS

G2414.1 (403.1) General. Materials used for *pipng systems* shall comply with the requirements of this chapter or shall be *approved*.

- ❖ This section dictates what materials and components can be used to construct gas distribution systems and also specifies the allowable applications of those materials.

G2414.2 (403.2) Used materials. *Pipe*, fittings, *valves* or other materials shall not be used again unless they are free of foreign materials and have been ascertained to be adequate for the service intended.

- ❖ Ideally, gas pipe installations should be constructed of new materials. However, this section recognizes that there are occasions when used piping materials may be perfectly acceptable for an installation if they meet a number of very strict criteria that intend to reduce the potential for poor performance. To judge equivalency of reused piping materials, compliance with approval criteria for new materials should be used.

G2414.3 (403.3) Other materials. Material not covered by the standards specifications listed herein shall be investigated and tested to determine that it is safe and suitable for the proposed service, and, in addition, shall be recommended for that service by the manufacturer and shall be *approved* by the *code official*.

- ❖ This section echoes the intent of Section R104.11.

G2414.4 (403.4) Metallic pipe. Metallic *pipe* shall comply with Sections G2414.4.1 and G2414.4.2.

- ❖ This section addresses the traditional metal pipes used in piping installations.

G2414.4.1 (403.4.1) Cast iron. Cast-iron *pipe* shall not be used.

- ❖ Because cast iron pipe is brittle compared to the malleable metals, it is more likely to fail under stress and therefore is not suitable for conveying fuel gases. Steel pipe will deform under extreme stress, but cast iron pipe will break.

G2414.4.2 (403.4.2) Steel. Steel and wrought-iron *pipe* shall be at least of standard weight (Schedule 40) and shall comply with one of the following standards:

1. ASME B36.10, 10M.
2. ASTM A53/A 53M.
3. ASTM A106.

- ❖ Steel pipe must be Schedule 40 or heavier, must comply with one of the listed standards and can be black iron or galvanized. Contrary to popular belief, natural gas does not adversely react with the zinc coating on galvanized pipe.

G2414.5 (403.5) Metallic tubing. Seamless copper, aluminum alloy and steel *tubing* shall not be used with gases corrosive to such materials.

- ❖ Aluminum and steel tubing are used in the manufacturing of appliances but are rarely used for gas distribution. Copper tubing is widely used in gas distribution systems and is used as an alternative to CSST in parallel distribution manifold systems. As with copper pipe, copper tubing cannot be used with gases that will cause it to corrode. Commentary Figure G2414.5 illustrates a type of sheathed copper tubing that is designed for gas distribution. The corrosiveness of the gas can be determined by contacting the gas supplier. Depending on the chemical composition of the gas, copper can form scale deposits on the interior pipe wall, and such scale can find its way into gas controls, regulators and valves causing malfunctions.

Figure G2414.5
PLASTIC-SHEATHED COPPER TUBING

G2414.5.1 (403.5.1) Steel tubing. Steel *tubing* shall comply with ASTM A254.

- ❖ Steel tubing is used only in industrial applications and in the construction of appliances.

G2414.5.2 (403.5.2) Copper and copper alloy tubing. Copper *tubing* shall comply with Standard Type K or L of ASTM B88 or ASTM B280.

Copper and copper alloy *tubing* shall not be used if the gas contains more than an average of 0.3 grains of hydrogen sulfide per 100 standard cubic feet of gas (0.7 milligrams per 100 liters).

- ❖ ASTM B88 applies to copper water tube, and Type K and L refers to wall thickness. Type M tubing is the thinnest wall and is not allowed for gas service.

G2414.5.3 (403.5.4) Corrugated stainless steel tubing. Corrugated stainless steel *tubing* shall be *listed* in accordance with ANSI LC 1/CSA 6.26.

- ❖ ANSI LC-1 contains material and performance criteria and installation requirements for corrugated stainless steel tubing (CSST) gas distribution systems. CSST systems are used as an alternative to more traditional

gas piping systems for the distribution of natural gas within buildings.

Corrugated stainless steel tubing is a semirigid stainless steel tubing with a plastic jacket and is available in coil lengths varying from 100 to 250 feet (30 480 to 76 200 mm) and in the following standard sizes: $\frac{3}{8}$, $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$ and 2 inch (larger sizes may be available) [see Commentary Figure G2414.5.3(1)]. Note that CSST sizes are designated by equivalent hydraulic diameters (EHD) not standard tube sizes in inches. Any standard size markings in inches provided by the manufacturer are approximations only. Special proprietary fittings are required for connection of the tubing [see Commentary Figures G2414.5.3(2) through G2414.5.3(4)]. CSST can be used in low-pressure systems [up to 0.5 psig (14 inches w.c.) (3.45 kPa)] and in higher pressure systems operating at pressures up to 5 psig (34.5 kPa). Commentary Figure G2414.5.3(5) shows a typical manifold installation using CSST and shows a multiport manifold with a pressure regulator and shutoff valve installed. To prevent damage or puncture by screws and nails, specialized steel shield plates and protective flexible conduit are used to protect CSST systems that pass through or near structural members. Such protection must employ the parts specified by the

CSST AND SYSTEM COMPONENTS

CSST manufacturer as opposed to standard off-the-shelf protection devices [see Commentary Figures G2414.5.3(1) and G2414.5.3(6)].

CSST systems are usually designed as parallel distribution (manifold) systems, whereas traditional gas distribution systems are typically designed as branch (series) systems [see Commentary Figure G2414.5.3(7)].

Medium-pressure CSST systems, typically 2 psig (13.8 kPa) maximum, are designed to allow the use of small diameter tubing for long runs. Significant distribu-
